Received 18 September 2012; accepted 6 October 2012

Key indicators: single-crystal X-ray study; $T = 298\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$; R factor = 0.039; wR factor = 0.095; data-to-parameter ratio = 7.5.

The title molecule, $\text{C}_{23}\text{H}_{26}\text{N}_2\text{O}_8$, was synthesized in three steps starting from *m*-nitrocinnamic acid. The central oxazolidine ring adopts an almost perfect envelope conformation with the O atom as the flap [puckering parameter $\varphi = 0.3(6)^\circ$]. The dihedral angle formed by the benzene rings is $61.81(9)^\circ$. In the crystal, molecules are connected into double chains parallel to [010] by $\text{C}-\text{H}\cdots\text{O}$ hydrogen bonds. The absolute configuration was assigned from the synthetic procedure.

3-*tert*-Butyl 5-methyl (2*R*,4*S*,5*R*)-2-(4-methoxyphenyl)-4-(3-nitrophenyl)-1,3-oxazolidine-3,5-dicarboxylate

Sara Montiel-Smith, Sylvain Bernès, Jesús Sandoval-Ramírez, Socorro Meza-Reyes and Joëlle Dubois

Comment

The title compound is related to a project about new synthetic routes to obtain isoserines (α -hydroxy- β -amino acids). The stereocontrol of the synthesis is a key point, since chiral isoserines are found in bioactive substances, as in the side chain of the emblematic anti-cancer agent Paclitaxel, initially marketed under the brand name Taxol. We focused our efforts toward the synthesis of (2*R*,3*S*)-*N*-Boc- β -phenylisoserines (Montiel-Smith *et al.*, 2002). Starting from commercially available *m*-nitrocinnamic acid, which was esterified in a first step, we probed various conditions for an asymmetric aminohydroxylation (Rudolph *et al.*, 1996), and the best results were obtained by using *tert*-butyl-*N*-chlorocarbamate as the nitrogen source, (DHQ)₂PHAL (hydroquinine 1,4-phthalazinediyl diether) as chiral ligand, and K₂OsO₂(OH)₄ as catalyst. The desired phenylisoserine was eventually obtained with 81% *ee* (see compound **2c** in Montiel-Smith *et al.*, 2002). The title compound resulted from the protection of the amine and hydroxyl groups, *via* the formation of an oxazolidine (Fig. 1).

The molecular structure (Fig. 2) allowed to check for the configuration of chiral atoms C2 and C3 in the precursor isoserine **3**, confirming that the chiral inductor (DHQ)₂PHAL affords the (2*R*,3*S*) isomer predominantly, as expected. The deduced configuration of the third stereocenter in the oxazolidine **I**, 2*R*, also agrees with literature data for related reactions (Denis *et al.*, 1994). The substituents in the oxazolidine skeleton are arranged in such a way that steric hindrance is avoided. The oxazolidine exhibits a conformation very close to the ideal envelope conformation on O1, the puckering parameters (Cremer & Pople, 1975) being $\varphi = 0.3$ (6) $^\circ$ and $q_2 = 0.331$ (3) Å. The ring conformation is related to the substituents distribution. For instance, the X-ray structure for another *N*-Boc protected oxazolidine with a different absolute configuration, (2*R*,4*R*,5*S*), showed a twisted oxazolidine ring (Tinant *et al.*, 1996).

The crystal structure (Fig. 3) is dominated by the stacking of bulky Boc groups, which are oriented along [100], with the molecules linked into double chains parallel to [010] by C—H \cdots O hydrogen bonds (Table 1).

Experimental

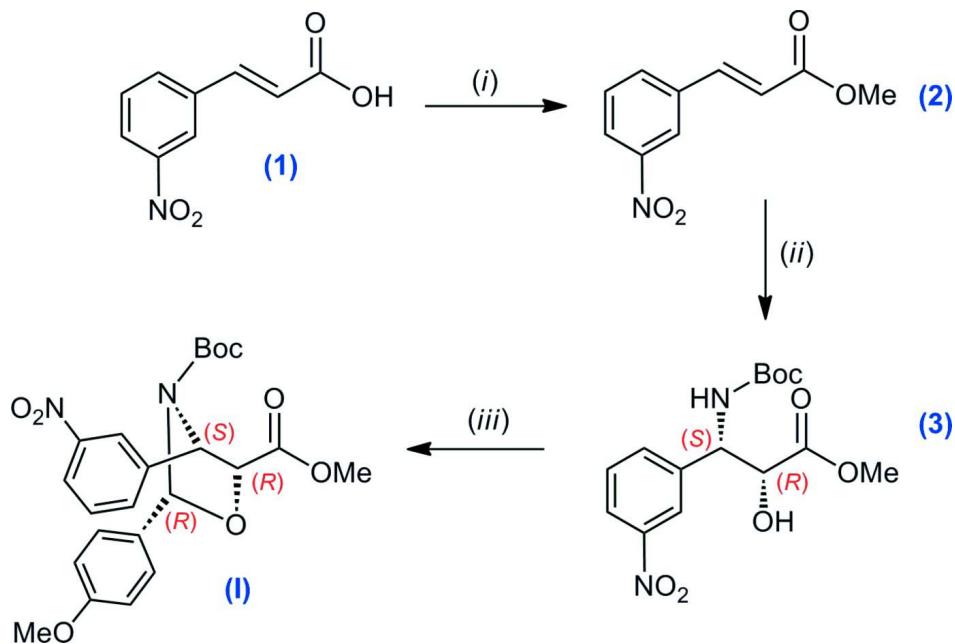

The synthesis starting from commercially available *m*-nitrocinnamic acid **1** is depicted in Fig. 1. The two steps preparation of the phenylisoserine **3** has been published (Montiel-Smith *et al.*, 2002; see compound **2c** therein). The enantiospecific aminohydroxylation reaction was carried out using 'BuOCONHCl as nitrogen source, reagent previously prepared *in situ* by reacting 'BuOCONH₂ and 'BuOCl in a NaOH solution. The last step to afford the title compound is a protection of the amine and hydroxyl groups of **3**, *via* the formation of an oxazolidine, carried out by reacting **3** with 1-(dimethoxymethyl)-4-methoxybenzene in presence of pyridinium *p*-toluenesulfonate, in refluxing toluene. The isolated compound **I** was crystallized from AcOEt/heptane.

Refinement

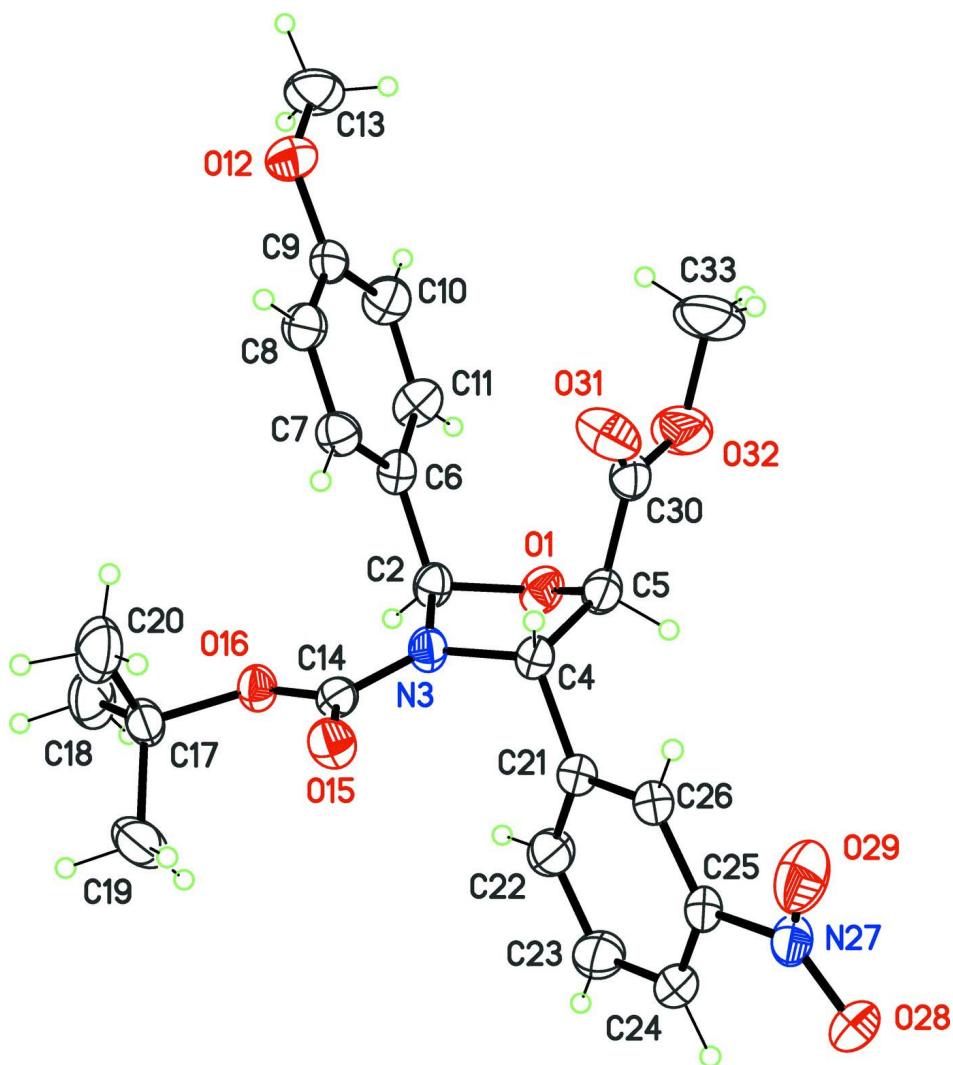

The assignment of the absolute configuration of the three chiral centers was based on the stereospecificity of the synthetic pathway. The second synthetic step (see Fig. 1) allows to fix the stereochemistry for C4 and C5 centers. The last chiral center on C2, formed in the third step, is assigned as *2R* relatively to the (4*S*,5*R*) stereoisomer. The reaction afforded a single stereoisomer. The formation of the chiral center *2R* in **I** is in agreement with reports for related compounds (Denis *et al.*, 1994). Measured Friedel pairs are not suitable for checking this assignation, and were merged (425 pairs). All H atoms were placed in idealized positions, with C—H bond lengths fixed to 0.98 (methine CH), 0.96 (methyl CH₃, rigid groups free to rotate about the C—C bonds) or 0.93 Å (aromatic CH). Isotropic displacement parameters for H atoms were calculated as $U_{\text{iso}}(\text{H}) = xU_{\text{eq}}(\text{carrier C})$, where $x = 1.5$ (methyl groups) or 1.2 (aromatic and methine CH).
