## New Insights into PI3K Inhibitor Design using X-ray Structures of PI3K $\alpha$ Complexed with a Potent Lead Compound

Xiuyan Yang<sup>1,2</sup>, Xi Zhang<sup>3</sup>, Min Huang<sup>2,5</sup>, Kun Song<sup>2</sup>, Xuefen Li<sup>3</sup>, Meilang Huang<sup>4</sup>, Linghua Meng<sup>3</sup> & Jian Zhang<sup>1,2</sup>

Phosphatidylinositol 3-kinase  $\alpha$  is an attractive target to potentially treat a range of cancers. Herein, we described the evolution of a reported PI3K inhibitor into a moderate PI3K $\alpha$  inhibitor with a low molecular weight. We used X-ray crystallography to describe the accurate binding mode of the compound YXY-4F. A comparison of the p110 $\alpha$ -YXY-4F and *apo* p110 $\alpha$  complexes showed that YXY-4F induced additional space by promoting a flexible conformational change in residues Ser773 and Ser774 in the PI3K $\alpha$  ATP catalytic site. Specifically, residue 773(S) in PI3K $\alpha$  is quite different from that of PI3K $\beta$  (D),  $\gamma$  (A), and  $\delta$  (D), which might guide further optimization of substituents around the NH group and phenyl group to improve the selectivity and potency of PI3K $\alpha$ .

Phosphatidylinositol 3-kinases (PI3Ks) are lipid kinases that play pivotal roles in a multitude of fundamental biological processes, including proliferation, survival, differentiation, and metabolism<sup>1–5</sup>. Recent reports have shown that the PI3K/AKT/mTOR pathway is crucial in T cell activation and function<sup>6</sup>. PI3Ks are currently divided into classes IA, IB, II, and III<sup>7</sup>. The class IA family consists of three isoforms,  $\alpha$ ,  $\beta$ , and  $\delta$ <sup>8</sup>. The class IB family consists of only the  $\gamma$  subtype. Among the different PI3K subfamily proteins, PI3K $\alpha$  is the most important isoform in cell proliferation in response to growth factor-tyrosine kinase pathway activation<sup>9,10</sup>. PI3K $\alpha$  is a heterodimer that contains a p110 $\alpha$  catalytic subunit and p85 $\alpha$  regulatory subunit<sup>11–13</sup>. The gene encoding the p110 $\alpha$  subunit, *PIK3CA*, is mutated at a rate of nearly 30% in human cancers, including colorectal cancer, glioblastoma, and gastric cancer. Importantly, hyper-activation of PI3K $\alpha$  directly correlates with resistance to current therapeutic agents and poor prognosis in most human cancers<sup>14–16</sup>. Therefore, PI3K $\alpha$  is a potential target for anti-cancer drug development.

Currently, there are a number of PI3K inhibitors in clinical development, including Buparlisib (Trial phase III), Pictilisib (Trial phase II), PX-866 (Trial phase II), Pilaralisib (Trial phase II), and Copanlisib (Trial phase I/II)<sup>17–26</sup>. In particular, the first isoform-specific PI3K inhibitor, idelalisib, a selective  $\delta$ -isoform inhibitor, has been approved in the USA and Europe for the treatment of chronic lymphocytic leukemia, follicular B-cell non-Hodgkin lymphoma, and small lymphocytic lymphoma; idelalisib will provide valuable information and references on PI3K $\alpha$  inhibitors as drug candidates<sup>27</sup>. The PI3K $\alpha$  inhibitor with the most potential, Alpelisib, is in a Phase III randomized trial in patients with HR+/HER2-advanced breast cancers<sup>28–31</sup>. Additionally, MLN1117, a potent selective PI3K $\alpha$  inhibitor, is in a Phase II trial in patients with advanced solid tumors<sup>32,33</sup>.

The design of new potent PI3K $\alpha$  inhibitors with drug-like properties is still a major challenge because of the highly conserved lipid kinase ATP binding sites and the similarity between their three-dimensional structures. Currently, X-ray crystallography is one of the most useful experimental methods employed in structure-assisted

drug design. Co-crystal structures of the protein of interest and ligands provide accurate structural insights into binding sites. Several complex structures of PI3K $\alpha$  and its ligands have been reported; however, limited useful information can be extracted from the existing structures<sup>12,13,34,35</sup>. Here, we determined the crystal structure of PI3K $\alpha$  in complex with the potential inhibitor YXY-4F. The description of the new crystal structure provides further insights into the potent and selective design of PI3K $\alpha$  inhibitors.

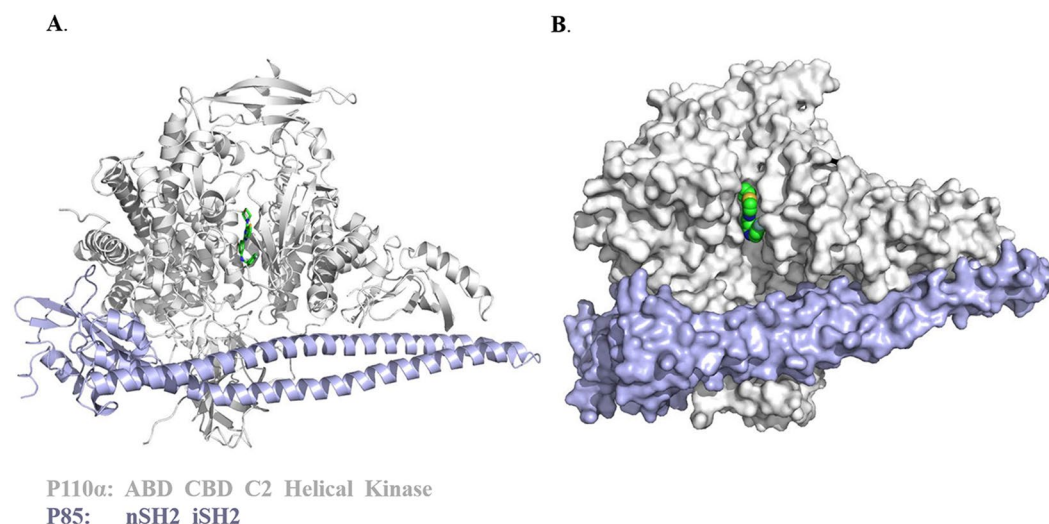

## Results

**Identification of YXY-4F as a potent PI3K $\alpha$  inhibitor.** In our previous research<sup>36</sup>, we designed a series of PI-103 derivatives and confirmed that compound **9e** is a potent analogue that can be used for further optimization. PI3K $\alpha$ -9d crystal-guided optimization led to the discovery of the thieno[3,2-d]pyrimidine derivative YXY-4F (Fig. 1), which is a potent PI3K $\alpha$  inhibitor with moderate inhibitory activity. As measured by the PI3-Kinase HTRF assay, the compound had an IC<sub>50</sub> value of 1.02  $\pm$  0.005  $\mu$ M for the inhibition of p110 $\alpha$ . To investigate the cellular effects of our compound, we performed a proliferation assay in PIK3CA-driven cell lines (SKOV3, PC-3, and Rh30) treated with the compound. The growth of the PIK3CA-driven cell lines was inhibited by exposure to YXY-4F. These data suggest that YXY-4F has a valid anti-proliferative effect in all PIK3CA-driven cancer cells (Table 1). YXY-4F is approximately 50 times less potent than PI-103 in the PI3-Kinase HTRF assay, while in cell inhibitory activity test, YXY-4F is only 10 times less potent than PI-103. Compared to PI-103, YXY-4F has a lower molecular weight and the potential to improve its inhibitory activity by further optimization. Considering these profiles, we chose YXY-4F as the starting point for our medicinal chemistry research. Therefore, the co-crystal structure of PI3K $\alpha$  and YXY-4F is crucial for crystal-based selective design of PI3K $\alpha$  inhibitors.

**Crystallization of p110 $\alpha$  complexed with YXY-4F.** To obtain the co-crystal structure of PI3K $\alpha$  and YXY-4F, we prepared and purified the protein for X-ray crystallography studies. The fused human PI3K $\alpha$  gene template containing p110 $\alpha$  and p85 linked by a sequence was sub-cloned into the vector. After transposition into

**Table 2.** Data collection and Refinement Statistic of the Crystal Structure. \*Values in parentheses are for highest-resolution shell.

**Figure 2.** Overview of the p110 $\alpha$ /niSH2 heterodimer. **(A)** Diagram of the p110 $\alpha$ /niSH2 heterodimer. The compound YXY-4F bound in the kinase domain is shown as sticks. **(B)** Surface diagram of the p110 $\alpha$ /niSH2 heterodimer, alternate view. The compound YXY-4F bound in the kinase domain is shown as spheres.

the bacmid, a selected positive clone was transfected into SF9 cells to express the protein for co-crystallization with YXY-4F. The harvested protein was purified for crystallization. After screening many crystallization conditions, a complex co-crystal was identified in a solution containing 0.2 M lithium sulfate, 0.1 M Tris pH 8.5, 10 mM YXY-4F, and PEG at a 5:1 ratio at 18 °C. X-ray characterization and data collection for the co-complex were performed, and the diffraction data were processed using *HKL2000*. The data processing and refinement statistics are summarized in Table 2. The final resolution was 2.97 Å, and the  $R_{\text{work}}/R_{\text{free}}$  value was 23.1/28.0. The structure maintained all five p110 $\alpha$  domains and a long p85 SH2 domain in an overall triangular shape (Fig. 2A).

We next described the inhibitor binding mode. The crystal structure of PI3K $\alpha$ -YXY-4F verified that the compound YXY-4F bound to the ATP-binding pocket of the p110 $\alpha$  kinase catalytic domain (Fig. 2B). YXY-4F was anchored by multiple hydrogen bonds and hydrophobic interactions within the pocket formed by residues Ile800, Asp810, Tyr836, Glu849, and Val851 on one side and residues Met922, Ile932, and Asp933 on the other

**Figure 3.** The interactions between YXY-4F and p110 $\alpha$ . **(A)** X-ray complex of YXY-4F to p110 $\alpha$  (PDB ID: 5XGH). The structure of YXY-4F is shown as a stick representation, and the key binding site residues are shown as sticks. Hydrogen bonds between YXY-4F and the protein are shown as a dashed line Diagram of the p110 $\alpha$ /niSH2 heterodimer. **(B)** Extensive residue-residue interactions on the interface of the YXY-4F-p110 $\alpha$  complex structure. The residues belonging to p110 $\alpha$  are labeled in ball. A distance between donor and acceptor of less than 3.5 Å indicates a hydrogen bond, and a 4.1 Å distance between two hydrophobic atoms indicates a hydrophobic interaction.

**Figure 4.** Comparison of *apo* p110 $\alpha$  and YXY-4F-p110 $\alpha$  complexes. **(A)** Overlay *apo* p110 $\alpha$  and YXY-4F-p110 $\alpha$  complexes. Apo p110 $\alpha$  is colored in wheat and YXY-4F-p110 $\alpha$  is colored in palegreen. **(B)** Interface between YXY-4F (orange) and p110 $\alpha$  (palegreen). Red curve indicates potential cavity of p110 $\alpha$  induced by the binding of YXY-4F.

side (Fig. 3A). Four H-bonds were formed between YXY-4F and the p110 $\alpha$  active site residues. The morpholino oxygen accepted a hydrogen bond from the amide of the hinge Val851 residue. The fluorine in the phenyl moiety also accepted a hydrogen bond from the Ser773 hydroxyl group. The hydroxyl group in the phenol moiety formed two H-bonds with the Asp810 carboxyl side chain and Tyr836 hydroxyl group (Fig. 3B). Additionally, van der Waals interactions from the surrounding hydrophobic residues, including Val850, Ile932, Ile848 and Pro778, significantly contributed to YXY-4F's affinity. Other interactions, including a divalent sulfur and  $\pi$  system, were also observed between the thienopyrimidine moiety and residue Trp780.

#### Conformational Flexibility of Ser773 and Ser774 in the p110 $\alpha$ -YXY-4F Complex Crystal Structure.

As shown in Fig. 4, the conformation of YXY-4F with p110 $\alpha$  was similar to that of the p110 $\alpha$ -PI103 complex<sup>36</sup>. A comparison of the p110 $\alpha$ -YXY-4F and *apo* p110 $\alpha$  complexes (PDB ID: 4L1B) suggested that a pronounced conformational change was associated with Ser773 and Ser774. The Ser774 side chain moved away from the ATP catalytic site in the YXY-4F-bound-p110 $\alpha$  complex (Fig. 4A), which produced ample space to accommodate the phenyl groups linked to the NH<sub>2</sub> group in compound YXY-4F. Ser773 also moved to accommodate the distance between the phenyl fluorine and the Ser773 hydroxyl group to form a hydrogen bond. Collectively, these data

Using two passes through an Avestin pressure drop homogenizer at 12 kpsi, cells were lysed and then centrifuged for 1 h at  $15,000 \times g$ . The supernatant was then mixed with Ni-NTA agarose (Qiagen) for 3 hours at 4°C. We collected the resin and washed it with 100 ml of buffer A (250 mM NaCl, 20 mM Tris-HCl pH 7.8, 20 mM imidazole, 2 mM TCEP, and 5% glycerol) and 100 ml of buffer B (250 mM NaCl, 40 mM imidazole, 20 mM Tris-HCl pH 7.8, 2 mM TCEP, and 5% glycerol) before elution with buffer C (250 mM NaCl, 250 mM imidazole, 20 mM Tris-HCl pH 7.8, 2 mM TCEP, and 5% glycerol). Buffer A (20 mM Tris-HCl pH 8.0 and 5% glycerol) was used to dilute the protein to a ratio of 1:5, and the proteins were purified by ion-exchange chromatography on a Sepharose Q column (eluted by a linear gradient from A to B [buffer A is 20 mM Tris-HCl pH 8.0 and 5% glycerol; buffer B is 20 mM Tris-HCl pH 8.0, 1 M NaCl, and 5% glycerol]). The protein was then concentrated to 5 ml and purified by size-exclusion chromatography on a Superdex 200 column with 20 mM Tris, 2 mM TCEP pH 7.8, 0.2 M NaCl, and 5% glycerol. The resulting protein was almost 95% pure and identified by SDS-PAGE.

The crystallization conditions were screened using 2  $\mu$ l hanging drops (1  $\mu$ l protein + 1  $\mu$ l reservoir) at 18°C with 11 mg of the His-p85 $\alpha$  (318–615)-linker-p110 $\alpha$  fusion protein in buffer (200 mM NaCl, 20 mM Tris-HCl, 2 mM TCEP pH 7.8, and 5% glycerol). After screening, a small crystal was identified in solution (0.2 M lithium sulfate, 0.1 M Tris pH 8.5, and PEG 2000 MME). We used hair seeding to obtain a larger crystal in optimized mother liquor (0.1 M Tris pH 8.5, 0.15 M lithium sulfate, and 30% (w/v) PEG 1000 MME). Finally, a diffraction-quality crystal was obtained after repeated rounds of macro-seeding. *Apo* crystals were soaked in 10 mM compound YXY-4F for 2 hours and then mounted according to the above method.

**In vitro PI3-Kinase Assays.** Compound YXY-4F was dissolved in 100% dimethylsulfoxide (DMSO) at 10 mM. The solution was diluted to the desired concentrations immediately before each experiment. The kinase activities of the purified PI3Ks were determined with the PI3K HTRF Assay (Millipore) according to the manufacturer's protocol. Briefly, the EC<sub>80</sub> concentration of each enzyme containing 10  $\mu$ M PIP2 was incubated in assay buffer on a white 384-well plate (Perkin Elmer). After incubation for 30 min at room temperature, the reaction was initiated by addition of ATP and terminated by addition of the stop solution and detection mix. The final concentration of ATP was 5  $\mu$ M for p110 $\alpha$ . The plate was then sealed and incubated overnight at room temperature. The intensity of the light emission was measured by an EnVision Multilabel Reader (PerkinElmer) in TR-FRET mode (excitation at 320 nm and emission at 665 nm) as previously described<sup>42</sup>. The IC<sub>50</sub> values<sup>43</sup> were calculated by fitting the data to a logistic curve using the GraphPad Prism 6 software.
