## ABSTRACT

**Background.** Elderly patients with chronic kidney disease (CKD) are often excluded from clinical trials; this may affect their use of essential drugs for cardiovascular complications. We sought to assess the impact of age on cardiovascular drug use in elderly patients with CKD.

**Methods.** We used baseline data from the Chronic Kidney Disease-Renal Epidemiology and Information Network (CKD-REIN) cohort including 3033 adult patients with CKD Stages 3 and 4. We studied the use of recommended drugs for coronary artery disease (CAD), stroke and atrial fibrillation by age, after adjusting for socio-demographic and clinical conditions.

**Results.** The patients' mean age was 66.8 years (mean estimated glomerular filtration rate 32.9 mL/min/1.73 m<sup>2</sup>). The prevalence of CAD was 24.5% [81.3% receiving antiplatelet agents, 75.6% renin-angiotensin system (RAS) blockers, 65.4%  $\beta$ -blockers and 81.3% lipid-lowering therapy], that of stroke 10.0% (88.8% receiving antithrombotic drugs) and that of atrial fibrillation 11.1% (69.5% receiving oral anticoagulants). Compared with patients aged <65 years, older age ( $\geq 65$  years) was associated with greater use of antithrombotic drugs in stroke [adjusted odds ratio (aOR) (95% confidence interval) = 2.83 (1.04–7.73) for patients aged (75–84 years)] and less use of RAS blockers [aOR = 0.39 (0.16–0.89) for patients aged  $\geq 85$  years],

$\beta$ -blockers [aOR = 0.31 (0.19–0.53) for patients aged 75–84 years] and lipid-lowering therapy [aOR = 0.39 (0.15–1.02) for patients aged  $\geq 85$  years, P for trend = 0.01] in CAD. Older age was not associated with less use of antiplatelet agents in CAD or oral anticoagulants in atrial fibrillation.

**Conclusions.** In patients with CKD, older age *per se* was not associated with the underuse of antithrombotic drugs but was for other major drugs, with a potential impact on cardiovascular outcomes.

**Keywords:** atrial fibrillation, chronic kidney disease, coronary artery disease, elderly, stroke, underuse

## INTRODUCTION

Older adults account for a growing proportion of patients with chronic kidney disease (CKD) [1]. Although the relative risk of end-stage renal disease remains constant across age groups with similar glomerular filtration rates (GFRs), the absolute risk of death is higher than the absolute risk of reaching CKD Stage 5 for elderly patients with CKD [2]. Cardiovascular disease (CVD) is the leading cause of death in patients with CKD [3]. Although CVD and CKD share several risk factors (such as diabetes and hypertension), CKD itself is a major risk factor for CVD [3]. The incidences of various types of CVD are higher in patients with CKD than in populations without CKD; these diseases include both atheromatous CVD [such as coronary artery disease (CAD) and stroke] and non-atheromatous CVD (such as atrial fibrillation and heart failure), which often accumulate with age [3, 4].

The current guidelines for CVD management are based on high-level evidence [5–7]. Most of these guidelines state that non-dialysed patients with CKD should be treated with the same drug classes as patients without CKD. Even though elderly patients with CKD experience a high CVD burden, they are often excluded from clinical trials assessing the efficiency of drugs used to treat CVD. It has also been reported that patients with CKD do not receive recommended treatment for various CVDs, relative to patients with normal kidney function [8–10]. Moreover, age has been associated with the underuse of cardiovascular drugs in non-CKD populations [9, 11–14]. However, the impact of age on CVD drug use by patients with CKD has not been extensively investigated.

By examining data from a large cohort of patients with CKD, we sought to accurately determine the impact of age and GFR level on the patients' use of drugs recommended for several CVDs. We hypothesized that elderly patients with CKD and CVD might be less frequently treated than younger patients with CKD and CVD.

## MATERIALS AND METHODS

### Population

The present analysis drew on baseline data collected from the Chronic Kidney Disease-Renal Epidemiology and Information Network (CKD-REIN) cohort (ClinicalTrials.gov identifier: NCT03381950), a prospective cohort comprising 3033 CKD Stages 3–4 patients receiving nephrologist-led care in France. These patients were recruited from July 2013 to April 2016 by 40 nephrology clinics that were representative in terms of their geographical location in France and their legal status (i.e. public or private ownership) [15].

Study eligibility required two measures of estimated GFR (eGFR) between 15 and 60 mL/min/1.73 m<sup>2</sup> at least 1 month apart, with no prior chronic dialysis or kidney transplantation. Patients aged <18 years or unable to give informed consent were excluded, as were those who planned to move or who

refused to participate. The CKD-REIN patients will be followed up once a year for at least 5 years. This study is a cross-sectional analysis of the entire cohort population at inclusion. The study protocol was approved by the Institut National de la Santé Et de la Recherche Médicale (INSERM) institutional review board (reference: IRB00003888), and all patients gave their informed consent to participation.

### Information

The CKD-REIN database includes information on medical variables (clinical variables, a set of routine laboratory values, the CKD's history, comorbidities and medications taken) and socio-demographic variables. The information was collected from patient interviews and from medical records by trained clinical research associates. For the data on medications, patients were asked to bring their prescriptions for the previous 3 months to each follow-up visit. Clinical research associates recorded the prescription drugs.

Age was divided into four categories: <65, 65–74, 75–84 and  $\geq 85$  years. The eGFR values [calculated according to the Chronic Kidney Disease - Epidemiology Collaboration (CKD-EPI) creatinine equation] were divided into two categories:  $\geq 30$  and <30 mL/min/1.73 m<sup>2</sup>. The CKD-EPI creatinine value was corrected for ethnicity in patients originating from the French West Indies or sub-Saharan Africa. Albuminuria (or proteinuria) was collected either from a 24-h urine sample or a single urine sample and then expressed as a Kidney Disease: Improving Global Outcomes (KDIGO) grade (A1, normal; A2, moderately increased; A3, severely increased) [16]. Participants were classed as having diabetes if (i) diabetes was reported in their medical records, (ii) they were being treated with a glucose-lowering medication or (iii) the blood HbA1c level was  $\geq 7\%$ . Dyslipidaemia was defined as a history of dyslipidaemia or ongoing treatment with lipid-lowering medication. Data were available for five activities of daily living (ADL) from the Katz Index (bathing, dressing, going to the toilet, transference and feeding) and four instrumental ADL (IADL) from the IADL scale (ability to use the telephone, handle finances, take medication and travel). Personal autonomy was defined in two ways: lack of impairment in the five ADLs or lack of impairment in the four IADLs. The educational level was defined as the number of years in full-time education, in two categories: <12 versus  $\geq 12$  years. The CHA2DS2-VASc score was calculated according to the current guidelines [6].

### CVDs studied and the corresponding recommended drugs

We studied the use of recommended drug classes whose several medications do not have contraindications for age and GFR: antiplatelet agents, renin-angiotensin system (RAS) blockers,  $\beta$ -blockers, and statins or ezetimibe in patients with CAD; oral anticoagulants in patients with atrial fibrillation and a

CHA2DS2-VASc score  $\geq 2$  in men and  $\geq 3$  in women; antithrombotic drugs in patients with a history of stroke or transient ischaemic attack [5–7]. Appropriate drugs for CAD included antithrombotic drugs, RAS blockers,  $\beta$ -blockers, and statins or ezetimibe. The RAS blockers included angiotensin-converting enzyme inhibitors and angiotensin receptor blockers. Oral anticoagulants included vitamin K antagonists and direct oral anticoagulants. Antithrombotic drugs included antiplatelet agents and oral anticoagulants.

### Statistical analysis

We first described the use of the drugs recommended for each CVD by age class. Next, we evaluated the number of appropriate drugs for CAD per patient, by age and by eGFR. The number of appropriate drugs in CAD was computed by ordinal logistic regression, and included an age  $\times$  eGFR interaction term. Finally, we analysed the use of recommended drugs in a logistic regression for each drug separately in the three disease subgroups. For each drug, the multivariate analysis included age and eGFR. The other variables included in the multivariate models were those with a  $P < 0.1$  in a univariate analysis. The following variables were tested for each drug: sex, albuminuria, diabetes, marital status, ADL, IADL, educational level, total number of drugs and a cardiology consultation in the previous year. The other tested variables were potential confounding factors for each drug: oral anticoagulant use, liver cirrhosis and a history of gastrointestinal bleeding for the analysis of antiplatelet agents; systolic blood pressure, a history of acute kidney injury (AKI) and heart failure for the analysis of RAS blockers; asthma or chronic obstructive pulmonary disease (COPD), systolic blood pressure, atrial fibrillation and heart failure for the analysis of  $\beta$ -blockers; body mass index and serum albumin for the analysis of statins or ezetimibe; liver cirrhosis, a history of gastrointestinal bleeding and a history of stroke or transient ischaemic attack for the analysis of oral anticoagulants in atrial fibrillation; liver cirrhosis, a history of gastrointestinal bleeding and a history of atrial fibrillation for the analysis of antithrombotic drugs in stroke or transient ischaemic attack. Since a small number of patients had experienced brain haemorrhages, this variable was not included in the analysis of antithrombotic drugs. The interaction between age and eGFR was tested for each drug.

Missing data were taken into account by performing multiple imputations. For each missing value, 20 imputations were computed, leading to 20 different databases. The results of the 20 databases were pooled according to Rubin's rules [17].

All statistical analyses were performed with R software (R Foundation, Vienna, Austria, version 3.3.0; library mice). The threshold for statistical significance was set to  $P < 0.05$ .

## RESULTS

All the 3033 patients in the CKD-REIN cohort were included in the present analysis. The characteristics of the study population are summarized in Table 1. The mean age was 66.8 years, 65% of the patients were male and 41.3% had diabetes. A total of 25% of the patients had a history of CAD, 11.1% had a history of atrial fibrillation with a CHA2DS2-VASc score  $\geq 2$  (men) or  $\geq 3$  (women) (the prevalence regardless of the CHA2DS2-VASc score was 11.5%) and 10.0% had a history of stroke or transient ischaemic attack. Among the patients with CAD, 81.3% were being treated with antiplatelet agents, 75.6% with RAS blockers, 65.4% with  $\beta$ -blockers and 82.7% with statins or ezetimibe. Oral

anticoagulants were used by 69.5% of the patients with atrial fibrillation and a CHA2DS2-VASc score  $\geq 2$  (men) or  $\geq 3$  (women); of these, 3.7% were being treated with a direct oral anticoagulant. Antithrombotic drugs were used by 88.8% of the patients with a history of stroke or transient ischaemic attack. The percentages of patients using drugs recommended in CVD are shown by age class in Figure 1. Results by sex are shown in Supplementary data. Older patients tended to use CAD drugs less than younger patients (univariate  $P$  for trend = 0.05 for antiplatelet agents, 0.01 for RAS blockers,  $<0.001$  for  $\beta$ -blockers and 0.001 for statins or ezetimibe). The numbers of appropriate drugs for CAD per patient are shown in Figure 2. Older age (but not lower eGFR) was significantly associated with a lower total number of appropriate drugs for CAD. The interaction term between age and eGFR was not significant ( $P = 0.47$ ). In contrast, there was no age trend for the use of oral anticoagulants in patients with atrial fibrillation ( $P$  for trend = 0.11). There was a trend towards the more frequent use of antithrombotic drugs in older patients with stroke or transient ischaemic attack ( $P$  for trend = 0.04). The numbers of appropriate drugs for CAD per patient by sex are shown in Supplementary data.

### Antithrombotic drug use

In a multivariate analysis, age was not associated with the use of antiplatelet agents in CAD after adjustment for oral anticoagulant use (Table 2). A higher number of prescribed drugs were associated with a greater probability of treatment with antiplatelet agents in CAD. The latter association was found to be statistically significant for all drugs analysed in this study (Tables 2 and 3). Similarly, age was not associated with the use of oral anticoagulants in patients with atrial fibrillation but was associated with elevated use of antithrombotic agents in patients with CKD and a history of stroke or transient ischaemic attack ( $P$ -value for trend = 0.05). A low eGFR was not significantly associated with the use of antithrombotic drugs studied here. A significant, positive interaction between age and eGFR was found only for the use of antithrombotic agents in patients with a history of stroke or transient ischaemic attack.

### Use of other specific drugs for CAD

In the multivariate analysis, patients with CKD and CAD aged  $>85$  years were significantly less likely to be treated with RAS blockers than patients aged  $<65$  years (Table 3). Patients aged between 65 and 85 years were less likely to be treated with  $\beta$ -blockers than patients aged  $<65$  years. The  $P$ -values for trend according to age were statistically significant for  $\beta$ -blockers and for statins or ezetimibe, indicating lower rates of use of these drugs in older patients with CKD and CAD.

Surprisingly, RAS blockers were significantly less used in patients with heart failure and an eGFR of  $<30$  mL/min/1.73 m<sup>2</sup>. A history of AKI was also associated with underuse of this drug class.  $\beta$ -blockers were less used in patients with asthma or COPD but more used in patients with heart failure. Statins or ezetimibe were used more frequently used in men (Table 3). The interactions between age and eGFR were not significant for these three drug classes.

## DISCUSSION

We found that the recommended drugs for CVD were being used in a large majority of patients with CKD receiving nephrology care. In the CKD-REIN cohort, age *per se* was not associated

Table 1. Characteristics of the study population by age category

Variable	Age (years)				CKD-REIN population	Imputed values (%)
	<65	65–74	75–84	≥85

<sup>a</sup>Expressed as the mean ± standard deviation.

<sup>b</sup>Expressed as the proportion of the age category.

ADL, activities of daily living; IADL, instrumental activities of daily living; eGFR, estimated glomerular filtration rate, according to the CKD-EPI equation; albuminuria or proteinuria was expressed as the KDIGO grade (A1: normal; A2: moderately increased; A3: severely increased); COPD, chronic obstructive pulmonary disease; antithrombotic drugs included antiplatelet agents and oral anticoagulants; RAS, renin-angiotensin system; LDL, low-density lipoprotein; HDL, high-density lipoprotein; AKI, acute kidney injury; CKD, chronic kidney disease.

with the use of antiplatelet agents in CAD or the use of oral anticoagulants in atrial fibrillation. Interestingly, we observed the greater use of antithrombotic drugs in older patients with a history of stroke or transient ischaemic attack. In contrast, RAS blockers, β-blockers and lipid-lowering therapies were used less in older patients with CAD than in younger ones, despite a higher overall number of prescribed drugs in the elderly

patients. Furthermore, a low eGFR (<30 mL/min/1.73 m<sup>2</sup>) was not associated with underuse of any studied drug classes, with the exception of RAS blockers in CAD.

In this study, the percentages of patients using a particular drug were in line with previous reports on patients with chronic CAD; these literature values range from 75% to 88% for antiplatelet agents, 52% to 86% for RAS blockers, 57% to 75% for

FIGURE 1: Percentage of CVD drug use by age class in patients with CKD. RAS: renin-angiotensin system; the antithrombotic drugs included antiplatelet agents and oral anticoagulants.

FIGURE 2: Percentages of patients according to the number of recommended drugs used to treat CAD: comparison by age class and estimated glomerular filtration rate (eGFR) class. The appropriate drugs for CAD included antithrombotic drugs (antiplatelet agents or oral anticoagulants), renin-angiotensin blockers,  $\beta$ -blockers, and statins or ezetimibe.

$\beta$ -blockers and 38% to 96% for lipid-lowering therapies [18–23]. Recent studies have reported that between 56% and 75% of patient with atrial fibrillation use oral anticoagulants, which is in line with the findings of our study [13, 14]. In the literature, the percentage of patients taking an antithrombotic drug on discharge after hospitalization for stroke is higher than that

recorded in this study, although data on the chronic use of antithrombotic drugs in patients with a history of stroke are scarce [12, 24].

CAD is frequent in patients with CKD [3]. The CAD drugs studied here have been shown to be effective in non-dialysed patients with CKD (although the evidence for  $\beta$ -blockers is

The odds ratios were calculated using multivariable logistic regression; the antithrombotic drugs include antiplatelet agents and oral anticoagulants; eGFR, estimated glomerular filtration rate, according to the CKD-EPI equation; the variables included were age, eGFR and variables with a P < 0.1 in the univariate analysis. aOR, adjusted odds ratio.

unclear) [25] and are therefore recommended in the current guidelines [5, 7]. However, previous studies have observed lower use of the recommended CAD drugs in patients with lower eGFRs [8, 9]. In fact, higher CKD stages have been associated with the less frequent initiation of these drugs and worse long-term adherence [8, 9, 19]. We did not observe this relationship in this study, although the range of eGFRs was narrower than in most of the literature publications. However, we did observe underuse of RAS blockers in patients with lower eGFRs and in patients with heart failure. The underuse of antiplatelet agents in patients treated with oral anticoagulants for another indication was observed elsewhere [22].

Older age has already been found to be associated with underuse of recommended drugs in non-CKD patients with CAD [9, 11]. There are also data on these recommended drugs in elderly patients with CAD [9, 21, 26, 27]. The current guidelines for CAD strongly recommend secondary prevention with these drugs in elderly patients [5, 7]. Our study distinguishes the different drug classes and found different use patterns according to age. We did not find any association between age and use of antiplatelet agents, but RAS blockers,  $\beta$ -blockers and lipid-lowering agents were all underused in the oldest patients studied here. As is the case for low GFR, the literature data show that older age is associated with less frequent initiation of these drugs after a coronary event and with worse long-term adherence [9, 11, 19].

Atrial fibrillation and CKD are strongly associated [3]. Whereas patients with CKD have a higher risk of thromboembolism than non-CKD patients, the risk of anticoagulant-related bleeding is also higher. This has prompted debate on the benefit–risk ratio of these drugs in patients with CKD, although most of the data come from observational studies [10, 28, 29]. Although the association between low GFR and underuse of oral anticoagulants in atrial fibrillation has not been thoroughly assessed, our present data did not highlight such a relationship.

Age has previously been found to be associated with the underuse of oral anticoagulants, despite the fact that the latter drugs are clearly effective in the elderly [13, 14, 30]. An earlier study found an association between loss of autonomy and underuse of oral anticoagulants [13]. In contrast to these literature studies, we did not observe underuse of oral anticoagulants in elderly patients with CKD. This disparity might be due to differences in medical practice between CKD and non-CKD patients, or between France and other countries.

We found that antithrombotic drugs were more frequently used in older patients with a history of stroke or transient ischaemic attack. Previous studies have found conflicting results for the association between age and the use of oral anticoagulants on discharge after hospitalization for a stroke due to atrial fibrillation [12, 24]. However, in a study of the use of antithrombotic drugs in patients with recurrent stroke, older age was not associated with drug underuse [23]. Moreover, a study of drug discontinuation 1 year after a stroke found that age was associated with greater use of drugs for secondary prevention of stroke [31]. Another study found that older age was associated with better long-term adherence to antiplatelet agents and worse adherence to oral anticoagulants after stroke [32].

Our analysis had several strengths. First, we used data from a large cohort of patients with CKD: a high proportion of the elderly patients had a history of CVD. Secondly, the database included a large number of variables, which made it possible to take account of potential confounding factors (e.g. personal autonomy and educational). However, our study also had some limitations. First, the cross-sectional design prevented us from establishing whether the studied drugs were never taken at all or were discontinued due to side effects, since elderly patients are particularly exposed to iatrogenic risks. Secondly, the ethical requirement for informed consent might mean that patients with dementia at baseline were not included; this might have led to selection bias. Lastly, our patients were recruited by

\*\*\*P < 0.05 versus the reference (ref.) in multivariate analysis.

The odds ratios were calculated using multivariable logistic regression; eGFR, estimated glomerular filtration rate, according to the CKD-EPI equation; albuminuria or proteinuria was expressed as the KDIGO grade (A1: normal; A2: moderately increased; A3: severely increased); AKI, acute kidney injury; COPD, chronic obstructive pulmonary disease; RAS, renin-angiotensin system; ADL, activities of daily living; IADL, instrumental activities of daily living; the variables included were age, eGFR and variables with P < 0.1 in the univariate analysis.

aOR, adjusted odds ratio.

nephrology departments and so might not reflect exactly prescription patterns in patients with CKD as a whole.

In a French cohort of patients with CKD receiving nephrology care, older age was not associated with the underuse of antithrombotic drugs for CAD, atrial fibrillation and stroke. However, in contrast to the current guidelines, elderly patients with CKD and CAD were less likely to be treated with RAS blockers,  $\beta$ -blockers and lipid-lowering agents than younger patients were. Robust evidence on the effectiveness of CVD drugs is available for elderly patients and for patients with CKD but not for elderly patients with CKD. The latter population has a high cardiovascular mortality rate; further randomized controlled trials and longitudinal studies are therefore needed to assess the benefits and risks of CVD drugs and the reasons for their underuse.

## SUPPLEMENTARY DATA

Supplementary data are available at [ckjonline](http://ckjonline.com).

## ACKNOWLEDGEMENTS

The authors would like to thank the CKD-REIN study coordination staff for their efforts in setting up the CKD-REIN cohort: M.M., Elodie Speyer, Céline Lange, Sophie Renault, Reine Ketchemin and all the clinical research associates. The CKD-REIN Study Group. Steering committee and coordinators include: Carole Ayav, Vanessa Besson-Dubourg, S.B., Dorothée Cannet, C.C., D.F., L.F., Yves-Edouard Herpe, C.J., M.L., Z.A.M., Christophe Pascal, Bruce M. Robinson, B.S., Céline Lange, Karine Legrand, S.L., M.M. and Elodie Speyer.

CKD-REIN investigators/collaborators include: Thierry Hannedouche, Bruno Moulin, Sébastien Mailliez, Gaétan Lebrun, Eric Magnant, Gabriel Choukroun, Benjamin Deroure, Adeline Lacraz, Guy Lambrey, Jean Philippe Bourdenx, Marie Essig, Thierry Lobbedez, Raymond Azar, Hacène Sekhri, Mustafa Smati, Mohamed Jamali, Alexandre Klein, Michel Delahousse, C.C., Séverine Martin, Isabelle Landru, Eric Thervet, Z.A.M., Philippe Lang, Xavier Belenfant, Pablo Urena, Carlos Vela, L.F., Dominique Chauveau, Viktor Panescu, Christian Noel, François Glowacki, Maxime Hoffmann, Maryvonne Hourmant, Dominique Besnier, Angelo Testa, François Kuentz, Philippe Zaoui, Charles Chazot, Laurent Juillard, Stéphane Burtsey, Adrien Keller, Nassim Kamar, D.F. and M.L.

## FUNDING

CKD-REIN is supported by the Agence Nationale de la Recherche through the 2010 *Cohortes-Investissements d'Avenir* programme and the 2010 national *Programme Hospitalier de Recherche Clinique* programme. CKD-REIN is also supported by a public-private partnership with Amgen, Fresenius Medical Care and GlaxoSmithKline (GSK) since 2012, Lilly France since 2013, Otsuka Pharmaceutical since 2015, Baxter and Merck Sharp & Dohme-Chibret (MSD France) from 2012 to 2017, Sanofi-Genzyme from 2012 to 2015 and Vifor Fresenius since 2018. Inserm Transfert set up the collaboration in 2011 and has managed it since then.

## AUTHORS' CONTRIBUTIONS

C.V., S.L., M.M., N.M., B.S. and Z.A.M. contributed to the study concept and design. S.L., M.M., C.C., D.F., L.F., C.J., M.L., S.B., R.L.P., B.S. and Z.A.M. performed the acquisition of data. C.V., S.L., M.M., B.S. and Z.A.M. performed the analysis and interpretation of data. C.V., B.S. and Z.A.M. contributed to drafting the article. S.L., M.M., C.C., D.F., L.F., C.J., M.L., S.B., R.L.P. and N.M. contributed to the critical revision of the manuscript for important intellectual content. All authors approved the final version of the manuscript.

## CONFLICT OF INTEREST STATEMENT

C.V., S.L., M.M., C.C., D.F., L.F., C.J., M.L., S.B., R.L.P. and N.M. have no disclosures relative to this study. B.S. declares being member of a scientific advisory board on a project funded by MSD. Z.A.M. has received grants for CKD-REIN and other research projects from Amgen, Baxter, Fresenius Medical Care, GlaxoSmithKline, Merck Sharp and Dohme-Chibret, Sanofi-Genzyme, Lilly, Otsuka and the French government, as well as fees and grants to charities from Amgen, Bayer and Sanofi-Genzyme.
