

## STAT5 fits the RISK profile for cardioprotection

Sean M. Davidson\* and Derek M. Yellon

**H**ow wonderful would it be if there were a simple, cheap, safe, non-invasive treatment that could be administered to a patient to protect their organs from ischemia and reperfusion? Such a treatment might be used to protect the organs during temporary loss of blood flow, as occurs for example during a heart attack or stroke. As unlikely as this may sound, such a treatment has indeed been discovered, although research into the mechanism is only just beginning. A recent paper by Heusch et al. in *Circulation Research* has taken the first step in this direction, as explained below.

The story begins in 1986 with studies of dogs undergoing experimental myocardial infarction (40 min of coronary artery occlusion to induce lethal myocardial ischemia, followed by reperfusion for 4 d). Murry et al. discovered by serendipity that the dogs' myocardium could be protected if the same coronary artery was subjected beforehand to four 5 min cycles of nonlethal ischemia and reperfusion. This protocol, called "ischemic preconditioning" (IPC), paradoxically reduced the subsequent infarct size to 25% of that observed in untreated control hearts.<sup>1</sup> Unfortunately, despite its robustness and its efficacy, surgical IPC is completely impractical for routine administration as a cardioprotective prophylactic. Consequently, a great deal of scientific effort has been expended in delineating the myocardial signaling pathways that are activated by IPC, in the hope of identifying a pharmacological mimetic of the phenomenon. Yellon and colleagues identified a centrally important kinase signaling network, commonly referred to

as the reperfusion injury salvage kinase (or "RISK") pathway<sup>2</sup> that appears to be at the heart of the observed protection. This definition encompasses all kinases which are specifically activated at reperfusion and improve cardiomyocyte survival (Fig. 1). Although originally described solely in terms of the ERK1/2 MAPK and Akt/PI3K kinase pathways, the JAK-STAT signaling pathway has recently been shown to form a critical "third arm" of the RISK pathway (sometimes referred to as the SAFE pathway).<sup>3,4</sup>

It has proven relatively straightforward to identify compounds which activate these kinases in isolated perfused heart preparation and which induce cardioprotection, even in animal models. For example, insulin the canonical activator of Akt/PI3K, is a highly effective IPC mimetic,<sup>5</sup> as is leptin, via JAK-STAT.<sup>6</sup> However translation of experimental cardioprotective pharmacological agents into clinically detectable benefits in humans has been disappointing, with one of the limitations being the undesirable side-effects of the drugs (e.g., the blood glucose lowering effect of insulin), but also questions about efficacy. There is also a lingering suspicion that the polypharmaceutical nature of IPC will always be more effective than single pharmacological agents.

Then, in 1997 the remarkable discovery was made that instead of it being necessary to apply the preconditioning stimulus directly to the target organ, it could be applied to a "remote" organ, and the conditioned status would also be conferred upon the heart. The first demonstration of "IPC at a distance" was in rabbits.<sup>7</sup> The technique was subsequently refined with the simple application of a tourniquet to

Commentary to: Heusch G, Musiolik J, Kottenberg E, Peters J, Jakob H, Thielmann M. STAT5 activation and cardioprotection by remote ischemic preconditioning in humans: short communication. *Circ Res* 2012; 110:111–5; PMID: 22116817; <http://dx.doi.org/10.1161/CIRCRESAHA.111.259556>

**Figure 1.** Ischemic preconditioning (IPC) involves repeated cycles of ischemia (red) and reperfusion (white) being applied directly to the target organ such as the heart, in order to protect it from an extended period of ischemia and reperfusion. A distinction is made between those kinases activated after IPC (IPC-K) and early during reperfusion (RISK). Remote ischemic preconditioning (RIPC) involves an additional step whereby protection is transmitted via a neuro-hormonal mechanism from the preconditioned limb to the heart. Here, a further distinction must be made between those kinases activated directly in the target organ by RIPC (RIPC-K), and the RISK kinases (RIPC RISK). In sham controls, no RIPC stimulus is applied.

the hind limb of a rat shown to reduce reperfusion arrhythmias.<sup>8</sup> In 2002, the effectiveness of remote ischemic preconditioning (RIPC) in human volunteers was demonstrated using a blood pressure cuff placed on the upper arm to apply three 5 min cycles of alternating ischemia and reperfusion to the skeletal muscle of the forearm.<sup>9</sup> This was sufficient to attenuate endothelial dysfunction due to ischemia and reperfusion injury in the contralateral limb.<sup>9</sup> In a pig model, a similar RIPC protocol decreased the injury of experimental myocardial infarction by 51%.<sup>9</sup>

It is more problematic to find an opportunity to study cardioprotection in human hearts, but there are rare occasions when a heart must be deliberately stopped, which could allow for the testing of protective strategies and further allow a

glimpse into their biochemical mechanisms. One such occasion is during coronary artery bypass (CABG) surgery, when the heart may be deliberately arrested for several hours before normal blood-flow is resumed. Despite all the protective measures in place during CABG surgery there is always an amount of what is termed peri-procedural (or peri-operative) injury that occurs and which can be quantified by measuring myocardial proteins released from dead cardiomyocytes into the circulation, e.g., troponin T or I. Several small, randomized trials have demonstrated that RIPC effectively decreases the extent of cardiac injury during cardiopulmonary bypass,<sup>10-12</sup> and these positive results have been replicated in the recent paper by Heusch et al.<sup>13</sup> To date, only secondary markers of cardiac

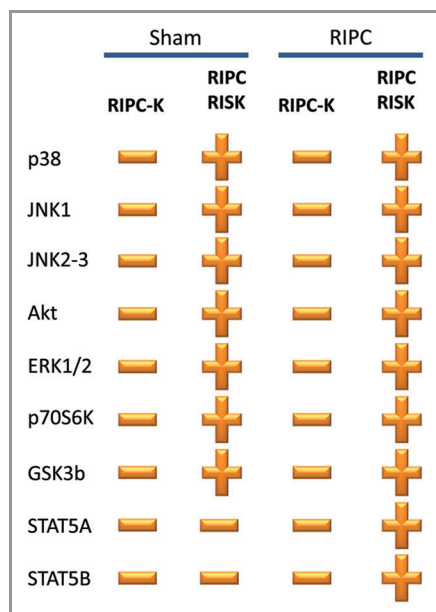

injury have been evaluated, but larger clinical outcome studies are underway, and the results are awaited with great anticipation.<sup>14</sup>

With regular IPC, kinase activation is required at two time-points: during the actual IPC stimulus and during reperfusion (the “RISK” pathway) (Fig. 1). Activation of these kinases at reperfusion is believed to be the most relevant to conditioning, since their inhibition eliminates IPC.<sup>2</sup> In the case of RIPC, analysis is further complicated since signaling initiates in the source organ, and is transmitted to the recipient organ. Transmission appears to involve both a neurally transmitted mechanism, as well as a peptide factor that is transmitted via the circulation.<sup>2,15</sup> Given the superficial similarity between RIPC and IPC procedures, they

might be expected to activate the same reperfusion injury kinases. On the other hand, it would be exciting if RIPC was found to activate a different kinase pathway from IPC, as this might reveal a new pharmacological target for cardioprotection.

The recent study by Heusch et al.<sup>13</sup> investigated a large panel of kinase pathways in order to identify one which fit the RIPC “RISK profile,” i.e., that the pathway’s activity should be increased at reperfusion after prior RIPC, but not activated after a sham control procedure. The authors took biopsies of human hearts immediately after the control or RIPC procedure (point “RIPC-K” in Fig. 1) and from the same patients after ischemia and 10 min into reperfusion (point “RIPC RISK”). Twelve of the 24 patients received prior RIPC stimulus. The researchers then examined a panel of phosphorylation sites of candidate kinases and kinase targets previously implicated in IPC, including PKC $\alpha$ , PKC $\epsilon$ , Src, JNK1, JNK2/3, H11/HSP22, VASP, eNOS $\text{Thr}$ , eNOS $\text{Ser}$ , Akt, Erk1/2, p70S6K, GSK3 $\beta$ , JAK2, STAT1 $\text{tyr}$ , STAT3 $\text{tyr}$ , STAT3 $\text{ser}$  and STAT5 $\text{tyr}$ . All of these phospho sites are known to be strongly correlated with kinase activity. The first thing to note is that there were no differences in phosphorylation at baseline<sup>13</sup> (i.e., at point “RIPC-K” in Fig. 1), suggesting that the factor mediating RIPC transmission does not activate these kinases in the target organ directly, (or alternatively that activation is transient and has returned to baseline in the intervening time between RIPC administration and tissue biopsy). Similar results have been obtained in the rat.<sup>16,17</sup> More importantly, a significant increase in phosphorylated Akt, Erk, p70S6K, STAT1 and STAT3 was seen at reperfusion vs baseline, but surprisingly, the increase was the same in those patients to whom no RIPC protocol had been applied<sup>13</sup> (Fig. 2). This suggests that, though they may be required for protection, they are certainly not sufficient.

In contrast, among nearly 20 phosphorylation sites, the only one matching the “risk profile” (i.e., activated at reperfusion after prior RIPC, but not after the sham control procedure), was STAT5<sup>13</sup> (Fig. 2). Consequently, STAT5 phosphorylation *may* be part of the RISK pathway

**Figure 2.** A summary of the proteins with increased phosphorylation levels detected by Heusch et al. in biopsies of human hearts that had been subjected to sham or RIPC procedures before coronary artery bypass operations. Only STAT5A and STAT5B fit the profile of differential activation.

after RIPC in humans. Conclusive demonstration would require specific inhibition of STAT5, experiments that are not possible to perform in humans. For these, we must rely instead on animal experiments, and to date the role of the JAK-STAT pathway has been investigated only in direct IPC and not in RIPC. As it turns out, IPC is prevented by perfusion of rat or mouse hearts with the JAK-STAT inhibitor, AG490.<sup>18,19</sup> Although AG490 is quite specific, it inhibits both JAK2 and JAK3<sup>20</sup> leading to inhibition of all cardiac isoforms of STAT<sup>21</sup> and therefore cannot be used to examine STAT5 alone. Indeed, there is evidence for opposing effects of different STAT isoforms, with STAT3 activation protecting against cardiac ischemia and reperfusion injury while STAT1 activating cell death pathways.<sup>22</sup> Experiments with knockout mice allow a more nuanced investigation of the role of specific STAT isoforms. These have suggested that hearts from STAT5A knockouts are unable to be preconditioned,<sup>21</sup> although neither are hearts lacking STAT3.<sup>23,24</sup> In contrast, hearts of STAT6 knockout mice remained amenable to IPC.<sup>21</sup>

Interestingly, the Akt inhibitor wortmannin when administered to pigs eliminated RIPC-induced cardioprotection against ischemia and reperfusion injury.<sup>25</sup> Furthermore, increased Akt phosphorylation was measured in myocardial biopsies taken after cardiac reperfusion.<sup>25</sup> This suggests that there may be differences in which kinase pathways are recruited by RIPC in different species, as has been suggested to be the case for a variant form of IPC called “postconditioning” (which is administered during early reperfusion).<sup>26</sup> Other experimenters have administered the MAPK inhibitors SB203580 (p38), PD98059 (ERK1/2) or SP600125 (JNK1/2) to rats, but as they were injected prior to the application of RIPC they may have acted on both the remote organ (the limb) and the target organ (the heart) at any point in Figure 1, and results are more difficult to interpret.<sup>16</sup> It is highly likely that there is a degree of cross-talk between the PI3K/Akt and JAK-STAT pathways. In fact, when RIPC is replicated in vitro by the transfer of coronary effluent from preconditioned rat hearts to naïve hearts, both PI3K/Akt and JAK-STAT pathways are involved.<sup>27,28</sup>

What might the mechanism of JAK-STAT cardioprotection be? Given the timescale, gene transcription is not likely to be involved, thereby implying a role for STAT independent of transcriptional regulation. A primary end-target of RISK pathways appears to be the mitochondria,<sup>29,30</sup> and STAT3 has recently been detected in the mitochondria.<sup>31</sup> Heusch et al. have previously shown that in pigs, STAT3 is activated in hearts subject to postconditioning, and is required for preservation of mitochondrial function.<sup>32</sup> Intracellular changes in STAT3 localization would have been missed in the current study which looked at total cellular levels. As mentioned in their discussion, other proteins such as PKC and Src are also regulated by intracellular localization and would have escaped notice. Other caveats to keep in mind are that the sample size (12 per group) was relatively small, and may not have been sufficiently powered to detect small differences in a heterogeneous patient population. Furthermore, only one time-point was

examined, so transient changes in phosphorylation may have been missed.

The revelation of STAT5 as an important target for human cardioprotection suggests further work should focus on ways to specifically and safely target STAT5 pharmacologically. Intriguingly, several GPCR ligands are known to

preferentially activate STAT5 over other STATs, including erythropoietin,<sup>33</sup> prolactin, IL-3, IL-5 and GM-CSF, and a number of these have been shown to be cardioprotective. STAT5 inhibitors would also be useful for investigating the role of STAT5 in cardioprotection, but transgenic mice with cardiac-restricted

deletion or overexpression will be even more useful. The other approach that will be interesting to take is to “reverse engineer” RIPC, by trying to identify the factor that activates STAT5 in humans. If this factor can be purified then we may finally find the wanted peptide matching the newly identified RISK profile.
