Received 21 July 2009; accepted 30 July 2009

Key indicators: single-crystal X-ray study; $T = 293\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$; R factor = 0.032; wR factor = 0.068; data-to-parameter ratio = 14.0.

The title compound, $[\text{Zn}(\text{C}_8\text{H}_6\text{O}_3)_2(\text{C}_{12}\text{H}_{12}\text{N}_2)]_n$, consists of $[\text{Zn}(\text{Hopa})_2]$ (H_2opa = 2-hydroxy-2-phenylacetic acid or mandelic acid) units bridged by 1,2-di-4-pyridylethane (bpe) ligands, forming a polymeric chain developing parallel to the b axis. The bridging bpe ligand is arranged around a twofold axis passing through the middle of the ethane C–C bond. The geometry around the Zn^{II} ion is distorted octahedral, constructed by four O atoms from two Hopa[−] ligands and two N atoms from two bridging bpe ligands. O–H···O hydrogen bonds link the chains, forming a three-dimensional network.

Comment

A great attention has been paid to transition metal ions as the major cation contributors to the biologically active molecules such as amino acids, proteins, sugars, nucleotides *etc* (Daniele, *et al.*, 2008). This interest has driven us to study on the interaction of the transition metal ions with fulvic acids or humic acids. As models to examine the interaction, therefore, we have previously used copper(II) and zinc(II) benzoates as building blocks and reported the structures of copper(II) and zinc(II) benzoates with quinoxaline, 6-methylquinoline, 3-methylquinoline, and di-2-pyridyl ketone(Lee *et al.*, 2008; Yu *et al.*, 2008; Park *et al.*, 2008; Shin *et al.*, 2009).

Mandelic acid (2-hydroxy-2-phenylacetic acid, H₂opa) is also one of the simplest bioactive molecules exhibiting a variety of coordinating and supramolecular interaction abilities (Balboa *et al.*, 2008; Beghidja *et al.*, 2005; Hao *et al.*, 2009; Wermester *et al.*, 2007). In order to study the interaction of the biologically active molecule mandelic acid with zinc(II) ion, in the present work, we have employed zinc(II) mandelate as a building block and 1,2-di-4-pyridylethane (bpe) as a ligand. We report herein the structure of new zinc(II) mandelate with 1,2-di-4-pyridylethane.

The crystal structure contains [Zn(Hopa)₂] units bridged by bpe ligands forming a polymeric chain developing parallel to the b axis. The bridging 1,2-di-4-pyridylethane (bpe) ligand is arranged around a two fold axis going through the middle of C26—C26ⁱⁱ bond (symmetry code: (ii) x, x-y+2, -z+1/6). The geometry around the Zn^{II} ion is distorted octahedral constructed by four oxygen atoms from two Hopa⁻ and two nitrogen atoms from two bridging bpe ligands (Fig. 1). The occurrence of O-H···O hydrogen bonds links the chains to form a three dimensionnal network.

Experimental

38.0 mg (0.125 mmol) of Zn(NO₃)₂·6H₂O and 38.4 mg (0.25 mmol) of 2-hydroxy-2-phenylacetic acid were dissolved in 4 ml water and carefully layered by 4 ml solution of a mixture of acetone, methanol and ethanol (2/2/2) of 1,2-di-4-pyridylethane ligand (46.0 mg, 0.25 mmol). Suitable crystals of the title compoundfor X-ray analysis were obtained in a few weeks.

Refinement

All H atoms attached to C atoms were fixed geometrically and treated as riding with C—H = 0.98 Å (methyne), 0.97 Å (methylene) or 0.93 Å (aromatic) with U_{iso}(H) = 1.2U_{eq}(C). H atom attached to O was located in difference Fourier maps and included in the subsequent refinement using restraints (O-H= 0.85 (1)Å) with U_{iso}(H) = 1.5U_{eq}(O). In the last stage of refinement, it was treated as riding on its parent atom.

Primary atom site location: structure-invariant direct methods	Flack parameter: -0.002 (16)
Secondary atom site location: difference Fourier map	

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
