ABSTRACT

A comparative analysis of two risk assessment (RA) frameworks developed to support the implementation of the international Ballast Water Management Convention (BWMC) and European Regulation on Invasive Alien Species (IAS) was performed. This analysis revealed both differences and similarities between the IMO Risk Assessment Guidelines (IMO, 2007) and EU Regulation supplement on RA of IAS (EU, 2018) in RA approaches, key principles, RA components and categories of IAS impacts recommended for assessment. The results of this analysis were used to produce a common procedure for the evaluation of the bioinvasion risk and impact assessment methods intended to support international, regional and/or national policy on IAS. The procedure includes a scoring scheme to assess compliance with the key principles, RA components and categories of bioinvasion impacts taken into account by the methods. In these methods the categories of impacts on human health and economy are underrepresented comparing with impacts on environment.

Subjects Aquaculture, Fisheries and Fish Science, Biodiversity, Conservation Biology, Environmental Impacts, Biological Oceanography

Keywords Risk assessment, Invasive alien species, Impact, IMO guidelines, Policy relevance, Biosecurity, EU regulation

INTRODUCTION

There is a need for standardized methods to measure the magnitude of invasive species impacts and to assess their risk. This has promoted a new direction in applied invasion ecology. More than seventy tools have been developed during recent decades aimed at bioinvasion impact and risk assessment (Roy *et al.*, 2017). They are named variously as “protocols” (Verbrugge *et al.*, 2012), “frameworks” (Dahlstrom, Hewitt & Campbell, 2011), “tool” (e.g., Drolet *et al.*, 2016), “kit” (e.g., Copp *et al.*, 2009), “scheme” (e.g., Baker *et al.*, 2008), “system” (e.g., Nentwig, Kühnel & Bacher, 2010), “index” (Olenin, Minchin & Daunys, 2007), etc. In this account, we have termed these all as “bioinvasion risk and impact assessment methods”, or “the methods” which may differ according to the geographical scale from local to regional and global, and by realm, either terrestrial or aquatic, or both. The principal aim of these methods was to provide information to support management decisions by prioritizing invasive species, choosing prevention measures, compiling target

lists and assessing their overall environmental status (Olenin, Minchin & Daunys, 2007; Molnar et al., 2008).

While the number of bioinvasion risk and impact assessment methods increases, there are difficulties in choosing the most appropriate method that best corresponds to the basic principles of risk assessment (RA). Some international legislation and administrative documents provide guidelines and methodologies for measuring bioinvasion risk and impact assessment methods (Dahlstrom, Hewitt & Campbell, 2011; Verbrugge et al., 2012; Tollington et al., 2017). For example, the International Maritime Organization (IMO) adopted the International Convention for the Control and Management of Ships' Ballast Water and Sediments (BWMC) aimed at reducing the spread of harmful aquatic organisms and pathogens (HAOPs) (IMO, 2004). Later the IMO developed Guidelines for risk assessment outlining methods enabling managers to identify risk scenarios and make decisions on granting ballast water management exemptions under BWMC Regulation A-4 (G7) (IMO, 2007), which came into force in September 2017 (IMO, 2017). Similarly, at the European level, the EU Parliament adopted the Regulation on the prevention and management of the introduction and spread of invasive alien species (IAS) (EU, 2014), and a few years later, provided a supplementary document with regard to IAS risk assessment (European Union, 2018).

Both the IMO Guidelines (IMO, 2007) and EU Regulation (European Union, 2018) provide a framework for RA, indicating RA principles, data needs, RA elements and the scope of each assessment. While the IMO Guidelines (IMO, 2007) is vector-specific, and are focused on minimizing the risk of HAOPs transferred in ballast water, the EU Regulation (European Union, 2018) is more generic, including all possible habitats (marine, freshwater, terrestrial) and a complete array of possible vectors for all taxa, with the aim of harmonizing common risk assessment methods.

Barry et al. (2008) reviewed eight “ballast water risk assessment systems” developed from 1992 to 2004. Later, David & Gollasch (2015) completed a review including four additional methods and assessed their compliance with the BWMC requirements. However, since then, new methods for ballast water RA (e.g., Drolet et al., 2016; Verna et al., 2016; Simard et al., 2017) and the updates of earlier reviewed methods have appeared (e.g., David & Gollasch, 2015). Dahlstrom, Hewitt & Campbell (2011) took a more general approach assessing the “biosecurity risk assessment frameworks” based on fourteen international, regional and national legal instruments. They proposed a set of recommendations to develop aquatic biosecurity risk frameworks in accord with mandates established by international bodies. With the advent of the EU Regulation (European Union, 2018), there is a need for an approach that enables comparison of the different bioinvasion risk and impact assessment methods, which ensures compliance with legislative and administrative requirements.

This paper aims to develop a general framework for evaluating and comparing bioinvasion risk and impact assessment methods. We first analyzed the IMO Guidelines (IMO, 2007) and the EU Regulation (European Union, 2018) by comparing (i) the key principles of RA, (ii) assessment components, (iii) and categories of bioinvasion impacts. In this context, the assessment components are “data necessary to enable a RA” (IMO, 2007) or

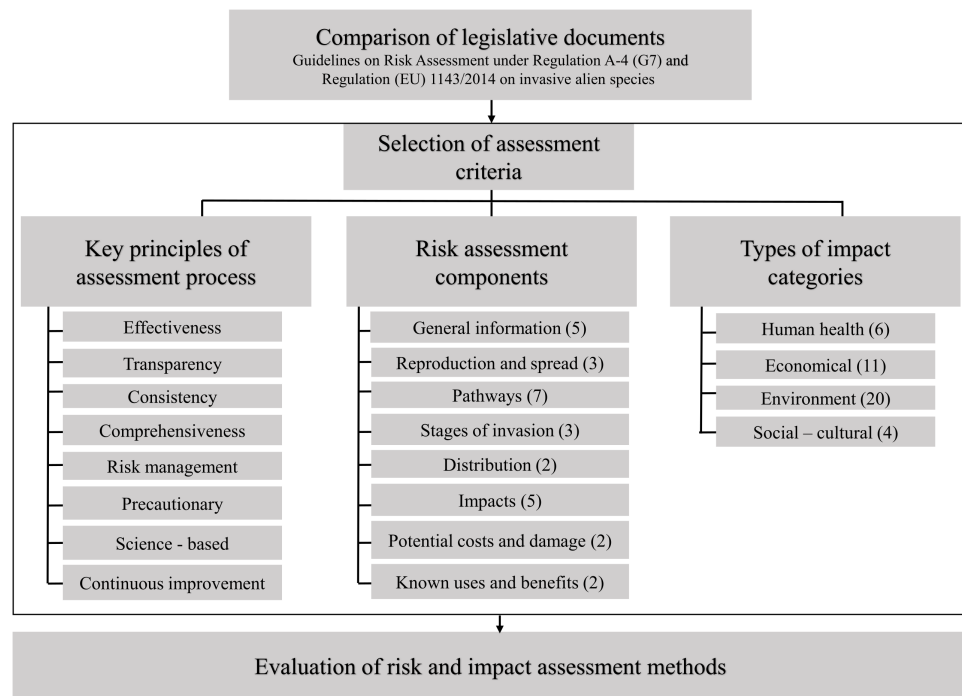

Figure 1 A stepwise process of the evaluation of bioinvasion risk and impact assessment methods: comparison of legislative documents, selection of criteria and evaluation. The number of elements in risk assessment components and categories in types of impact is given in brackets (listed in Tables S1 and S2, accordingly).

Full-size DOI: 10.7717/peerj.6965/fig-1

“the common elements that are to be considered in the risk assessment” (*European Union, 2018*), such as reproduction and spread, pathways, distribution, etc.

To our knowledge, this is the first comparison of these two frameworks, based on the legal instruments (*IMO, 2007* and *European Union, 2018*, respectively) intended to minimize bioinvasion risk. In this account we develop a common procedure that amalgamates the elements of both RA frameworks. The procedure includes a scoring scheme to assess how the methods comply with (i) the key principles, (ii) in which extent they cover the RA components and (iii) what categories of bioinvasion impacts they take into account.

METHODS

Setting the scene: comparison of the IMO and EU risk assessment frameworks

The frameworks of both the *IMO (2007)* and *European Union (2018)* regulations were compared to provide a support for a common evaluation procedure (*Fig. 1*; see also *Tables S1* and *S2*). Accordingly, we screened the RA frameworks as follows: (i) key principles of an assessment process, (ii) assessment components and, (iii) categories of bioinvasion impacts to be taken into account using the above RA frameworks.

The evaluation procedure

Based on the comparison of the IMO Guidelines and the EU Regulation, the evaluation procedure included eight key principles of the IMO Guidelines, twenty-nine RA components of the EU Regulation and four main bioinvasion impact types, compiled from both documents (Fig. 1). In addition, we incorporated impact categories as proposed in earlier risk assessment frameworks (Emerton & Howard, 2008; David & Gollasch, 2015; Olenin et al., 2016; Vilà & Hulme, 2017). In all, 41 categories were defined: human health (six categories), economy (11), environment (20), social-cultural aspects (four). Descriptions of the impact categories are provided in the supplementary table (Table S2).

We developed a scoring scheme in order to assess the compliance with each of the eight key principles (Table 1). The RA components and the categories of impact were considered to be either present or absent based on the original description of the selected. The overall ranking of selected methods is based on an accumulated score, and expressed as a percentage of compliance with our selected criteria. We discuss the advantages and limitations of this approach.

Selection and review of the bioinvasion impact and risk assessment methods

To select the bioinvasion impact and risk assessment methods for the analysis we used the list of the most relevant methods identified Roy et al. (2017) and the COST Action Alien Challenge TD1209. They performed a worldwide literature search for the methods of invasive species risk assessment (RA), and crosschecked the references for additional relevant publications to obtain twenty-nine original RA methods. We used these methods for an analysis based on the following criteria: (a) the method is applicable for the aquatic realm; (b) the assessment results are either in a quantitative or in qualitative form, and (c) it takes into account at least one of the four categories of bioinvasion impacts. From this preliminary analysis we selected nine methods out of the 29 reviewed by Roy et al. (2017) and we searched the literature to include any further methods which were not considered relevant in their review, yet met our criteria. We found fifteen methods suitable for our analysis (Table 2). The selected methods represent different regions and we recognize that there might be further methods worldwide which did not come to our attention. It should be noted that our main goal was to test the evaluation procedure on a sufficient number of methods.

We refer to each method by an acronym (Table 2), while some have changed their names with further development, for example, AS-ISK (Copp et al., 2016) was originally known as FISK “Fish Invasiveness Screening Kit” (Copp et al., 2009) and the Biopollution level (BPL) (Olenin, Minchin & Daunys, 2007) was later computerized and renamed as the Bioinvasion impact/ Biopollution assessment system, BINPAS (Narščius et al., 2012). Most of the methods (75%) were published in peer-reviewed journals, one as a book chapter, and three appeared in national or international environmental reports. The methods were divided into three groups, according to their assessment goals as: (1) the screening tools (AS-ISK, CMIST, HARMONIA+), (2) risk assessment tools (GB NNRA, TRAAIS,

Table 1 A scoring system to assess the compliance to the key principles of the risk assessment. “1” the method fully meets a criterion, “0” the method is not compliant with criteria.

Key principle	Definition by <i>IMO (2007)</i>	Scoring criteria
Effectiveness	<i>That risk assessments accurately measure the risks to the extent necessary to achieve an appropriate level of protection.</i>	1 definitions of all parameters provided, the calculation scheme is clear, the result is obtained either automatically using an online platform or by a questionnaire.
		0 definitions of all parameters are not provided, no calculation included, overall result is not obtained.
Transparency	<i>That the reasoning and evidence supporting the action recommended by risk assessments, and areas of uncertainty (and their possible consequences to those recommendations), are clearly documented and made available to decision-makers.</i>	1 the reasoning and evidence supporting the assessment is documented and (or) is available via a free online information system or on request from the authors.
		0 not compliant.
Consistency	<i>That risk assessments achieve a uniform high level of performance, using a common process and methodology.</i>	1 the consistency of a method was tested by assessing the repeatability of the test outcome, the results are published in peer-reviewed literature.
		0 the assessment of the consistency of a method is not available publically.
Comprehensiveness	<i>That the full range of values, including economic, environmental, social and cultural, are considered when assessing risks and making recommendations.</i>	1 the method considers all four categories of risks and impacts (human health, economic, environmental /ecological, social and cultural aspects).
		0 a method considers less than four categories.
Risk management	<i>That low risk scenarios may exist, but zero risk is not obtainable, and as such risk should be managed by determining the acceptable level of risk in each instance.</i>	1 the method clearly defines the level of risk /bioinvasion impact that can be used for the risk management.
		0 no definition of the magnitude of risk /bioinvasion impact is given.
Precautionary	<i>That risk assessments incorporate a level of precaution when making assumptions, and making recommendations, to account for uncertainty, unreliability, and inadequacy of information. The absence of, or uncertainty in, any information should therefore be considered an indicator of potential risk.</i>	1 incorporates level of confidence for all risk assessment steps, including the level of confidence for the final risk score, clear instructions how to define uncertainty.
		0 no level of confidence is taken into account.
Science-based	<i>That risk assessments are based on the best available information that has been collected and analyzed using scientific methods.</i>	1 at least part of the assessment requires quantitative experimental and/or field study data, or the review of scientific literature.
		0 the method takes into account impacts and risks of invasive species based only on expert judgement, no quantitative experimental and/or field studies data used.
Continuous improvement	<i>Any risk model should be periodically reviewed and updated to account for improved understanding.</i>	1 the method has been updated since publication of the original version.
		0 only original version exists, has no updated version until know.

SBRA, WISC, RABW), (3) impact assessment indexes/schemes (CIMPAL, BINPAS, GISS, GABLIS, GEIAA, GISS IUCN, GLOTSS).

RESULTS

Similarities and differences between the two legislative documents

The screening revealed differences and similarities between two documents, which are summarized in [Table 3](#).

Notes.

^aIMO (2007); European Union (2018).

^bPrecise definitions of the key principles are given in Table 1.

Key principles

The IMO Guidelines define eight key principles that should be taken into account in a RA. The EU Regulation mentions the RA principles, but not as explicit as the IMO guidelines. Consequently, our evaluation has been based on the key principles listed in the IMO Guidelines (Tables 1, 3).

RA components

The IMO Guidelines define three approaches of RA: (i) environmental matching, (ii) biogeographical and (iii) species-specific. All of these approaches are reflected in each of the eight articles outlining RA components in the EU Regulation. However, the IMO guidelines do not directly correspond with the two equivalent articles within the EU Regulation (*Art 5(1)(g)* and *Art 5(1)(h)*) (Table 3), and only partially refer to the six other articles. Furthermore, the EU Regulation gives a brief description of those components that need to be addressed in RA methodologies. In our study we included all twenty-nine RA components of the EU Regulation in an overall evaluation procedure (Table 3).

Impact categories

The IMO Guidelines mention four impacts: “*on environment, economy, human health, property or resources*” (IMO, 2007). The EU Regulations include five impacts “*on biodiversity and related ecosystem services, including on native species, protected sites, endangered habitats, as well as on human health, safety, and the economy including an assessment of the potential future impact*” (European Union, 2018). The impacts referred to in both documents can be narrowed to four types: (a) human health, (b) economy, (c) environment (incl. biodiversity and ecosystem services), and (d) social-cultural values.

Key principles of assessment process

The summary of the evaluation of compliance with the key principles is presented in Table 4 and detailed evaluation results are given in Table S3.

Effectiveness

All methods complied with this principle and provided definitions of each parameter used and, included basic information as to how the assessment process could be undertaken.

Transparency

Was adequately addressed in three methods (BINPAS, CMIST, HARMONIA+). These tools are freely available as online information systems (Table S3). Other methods, while compliant with this principle, were less developed in this respect. Some methods (e.g., GB NNRA, GEIAA) provided either fully or in part through an available online service with an option to enter results to an online database. A further group of methods (e.g., AS-ISK, CIMPAL, GABLIS) based on case studies in the scientific literature, but these do not store results in an available database.

Consistency

According to the published data there were only four methods (AS-ISK, CMIST, GISS, HARMONIA+) we were able to examine for consistency, i.e., for repeatability of the test

Table 4 Compliance of RA methods with key principles. “1” means that the method complies with key principle, according their criteria; 0 the method is not designed to cover key principle and their criteria.

outcomes (Table S2). Such consistency was evaluated based on either expert judgment (e.g., D'hondt *et al.*, 2015) or statistical scrutiny (Drolet *et al.*, 2016). All remaining methods were considered to be non-compliant with the “consistency” principle as no relevant available published results found.

Comprehensiveness

Three methods complied with this principle (e.g., GB NNRA, SBRA, RABW) that considered all four bioinvasion impacts, i.e., human health (HH), economic (EC), environmental (EN) and social–cultural (SC). Three other methods (AS-ISK, GABLIS and HARMONIA+) considered EN, EC, SC, and a further three (TRAAIS, WISC and GISS) only two impacts EN, EC, while all other methods considered just environmental impacts.

Risk management

The majority of the methods (12 out of 15) fully addressed the “risk management” key principle by providing rankings of impact magnitude that could be used for making risk management decisions.

Precautionary

Fourteen out of fifteen methods fully addressed this principle and provided confidence levels for a final score and how to define uncertainty. Two methods (GB NNRA and GEIAA) incorporated levels of confidence for all risk assessment steps, but did not deal with levels of uncertainty. One method (GABLIS) did not provide any level of uncertainty or a confidence level.

Science based

All methods either complied fully, or in part, with justifying statements based on either experimental, field studies, or literature reviews.

Continuous improvement

Ten of the methods had been updated as in the case of AS-ISK (Copp *et al.*, 2016), which evolved from the first version of FISK (Copp *et al.*, 2009), while the original design was based on the Weed Risk Assessment methodology (Pheloung, Williams & Halloy, 1999). Two methods (BINPAS and CMIST) have been computerized following a theoretical background (Olenin, Minchin & Daunys, 2007 and IASWG, 2009) in order to provide an opportunity for online application (Narščius *et al.*, 2012; Drolet *et al.*, 2016).

Risk assessment components

Based on the analysis we found that all methods incorporated at least some general information about non-indigenous species under consideration (Table 5; Table S1), i.e., taxonomic identity, scope of a RA, etc. (Art 5 (1) (a) (EU, 2018). The RA components concerning reproduction and spread (Art 5 (1) (b)), pathways (Art 5 (1) (c)), stages of invasion process (Art 5 (1) (d)), distribution (Art 5 (1) (e)) and impacts (Art 5 (1) (f)) were incorporated within most methods (Table 5). The least covered components were the estimated consequences of economic damage (Art 5(1)(g)) and any known uses and benefits (Art 5(1)(h)). This involved four and two methods, respectively.

Table 5 Incorporation of the RA components and their elements into the selected methods (%). The total number of elements in each RA component indicated in brackets.

RA components ^a	Relative proportion of RA elements (%) in the methods

Coverage (%)	72	38	69	52	76	83	55	38	41	79	59	72	90	72	

Notes.

^aAdditional information of RA components, elements and details of the analysis are in [Table S4](#), for the methods see [Table 2](#).

The incorporation of a RA component into a method was considered as being complete, should all of the elements be covered. For example, all three elements for reproduction and spread were incorporated within eight methods (Table S1). Only one method (SBRA) incorporated in full or in part all the components, while four methods (GABLIS, GB NNRA, HARMONIA+, WISC) incorporated more than 75% of the RA components.

Types of impact

The impacts on human health were considered in 57% of the methods, however, this was mostly as a “general impact on human health”, without further clarification. While three methods (GB NNRA, GISS, HARMONIA+) included more detailed information on human health, accordingly: parasites, pathogens, toxic compounds, poisoning and venomous organisms. These results are summarized in Table 6, Fig. 2 and additional information in Table S4.

No method included all environmental impact categories. However, all had at least one environmental impact category: parasites and pathogens affecting native species, parasite vector, predation, competition, hybridization, habitat change, or population loss caused by an invasive species, etc. A single method (GISS) incorporated 90% of all of the environmental categories, followed by TRAAIS (80%) and SBRA (75%).

Sixty per-cent of the methods included an economic impact category with either general management costs (60%) or impacts to aquaculture (47%), fisheries (40%) or in relation to irrigation and abstraction (40%). The methods GABLIS, GISS, and SBRA covered more than a half of these economic categories: 55, 64 and 64%, respectively.

Social-cultural impacts were taken into account by 53% of methods, the most frequent category being consequences for recreation and tourism (53%). SBRA took into account seventy-five per-cent of the social-cultural impact categories, the highest coverage of any RA method.

Overall evaluation of the methods

Our general assessment of the methods by the key principles, RA components and categories of impacts are presented in Fig. 3, while the assessment of the methods according to criteria appears in Fig. S1. The method that met most of our criteria was SBRA. This complied with most of the key principles and RA components, and covered the broadest spectrum of the impact categories, followed by HARMONIA+ and AS-ISK. However, none of the methods complied with all our criteria.

A further method that generally complied well with key principles and RA components was RABW, a method developed for the BWMC. However, it has fewer impact categories, focusing only on those associated with aquatic environments. In contrast, GISS incorporates the highest number of impact categories, but has comparatively low compliance with RA components.

DISCUSSION

Key principles and quality of methods

The two legislative documents reviewed in this study were developed for different purposes: while the EU regulation (*European Union*) has a wide spectrum of application and addresses

Table 6 Summary of incorporation of types of impacts and their categories into the selected methods. Total number of categories in each types of impact indicated in brackets.

Types of impact	Relative proportion of types of impacts categories (%) in the methods														
	AS-ISK	BINPAS	CIMPAL	CMIST	GABLIS	GB NNRA	GEIAA	GISS	GISS IUCN	HARMONIA+	GLOTSS	RABW	SBRA	TRAAIS	WISC
Human health (6)	33	0	17	0	50	50	0	100	0	50	0	17	67	33	50

the invasive alien species of all taxa and within all habitats, the IMO Guidelines (*IMO*) focuses on harmful aquatic organisms and pathogens transferred by a single vector of introduction. However, the cross-comparison of both documents highlighted the common

features that stem from their overall orientation on biosecurity. Such comparative analysis is especially needed nowadays when EU countries are to implement both legally binding instruments, the BWM (IMO, 2004), which entered into force in 2017 (IMO, 2017) and the EU the Regulation on the prevention and management of the introduction and spread of invasive alien species (Union European, 2014).

The comparison of the related risk assessment frameworks (IMO, 2007 and European Union, 2018) helps to achieve a more comprehensive, integrative view on the risk assessment process. As the result, the approach developed in this study is based on three criteria. Of these, the key principles and assessment components form the basic criteria in risk assessment, while the categories of the bioinvasion impacts were complimentary and added to complete the full evaluation procedure. This is because such impacts were not specified in either document.

The screening of similar regional and international regulations and frameworks, e.g., Convention on Biological Diversity (CBD, 2011), North America Free Trade Agreement—(General Accounting Office, GAO), Asia-Pacific Economic Cooperation (Williamson et al., 2002), ICES Code of Practice on the Introductions and Transfer of marine organisms (2005) did not reveal different criteria to what we have examined. Barry et al. (2008), Dahlstrom, Hewitt & Campbell (2011) and David & Gollasch (2015) who analyzed biosecurity risk assessment regulatory documents and bioinvasion risk and impact assessment methods also did not reveal criteria other than what we have used. It would seem that the key principles and RA components are universal for evaluation of bioinvasion risk and methods. The categories of the bioinvasion impacts may vary depending on the scope of the assessment and should be used as complimentary criteria.

In our opinion, the compliance with the key principles shows the quality of a method. Our analysis showed that only three methods made their assessment tools and documentation available *via* an online database. This must be considered the highest “Transparency” level and an example for other methods to follow. This is because decision-makers should have access to the full information to be able to compare the usage of bioinvasion risks and impacts assessment methods in similar situations worldwide.

Online information sources for NIS already exist for specific areas, e.g., for prioritizing most impacting NIS (e.g., target species lists), defining their pathways and vectors and with recommendations for their management (Olenin et al., 2014). Lehtiniemi et al. (2015) have stated that there is little value in monitoring of NIS unless the knowledge obtained is timely and can be directly used. The importance of dissemination of information, the transparency principle, was stressed many times at international and national levels (e.g., Awad et al., 2014; Costello et al., 2014; Sing & Tan, 2018). In addition, the availability of the information is important to achieve “a uniform high level of performance, using a common process and methodology” (IMO, 2007).

Policy relevance of the methods

All bioinvasion risk and impact assessment methods reviewed here have been designed to support management decisions in a manner consistent with recommendations from multiple publications, e.g.: the method allows “a comparison and thus a prioritization

of species” (*Nentwig, Kühnel & Bacher, 2010*), “enables an effective prioritization of management efforts” (*Sandvik et al., 2013*), “identification of hotspots areas, and prioritization of sites, pathways and species for management actions” (*Katsanevakis, Tempera & Teixeira, 2016*), “inform management and policy decisions” (*Drolet et al., 2016*). Consequently, the methods should conform with the policy documents involved. In our study, the policy relevance may be defined as usefulness of a method for those who make decisions on biosecurity.

Our approach may help in choosing the most appropriate method, for example, to test the policy relevance of a method for the implementation of the BWMC. While only one method purposefully designed for the BWMC was analyzed in our study (RABW), several other methods may be used for the BWMC purposes with adjustment, should they follow the key principles and take into account RA components. For example, the GB NNRA method covers the components such as NIS spread, pathways, distribution and impacts, which are needed when considering a risk assessment of ballast water (*Behrens, Leppäkoski & Olenin, 2005; Werschkun et al., 2014; Olenin et al., 2016*). It is noteworthy that the method integrating most of the RA components (SBRA) was especially designed for one of the shipping vectors, i.e., for the species biofouling risk assessment (*Hewitt et al., 2011*). Ideally, all methods should comply with the key principles and RA components as far as possible, while the bioinvasion impact categories may vary and should be selected according to the purpose of the RA. For example, the risk to human health is an important issue (*Conn, 2014*); however, not all methods, even those purposefully designed for BWMC, take into account this impact category. In the earlier study by *Barry et al. (2008)* only two out of the eight reviewed “ballast water risk assessment systems” refer to the importance of human health categories without considering any details. Generally, our study has shown that more attention is paid to environmental impacts rather than to human health or economic impacts.

CONCLUSION

Our study has shown that the IMO Guidelines and EU Regulation provide a common view of risk assessment process. The EU Regulation provides a broader coverage of the RA components and, in principle, incorporates all three IMO Guidelines requirements. This includes data needs for approaches towards environmental matching, biogeographical and species-specific matters. The common procedure developed for the evaluation of the bioinvasion risk and impact assessment methods includes a scoring scheme to assess compliance with the key principles, RA components and categories of bioinvasion impacts. It may be recommended for future methods, especially those designed for management of ballast water, to incorporate the EU Regulations RA components in addition to those recommended by the IMO Guidelines. Concerning the categories of the bioinvasion impacts, more attention should be paid to the impacts on human health and economy.

ACKNOWLEDGEMENTS

We thank Dr. John Darling, Dr. Stephan Gollasch and anonymous reviewer for constructive reviews that greatly improved the quality of the manuscript.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This work was supported by the Doctorate Study programme in Ecology and Environmental Sciences, Klaipėda University (for Greta Srėbalienė), and the Interreg Baltic Sea Region Programme 2014–2020 project COMPLETE (Completing management options in the Baltic Sea Region to reduce risk of invasive species introduction by shipping). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:
Doctorate Study programme in Ecology and Environmental Sciences.
Klaipėda University.
Interreg Baltic Sea Region Programme 2014–2020 project COMPLETE.

Competing Interests

The authors declare there are no competing interests.

Author Contributions

- Greta Srėbalienė conceived and designed the experiments, performed the experiments, analyzed the data, contributed reagents/materials/analysis tools, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft, main manuscript idea.
- Sergej Olenin and Dan Minchin analyzed the data, contributed reagents/materials/analysis tools, authored or reviewed drafts of the paper, approved the final draft.
- Aleksas Narščius contributed reagents/materials/analysis tools, authored or reviewed drafts of the paper, approved the final draft.

Data Availability

The following information was supplied regarding data availability:
The raw data is available in [Table 3](#) and the [Supplemental Files](#).

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.6965#supplemental-information>.
