16 **Abstract**

17 The outbreak of a novel human coronavirus (SARS-CoV-2) has evolved into global health  
18 emergency, infecting hundreds of thousands of people worldwide. In an effort to find antiviral  
19 medications, many computational groups have pursued the 3C-like protease of the virus, also  
20 known as main protease ( $M^{Pro}$ ), as a drug target. We have identified experimental data on the  
21 inhibitory activity of compounds tested against closely related (96% sequence identity, 100%  
22 active site conservation) protease of SARS-CoV and employed this data to build Quantitative  
23 Structure-Activity Relationships (QSAR) models for this dataset. We employed these models for  
24 virtual screening of all marketed, withdrawn, experimental, and investigational drugs from  
25 DrugBank, including compounds in clinical trials. Molecular docking and similarity search  
26 approaches were explored in parallel with QSAR modeling, but molecular docking failed to  
27 correctly discriminate between experimentally active and inactive compounds, so we did not rely  
28 on this approach in prospective virtual screening. As a result of our studies, we recommended 41  
29 approved, experimental, or investigational drugs as potential agents against SARS-CoV-2 acting  
30 as putative inhibitors of  $M^{Pro}$ . Ten compounds with feasible prices were purchased and are  
31 awaiting the experimental validation. This manuscript will be updated once results are available  
32 and submitted for peer-review publication if compounds are found to be active in SARS-CoV-2  
33 phenotypic screen.

## 34 **Introduction**

35           On December 8th, 2019, Chinese health authorities in Hubei detected the first case of an  
36 infection caused by a novel coronavirus since named SARS-CoV-2.<sup>1,2</sup> On January 31, less than  
37 two months later, the World Health Organization declared the SARS-CoV-2 outbreak a global  
38 health emergency.<sup>3</sup> The new coronavirus is most similar to a bat betacoronavirus that does not  
39 infect humans, but it is also in the same family as the notorious human coronaviruses SARS-CoV  
40 (sudden acute respiratory syndrome coronavirus) and MERS-CoV (Middle Eastern Respiratory  
41 Syndrome coronavirus), which have reported fatality rates of 10% and 35%, respectively.<sup>4,5</sup>  
42 Current (as of April 16<sup>th</sup>, 2020) estimates of the fatality rate of COVID-19 vary per age cohort and  
43 the virus to date is estimated to have infected over two million people, though these statistics are  
44 approximate due to established asymptomatic transmission of the disease or likely underreporting  
45 or lack of testing by health authorities.<sup>6,7</sup> While the fatality rate of the current virus is estimated  
46 to be less than that of SARS and MERS-CoV, it has been shown to be highly transmissible,  
47 infecting the first 1,000 patients in only 48 days, whereas SARS took 130 days and MERS took  
48 2.5 years.<sup>8</sup> The initial velocity of the spread of SARS-CoV-2 was enough to indicate pandemic  
49 potential at the start of the outbreak, and now and hundreds of thousands of cases have been  
50 reported worldwide despite strict quarantine and travel protocols set in place in many countries.

51           No antivirals or vaccines exist against SARS-CoV-2 or past epidemic betacoronaviruses,  
52 which represents a larger-scale paucity of data on this genus of viruses.<sup>9</sup> Genomic sequences of  
53 the SARS-CoV-2 continue to be uploaded to GenBank, hosted by the National Center for  
54 Biotechnology Information (NCBI), and there are 1084 distinct sequences listed there to date.<sup>10</sup>  
55 The first protein crystal structure for SARS-CoV-2 deposited in the Protein Data Bank in February  
56 2020 was the 2019-nCoV main protease (also known as 3C-like protease or M<sup>pro</sup>) in complex with

57 an inhibitor N3 (PDB ID: 6LU7).<sup>11</sup> One of the only papers to date investigating compounds with  
58 anti-SARS-CoV-2 activities tested seven compounds total and reported four hits, most notably  
59 remdesivir and chloroquine.<sup>12</sup> Other studies have reported other compounds with anti-SARS-CoV-  
60 2 activities such as ivermectin<sup>13</sup> and  $\beta$ -D-N4-hydroxycytidine (NHC, EIDD-1931).<sup>14</sup> Another  
61 study identified six compounds to have activity against SARS-CoV-2 M<sup>pro</sup>, but only only ebselen  
62 showed activity in phenotypic screen.<sup>15</sup> Already COVID-19 clinical trials are being performed that  
63 utilize repurposing of existing experimental nucleoside analogs such as remdesivir, ribavirin, and  
64 favipiravir that have demonstrated past antiviral activities.<sup>16</sup>

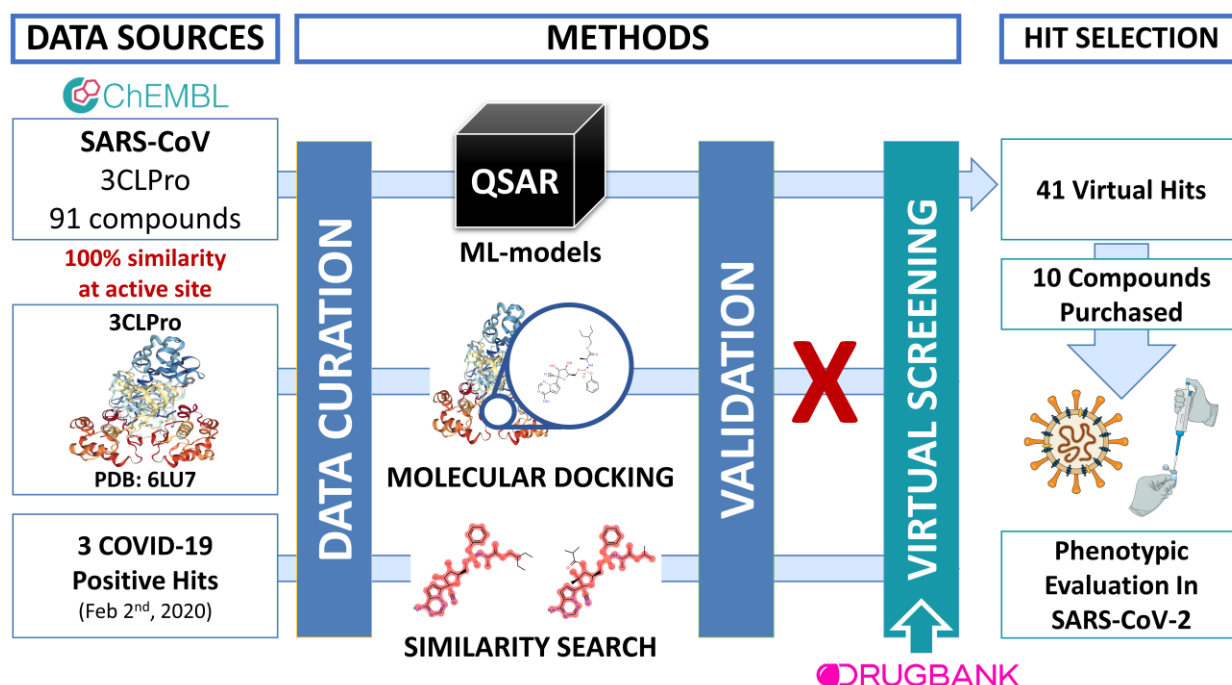

65 Past research has identified several targets for coronavirus drug development, namely  
66 nonstructural protein 14 (nsp14-ExoN) and the proteins involved in the coronaviral RNA  
67 replication process (replicase polyprotein 1ab and M<sup>pro</sup>)<sup>17</sup>. The replicase polyprotein 1ab is  
68 responsible for the synthesis of the large, functional polyproteins pp1a and pp1ab, which are  
69 precursors of 16 non-structural proteins that are important in the replication of coronavirus  
70 RNA.<sup>18-20</sup> The replicase polyprotein 1ab (ChEMBL5118) is a precursor of 16 non-structural  
71 proteins,<sup>21</sup> such as RNA polymerase, helicase, 3'-5' exonuclease, and 2'-O-ribose  
72 methyltransferase. The polyprotein 1ab along with polyprotein 1a are precursors of all proteins  
73 that form the viral replication complex (e.g., 1ab has 7,095 aminoacids). These are not functional  
74 unless proteases (M<sup>pro</sup> and papain-like proteinase) cleave them into those 16 smaller proteins.<sup>22</sup>  
75 The virus-encoded M<sup>pro</sup> is integral to the proteolytic processing of these polyproteins and is highly  
76 conserved in coronaviruses, as are the cleavage sites and lengths of the polyproteins  
77 themselves.<sup>19,23,24</sup> Furthermore, M<sup>pro</sup> has been considered before in the design of broad-spectrum  
78 antiviral compounds as demonstrated in a 2012 study by Kim et al.<sup>25</sup> that reported in vitro  
79 inhibition of SARS-CoV replication by inhibitors of this protease.<sup>19</sup>

80 Given the lack of publicly available data on the new coronavirus, we emphasize the  
81 message of the recent editorial titled “Calling all coronavirus researchers: keep sharing, stay open,”  
82 that calls for researchers to collaborate and share all data on the new coronavirus to better prevent  
83 its spread and morbidity.<sup>26</sup> Many studies reporting compounds identified by computational  
84 approaches have been published in both peer-reviewed<sup>27,28</sup> and arXiv journals<sup>29,30</sup> since the  
85 outbreak of SARS-CoV-2 was reported. In line with this call, we curated all available open-source  
86 data on SARS-CoV-2 and SARS-CoV and employed both structure- and ligand-based  
87 computational approaches to select a set of compounds that may have the potential to inhibit  
88 SARS-CoV-2 replication. In this initial investigation, we have exclusively focused on FDA  
89 approved medications or experimental/investigational compounds because these could be quickly  
90 repurposed as COVID-19 treatments if their experimental validation is successful.

91

## 92 Materials and Methods

93 The workflow employed in this study can be seen in **Figure 1**.

94

95 **Figure 1.** Study design.

96

## 97 **Quantitative Structure-Activity Relationship (QSAR) modeling**

### 98 *Data collection and curation*

99 We collected 201 datapoints for the SARS-CoV M<sup>pro</sup> assay (ChEMBL ID: X) and, after  
100 curation, 91 compounds (27 actives and 64 inactives, considering a threshold of 10  $\mu$ M) were kept.  
101 We found 22 additional compounds in PDB (13 actives and 9 inactives) that were not available in  
102 ChEMBL. At the end, 113 compounds (40 actives and 73 inactives) were kept for modeling. All  
103 chemical structures and correspondent biological information were carefully standardized using  
104 Standardizer v.20.8.0 (ChemAxon, Budapest, Hungary, <http://www.chemaxon.com>) according to  
105 the protocols proposed by Fourches and colleagues.<sup>31,32</sup> Briefly, inorganics, counterions, metals,  
106 organometallic compounds, and mixtures were removed. In addition, specific chemotypes such as  
107 aromatic rings and nitro groups were normalized. Furthermore, we performed the analysis and  
108 exclusion of duplicates: (i) if duplicates presented discordance in biological activity, both entries  
109 would be excluded; and (ii) if the reported outcomes of the duplicates were the same, one entry  
110 would be retained in the dataset and the other excluded.

### 111 *Molecular descriptors*

112 The QSAR models were developed using three types of descriptors: Morgan fingerprints,<sup>33</sup>  
113 2D Simplex Representation of Molecular Structure (SiRMS) descriptors<sup>34</sup> and Dragon (v.7 Kode  
114 Chemoinformatics srl – Pisa, Italy). The open-source Morgan fingerprints with 2048 bits and an  
115 atom radius of 3 calculated in RDKit (<http://www.rdkit.org>) using Python 3.6. SiRMS were  
116 calculated using HiTQSAR<sup>35</sup> at the 2D level. SiRMS descriptors account not only for the atom  
117 type, but also for other atomic characteristics that may impact biological activity of molecules,  
118 e.g., partial charge, lipophilicity, refraction, and atom ability for being a donor/acceptor in

119 hydrogen-bond formation (H-bond). Detailed description of HiTQSAR and SiRMS can be found  
120 elsewhere.<sup>35</sup> Dragon descriptors were calculated at 2D level as well. For both SiRMS and Dragon,  
121 descriptors with less than 0.01 variance were removed. Correlated descriptors were also removed.

### 122 *Model generation*

123 QSAR models were built and rigorously validated following best practices.<sup>36</sup> The models  
124 were built using the Random Forest (RF) algorithm<sup>37</sup> implemented in scikit-learn ([http://scikit-](http://scikit-learn.org)  
125 [learn.org](http://scikit-learn.org)). Random Forest hyperparameters were tuned using the GridSearchCV module  
126 implemented in scikit-learn. Trees were decorrelated by randomly bootstrapping compound  
127 instances used in modeling with replacement and selecting a random sample of root(N)-many  
128 features for each tree, where N is the total number of features available. Trees were configured to  
129 evaluate features on classification accuracy at the median value and to use gini as the split criterion.

130 A 5-fold external cross-validation procedure was performed using the following protocol.  
131 The full set of compounds with known experimental activity is randomly divided into five subsets  
132 of equal size. One of these subsets (20% of all compounds) is set aside as the external validation  
133 set, while the remaining four sets form the modeling set (80% of all compounds). This procedure  
134 is repeated five times, allowing each of the five subsets to be used as an external validation set.  
135 Models are built using the training set only, and it is important to emphasize that compounds are  
136 never simultaneously part of both the training and external validation set.

137 Two types of consensus were performed: consensus is a majority average of predictions  
138 from the independent models developed with Morgan, SiRMS, and Dragon. Consensus AD is a  
139 majority average prediction from independent models when predictions are inside the applicability  
140 domain of that model. The local (tree) applicability domain approach<sup>38</sup> setting a threshold of 70%  
141 was used for all RF models developed in this study.

142

### 143 **Molecular Docking**

144 Molecular docking experiments were performed using the structure of M<sup>Pro</sup> from SARS-  
145 CoV-2 (PDB ID: 6LU7). To enable these calculations, the structure was prepared in Maestro<sup>39</sup>  
146 under pH 7.0±2.0 and optimized with OPLS3e force field. All ligands were prepared under the  
147 same conditions and submitted to molecular docking using Glide<sup>12</sup> with the standard precision  
148 (SP) option.

149

### 150 **Similarity Search**

151 Similarity search was performed in the KNIME platform (<https://www.knime.com/>) using  
152 Morgan fingerprints using the three compounds described by Wang et al.<sup>12</sup> as active in the  
153 phenotypic screen (remdesivir, chloroquine, and nitazoxanide). A threshold of 75% similarity in  
154 Tanimoto coefficient was employed to select compounds from DrugBank as putative actives.

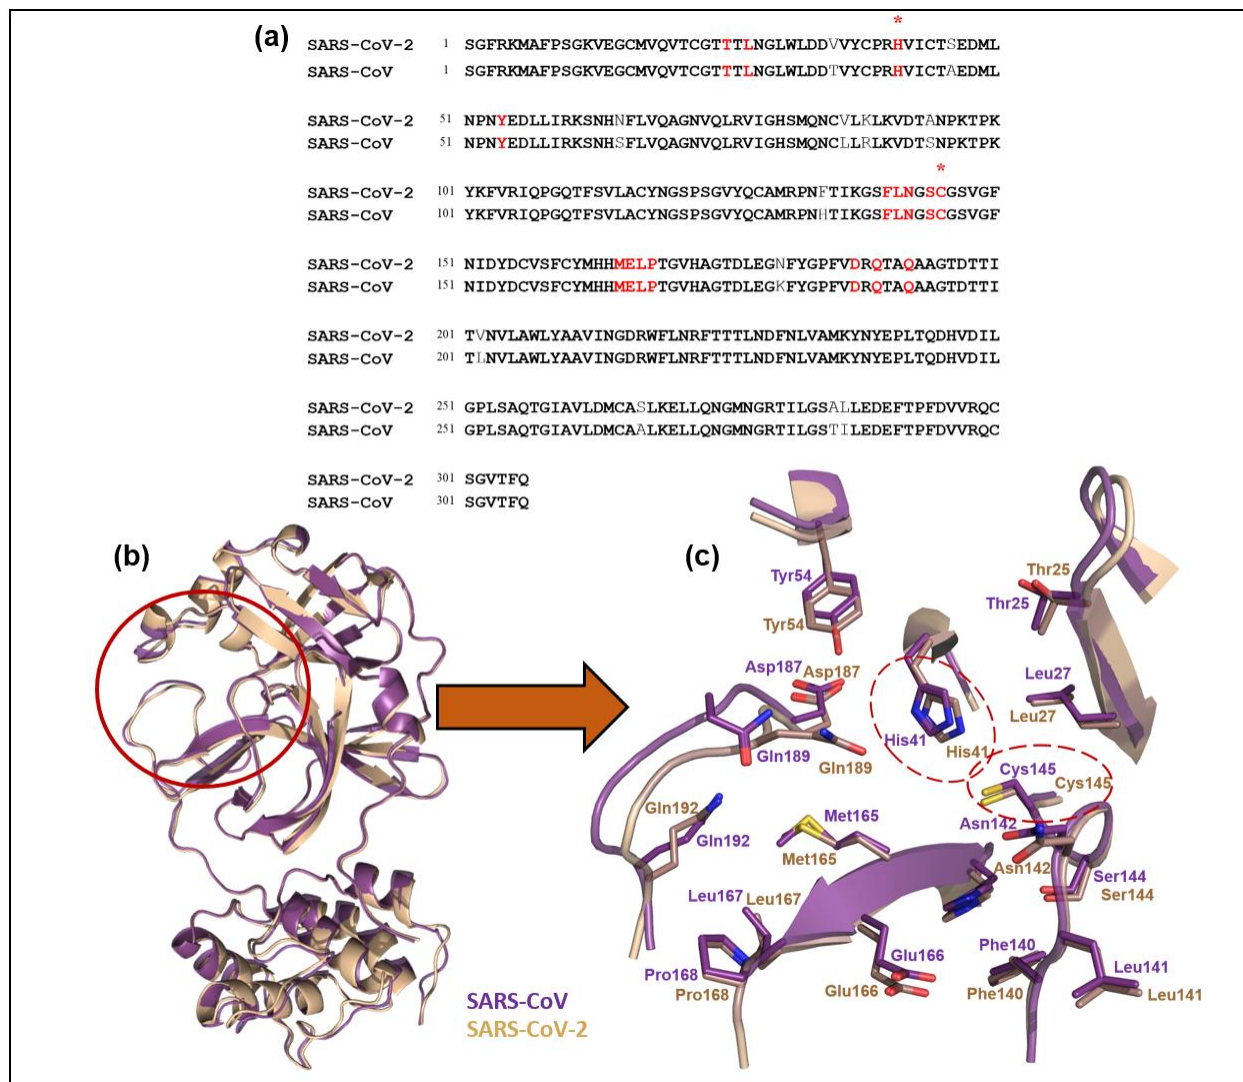

155

### 156 **Results and Discussion**

157 As seen in Figure 1, we employed three different computational strategies to screen a wide  
158 array of compounds from DrugBank in order to suggest preexisting compounds with possible  
159 inhibitory activities against SARS-CoV-2. We started by collecting all publicly available data on  
160 the SARS-CoV-2 and other coronaviruses. We excluded all phenotypic assays from modeling on  
161 the basis of a recent study by Wang et al.<sup>40</sup> which demonstrated that some compounds active  
162 against SARS-CoV were not active against SARS-CoV-2 in a phenotypic screen. The replicase  
163 polyprotein 1ab was discarded because its whole structure is not available in PDB, but just its  
164 derivatives. Using Basic Local Alignment Search Tool (BLAST) available in UniProt

165 (<https://www.uniprot.org/blast/>)<sup>41</sup>, we observed that the primary sequences of M<sup>pro</sup> in both SARS-  
 166 CoV and SARS-CoV-2 had 96% identity (Figure 2a). The crystal structure of SARS-CoV-2 M<sup>pro</sup>  
 167 was recently elucidated and superposition of the respective 3D protein structures (PDB IDs: 5N19,  
 168 6LU7) revealed a conserved binding site around the co-crystallized inhibitors including the  
 169 catalytic dyad represented by His41 and Cys145 (Figures 2b and 2c).<sup>42</sup>

170  
 171 **Figure 2.** Alignment of SARS-CoV and SARS-CoV-2 M<sup>pro</sup> monomers. (a) Primary sequence  
 172 alignment highlighting the conserved residues in bold font. The binding site residues are shown in  
 173 red and the catalytic dyad, represented by His41 and Cys145, is marked with asterisks. (b)  
 174 Alignment of M<sup>pro</sup> monomers available in PDB (IDs: 5N19, 6LU7). (c) Visualization of the  
 175 overlap between residues at the M<sup>pro</sup> active site for SARS and SARS-CoV-2. The red dashed

176 circles show the conserved catalytic dyad and the remarkable conservation of the binding site of  
177 M<sup>Pro</sup> between the coronaviruses.  
178

179 The 113 compounds (40 actives and 73 inactives) kept after curation were used for binary  
180 QSAR modeling. The statistical characteristics of our QSAR models are available in Table 1. Due  
181 to the limited size of the dataset, models were only validated by 5-fold external cross validation  
182 and achieved external correct classification rate of 71-83% (sensitivity = 55-72%, positive  
183 predicted value = 72-100%, specificity = 88-100%, negative predicted value = 78-85%). Models  
184 were generated with the entire (unbalanced) dataset. Although sensitivity was only acceptable<sup>36</sup>  
185 (> 60% for majority of the models) and below this threshold for Dragon models, we decided to  
186 proceed with this model because the PPV was higher. This guarantees that a lower number of hits  
187 would be found, but a higher confidence is expected.

188

189 **Table 1.** Statistical characteristics of QSAR models for SARS-CoV M<sup>Pro</sup> assessed by 5-fold  
190 external validation.

Model	CCR	Sensitivity	PPV	Specificity	NPV	Coverage
Morgan	0.78	0.65	0.81	0.92	0.83	1.00
Morgan AD	0.80	0.62	0.94	0.98	0.85	0.69
SiRMS	0.76	0.65	0.72	0.86	0.82	1.00
SiRMS AD	0.83	0.72	0.86	0.93	0.85	0.61
Dragon	0.71	0.55	0.71	0.88	0.78	1.00
Dragon AD	0.78	0.56	1.00	1.00	0.87	0.54
Consensus	0.74	0.60	0.73	0.88	0.80	1.00
Consensus (AD)	0.78	0.62	0.86	0.95	0.83	0.77

191

192 Recently, Wang et al.<sup>39</sup> demonstrated that remdesivir and chloroquine were highly active;  
193 nitazoxanide was moderately active; and ribavirin, penciclovir, nafamostat, faviparir were inactive  
194 against SARS-CoV-2 in phenotypic assays. The SiRMS models predicted remdesivir and ribavirin

195 as active, while Dragon predicted ribarivir only. Currently, there are no evidence none of these  
196 targets act on M<sup>pro</sup>; remdesivir is a known RNA polymerase inhibitor.<sup>43</sup>

197 In addition, Jin et al.<sup>44</sup> submitted a library of ~ 10,000 compounds to a high-throughput  
198 screening (HTS) and identified six inhibitors of SARS-CoV-2 M<sup>pro</sup>, namely, ebsele, disulfiram,  
199 tideglusib, carmofur, shikonin, and PX-12. After additional phenotypic assays, only ebsele  
200 inhibited *in vitro* viral replication. Despite the large amount of compounds tested in HTS, only the  
201 activity of those six inhibitors was reported, so there is no publicly available data on SARS-CoV-  
202 2 M<sup>pro</sup> yet that could enable the development of QSAR models.

203 Due to the small amount of publicly available SARS-CoV-2 M<sup>pro</sup> assay data and the high  
204 similarity 96% identity sequence of M<sup>pro</sup> in SARS-CoV and SARS-CoV-2, including conserved  
205 active site (see above), we hypothesized that compounds predicted to be active in the SARS-CoV  
206 M<sup>pro</sup> assay<sup>45</sup> (used for compounds in our modeling set) could be active against SARS-CoV-2.

207 In addition, we have also predicted M<sup>pro</sup> activity for twenty three compounds reported to  
208 undergo clinical trials (as of March 23, 2020)<sup>46</sup> (See Table S1 in Supplementary Materials). Of  
209 these compounds, lopinavir, ritonavir, tetrandrine, cobicistat, losartan, ribavirin, remdesivir,  
210 aripravadil, and danoprevir were predicted as active by SiRMS models. Lopinavir was also predicted  
211 as active by Dragon. None of the molecules were predicted as active by Morgan models. Lopinavir  
212 is an established protease inhibitor that approved for use in HIV patients and is usually used in  
213 conjunction with ritonavir, another protease inhibitor.<sup>47</sup> Lopinavir and lopinavir/ritonavir have  
214 been tested previously on SARS<sup>48</sup> and MERS-CoV<sup>49</sup>, but recent clinical trials suggest that the drug  
215 combination is not as successful as expected against SARS-CoV-2.<sup>50</sup>

216 Since no data is available to build models for SARS-CoV-2 M<sup>pro</sup> and considering the high  
217 similarity between these targets, we we decided to employ these models to virtually screen the

218 curated DrugBank dataset and submit these molecules for experimental evaluation.. Applying our  
219 models to screen this dataset of 9,615 compounds yielded 41 compounds predicted as actives using  
220 a Consensus and Consensus AD models.

221 In parallel, we have also conducted molecular docking experiments using the structure of  
222 M<sup>Pro</sup> from SARS-CoV-2 (PDB ID: 6LU7).<sup>11</sup> Before using docking as a virtual screening tool, it is  
223 crucial to validate the approach with known experimental data. Therefore, known inhibitors and  
224 non-inhibitors of M<sup>Pro</sup> were used to evaluate if the docking score was capable of ranking active  
225 compounds better than inactives. For this purpose, the curated dataset (ChEMBL3927) used for  
226 QSAR modeling was applied in a docking validation run. Then, compound ranking by the docking  
227 score was compared with ranking by activity in the ChEMBL assay. The results suggested that  
228 docking scores were poorly correlated with the binding affinity as indicated by the area under the  
229 receiver operating characteristic (ROC) score of 0.49 (Figure 3), implying that docking scores  
230 randomly assigned compounds as actives and inactives. Additionally, the early enrichment was  
231 poor with sensitivity of only 0.11 for the top 10% ranked compounds, i.e., actives were ranked  
232 poorly while inactives were occupying the top of the list of virtual hits. The top 15% also presented  
233 poor sensitivity (0.14) . Only after the top 69% of the list was considered, the sensitivity reached  
234 reasonable values (0.70). Based on these results, docking was discarded as a virtual screening  
235 approach.

236

237 **Figure 3.** Receiver operating characteristic (ROC) after running the docking validation screening  
 238 with known inhibitors and non-inhibitors of  $M^{pro}$ .

239

240 We also employed a similarity search using three compounds described by Wang et al.<sup>12</sup>  
 241 as<sup>39</sup> active in the phenotypic screen (remdesivir, chloroquine, and nitazoxanide). We found that  
 242 only the following 13 compounds from the curated DrugBank dataset had Tanimoto similarity  
 243 coefficient higher than 75% to any of those three drugs: anhydrovinblastine, GS-6620,  
 244 hydroxychloroquine, lurbnectedin, quinacrine, quinacrine mustard, rifalazil, vinblastine,  
 245 vincristine, vindesine, vinflunine, vinorelbine, and 3''-(beta-chloroethyl)-2'',4''-dioxo-3, 5''-spiro-  
 246 oxazolidino-4-deacetoxy-vinblastine.

247 Five out of 13 compounds were predicted as active by SiRMS models, including  
 248 anhydrovinblastine, vincristine, vindesine, vinflunine, vinorelbine. SiRMS and Dragon together  
 249 also predicted lurbnectedin, rifalazil, vinblastine and 3''-(beta-chloroethyl)-2'',4''-dioxo-3, 5''-

250 spiro-oxazolidino-4-deacetoxy-vinblastine as active. Most of these compounds are vinca  
251 alkaloids. Most literature on this class of alkaloids concerns cancer biology, since many are  
252 chemotherapy drugs, but other classes of alkaloids have been noted to have antiviral activities.<sup>51-</sup>  
253 <sup>54</sup> Interestingly, ritonavir, a protease inhibitor used in the treatment of HIV and that is being tested  
254 currently in clinical trials for COVID-19 boosts the levels of chemotherapy drugs, including vinca  
255 alkaloids.<sup>55</sup> Vinca alkaloids are used as chemotherapy drugs, but can have problematic side  
256 effects.<sup>56</sup> Lurbinectedin and rifalazil are both potent RNA polymerase inhibitors; lurbinectedin is  
257 used as an anticancer agent<sup>57</sup> while rifalazil has shown success in treating Chlamydia trachomatis  
258 infections.<sup>58</sup>

259 Thus, we selected 41 hits from DrugBank based on QSAR predictions, including four  
260 compounds identified by similarity search and predicted by both SiRMS and Dragon. These hits  
261 have been found among commercially available compounds listed in ZINC database<sup>59</sup> and the  
262 vendors selling these compounds were identified using our in-house ZINC-Express software  
263 (<https://zincexpress.mml.unc.edu/>) (Table S1 in Supplemental Materials). We purchased 10  
264 compounds (Table 2) that were financially feasible for testing and submitted them for experimental  
265 evaluation by our collaborators at the University of Kentucky. The experimental data for testing  
266 these compounds in M<sup>Pro</sup> assay will be reported in the updated version of this manuscript once the  
267 results become available. The complete list of hits is available in the supplementary materials.

268

269 **Table 2.** Selected hits for experimental evaluation.

Generic name	Primary use	DrugBank ID
Ipamorelin	postoperative ileus	investigational
Tilmicosin	antibiotic	investigational; vet_approved
Budipine	antiparkinson	experimental
Atazanavir	HIV	approved; investigational
Pentagastrin	stimulates gastric acid secretion	approved

Indinavir	HIV	approved
Vinblastine	Anti-cancer	approved
Afimoxifene	estrogen receptor modulator/anti-cancer	investigational
Navitoclax	Bcl-2 inhibitor/anti-cancer	investigational
Venetoclax	chronic lymphocytic leukemia	approved; investigational

270

271 Of the model's top hits, two of the most promising are camostat and nitazoxanide, which are  
 272 currently being tested in clinical trials<sup>60,61</sup> and have demonstrated anti-coronaviral activities in past  
 273 studies.<sup>62</sup> Camostat is a serine protease inhibitor<sup>63</sup> and nitazoxanide is a broad-spectrum antiviral  
 274 drug.<sup>62,64,65</sup> Analysis of the literature suggests that selumetinib, PD-0325901, and leflunomide (see  
 275 Table 3) are also promising candidates, as they are known kinase inhibitors that also have  
 276 suggested antiviral activity.<sup>43,65</sup> Leflunomide is an anti-rheumatic drug that has shown past  
 277 antiviral activity against cytomegalovirus as well as immunosuppressivity. Its metabolite, A77  
 278 1726, can inhibit protein kinase activity and the activity of dihydroorotate dehydrogenase  
 279 (DHODH), the latter which has been suggested as a possible host antiviral target for SARS-CoV-  
 280 2.<sup>64</sup> Selumetinib and PD-0325901 are MEK inhibitors; of the two, selumetinib is the only to have  
 281 demonstrated anticoronaviral activity (against SARS- and MERS-CoV) in past studies.<sup>66</sup> In  
 282 combination with another hit from Table 3, oseltamivir, PD-0325901 has shown antiviral activity  
 283 against the influenza virus,<sup>62</sup> though it has been suggested that it could serve as a possible antiviral  
 284 drug by itself.<sup>43</sup>

285

## 286 **Conclusions**

287 In this study, we utilized previous experimental data on SARS-CoV M<sup>PRO</sup> to develop a  
 288 QSAR model that was used to virtually screen DrugBank in the search for novel potential hits  
 289 against SARS-CoV-2 M<sup>PRO</sup>. As shown in Figure 2, the binding site of M<sup>PRO</sup> is conserved across  
 290 SARS-CoV and SARS-CoV-2. Collectively, the high conservation of M<sup>PRO</sup> among coronaviruses

291 has been noted in the past and previous studies have explored the potential of developing broad-  
292 spectrum antivirals by targeting this enzyme.<sup>16</sup> Molecular docking was not sufficient to  
293 discriminate between experimental actives and inactives and was ultimately not used to select hits.  
294 The generation of QSAR models according to best practices resulted in 41 virtual hits. Of the other  
295 top hits, several compounds currently being tested in clinical trials such as lopinavir and ritonavir  
296 were predicted to be active by our models.

297 The 41 virtual hits were analyzed for availability and price feasibility using our in-house  
298 ZINC Express software (<https://zincexpress.mml.unc.edu/>). At the end, 10 compounds (Table 2)  
299 were selected for experimental testing by our collaborators at the University of Kentucky. Our  
300 group has also selected compound combinations through other methods that will be tested at the  
301 National Center for Advancing Translational Sciences. All collected and curated data, models, and  
302 virtual screening results are publicly available in the Supplementary Materials of this paper and at  
303 GitHub (<https://github.com/alvesvm/sars-cov-mpro>). The curated data are also available in the  
304 Chembench web portal (<https://chembench.mml.unc.edu/>).

305

### 306 **Associated Content**

307 Supporting information includes curated datasets and virtual screening results.

308

### 309 **Acknowledgments**

310 This study was inspired by “Calling all coronavirus researchers” Nature editorial<sup>26</sup> and represents  
311 goodwill toward the contribution of the authors.

312

### 313 **Conflicts of Interest**

314 The authors declare no actual or potential conflicts of interest.
