Received 23 September 2010; accepted 25 October 2010

Key indicators: single-crystal X-ray study; $T = 100$ K; mean $\sigma(\text{C}-\text{C}) = 0.002 \text{ \AA}$; R factor = 0.022; wR factor = 0.066; data-to-parameter ratio = 15.7.

In the title compound, $[\text{Cu}(\text{C}_8\text{H}_8\text{NO})_2]$, a strictly square-planar geometry about the Cu^{II} metal atom is observed. Substitution of an O atom with a methyl-functionalized N atom does not significantly alter the bond distances and angles in the copper(II) complex when compared with a similar bis(tropone) copper(II) complex. $\pi-\pi$ stacking is observed between the tropone rings, with interplanar distances of 3.5039 (16) and 3.2933 (15) \AA , respectively. Additional stabilisation of the structure is accomplished through C–H \cdots O hydrogen-bonding interactions.

Bis[2-(methylamino)troponato]copper(II)

G. Steyl, T. J. Muller and A. Roodt

Comment

Complexes containing tropolonato type derivatives have steadily increased over the last few decades (Roesky, 2000), with most of the work having involved the first and second row transition elements. This attention has been to a large extent due to the medical application of tropolone in radio-pharmaceuticals (Nepveu *et al.*, 1993) and catalyst precursors (Crous *et al.*, 2005; Roodt *et al.*, 2003). Functionalization of the tropolonato backbone (seven-membered ring) has also been investigated with a range of Rh^I and Pd^{II} complexes reported to date (Steyl *et al.*, 2001; Steyl, 2005).

Heteroatom substitution of the tropolonato moiety has also been reported, most notably the O atoms are replaced with functionalized amino groups, resulting in either the 2- (aminotropone) or 1,2- (aminotropoimine) compounds (Roesky & Burgstein, 1999; Claramunt *et al.*, 2004). Thus, a host of amino and anilino derivatives of tropolone have been reported (Roesky & Burgstein, 1999; Roesky, 2000; Claramunt *et al.*, 2004). The addition of electron-donating or -withdrawing moieties to the N atom can significantly increase the application of these compounds in coordination chemistry. The most interesting observation concerning the Cu^{II} metal centres in general is the difference in the coordination behaviour of the bidentate-*O,O* donor atoms compared to the *N,N* donor atom complexes; the geometrical conformation changes from a square planar (Starikova & Shugam, 1969; Byrn *et al.*, 1993) to a tetrahedral geometry (Park & Marshall, 2005; Dessy & Fares, 1979), respectively. The *N*-methylaminoacetylacetonato derivative have been reported (Baidina *et al.*, 2004) as a distorted tetrahedral complex.

In an effort to further investigate these types of complexes, the crystal structure of [Cu(TropNMe)₂] is presented.

The copper(II) ion is coordinated by two TropNMe ligands in a square-planar geometry (Fig 1). The Cu²⁺ ion chelates the TropNMe ligand *via* N1 and O1 to form a five-membered ring. The N1—O1—Cu—N2—O2 moiety is strictly planar. The ligand planes form angles of 6.54 (1) $^{\circ}$ and 3.12 (1) $^{\circ}$, respectively with the 5-membered ring. This compares with literature (Hill & Steyl, 2008). π — π stacking between C11—C17 and C11—C17ⁱ ($-x, 1 - y, -z$) as well as C11—C17 and C21—C27ⁱⁱ ($-x, 2 - y, -z$) with intercentroid distances of 4.1483 (4) Å and 3.7827 (4) Å respectively as defined by the seven-membered ring system. Cu—O1 and Cu—O2 bond distances is 1.9313 (2) Å and 1.9386 (2) Å, respectively. This correlates well with literature (Zhang *et al.*, 2008). The Cu—N1 and Cu—N2 bond distances is 1.9276 (2) Å and 1.9291 (2) Å respectively. The O1—Cu—N1 and O2—Cu—N2 angles is 82.292 (4) $^{\circ}$ and 82.090 (4) $^{\circ}$ respectively. This correlates well with literature (Kristiansson 2002). The N1—Cu—N2 angle is 175.769 (5) $^{\circ}$ this is smaller than the O1—Cu—O2 angle, which is 179.229 (6) $^{\circ}$. This is in accordance with literature (Liang *et al.*, 2001). The title compound is further stabilized by weak intramolecular C15—H15A···O1 and C16—H16A···O2 hydrogen interactions.

Experimental

Synthesis of 2-(*N*-methylamino)tropone (HTropNMe) was done according to the literature procedure (Roesky & Burgstein, 1999; Claramunt *et al.*, 2004), while all other starting materials were obtained from commercially available sources.

supplementary materials

Cu(NO₃)₂ (100 mg, 0.44 mmol) was dissolved in CHCl₃ or MeOH and refluxed with HTropNMe for 30 min. The product was filtered from the cold solution and dried in air for 24 h. Rhombic dark-green crystals suitable for X-ray diffraction was obtained from a chloroform/ether (1:1, 10 ml) mixture after 2 d. (Yield: 117 mg, 70%) ¹H NMR (300 MHz, CDCl₃, 25°C) 7.32 (m, 2H), 7.12 (d, 1H), 6.95 (d, 1H), 6.81 (t, 1H), 1.56 (s, 3H)

Refinement

All H atoms were positioned geometrically and allowed to ride on their parent atoms, with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{parent})$ of the parent atom with a C—H distance of 0.93. The methyl H atoms were placed in geometrically idealized positions and constrained to ride on the parent atoms with $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ and at a distance of 0.96 Å.

Refinement

Refinement on F^2	Primary atom site location: structure-invariant direct methods
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.022$	Hydrogen site location: inferred from neighbouring sites
$wR(F^2) = 0.066$	H-atom parameters constrained
$S = 1.06$	$w = 1/[\sigma^2(F_o^2) + (0.0363P)^2 + 0.8483P]$ where $P = (F_o^2 + 2F_c^2)/3$
2985 reflections	$(\Delta/\sigma)_{\max} < 0.001$
190 parameters	$\Delta\rho_{\max} = 0.36 \text{ e } \text{\AA}^{-3}$
0 restraints	$\Delta\rho_{\min} = -0.38 \text{ e } \text{\AA}^{-3}$

Special details

Experimental. First 80 frames repeated after collection for monitoring possible decay.

Geometry. All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
