Abstract

Introduction: To report two cases of Acute Macular Neuroretinopathy (AMN) presented as the first stage of SARS-CoV-2 infection in two European countries during the third wave of pandemic viral infection in the early months of 2021.

Observations: A unilateral case of type 1 AMN in a man and a bilateral case of type 2 AMN in an otherwise healthy patients were reported. Sudden onset of paracentral scotoma characterized the cases with no systemic symptoms. Structural optical coherence tomography (OCT) shows multifocal middle and inner retinal hyperreflective infarctions. OCT-Angiography showed the presence of hypoperfusion of the deep capillary plexus (DCP) corresponding to the hyperreflective lesions visible on structural OCT, confirming the diagnosis.

Conclusions and importance: Type 1 and type 2 AMN may be the first stage of SARS-CoV-2 infection. We suggest testing all patients with AMN for SARS-CoV-2. In our cases, the natural history of AMN associated with SARS-CoV-2 infection was similar to already described cases of AMN.

Introduction

Acute macular neuroretinopathy (AMN), described by Bos and Deutman in 1975,^{1,2} is a rare disease of the outer retina predominantly affecting young-to-middle-aged healthy females and characterized by the sudden appearance of one or more paracentral scotomas.

With the advent of more sophisticated retinal imaging modalities, two types of AMN were classified by Sarraf et al. in 2013, depending on the structural OCT location of the lesion: either above (type 1) or below (type 2) the outer plexiform layer (OPL).³ Type 1 AMN is also called paracentral acute middle maculopathy (PAMM).³

While the exact pathophysiology of AMN is still unknown, it is thought to be due to an ischemic insult at the level of the deep retinal capillary plexus (DCP).⁴ AMN was reported to occur after the consumption of oral contraceptives,² post-viral illness, trauma, anemia, thrombocytopenia, and also after routine influenza vaccination.^{1,4,5}

For over a year now, the new severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic has drastically changed peoples' lives across the globe, and a multitude of systemic and organ-specific manifestations have been associated with infection by the virus.⁶ Regarding the retina, these appear in the form of microvascular, ischemic or inflammatory events.^{7,8} In addition, these microvascular alterations seem to occur even in the

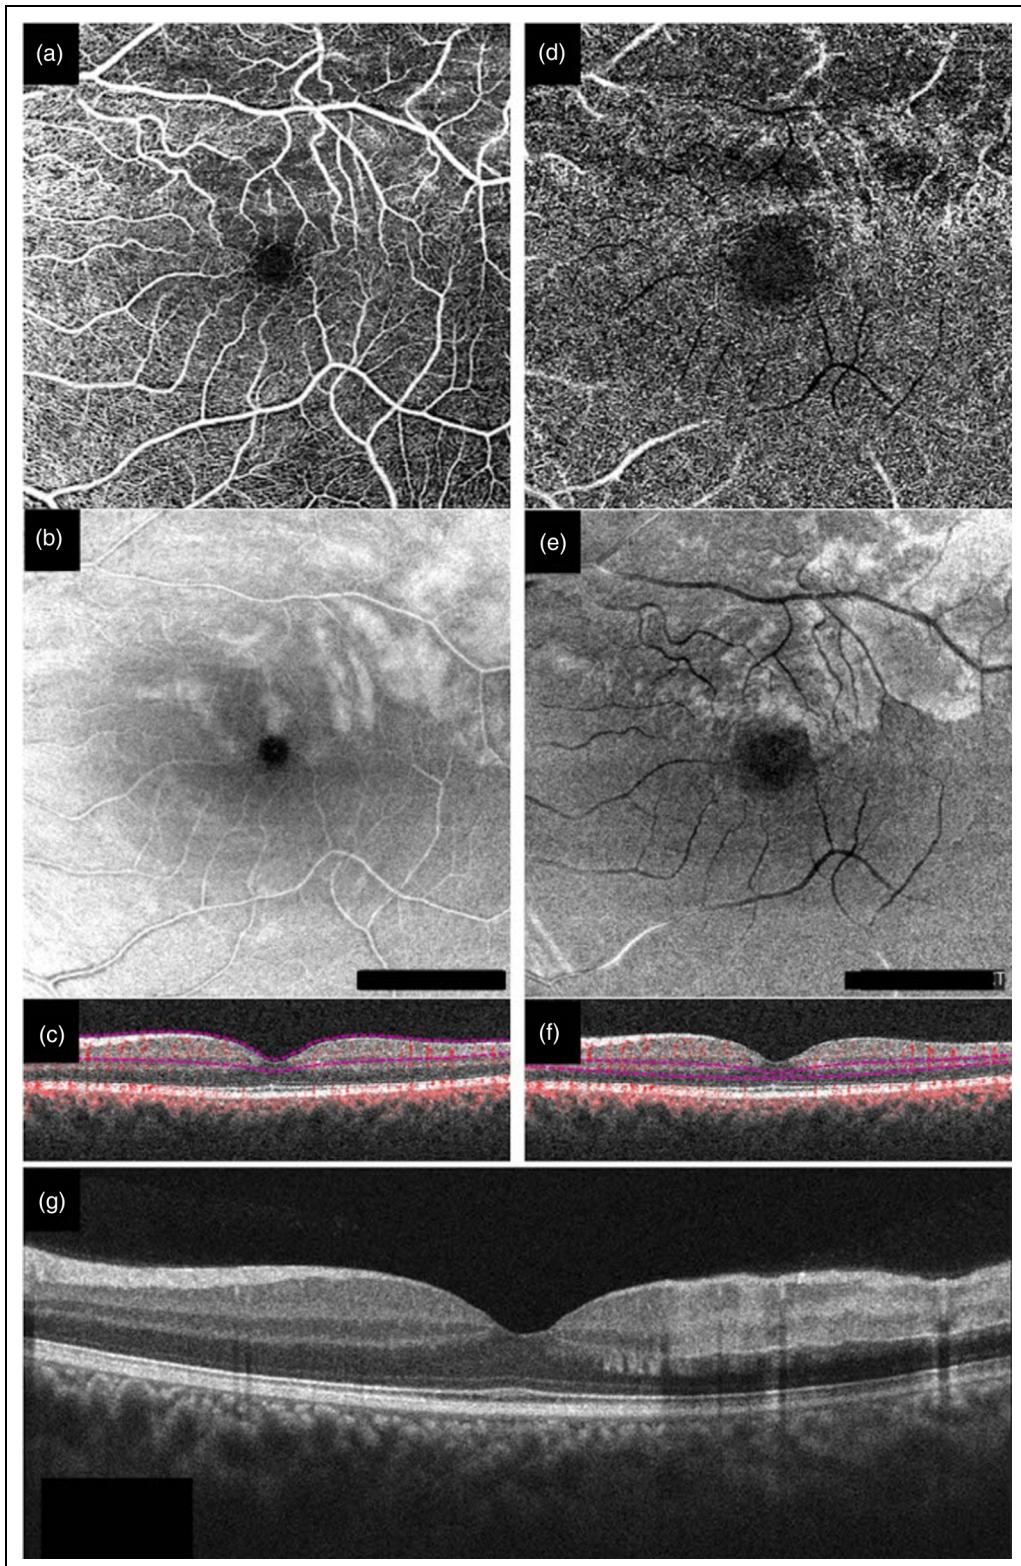

Figure 1. Structural optical coherence tomography (OCT) and OCT-angiography (OCTA) of the left eye in case #1 at the baseline En-face 6 × 6 OCTA, en-face structural OCT, and b-scan OCT with flow of the superficial capillary plexus (a, b, and c, respectively) and the deep capillary plexus (d, e, and f, respectively) showing the presence of hypoperfusion especially in the deep capillary plexus (d), corresponding to the lesions on en-face structural OCT (e). Structural b-scan OCT passing through the fovea (g), showing the presence of multifocal middle and inner retinal hyperreflective infarctions (Angioplex cirrus 5000, Carl Zeiss Meditec, Inc, Dublin, California, USA).

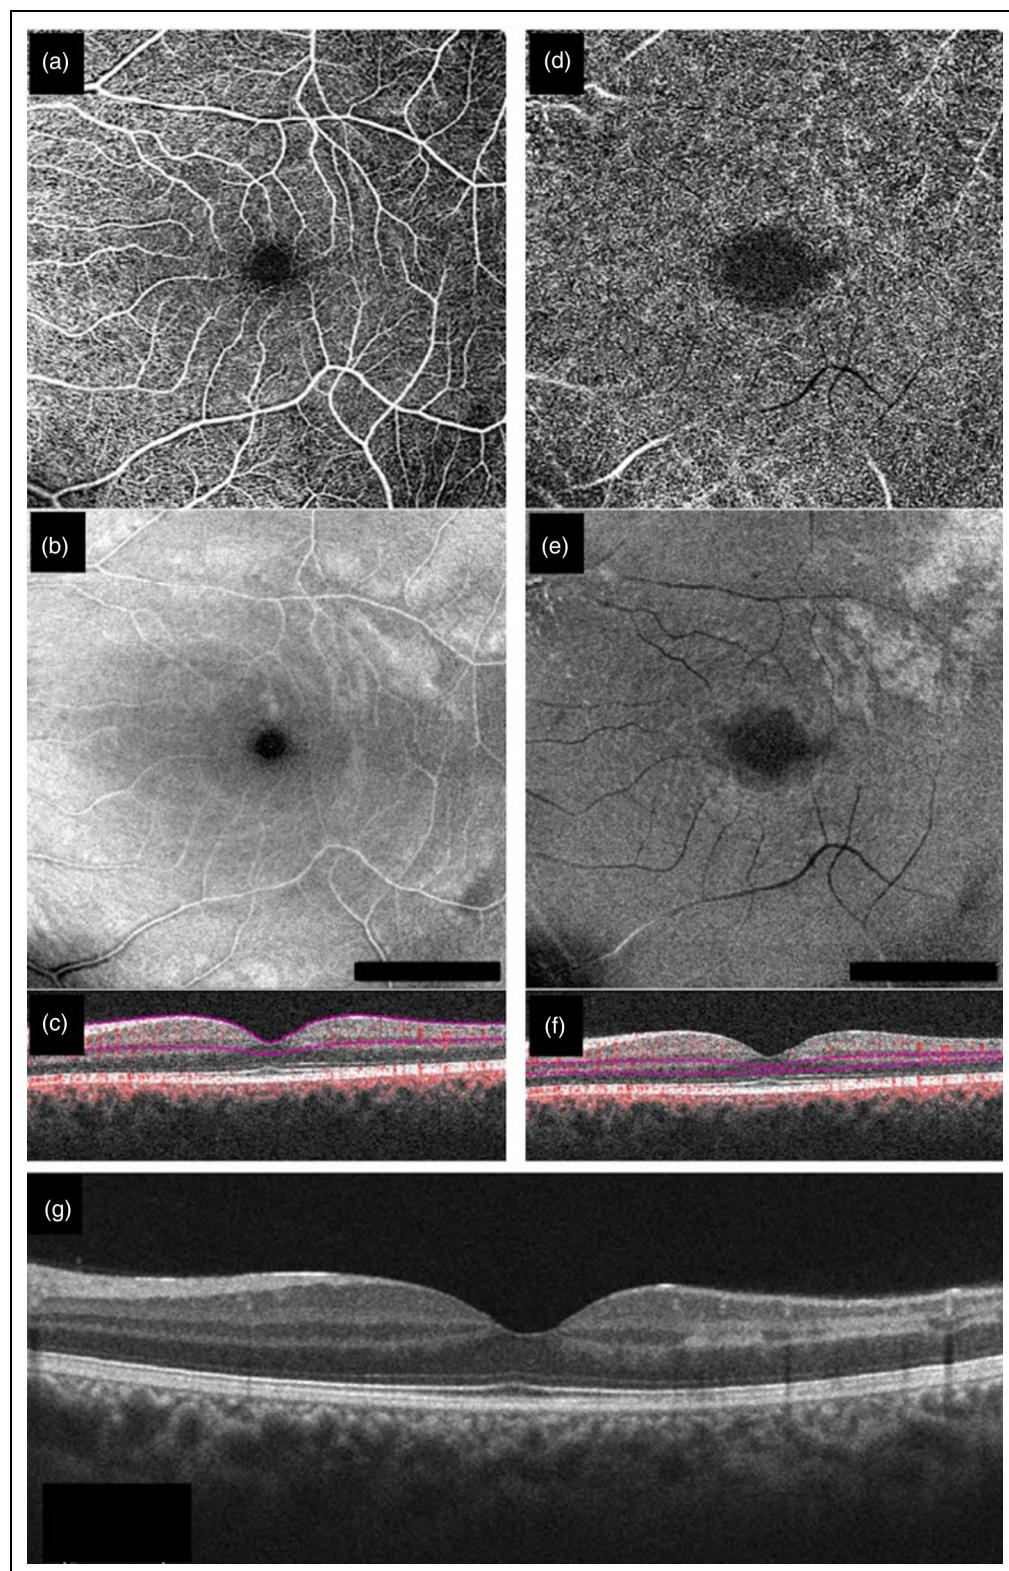

Figure 2. Structural optical coherence tomography (OCT) and OCT-angiography (OCTA) of the left eye in case #1 at 2-week follow-up. En-face 6×6 OCTA, en-face structural OCT, and b-scan OCT with flow of the superficial capillary plexus (a, b, and c, respectively) and the deep capillary plexus (d, e, and f, respectively), showing the improvement of hypoperfusion in both plexuses. Structural b-scan OCT passing through the fovea (g) showing improved multifocal middle and inner retinal hyperreflective infarctions (Angiopix cirrus 5000, Carl Zeiss Meditec, Inc, Dublin, California, USA).

absence of overt retinal pathology, as demonstrated by decreased vessel density in optical coherence tomography angiography (OCTA) in patients with SARS-CoV-2 infection.^{9–11}

Here, we describe here a series of three eyes of two patients with AMN concomitant to SARS-CoV-2 infection, along with their multimodal imaging characteristics, including OCTA.

Observations:

Case #1. A 27-year-old Caucasian man presented with an acute onset of unilateral dyschromatopsia and paracentral scotoma in his left eye (LE), with no other systemic symptoms. His past medical history was unremarkable: he takes no medication, and he denied any eye trauma. The patient, a bar worker, had had several interpersonal contacts without personal protective equipment (PPI) over the preceding weeks. At presentation, best corrected visual acuity (BCVA) was 20/20 in both eyes.

An ophthalmic examination consisting of fundoscopy, OCT, and OCTA was performed (Figure 1). Fundus examination showed a subtle yellowish perifoveal halo in the perifoveal area of the LE. OCTA showed the presence of hypoperfusion of the DCP corresponding to the hyperreflective lesions on structural OCT (Figure 1 a and b, d and e).

Structural OCT revealed the presence of multifocal middle and inner retinal hyperreflective infarctions (Figure 1 c, f, g).

A diagnosis of type 1 AMN (i.e. PAMM) was performed on the basis of pathognomonic OCTA and OCT lesions. On the advice of the ophthalmologist, the patient performed blood tests and a complete screening for coagulation abnormalities, along with testing for SARS-CoV-2 infection. Laboratory investigations revealed slight elevation of liver enzymes and hypertriglyceridemia, compatible with moderate alcohol consumption. The C-reactive protein level and platelets count were slightly elevated. Coagulation testing detected markedly decreased free protein S levels (28.3%, normal laboratory range >72.2%). COVID-19 infection

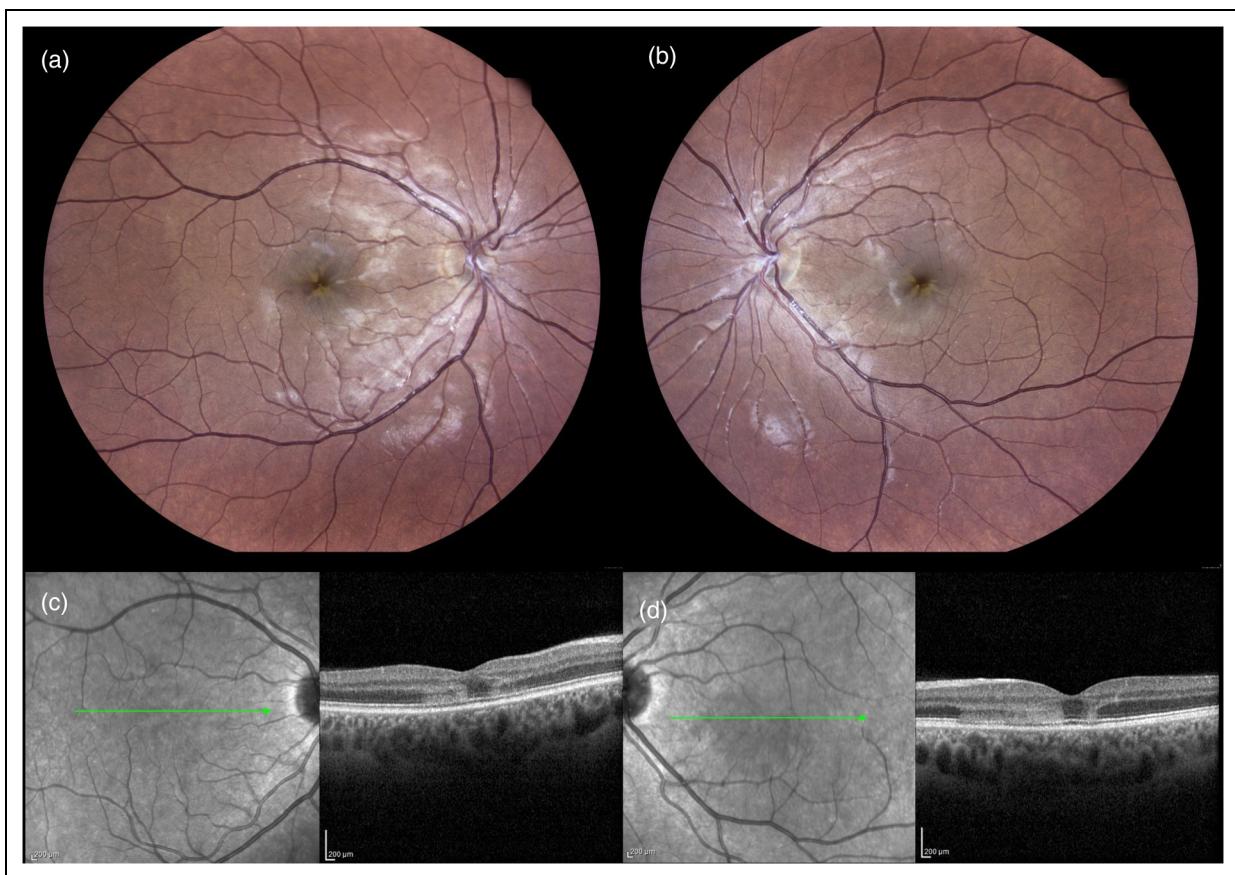

Figure 3. Multimodal imaging of case #2 at baseline. Color confocal retinal image (CRI) (EIDON, Centervue, Italy) shows an alternated foveal reflex without hemorrhages in both eyes (a-b). Structural optical coherence tomography (OCT) disclosed features of Acute Macular Neuroretinopathy (AMN) in both eyes, such as hyper-reflective infarction involving the outer plexiform layer (OPL) and the outer nuclear layer (ONL) with associated disruption of the inner/outer segment (IS/OS) and outer segment/retinal pigment epithelium (OS/RPE) layers consistent with a type 2 Acute Macular Neuropathy (AMN) (c-d). (Heidelberg Engineering, Heidelberg, Germany).

was confirmed by PCR testing with nasopharyngeal swab and progressed in a paucisymptomatic form.

The patient was re-evaluated two weeks later, and his symptoms partially resolved without any treatment (Figure 2).

Case #2. A 37 -year-old healthy female was referred in April 2021 for classic clinical manifestation of AMN (paracentral scotoma). As pro forma, a PCR test for SARS-CoV-2 was performed. At first ophthalmological consultation, patient's BCVA was 20/20 in both eyes with hyperopic correction.

The patient was healthy with no previous significant systemic or ophthalmic history. Anterior segment examination and tonometry were normal.

Color confocal retinal image (CRI) shows an alternated foveal reflex without hemorrhages (Figure 3 a and b). Structural OCT disclosed features of AMN in both eyes, such as hyper-reflective infarction that involved the OPL and outer nuclear layer (ONL), with associated disruption of the inner/outer segment (IS/OS) and outer segment/retinal pigment epithelium (OS/RPE) layers consistent with type 2 AMN (Figure 3 c and d). In order to limit

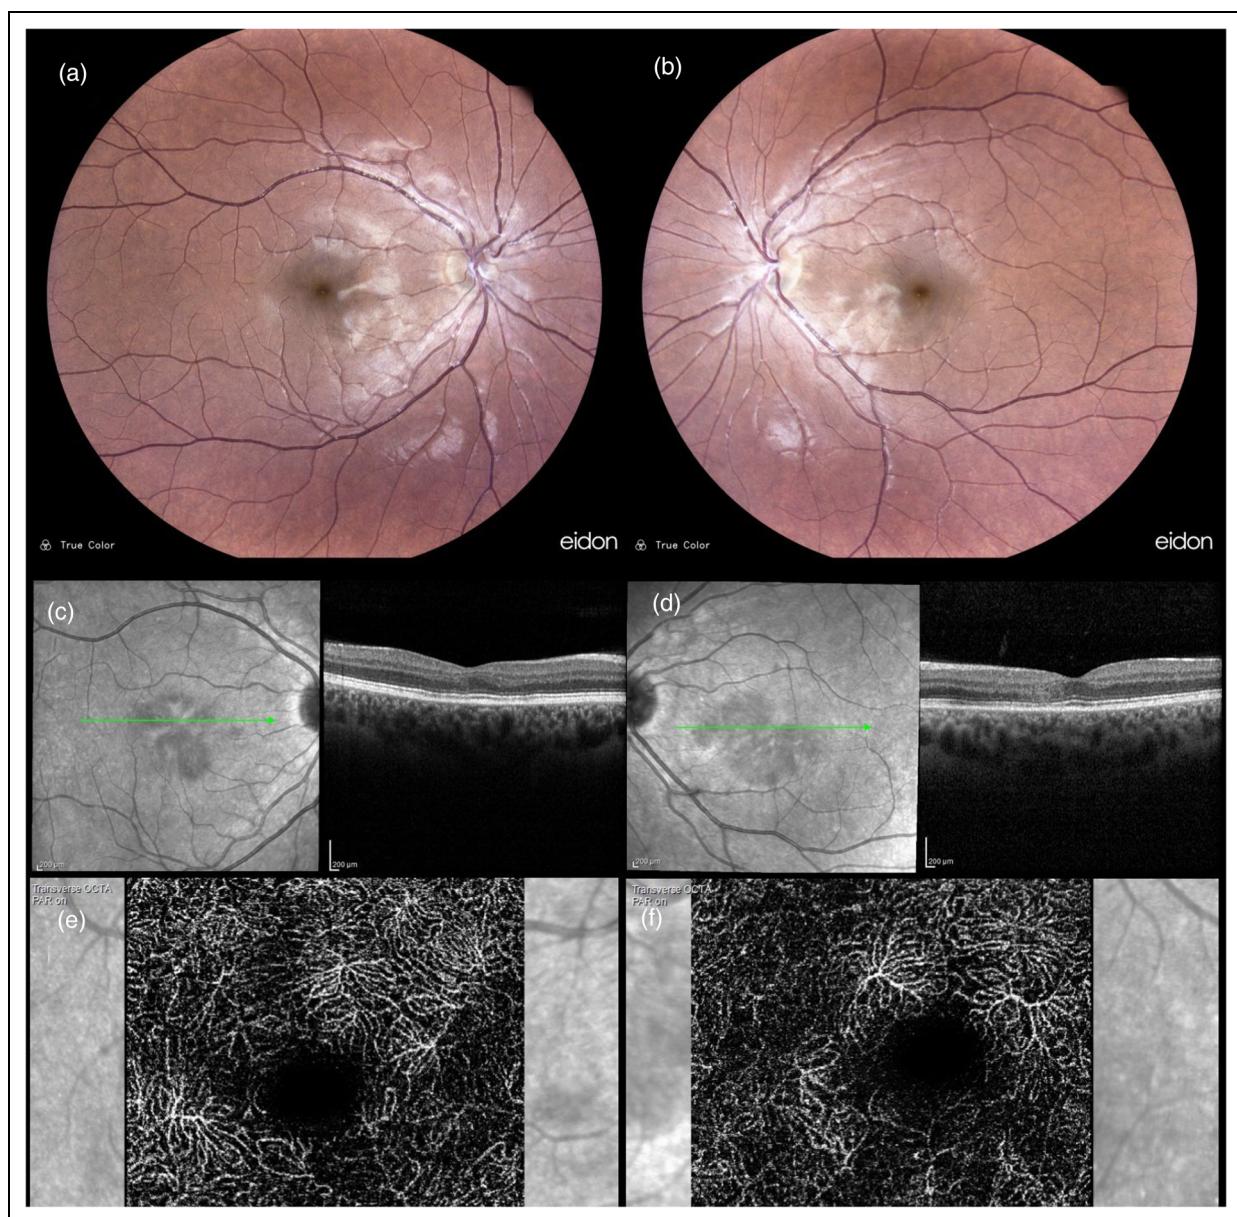

Figure 4. Multimodal imaging of case #2 at month 1 follow-up. Color confocal retinal image (CRI) (EIDON, Centervue, Italy) returned unmarkable (a-b), and OCT shows resolution of infarction, localized atrophy of ONL, and a compromised OS/RPE (c-d). OCTA of the DCP shows a parafoveal flow void (e-f) Spectralis HRA + OCT (Heidelberg Engineering, Heidelberg, Germany).

contact while awaiting the PCR results, first author decided not to perform visual field or other ancillary tests.

Patient was followed weekly. PCR for SARS-CoV-2 disclosure for active SARS-CoV-2 infection revealed she had few systemic symptoms. At last follow-up (month one), PCR for SARS-CoV-2 was negative, BCVA was stable at 20/20 in both eyes, and scotoma r was reduced. CRI results were unmarkable, and OCT shows resolution of infarction, localized atrophy of ONL and a compromised OS/RPE (Figure 4 a to d). OCTA of the DCP shows a parafoveal flow void (Figure 4 e and f).

Discussion

In this report, we observed that two cases of AMN (type 1 in one eye and type 2 in two eyes) are the first stage of SARS-CoV-2 infection. The report suggests an association between this rare retinal inflammation and the prodromal phase of SARS-CoV-2 infection.

To date, only a few cases of association between AMN and SARS-CoV-2 have been published. Two of them referred to elderly patients (70 years old).^{12,13} Another report concerned two younger patients;¹⁴ however, the above-mentioned cases report AMN following COVID infection and symptomatology, while we reported two cases in which the AMN represent a prodromal manifestation of SARS-CoV-2 infection.

The rationale of the association between AMN and SARS-CoV-2 infection arises from the fact that AMN has already been associated with viral infections⁵⁻¹⁵ and SARS-CoV-2 has already been associated with retinal microvascular alteration.^{16,17} An original article has recently suggested that Protein S deficiency (as found in case #1) could be capable of increasing susceptibility to thrombosis.¹⁸ Unfortunately, protein S levels are not available for case #2. Another hypothesis has been proposed by Padhy et al. concerning the role of the D-dimer.¹⁹ This hypothesis needs confirmation by further studies. Moreover, the natural history of our patients did not differ from other reports regarding the association between AMN and viral infections.

Our report has several limitations, the first of which is linked to the very small study population. Although AMN is a rare retinal inflammation, SARS-CoV-2 infection has been diagnosed in several million patients, creating an unlikely statistical association. Second, concerning the visual symptoms: in order to avoid potential virus spread, we did not perform visual field tests to confirm the symptoms. Third, concerning visual prognosis, we report two cases with a one-month follow-up, but late damages could appear in the future. However, the OCT-A images showing hypoperfusion of both plexuses support the hypothesis of ischemic lesion already described lesions associated with AMN. Although retinal vascular events are relatively rare in young patients, there is no definitive evidence that the observations in this

report are linked to SARS-CoV-2. Given the high incidence of SARS-CoV-2 during the pandemic, a report of only 2 cases of retinal ischemia without providing definitive evidence to link both findings remain speculative. Moreover, in the recently published manuscript by Fonollosa et al.,²⁰ concerning retinal vascular occlusions in thirty-nine patients, the authors underlined that they did not find unquestionable link between SARS-CoV-2 infection and their cases. Lastly, we cannot be sure that prodromal symptoms such as headaches are not already present in the patients, as they are quite frequent among workers. Finally, we described only speculative association between AMN and SARS-CoV-2 and not a certain link.

In conclusion, we report three cases of AMN (type 1 in one eye and type 2 in two eyes) during the first stage of SARS-CoV-2 infection in order to emphasize that any apparently healthy patient should test for SARS-CoV-2 if they present type 1 or type 2 AMN.
