## ABSTRACT

To understand how tropical plants have adapted to acid soils, we analyzed the transcriptome of seedlings of *Psychotria rubra*, a typical species found on acid soils. Using RNA-seq, we identified 22,798 genes, including several encoding proteins of the Al<sup>3+</sup>-activated malate transporter (ALMT) and multidrug and toxic compound extrusion (MATE) families. Molecular phylogenetic analysis of ALMTs and MATEs revealed the grouping of those from *P. rubra*, which may be useful to select targets for elucidating the molecular basis of *P. rubra* adaptation to acid soils in the future. The transcriptome datasets obtained in this study would help us to further understand the physiological and ecological aspects of soil adaptation of *Psychotria* species.

## INTRODUCTION

Understanding how plants adapt to various soils is essential in plant biology (*Hiradate, Ma & Matsumoto, 2007*) because plants are sessile and need to grow roots in settled soils. Adaptation to acid soils is an important issue because acid soils cover a considerable part of Earth's arable land and prevent agriculture of most plants (*Von Uexküll & Mutert, 1995*). In acid soils, aluminum is toxic to root tip growth, and various aspects, from molecular to physiological, of the mechanisms of aluminum toxicity have been explored in detail (reviewed in *Ma, 2007*).

Proteins of the Al<sup>3+</sup>-activated malate transporter (ALMT) and multidrug and toxic compound extrusion (MATE) families are likely involved in plant adaptation to acid soils (*Delhaize, Gruber & Ryan, 2007; Delhaize, Ma & Ryan, 2012; Ma, 2007; Ma, Chen & Shen, 2014*). ALMTs and MATEs release organic acids (malate and citrate, respectively), which bind Al<sup>3+</sup> and detoxify it. ALMTs and MATEs related to aluminum tolerance have been

identified in model and agricultural plants (wheat: [Sasaki et al., 2004](#); barley: [Delhaize et al., 2004](#); [Furukawa et al., 2007](#); maize: [Maron et al., 2010](#); *Arabidopsis*: [Hoekenga et al., 2006](#); [Liu et al., 2009](#)), but the composition of those families in non-model wild plants has hardly been explored.

*Psychotria* (Rubiaceae) is a highly diversified genus comprising more than 1,600 species distributed in all tropical and some subtropical regions ([Hamilton, 1989](#); [Davis et al., 2001](#); [Razafimandimbison et al., 2014](#)). Because *Psychotria* species adapt to several types of soils (e.g., soils with high concentrations of nickel; [Merlot et al., 2014](#)), the genus is an ideal target to use to understand how adaptation of wild plants to different types of soils has evolved. In this study, we report ALMTs and MATEs of *P. rubra*, which grows on acid soils ([Miyawaki, 1989](#)).

## MATERIALS AND METHODS

### Sampling, RNA extraction, RNA-seq library preparation, and sequencing

Seeds of *P. rubra* were collected on Mt. Nago-dake, in the north of Okinawa Island, and seedlings were grown in a greenhouse of the National Institute of Technology, Okinawa College ([Fig. 1](#)). RNA was extracted from the seedlings (three–five cm height) using an RNeasy Plant Mini kit (Qiagen, Hilden, Germany). An RNA-seq library was prepared using a TruSeq Stranded mRNA Sample Prep Kit (Illumina, San Diego, CA, USA). The library was sequenced (100-bp paired-end reads) on an Illumina HiSeq 2500 platform. The above procedures on RNA-seq were outsourced to Hokkaido System Science Corporation, Japan.

**Table 1** Summary of de novo assembly.

Number of contigs	131,578
Total bases (bp)	161,583,381
Longest contig length (bp)	16,195
Shortest contig length (bp)	185
Average contig length (bp)	1,228
N50	2,007

### De novo assembly and annotation of transcriptome sequences

FASTQ files were filtered, the reads with poor-quality bases ( $Q < 20$ ) and those shorter than 20-bp were excluded, and adapter sequences were removed in cutadapt v. 1.9.1 software (Martin, 2011). PCR duplicates that arose during library preparation were removed by ConDeTri software (Smeds & Künstner, 2011). The remaining paired-end reads were assembled in Trinity v. 2.8.4 software (Grabherr et al., 2011) with the default options. Open reading frames of >150 amino acids were identified by using TransDecoder software (Haas et al., 2013) and the results of BLASTP searches within the Swiss-Prot database ( $e$ -value  $< 1e^{-5}$ ). Redundant amino acid sequences were removed in CD-HIT v. 4.7 software ( $-c$  0.95; Li & Godzik, 2006). The remaining sequences were used as queries in BLASTP searches ( $e$ -value  $< 1e^{-5}$ ) of *Arabidopsis thaliana* sequences (TAIR10; Swarbreck et al., 2007) and selected sequences assumed to be *P. rubra* itself. Basic information on sequences was obtained in SeqKit v. 0.9.3 software (Shen et al., 2016). Sequence data are accessible under the DNA Data Bank of Japan (DDBJ) Sequence Read Archive (accession: DRA008339). The raw data has been also available at Figshare (<https://doi.org/10.6084/m9.figshare.7848425.v2>).

### Extraction of ALMTs and MATEs of *P. rubra* and molecular phylogenetic analysis

We searched for *P. rubra* ALMTs and MATEs by BLASTP ( $e$ -value  $< 1e^{-5}$ ) using sequences of TaALMT1 (UniProt database ID: Q76LB1) and HvAACT1 (UniProt ID: A7M6U2; this was the first MATE identified in barley (Furukawa et al., 2007) as queries). We then performed BLASTP searches against the Swiss-Prot database ( $e$ -value  $< 1e^{-5}$ ) with each ALMT and MATE of *P. rubra* and selected the top 10 hits for each. The amino acid sequences of ALMTs and MATEs from *P. rubra* and related sequences from Swiss-Prot and other studies (Dreyer et al., 2012; Liu et al., 2016) were aligned in MAFFT v. 7.407 software (Kato & Standley, 2013). We excluded four *P. rubra* ALMT sequences (Prub\_02169, Prub\_02171, Prub\_08405, Prub\_08554) from the following analysis because of poor alignment. We selected only plant MATEs, including HvAACT1 and those from (Liu et al., 2016), for the following analysis. Neighbor-joining trees of ALMTs and MATEs were constructed in MEGA7 software (Kumar, Stecher & Tamura, 2016) with the following settings: Poisson model, Uniform rates, and Pairwise deletion. To evaluate the confidence of phylogenetic trees, bootstrap tests were performed with 1,000 replicates.

**Table 2** Summary of blastp of TaALMT1 and HvAACT1 against *P. rubra* amino acid sequences and annotation of *P. rubra* sequences from the Swiss-Prot database.

## RESULTS AND DISCUSSION

Our RNA-seq analysis of *P. rubra* yielded 57,110,261 paired-end reads, of which 53,994,410 remained after filtering. De novo assembly of the remaining reads resulted in 131,578 contigs (Table 1), in which we found 24,687 non-redundant amino acid sequences; 22,798 of them were expected to originate from *P. rubra* itself as indicated by BLASTP analysis of TAIR10 (the remaining 1,889 sequences were almost no-hit in Swiss-Prot database or included those from microorganisms, etc). Among these 22,798 sequences, 19,701 ones were hit against Swiss-Prot database, and gene ontology (GO) numbers were found in 1,0348 ones. From these sequences, we found 14 ALMTs and 12 MATEs (Table 2).

**Figure 3** Phylogenetic tree of MATEs of *P. rubra* and related proteins. Sequences of *P. rubra* are shown using red shades. For sequences other than *P. rubra* MATEs, the labels are UniProt database IDs, and ones from Liu et al. (2016). Number at each node is the bootstrap value.

Full-size DOI: 10.7717/peerj.7739/fig-3

Using 14 ALMTs from *P. rubra* as queries in a BLASTP search against the Swiss-Prot database, we found 14 homologs, all of plant origin (mainly from *Arabidopsis*). Using a similar approach, we found 13 homologs of MATEs (six from *Arabidopsis* and seven from non-plant organisms). Molecular phylogenetic analysis did not detect *P. rubra* orthologs of TaALMT1 (UniProt ID: Q76LB1) (Fig. 2). ScALMT1 (accession number: ABA62397) from rye (*Secale cereale*) is the only known clear ortholog of TaALMT1 (Delhaize, Gruber & Ryan, 2007). ALMT1 of *Arabidopsis* (UniProt ID: Q9SJE9), encoded by an aluminum tolerance gene (Hoekenga et al., 2006), is clearly distinct from TaALMT1 (Delhaize, Gruber & Ryan, 2007). Thus, ALMTs related to aluminum tolerance may have multiple origins. Molecular phylogenetic analysis of MATEs revealed no clear orthologs of HvAACT1 (UniProt ID: A7M6U2) in *P. rubra* (Fig. 3).

Expression and functional analyses of ALMTs and MATEs of *P. rubra* would be useful for understanding their roles in soil adaptation of *Psychotria* (e.g., with and without Al treatment). Another aluminum tolerance mechanism of plants (different from releasing

organic acids), aluminum accumulation, has been reported in several species of the Rubiaceae (*Jansen et al., 2003*). Genes related to this function are also good targets for future studies to explain the molecular basis of acid soil adaptation of *P. rubra*.

## CONCLUSIONS

We succeeded in identifying transcriptome sequences including ALMTs and MATEs from *P. rubra* in this study. Comparative transcriptome analysis of several *Psychotria* species would help us to clarify the physiological and ecological aspects of diversification of this genus (e.g., adaptation to metalliferous soils; *Merlot et al., 2014*). In particular, *Psychotria manillensis*, which is closely related to *P. rubra*, is reportedly adapted to non-acid soils (*Miyawaki, 1989*). Thus, comparative analysis of *P. rubra* and *P. manillensis* should help to explain how soil adaptation–related genes are involved in adaptive evolution of *Psychotria* species.

## ACKNOWLEDGEMENTS

We thank students of Department of Bioresources Engineering, National Institute of Technology, Okinawa College for their help in maintaining seedlings in a greenhouse.

## ADDITIONAL INFORMATION AND DECLARATIONS

### Funding

This study was supported by a grant from the Nissei Science Foundation to Akira Iguchi (No. 03) and JSPS KAKENHI Grants to Kenta Watanabe (Nos. JP26840130 and JP18K14782). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

### Grant Disclosures

The following grant information was disclosed by the authors:

Nissei Science Foundation: 03.

JSPS KAKENHI: JP26840130, JP18K14782.

### Competing Interests

The authors declare there are no competing interests.

### Author Contributions

- Akira Iguchi conceived and designed the experiments, performed the experiments, analyzed the data, contributed reagents/materials/analysis tools, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft.
- Kazutsuka Sanmiya and Kenta Watanabe performed the experiments, contributed reagents/materials/analysis tools, authored or reviewed drafts of the paper, approved the final draft.

## DNA Deposition

The following information was supplied regarding the deposition of DNA sequences:

Sequence data are accessible at the DNA Data Bank of Japan (DDBJ) Sequence Read Archive: [DRA008339](https://www.ncbi.nlm.nih.gov/sra/DRA008339).

## Data Availability

The following information was supplied regarding data availability:

The raw data is available at Figshare: Iguchi, Akira (2019): Transcriptome of *Psychotria rubra* (Rubiaceae). figshare. Dataset. <https://doi.org/10.6084/m9.figshare.7848425.v2>.
