# Prevalence and predictors of cervicitis in female sex workers in Peru: an observational study

Simon Pollett<sup>1,2\*</sup>, Martha Calderon<sup>3,4</sup>, Kristen Heitzinger<sup>1,5</sup>, Vicky Solari<sup>4</sup>, Silvia M Montano<sup>1,3</sup> and Joseph Zunt<sup>6</sup>

## Abstract

**Background:** Cervicitis is a syndrome of cervical inflammation and a common condition in female sex workers (FSW), a subpopulation vulnerable to sexually transmitted infections. Local data is essential for guiding syndromic management of cervicitis in FSW working in Peru. We sought to describe the prevalence and etiologies of cervicitis in this population. We also aimed to identify sociodemographic, behavioral and biological factors associated with cervicitis, including bacterial vaginosis (BV), a condition with a possible role in cervicitis.

**Methods:** FSW 18 years of age or older presenting to a free public sexual health clinic in Callao-Lima, Peru were eligible for inclusion upon consent. 467 participants completed a face-to-face questionnaire and underwent genital examination. Vaginal, endocervical and blood samples were collected and tested for *C. trachomatis* (CT), *N. gonorrhoea* (GC), *T. vaginalis* (TV), BV, HIV and Human T-Cell Lymphotropic Virus –1. Logistic regression was used to determine whether sociodemographic, behavioral, or other sexual health related characteristics were associated with the diagnosis of cervicitis.

**Results:** Cervicitis was detected in 99 (24.9%) of 397 FSW. The presence of cervicitis was unable to be determined in 70 participants. In women with cervicitis, CT was present in 4.6% (4/87), TV in 4.0% (4/99), GC in 0% (0/87) and no pathogen was detected on cervical microbiology in 91.9% (91/99). BV was detected on vaginal microbiology in 36.9% (31/84) of cervicitis cases. BV was more common in women with cervicitis, however this association did not reach statistical significance ( $aOR = 1.47 [0.87, 2.48]$ ,  $p = 0.15$ ). Other STI were not associated with cervicitis. Regular clinic attendance ( $aOR = 0.54 [0.34, 0.87]$ ,  $p = 0.01$ ) and Ecuadorian nationality ( $aOR = 0.31 [0.13, 0.76]$ ,  $p = 0.01$ ) were associated with reduced risk of cervicitis.

**Conclusions:** Cervicitis was common in FSW working Peru and was predominantly nongonococcal and non-chlamydial in etiology. Further study is warranted to clarify the role of BV and other emerging cervicitis pathogens in this population. The current Peruvian program of free health checks for FSW may be effective for reducing rates of cervicitis. The protective effect of Ecuadorian nationality prompts further study.

**Keywords:** Cervicitis, FSW, Peru, Bacterial vaginosis, Sexually transmitted infection

## Background

Cervicitis is a syndrome of cervical inflammation and a common manifestation of sexually transmitted infections (STI) such as *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoea* (GC) [1,2]. Vaginal discharge or intermenstrual bleeding are frequent symptoms of cervicitis, although it may be asymptomatic [1,3]. Cervicitis can progress to

pelvic inflammatory disease (PID) with severe reproductive sequelae, even in asymptomatic cases [3]. Cervicitis may also affect sexual health at a population level, as it increases shedding of other STI such as Human Immunodeficiency Virus (HIV) and Human T-cell Lymphotropic Virus (HTLV) [4,5].

While cervicitis is considered to arise as a consequence of STI, understanding of its etiology and pathogenesis is still evolving. Even with advanced microbiological assays, no causative pathogen is identified in the majority of cervicitis cases. When a pathogen is detected, CT and GC are the usual culprits. Less commonly, *Mycoplasma genitalium*,

Full list of author information is available at the end of the article

*Trichomonas vaginalis* (TV) and Herpes simplex Virus (HSV) are implicated [1,2]. More recently, bacterial vaginosis (BV) has been linked to cervicitis, in addition to an increased risk of HIV acquisition, adverse pregnancy outcomes and gynaecological surgery complications [3,6]. Although not an STI *per se*, BV is an endogenous vaginitis associated with sexual activity and characterized by an overgrowth of vaginal anaerobic flora and reduction of H<sub>2</sub>O<sub>2</sub>-producing lactobacilli [3].

Cervicitis is a common condition in FSW, with prevalences as high as 20% [7]. In studies of cervicitis in FSW living in Africa, CT, GC, *M. genitalium* and TV were common pathogens [7-9]. Factors such as lower education level, greater numbers of clients and decreased condom usage were associated with cervical infection in FSW working in Madagascar [10]. Although cervicitis has been reported in Peruvian FSW, detailed data regarding the prevalence, etiologies and risk factors for cervicitis in FSW working in Peru or other Latin American countries is lacking [4,11]. As FSW may receive only intermittent healthcare and advanced diagnostics in low resource settings are limited, cervicitis in FSW, when diagnosed, is most often treated syndromically [12]. Syndromic management has drawbacks such as the underdiagnosis of subclinical STI and a potential overuse of antimicrobials [13]. Since FSW are particularly vulnerable to STI, and cervicitis may increase rates of STI transmission to the general population, accurate local epidemiological data is essential for guiding syndromic management of cervicitis in FSW.

The objectives of this observational, cross-sectional study were to describe the prevalence and etiologies of cervicitis in FSW receiving care at a public health clinic and associated mobile clinic in Callao-Lima, Peru. We also sought to identify sociodemographic, behavioral and biological factors associated with cervicitis. In particular, we sought to determine if an association between BV and cervicitis existed in these women, particularly given the high reported rates of BV in Peruvian FSW [11].

## Methods

### Setting, study participants & enrolment

In Peru, sex work is permitted by FSW who are registered at a public health clinic and are of 18 years of age or older. Registration requires monthly health assessments which are free of charge, including treatment [11]. Approximately two-thirds of Lima's estimated 15,000 FSW are registered. The Centro de Salud 'Alberto Barton' (CSAB), located in the port city of Callao-Lima, provides healthcare to registered FSW, while an associated mobile clinic provides care to unregistered FSW. These monthly healthcare checks are provided by Peruvian Ministry of Health clinicians, and include genital examination and collection of cervical and vaginal swabs for basic onsite

microbiology (including Gram stain, wet mount and KOH staining) in addition to gonococcal culture. Syphilis screening (by non-treponemal assay) is performed quarterly and HIV testing is performed twice per year. If required, much of the treatment is syndromic as per the National STI Guidelines [11].

FSW presenting for medical assessment at either of these clinics between November 2008 and January 2011 were invited to participate in this cross-sectional study. Unregistered and registered FSW were eligible to participate, with registration status determined on routine assessment. Unregistered FSW were offered enrolment (if eligible) when presenting for routine assessment at the mobile clinic. FSW 18 years of age or older were eligible for inclusion. Informed consent was obtained from all study participants. The study was approved by the Institutional Review Boards of the University of Washington, Universidad Nacional Mayor de San Marcos, the Directorate of Callao, and US Naval Medical Research Unit No. 6 (NAMRU-6), Callao, Peru.

### Study procedures

All participants completed a face-to-face questionnaire to provide data on sociodemographic and behavioral variables and underwent genital examination with collection of vaginal, endocervical and blood samples. Genital examination was performed by one of the regular clinic doctors as an assigned study physician. Cervicitis was defined as the presence of mucopus and friability in concurrence with the Centers for Disease Control and Prevention recommendations [3]. PID was defined as cervicitis in the presence of lower abdominal pain plus cervical motion tenderness, adnexal tenderness or uterine tenderness.

Saline wet-mount microscopy was performed on cervical samples for detection of *Trichomonas vaginalis* (TV) at an on-site laboratory at CSAB. Further cervical specimen testing occurred at NAMRU-6 laboratories in Lima, Peru. One cervical sample was placed in specimen transport medium (Digene Diagnostics, Silver Spring, MD) for molecular testing of *Chlamydia trachomatis* (CT), *Neisseria gonorrhoea* (GC) and Human Papillomavirus (HPV). CT and GC testing was performed using Amplicor CT/GC PCR according to the manufacturer's instructions (Roche, Pleasanton, California, USA). HPV DNA was extracted and PCR analysis performed according to methods described elsewhere [14]. Vaginal swabs were evaluated with Gram stain, KOH and saline wet mount tests for the detection of candidiasis, TV and BV. In accordance with recently standardised research definitions, BV was diagnosed by positive Amsel criteria and Nugent scoring [15]. All vaginal swab testing occurred at CSAB.

Blood samples were transported to NAMRU-6 laboratories for analysis. Serum was screened for HIV using a Vironostika HIV Ag/Ab assay (bioMérieux, Marcy l'Etoile,

France); positive assays were confirmed by line immunoblot assay (INNO-LIA HIV I/II Score, Innogenetics, Gent, Belgium). Serum samples were also tested for HTLV-1/2 antibody by ELISA assay (BioElisa HTLV I/II 5.0 BioKit, Llica d'Amunt, Barcelona, Spain) with confirmatory testing using line immunoblot assay (HTLV I/II score, Innogenetics, Gent, Belgium). Serum was screened for syphilis using Rapid Plasma Reagins (RPR-nosticon II, bioMérieux, Marcy l'Etoile, France) and confirmed by Treponema Pallidum Hemagglutination Assay (TPHA; Syphagen TPHA - Biokit, Llica d'Amunt, Barcelona, Spain). Women with positive STI test results were counselled and treated according to Peruvian Ministry of Health Guidelines [11].

### Statistical analysis

All data were double entered into an electronic database and analyzed using STATA, version 12.0 (StataCorp, College Station, TX). Bivariate associations of cervicitis with sociodemographic, behavioral, and biological variables were examined using Chi-squared tests to determine significant differences between groups. Logistic regression was used to determine whether sociodemographic, behavioral, or other sexual health-related characteristics were associated with the diagnosis of cervicitis. Both unadjusted and adjusted logistic models were fit to estimate odds ratios (OR) and 95% confidence intervals (95% CI). For sociodemographic variables, we used the criterion of a greater than 10% change in the OR to identify confounders in adjusted models. For biological variables, we specified the presence of genital tract infections associated with both cervicitis and bacterial vaginosis (namely CT, GC or TV) as *a priori* confounders in an adjusted model. A significance level of 0.05 was used for all hypothesis tests.

### Results

A total of 467 FSW were enrolled. The presence of cervicitis was unable to be assessed in 70 women due to menses, pessary use, hysterectomy or other examination difficulties. Cervicitis was present in 24.9% (99/397) of the remaining participants. Table 1 presents the socio-demographic, behavioral and biological characteristics, including frequency of STI and other genital tract infections, in those FSW with and without cervicitis. In the

women with cervicitis, CT was present in 4.6% (4/87), TV in 4.0% (4/99), GC in 0% (0/87) and no pathogen was detected on cervical microbiology in 91.9% (91/99). There were nil cervical co-infections detected. Bacterial vaginosis was detected on vaginal microbiology in 36.9% (31/84) of cervicitis cases for whom a definitive BV diagnosis could be made. Bivariate analyses of associations between sociodemographic and biological variables with cervicitis are presented in Table 2. Regular use of healthcare services and Ecuadorian nationality were significantly associated with a reduced risk of cervicitis, even after multivariate analysis. BV was more common in women with cervicitis, however this association did not reach statistical significance (aOR = 1.47 [0.87, 2.48], p = 0.15).

Further analyses were conducted to examine the association between cervicitis and regular clinic attendance, Ecuadorian nationality, and BV. The most common STI associated with cervicitis, namely CT, GC and TV, were less common in regular clinic attendees (OR = 0.39 [0.15, 0.99], p = 0.04). BV was also less common in regular clinic attendees (OR = 0.39, 95% [0.24, 0.62] p < 0.001). Regular clinic attendance was more common in Ecuadorian FSW (OR = 2.72, [1.49, 4.94], p = 0.001).

### Discussion

Almost one quarter of FSW in this study had cervicitis, second only to vaginal discharge as the most common syndrome. Cervicitis in this study was predominantly non-gonococcal, non-chlamydial in etiology, and no pathogen was detected in cervical samples in over 90% of participants with cervicitis. Cervicitis that is not associated with chlamydial or gonococcal infections is the most common type of cervicitis overall and is referred to as 'non-specific cervicitis' (NSC) [1]. The rate of NSC determined here was higher than some rates reported in non-FSW women [6].

Studies in other FSW populations have demonstrated a strong association between gonococcal, chlamydial or *Trichomonas* infection with clinical manifestations of cervicitis [8,9]. No such association was found in the women studied here, and this likely reflects the low overall prevalence of STI diagnosed, in contrast to the higher STI prevalence reported in FSW in other Latin American countries, Asia and Africa [8,9,11,16,17].

Other potential reasons for the high frequency of NSC and lack of association with typical cervicitis-causing organisms may include ongoing inflammation of the cervix after previously treated chlamydial or gonorrhoeal infections, perhaps mediated by an abnormal immune response [2]. Data was unfortunately not collected on prior antimicrobial treatment for cervicitis or other genital tract syndromes in these women, which is a significant limitation to this study.

Cervical irritation due to douches and spermicides may also have contributed to high NSC rates [2]. While no data was collected on the use of spermicides or frequency of douching, douching is common in this population (personal observation by authors). Additionally, testing for other potential pathogens associated with cervicitis such as HSV-2 and *M. genitalium* were not performed in this study [1]. Furthermore, microscopy was used for the detection of trichomoniasis in this study, a method that is less sensitive compared to culture-based, molecular and immunochromatographic methods [3]. This relatively insensitive method of TV detection is a limitation of this study, and future studies should consider the use of newer generation diagnostic methods such as PCR.

Bacterial vaginosis may play a causative role in some NSC cases. BV was the second most common genital tract infection in our study and was present in over a third (36.9%) of cervicitis cases. On bivariate analysis, the association between BV and cervicitis failed to reach significance, but this may reflect insufficient power due to the number of FSW enrolled. There is growing evidence from other studies that BV is an independent risk factor for cervicitis [6]. Bacterial vaginosis could lead to cervicitis through a loss of bactericidal H<sub>2</sub>O<sub>2</sub>-producing lactobacilli, reduced levels of protective vaginal mucins, and increased pro-inflammatory enzymes and cytokines, which in turn may decrease the cervical mucus barrier [6].

Regular clinic attendance was associated with a 46% reduced risk of cervicitis, possibly due to the reduced rates of STI and BV noted in the regular clinic attendees. This may reflect frequent and early antibiotic treatment of genital tract syndromes and infections, although the exact frequency of antibiotic treatment

was not determined. Self-treatment with antimicrobials was also considered as a confounding factor in women who attended clinics, however only one participant reported receiving treatment outside of clinics (data not shown). Preventative STI education delivered during clinic attendance may also contribute to the protective effect associated with regular clinic attendance. Regardless of the mechanism, the current Peruvian Ministry of Health program of free monthly health checks for FSW may be effective for reducing rates of cervicitis, BV and cervicitis-causing STI noted in FSW with regular clinic attendance.

Ecuadorian nationality was also protective against cervicitis, even after controlling for regular clinic attendance, which was more common in the Ecuadorian participants. The effect of Ecuadorian nationality may reflect unmeasured cultural differences in sexual practices, douching or other risk behaviors for cervicitis and STI.

## Conclusion

In conclusion, cervicitis was a common condition in Peruvian FSW and in the context of very low STI rates was predominately non-specific cervicitis. Our findings may not be generalizable to other populations of FSW, particularly those with higher rates of STI, but encourage further evaluation of the etiologies and treatment of cervicitis in FSW populations. The protective effect of Ecuadorian nationality is intriguing, and future studies could examine the effect of migration upon the sexual health and risk behaviors of FSW. Defining the role of *M. genitalium*, HSV and other emerging pathogens such as *Ureaplasma urealyticum*, adenovirus and cytomegalovirus in FSW with cervicitis may also reveal new associations [2,3].

Submit your next manuscript to BioMed Central and take full advantage of:

- Convenient online submission
- Thorough peer review
- No space constraints or color figure charges
- Immediate publication on acceptance
- Inclusion in PubMed, CAS, Scopus and Google Scholar
- Research which is freely available for redistribution
