Background: Primary immune thrombocytopenia (ITP) is defined as an acquired autoimmune disease characterized by isolated thrombocytopenia. This work is to further clarify the relationship between T cell immune dysfunction and the pathogenesis of ITP.

Methods: 37 adult patients with ITP were selected and were classified into newly diagnosed ITP (nITP, n = 13), persistent ITP (pITP, n = 6) and chronic ITP (cITP n = 18). The frequency of cytotoxic T lymphocytes (Tc1, Tc2, and Tc17) and helper T cells (Th1, Th2, and Th17), Tregs, and the expression of chemokine receptors and PD-1 on CD4⁺ T cells were investigated by flow cytometry. Plasma levels of T cell-related cytokines (IL-2, IL-4, IL-6, IL-10, TNF- α , IFN- γ , IL-17) were measured by cytometric beads array (CBA).

Results: The percentage of Tc1 in cITP was greatly higher than nITP and healthy controls ($p < 0.05$, $p < 0.01$). The percentage of Treg in nITP and cITP groups was remarkably lower than those in healthy control group ($p < 0.05$, $p < 0.001$); and according to platelet count analysis (PLT < 50x10⁹/L or PLT > 50x10⁹/L), Treg cells in ITP group were significantly lower than those in healthy control group ($p < 0.001$, $p < 0.05$). The percentage of CD4⁺CXCR3⁺ of cITP was significantly higher than healthy controls and nITP ($p < 0.01$, $p < 0.05$). The percentage of CD4⁺CCR6⁺ in cITP was significantly higher than healthy controls and nITP ($p < 0.001$, $p < 0.05$). The expression of PD-1 in cITP patients was higher than healthy control ($p < 0.05$), but there was no significant difference among nITP, pITP and cITP ($p = 0.25$). The levels of IL-2, IFN- γ and TNF α in nITP group and cITP group were significantly higher than those in healthy control group ($p < 0.01$, $p < 0.05$; $p < 0.01$, $p < 0.05$; $p < 0.05$, $p < 0.05$), and the level of IL-10 in nITP group was significantly higher than that in pITP group ($p < 0.05$).

Conclusion: Our results suggest that T lymphocyte immune dysfunction does exist in adult ITP patients and plays an important role in the pathogenesis of ITP.

Keywords: primary immune thrombocytopenia, T helper cells, cytotoxic T lymphocyte, regulatory T cells

Introduction

Primary immune thrombocytopenia (ITP) is an acquired autoimmune hemorrhagic disease characterized by isolated peripheral blood thrombocytopenia without explicit inducement.¹⁻³ The classic pathogenesis of ITP is that platelet surface glycoprotein and antiplatelet antibody combine to form an immune complex, and Fc receptor of monocyte macrophage system combines with Fc segment of autoantibody, which mediates macrophage phagocytosis and destruction of platelets, leading to peripheral thrombocytopenia.⁴⁻⁸ However, the above humoral immune mechanism cannot fully explain all the clinical manifestations of ITP.

CD4⁺ and CD8⁺ T cells are important components of T lymphocytes, and the CD4⁺/CD8⁺T cell ratio is associated with autoimmune diseases.^{9,10} However, the

impact of cytotoxic T lymphocytes dysfunction on the severity of the different courses of ITP remains unclear. CD8⁺ T cells may play a major role in the protection of individual autoimmunity.^{11,12} CD8⁺ T cells can directly dissolve platelets, and increased platelet destruction was observed in ITP patients.^{13–16} In addition, helper T cell (Th) subsets coordinate different immune responses and mediate the production of different cytokines, and abnormal Th cell activity may lead to chronic inflammation and autoimmune diseases, and recent studies have shown that normalization of T regulatory cells (Tregs) can also significantly increase platelet count.^{17–19}

The migration and differentiation of Th1, Th2 and Th17 subsets are affected by chemokine receptors. Chemokine receptors are dynamically regulated during the activation and differentiation of naive CD4⁺T cells.²⁰ Some studies have found that CCR6⁺CD4⁺T cells in ITP patients have the properties of activated memory, which can be used to monitor disease activity and treatment response.²¹ Overexpression of CCR6 + Th cells and their marker cytokines is associated with persistent inflammation and autoimmune diseases. Some studies indicated that the expression of CXCR3 in ITP patients was increased when comparing with healthy control.^{22,23} CCR4 was mainly expressed on Th2, NK and immature dendritic cells, skin-homing T cells and Treg cells.²⁴ In ITP patients, the expression of CCR4 on CD4⁺T cells has not been studied. It has been reported that the PD-1/PD-L1 signaling pathway plays a negative regulatory role in many autoimmune diseases.^{25–29} We speculate that loss of PD-1 inhibition regulation and the continuous activation of T cells may lead to excessive immunity, and eventually lead to ITP immune dysfunction.

In this study, we intend to further clarify the relationship between T-cell immune dysfunction and the pathogenesis of ITP.

Patients and Methods

Patients

37 adult patients with ITP were selected from the First Affiliated Hospital of the University of Science and Technology of China. The criteria of definitions and classifications of ITP were according to the report from ITP international working group. Secondary thrombocytopenia should be excluded, such as tumor infiltration, chronic liver diseases, hypersplenism, common variant immunodeficiency disease (CVID), infection, and vaccination, etc. There were 10 males

with a median age of 62 years (27–88) and 27 females with a median age of 48 years (25–89). According to the course of disease, 37 patients with ITP were classified into newly diagnosed ITP (nITP, patients within 3 months after diagnosis, n = 13), persistent ITP (pITP, patients with continuous thrombocytopenia for 3–12 months) (n = 6) and chronic ITP (cITP, patients with continuous thrombocytopenia for more than 12 months, n = 18). According to platelet counts, these patients were divided into PLT < 50 × 10⁹/L (n = 21) group and PLT ≥ 50 × 10⁹/L group (n = 16). A control group consisted of 20 adult healthy volunteers (8 males and 12 females; median age, 54 years; range, 26–87 years).

There was no significant difference in gender (*p*=0.11) and age (*p*=0.19) among nITP, pITP and cITP. Moreover, there was no significant difference between our studied groups as regard to hemoglobin (HGB) (*p*=0.11), white blood cells (WBC) (*p*=0.82), lymphocytes (*p*=0.52) and last platelet count (*p*=0.15). All these patients were treated according to the American Society of Hematology 2011 evidence-based practice guideline for ITP. This study was approved by the medical ethics committee of the First Affiliated Hospital of the University of Science and Technology of China, and informed consent was obtained from all the participants. This study was conducted in accordance with the Declaration of Helsinki. The detailed clinical characteristics of the selected patients are indicated in [Table 1](#).

Antibodies and Reagents

The following antibodies were used for flow cytometric analysis of lymphocyte subsets and intracellular cytokines: Anti-CD3-APC-H7 (BD Biosciences). Anti-CD4-Brilliant Violet 421, Anti-CD8a-Percp-cyanine 5.5, Anti-CXCR3-Percp-cyanine 5.5, Anti-CCR4-PE, Anti-CCR6-APC, Anti-PD-1- PE (Biolegend), Anti-CD45-FITC, anti-IFNγ-eFluor[®]450, Anti-IL4-APC, Anti-IL17-PE (eBioscience), FcR Blocking reagent (Miltenyi Biotec MACS). Fixable viability stain 510, Leukocyte Activation cocktail, with BD Golgiplu (BD Biosciences). Red Blood Cell Lysis Buffer (Solarbio Life Science). Human Lymphocyte Separation Medium (TBD Science). Cytometric Bead Array (BD Biosciences). RPMI1640 (Hyclone).

Preparation of Plasma and Cells

4 mL venous blood was collected from ITP and normal control by heparin sodium tube and then centrifuged for 5 min at 1000 rpm. Plasma was separated and stored at –80° C until used. The peripheral blood mononuclear cells

Table I Clinical Characteristics of Adult ITP

(PBMC) were prepared by Ficoll-Paque plus density gradient centrifugation according to the standard procedure.

Cell Stimulation and CD8+ and CD8-T Cell Cytokine Production

After washing for three times, the mononuclear cells were resuspended in RPMI1640 complete medium, and the cell density was adjusted to 1×10^6 /mL. Leucocyte activation cocktail (with BD GolgiPlug) was added to 1 mL of complete medium and the cells were incubated in 5% CO₂ incubator at 37 °C for 5 hours. Before antibody staining, human FCR blocking agent was added to all tubes to reduce nonspecific binding, and the fixed active staining agent (Bv510) was added to remove dead cells. Then, CD45-FITC, CD3-APC-H7, CD8-PerCP-Cy5.5 were added and incubated for 30 min at 4 °C in the dark. Cells were then washed, fixed, and permeabilized, followed by intracellular cytokines stained with anti-IFN- γ -e Fluor 450, anti-IL4 APC, anti-IL17 PE at 4 °C in the dark for 30 min. After washing three times, cells were resuspended with 200 μ L PBS. Data were collected by Beckman CytoFLEX flow cytometric and analyzed by

FlowJo version 10 software. Cell subset are defined as follows: Tc1: CD3⁺CD8⁺IFN- γ ⁺; Tc2: CD3⁺CD8⁺IL-4⁺; Tc17: CD3⁺CD8⁺IL-17⁺, Th1 CD3⁺CD8⁻IFN- γ ⁺; Th2: CD3⁺CD8⁻IL-4⁺; Th17: CD3⁺CD8⁻IL-17⁺.

Detection of Tregs, Chemokine Receptor and PD-1 Expression by Flow Cytometry

The following antibody to human cell surface antigens were used: 100 μ l blood was added to each tube and then 2 μ L CD45-FITC, CD3-APC-H7, CD4-BV421, CD127-PE and CD25-APC, CXCR3-APC, CCR4-PE, CCR6-APC, PD-1-PE, respectively, reagents were added in turn.

After the antibody was added, it was incubated at 4 °C in the dark for 30 min, and then 1mL of red blood cell lysate was added. After shaking, red blood cells were dissolved at room temperature away from light for 10 min. The supernatant was centrifuged and washed with phosphate buffer (PBS + 1% FBS). Cells were resuspended with 200 μ l PBS. FCM was used to detect the number of lymphocytes and the expression of subsets (200,000 cells).

Detection of T Cell Related Cytokines in Serum by CBA

CBA detection: the required reagents and instruments are mainly BD CBA human Th1/Th2/Th17 cytokine kit and Fortessa analytical flow cytometric (BD). The serum was taken from the -80°C ultra-low temperature refrigerator for standby. It was placed at room temperature for 2 h, and then, the relevant experimental operation was carried out according to the CBA kit instructions and the detection was performed on the flow cytometric analysis within 3 hours. According to the test data, the standard curve was drawn automatically by using software mELISA, and the cytokine content in the sample was calculated automatically according to the standard curve.

Statistical Analysis

Statistical analysis was performed using prism software (GraphPad prism) by *t*-test (or unpaired). One-way ANOVA was performed for data comparison among multiple groups. The chi-square test was used to analyze the gender differences between different disease courses of ITP. The data were expressed as mean \pm standard error of mean (SEM) or standard deviation (SD). $p < 0.05$ was considered significant.

Results

Increased Percentage of Tc in Chronic ITP

The flow gating strategy of CD8⁺T lymphocytes and Tc cell subsets according to representative plots of flow cytometry analysis are shown in Figure 1A-B. The rate of CD4⁺/CD8⁺ in healthy control was similar to different course of ITP ($p=0.38$, Figure 1C) and there was no significant difference between PLT $<50 \times 10^9/\text{L}$ and PLT $>50 \times 10^9/\text{L}$ group ($p = 0.88$, Figure 1D). We found that the percentage of Tc1 in cITP was greatly higher than nITP and healthy controls ($p < 0.05$, $p < 0.01$, Figure 1E); however, the difference was not statistically significant in PLT $<50 \times 10^9/\text{L}$ and PLT $>50 \times 10^9/\text{L}$ group ($p = 0.52$, Figure 1F). The percentage of Tc2 was no significant difference in nITP, pITP and cITP ($p = 0.34$, Figure 1G); furthermore, the difference was not statistically significant in PLT $<50 \times 10^9/\text{L}$ and PLT $>50 \times 10^9/\text{L}$ group ($p = 0.33$, Figure 1H). The percentage of Tc17 was no significant difference in nITP, pITP and cITP ($p = 0.21$, Figure 1I), and the difference was not statistically significant in

PLT $<50 \times 10^9/\text{L}$ and PLT $>50 \times 10^9/\text{L}$ group as well ($p = 0.14$, Figure 1J).

The Percentage of Th Cell Subsets in ITP

Th cell subsets according to representative plots of flow cytometric analysis are shown in Figure 2A. The percentage of Th1 ($p = 0.35$, $p = 0.98$, Figure 2B and C), Th2 ($p = 0.30$, $p = 0.52$, Figure 2D and E) and Th17 ($p = 0.73$, $p = 0.87$, Figure 2F and G) was no significant difference in different course of ITP or platelet counts (PLT $<50 \times 10^9/\text{L}$ and PLT $>50 \times 10^9/\text{L}$).

Decreased Levels of Treg Cells in nITP and cITP

The flow gating strategy of CD4⁺T lymphocytes and the representative dot-plots of flow cytometric analysis of Treg cells are shown in Figure 3A. According to platelet count analysis (PLT $<50 \times 10^9/\text{L}$ or PLT $>50 \times 10^9/\text{L}$), we found that Treg cells in ITP group were significantly lower than those in healthy control group ($p < 0.001$, $p < 0.05$, Figure 3B). Treg cells in PLT $>50 \times 10^9/\text{L}$ group were slightly increased compared to PLT $<50 \times 10^9/\text{L}$ group without statistically significant ($p = 0.22$, Figure 3B). According to the course of disease, the percentage of Treg in nITP and cITP groups was remarkably lower than those in healthy control group ($p < 0.05$, $p < 0.001$, Figure 3C); however, there was no significant difference among nITP, pITP and cITP ($p = 0.27$, Figure 3C).

Elevated Levels of CD4⁺CXCR3⁺, CD4⁺CCR6⁺ and CD4⁺PD-1⁺ T Cells in ITP

In order to research the role of CD4⁺T cells in the pathogenesis of ITP, we analyzed the expression of chemokine receptor and PD-1 on CD4⁺T lymphocytes, and the representative histograms of flow cytometric analysis are shown in Figure 4A. The percentage of CD4⁺CXCR3⁺ of cITP was significantly higher than healthy controls and nITP ($p < 0.01$, $p < 0.05$, Figure 4B). The percentage of CD4⁺CXCR3⁺ in patients with pITP was obviously increased in comparison with healthy controls ($p < 0.05$, Figure 4B). Compared with healthy control, the expression level of CD4⁺CXCR3⁺ was dramatically increased in PLT $>50 \times 10^9/\text{L}$ group ($p < 0.05$, Figure 4C). Nevertheless, there was no significant difference of the expression CD4⁺CCR4⁺ in different disease course ($p=0.46$, Figure 4D) and different platelet count ($p=0.88$, Figure 4E). The percentage of CD4⁺CCR6⁺ in cITP was significantly higher than

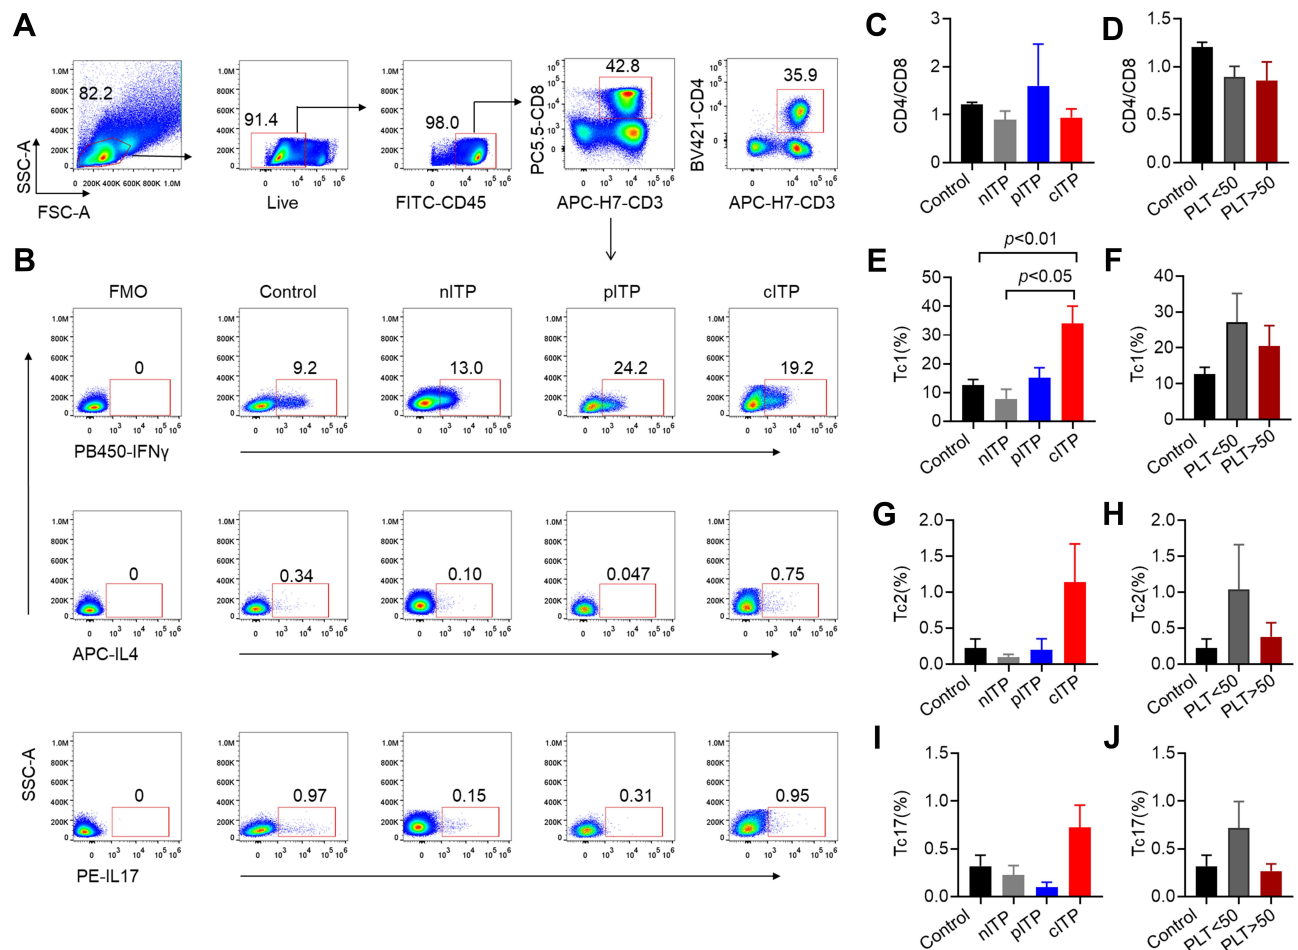

Figure 1 The percentage of Tc increased in chronic ITP.

Notes: (A–B) In the flow gating strategy, lymphocytes were first gated by forward scattering FSC and side scattering SSC, and then cells were stained for live cells, lymphocytes were gated by CD45, T lymphocytes were circled by CD3 and CD8 simultaneously in (A). Representative of IFN- γ , IL-4 and IL-17 expression on CD3+CD8+ T subsets was shown in (B). Cells are defined as follows: Tc1: CD3+CD8+IFN γ +, Tc2:CD3+CD8+IL4+, Tc17: CD3+CD8+IL17+. (C) The rate of CD4+/CD8+ in healthy control and different course (1.20±0.10 control vs 0.89±0.37 nITP, 1.60±1.23 pITP and 0.94±0.51 cITP, respectively, $p = 0.38$). (D) The rate of CD4+/CD8+ was no significant difference between PLT<50×10⁹/L and PLT>50×10⁹/L group (0.89±0.27 vs 0.85±0.55, $p = 0.88$). (E) The percentage of Tc1 in cITP was greatly higher than nITP and healthy controls (33.98 ± 17.17 vs 7.76 ± 6.81, $p < 0.05$; 33.98 ± 17.17 vs 12.61 ± 5.14, $p < 0.01$). (F) There was no significant difference in Tc1 between PLT<50×10⁹/L and PLT>50×10⁹/L group (27.08 ± 21.32 vs 20.26±13.95, $p = 0.52$). (G–J) The percentage of Tc2 (G, H), and Tc17 (I, J) was no significant difference in nITP, pITP and cITP (0.10 ± 0.07, 0.20±0.22 and 1.14±1.51, respectively, $p = 0.34$ for Tc2; 0.22±0.20, 0.10±0.08 and 0.72±0.66, respectively, $p = 0.21$ for Tc17) or platelet count (1.04 ± 1.65 vs 0.34 ± 0.49, $p = 0.33$ for Tc2; 0.72 ± 0.73 vs 0.25 ± 0.19, $p = 0.14$ for Tc17). Bars represent means ± SEM. $p < 0.05$ was considered significant.

healthy controls and nITP ($p < 0.001$, $p < 0.05$; Figure 4F). The percentage of CD4⁺CCR6⁺ in the PLT<50×10⁹/L group and PLT>50×10⁹/L group was prominently higher than healthy control group ($p < 0.01$, $p < 0.05$ Figure 4G). The percentage of CD4⁺CCR6⁺ was slightly increased in PLT<50×10⁹/L group compared with PLT>50×10⁹/L, however, this elevation is statistically insignificant ($p = 0.32$, Figure 4G). Next, we detected the expression of PD-1 on CD4⁺ T cells. We found that the expression of PD-1 in cITP patients was higher than that in healthy control ($p < 0.05$, Figure 4H), but there was no significant difference among nITP, pITP and cITP ($p = 0.25$, Figure 4H). The data of PD-1 in PLT<50×10⁹/L have no statistically significant difference when compared with PLT<50×10⁹/L group ($p = 0.35$, Figure 4I).

Increased Serum Levels of IL-2, IFN- γ and TNF- α in ITP

The serum levels of IFN- γ , IL-2, TNF- α and IL-4, IL-6, IL-10, IL-17 in ITP patients and healthy controls were detected by CBA technology. According to different course of disease analysis, IL-2, IFN- γ and TNF α in nITP group and cITP group were significantly higher than those in healthy control group ($p < 0.01$, $p < 0.05$, Figure 5A; $p < 0.01$, $p < 0.05$, Figure 5B; $p < 0.05$, $p < 0.05$, Figure 5C). The level of IL-10 in nITP group was significantly higher than that in pITP group ($p < 0.05$, Figure 5D). The levels of IL-4, IL-6 and IL-17 were no significant differences among different disease duration and healthy controls ($p = 0.69$, $p = 0.35$, $p = 0.53$, Supplement Figure 1A–C). According to the platelet count

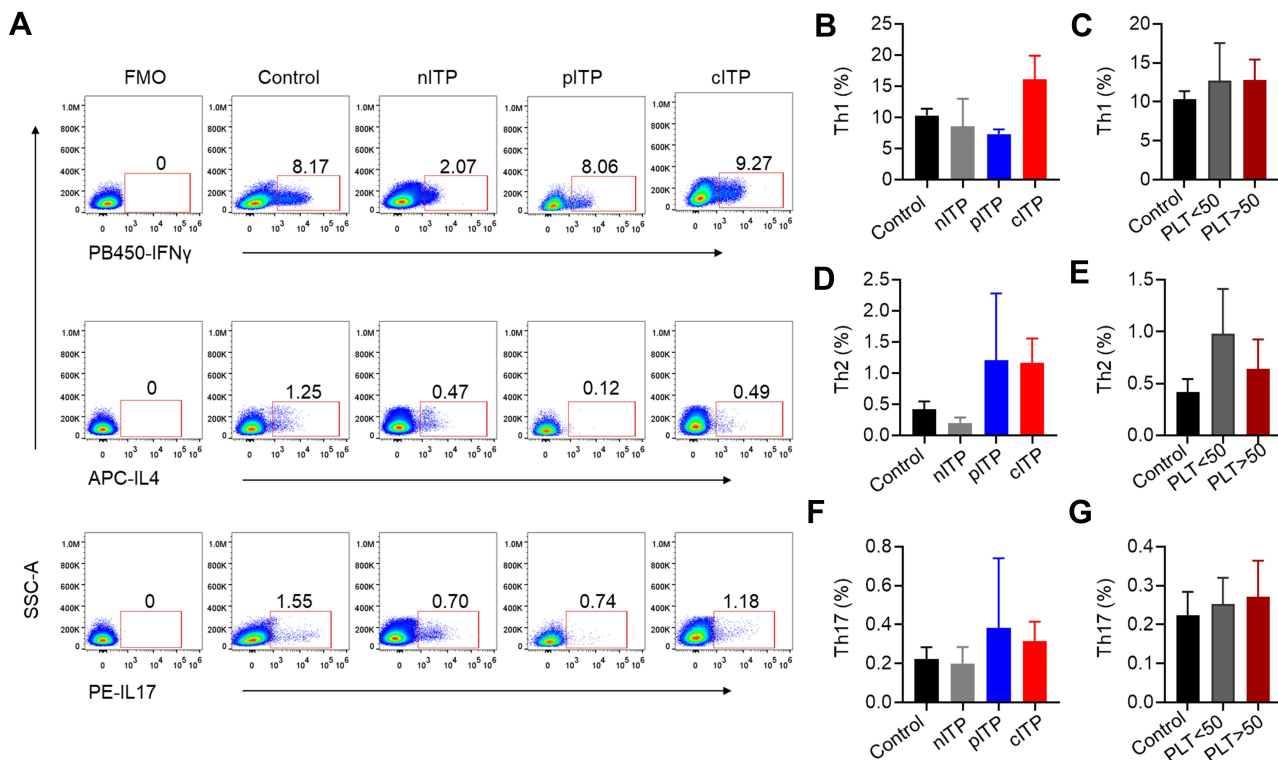

Figure 2 The percentage of helper cell T cells in ITP.

Note: (A) Representative IFN- γ +, IL-4+ and IL-17+ expression on CD3⁺CD8⁺T subsets (CD4⁺T subsets) was shown. Cells are defined as follows: Th1: CD3⁺CD8⁺IFN γ ⁺, Th2: CD3⁺CD8⁺IL4⁺, and Th17: CD3⁺CD8⁺IL17⁺. (B–G) The percentage of Th1 (B, C), Th2 (D, E) and Th17 (F, G) was no significant difference in nITP, pITP and cITP (8.56 \pm 8.84, 7.33 \pm 1.03 and 16.09 \pm 10.79, respectively, $p = 0.35$ for Th1; 0.20 \pm 0.17, 1.20 \pm 1.53 and 1.16 \pm 1.11, respectively, $p = 0.30$ for Th2; 0.20 \pm 0.17, 0.38 \pm 0.51 and 0.32 \pm 0.28, respectively, $p = 0.73$ for Th17) or platelet count (12.70 \pm 12.81 vs 12.82 \pm 7.42, $p = 0.98$ for Th1; 0.98 \pm 1.15 vs 0.64 \pm 0.81, $p = 0.52$ for Th2; 0.25 \pm 0.18 vs 0.27 \pm 0.26, $p = 0.87$ for Th17). Bars represent means \pm standard error of mean. $p < 0.05$ was considered significant.

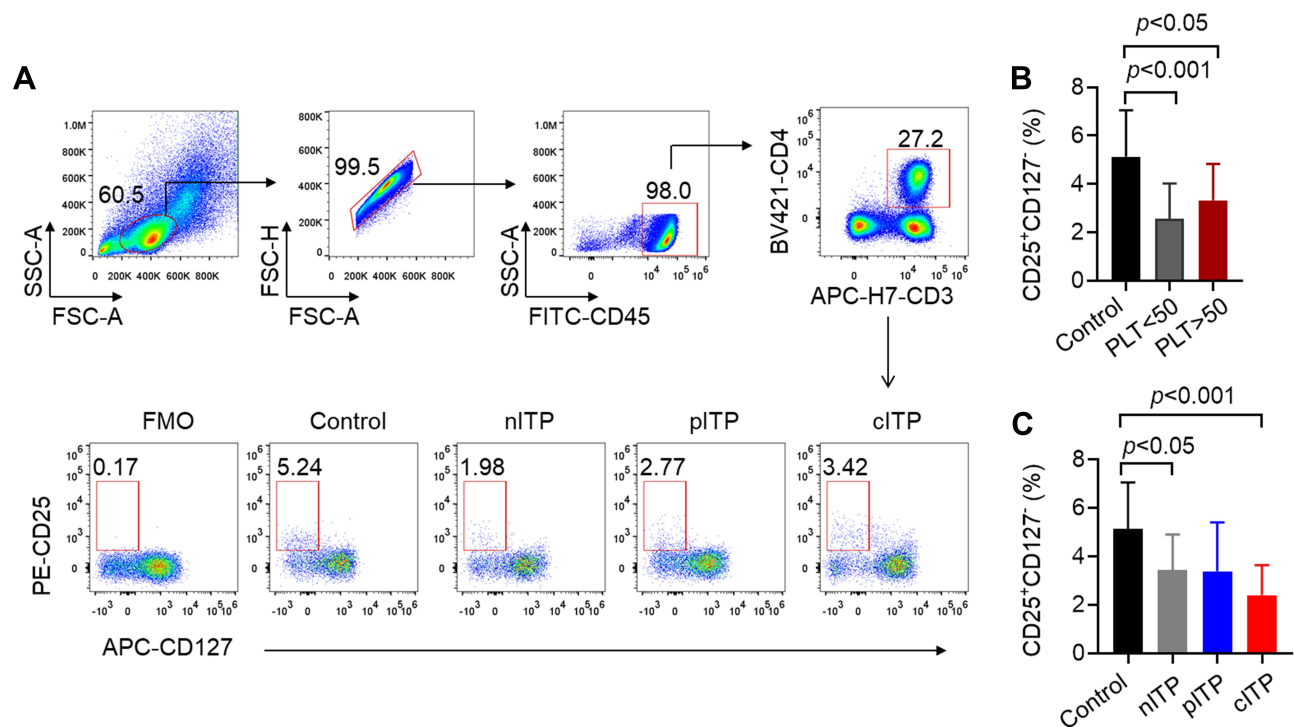

analysis, the levels of IL-2 and IFN- γ in ITP patients with PLT $<50 \times 10^9/L$ and PLT $>50 \times 10^9/L$ were higher than those in healthy control group ($p < 0.05$, $p < 0.05$ Figure 5E; $p < 0.05$, $p < 0.05$ Figure 5F). Compared with the healthy control, the ITP patients of PLT $<50 \times 10^9/L$ had significantly higher TNF- α levels ($p < 0.05$, Figure 5G). Nevertheless, there was no significant difference in IL-10 ($p = 0.16$, Figure 5H), IL-4, IL-6 and IL-17 ($p = 0.54$, $p = 0.16$, $p = 0.85$, Supplement Figure 1D–F) between PLT $<50 \times 10^9/L$ and PLT $>50 \times 10^9/L$.

Discussion

The main pathogenesis of ITP is characterized by the platelet autoimmune as a result of loss of immune tolerance, which leads to abnormal activation of humoral and cellular immunity. They jointly mediate the acceleration of platelet destruction and the production of platelet insufficiency by megakaryocytes.³⁰ However, the pathophysiological mechanism of ITP is very complex and needs further study. In the immune pathogenesis of ITP, T cells are still in the central stage and play an important role in initiation, transmission and maintenance of antiplatelet

autoimmunity.³¹ The imbalance of immune response and the loss of immune tolerance, such as Th1/Th2/Th17, play an important role in the pathogenesis of ITP.^{32–34}

In this study, we found that helper T cells did not differ significantly about different stages of the disease and platelet count. CD4⁺T cells may play a major role by secreting some related cytokines. Platelet self-reactivity T cells were activated and IL-2 and IFN- γ cytokine imbalance increased in ITP patients.^{35,36} Recently, it has been reported that IL-17 cytokines increase in ITP patients, suggesting that IL-17 may play a role in ITP immunopathology.^{37–39} This cytokines may lead to the activation of B cells and be related to the activation of macrophages.⁴⁰ Panitsas et al showed that serum level of IFN- γ was markedly elevated in patients with cITP.⁴¹ We found that IFN- γ and IL-2 in nITP and cITP patients were significantly increased in relation to healthy controls, with maximum elevation in cITP patients. Andersson et al suggest that patients with active disease may have a Th1-cytokine activation pattern.⁴² We also found that the levels of TNF- α in the serum of nITP and cITP patients were

significantly higher than the healthy controls. These results support the evidence that the increase of TNF- α induces the activation of macrophages.^{43,44}

In addition, the polarization of CD8⁺ T lymphocytes in ITP patients is not completely clear. Platelets are susceptible to CD8⁺ T cell immunomonitoring. When CD8⁺ T cells recognize the homologous peptide presented by MHC I, it will degranulate the target cells and induce apoptosis.⁴⁵ We found that there was a significant increase in Tc1, compared with healthy control group, with maximum elevation in cITP patients. It strongly supported the cytotoxicity mediated by cytotoxic T lymphocytes, which may be one of the main mechanisms of ITP. Therefore, it is speculated that Tc1 cells may affect the development and function of other lymphocytes in specific microenvironment. In addition, we also found that the expression of Tc1 in cITP was greatly higher than that in nITP, indicating that cytotoxic T lymphocyte may directly affect the duration of ITP.

It has been found that the functional defects of CD4⁺CD25⁺regulatory T cells lead to the destruction of ITP tolerance.⁴⁶ Treg cells inhibit the activation and

proliferation of CD4⁺ T cells or CD8⁺ T cells mainly through the direct intercellular interaction and the production of IL-10 and TGF- β cytokines. In our study, we found that Treg cells in patients of nITP, pITP and cITP were decreased when compared with healthy control group. We assumed that Treg may be involved in the pathogenesis of ITP by regulating immune function, and the disorder may become more serious with the prolongation of the disease course.

Chemokine and chemokine receptors play an important role in autoimmune diseases.⁴⁷ However, its role in immune thrombocytopenia (ITP) is unclear. Chemokine receptors are essential for the migration and differentiation of T lymphocyte subsets. In this study, CXCR3, CCR4 and CCR6 expressed on CD4⁺ T cells were analyzed. Interestingly, in our study, we found that the percentages of CXCR3+CD4⁺ T cells and CCR6+CD4⁺ T cells increased significantly, with maximum elevation in cITP patients. CCR6+Th cell population is heterogeneous and can be divided into several subgroups, including interleukin (IL)-17, IL-22 and IFN - γ - secreting cells.⁴⁸ Therefore, we speculate that CXCR3 and CCR6 may

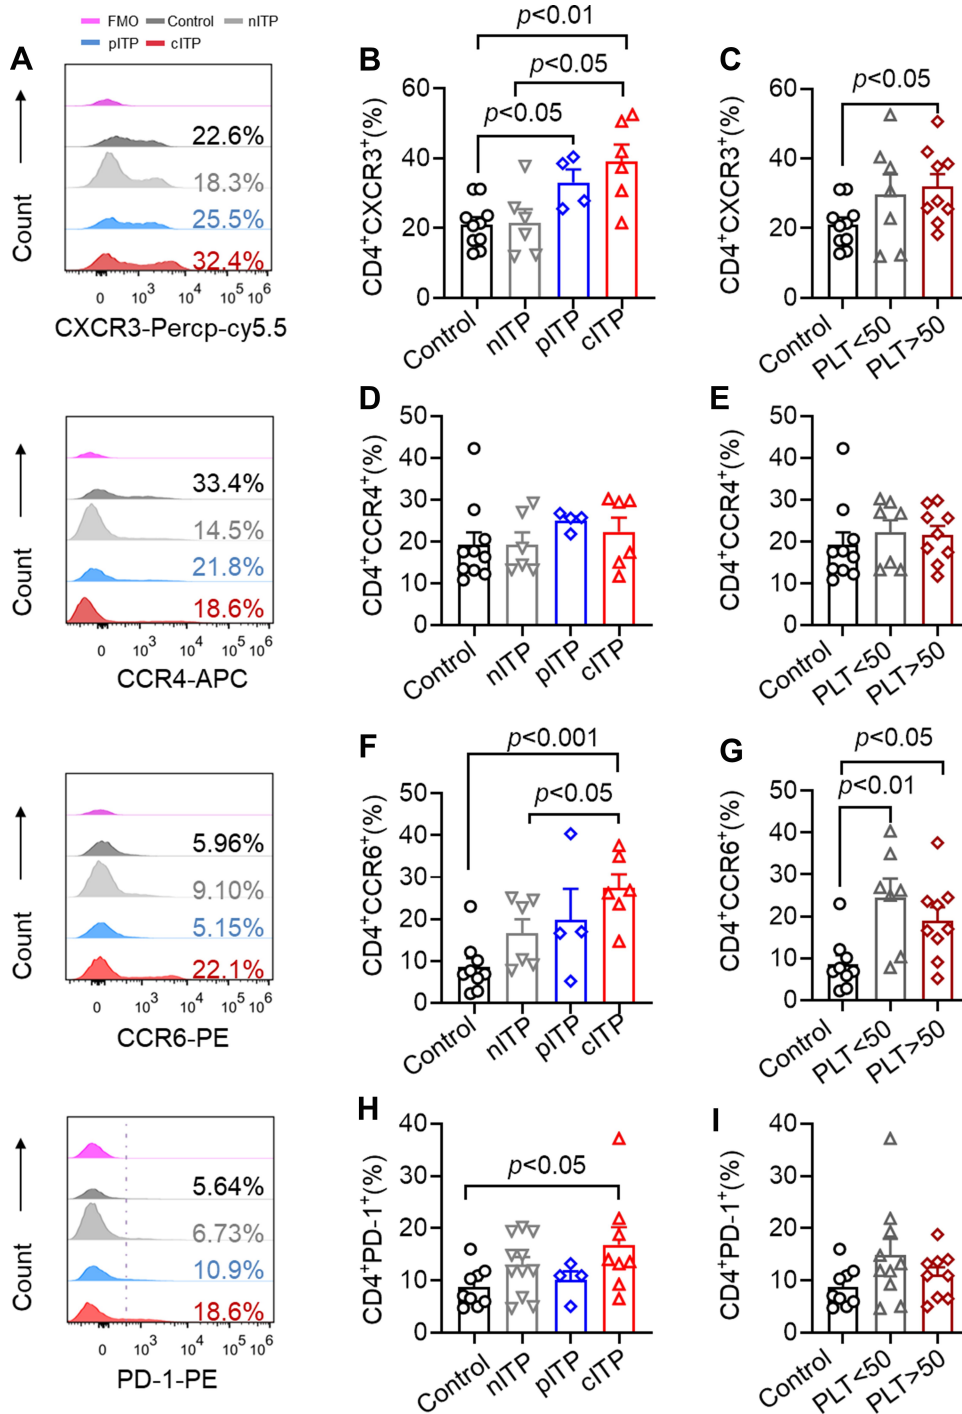

Figure 4 The expression of CXCR3, CCR6 and PD1 on CD4⁺ T cells increased in ITP patients.

Notes: (A) Representative histograms of the expression of CXCR3, CCR4, CCR6 and PD-1 on the surface of CD4⁺ T cells were detected by flow cytometry. (B) Compared with healthy controls, CXCR3 was significantly increased in the pITP and cITP groups (33.05 ± 7.49 vs 21.03 ± 6.52 , $p < 0.05$; 39.10 ± 11.86 vs 21.03 ± 6.52 , $p < 0.01$). There was no significant difference between nITP and healthy controls (21.45 ± 9.70 vs 21.03 ± 6.52 , $p = 0.92$). Compared with nITP, CXCR3 in cITP increased significantly (39.10 ± 11.86 vs 21.45 ± 9.70 , $p < 0.05$). (C) Compared with healthy controls, CD4⁺CXCR3⁺ was significantly increased in PLT<50x10⁹/L groups (31.23 ± 11.22 vs 21.03 ± 6.52 , $p < 0.05$). (D) There was no significant difference in CCR4 expression among nITP, pITP, cITP patients (19.23 ± 7.16 vs 24.95 ± 2.16 vs 22.25 ± 8.47 , respectively, $p = 0.46$). (E) There was no significant difference in CD4⁺CCR4⁺ between PLT<50x10⁹/L and PLT>50x10⁹/L groups (21.33 ± 8.35 vs 20.60 ± 6.21 , $p = 0.88$). (F) The expression of CD4⁺CCR6⁺ in cITP was significantly higher than that of healthy controls and nITP (27.33 ± 8.24 vs 8.59 ± 6.24 , $p < 0.001$; 27.33 ± 8.24 vs 16.56 ± 8.30 , $p < 0.05$). (G) Compared with healthy controls, CD4⁺CCR6⁺ was significantly increased in the PLT<50x10⁹/L and PLT>50x10⁹/L groups (21.86 ± 10.57 vs 8.59 ± 6.24 , $p < 0.01$; 18.99 ± 9.55 vs 8.59 ± 6.24 , $p < 0.05$). The percentage of CD4⁺CCR6⁺ was increased in PLT<50x10⁹/L group compared with PLT>50x10⁹/L, however, this elevation is statistically insignificant (21.86 ± 10.57 vs 17.58 ± 5.76 , $p = 0.32$). (H) Compared with healthy controls, the expression of CD4⁺PD-1⁺ in cITP was significantly increased (17.01 ± 9.49 vs 8.70 ± 3.79 , $p < 0.05$), but here was no significant difference of the expression CD4⁺PD-1⁺ among nITP, pITP and cITP (12.02 ± 6.25 vs 10.00 ± 3.51 vs 17.01 ± 9.49 , respectively, $p = 0.25$, Figure 4H). (I) There was no significant difference between PLT< 50x10⁹/L and PLT > 50x10⁹/L (15.24 ± 9.56 vs 11.98 ± 5.07 , $p = 0.35$). Bars represent means \pm SEM. $p < 0.05$ was considered significant.

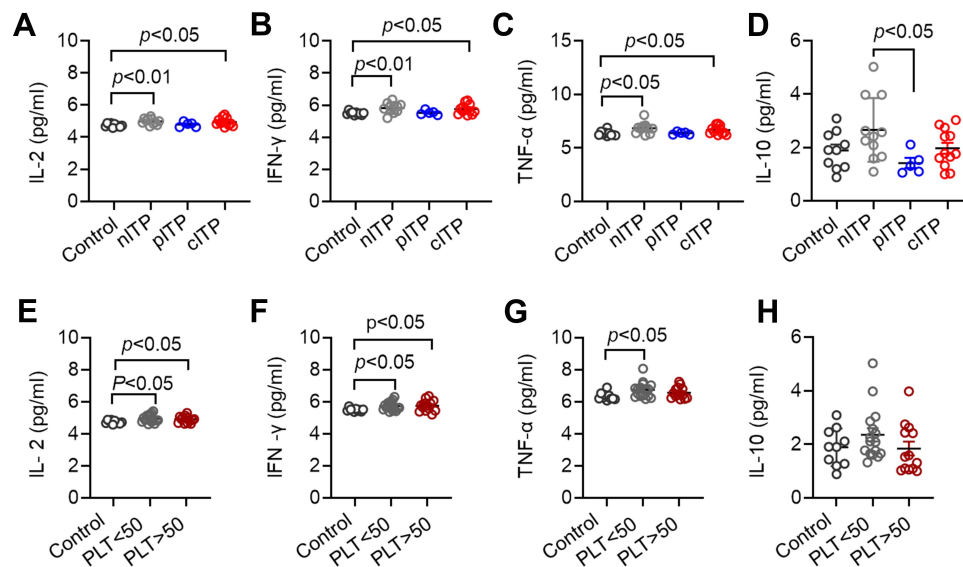

Figure 5 Serum levels of IL-2, IFN- γ , TNF- α in ITP patients were increased.

Notes: (A–C) The levels of IL-2, IFN- γ and TNF- α in nITP group and cITP group were significantly higher than those in healthy control group (A: 4.96 ± 0.22 vs 4.73 ± 0.11 , $p < 0.01$, 4.93 ± 0.25 vs 4.73 ± 0.11 , $p < 0.05$; (B) 6.16 ± 1.25 vs 5.49 ± 0.11 , $p < 0.01$, 5.74 ± 0.30 vs 5.49 ± 0.11 , $p < 0.05$; (C) 6.71 ± 0.53 vs 6.33 ± 0.24 , $p < 0.05$, 6.65 ± 0.38 vs 6.33 ± 0.24 , $p < 0.05$). (D) Compared with pITP, the secretion of IL-10 in nITP was increased, and the difference was statistically significant (2.61 ± 1.27 vs 1.75 ± 1.30 , $p < 0.05$). (E, F) The levels of IL2 and IFN- γ in ITP group (PLT $< 50 \times 10^9/L$ and PLT $> 50 \times 10^9/L$) were significantly increased compared with healthy controls (E: 4.94 ± 0.24 vs 4.73 ± 0.11 , $p < 0.05$, 4.89 ± 0.21 vs 4.73 ± 0.11 , $p < 0.05$; (F) 5.72 ± 0.27 vs 5.49 ± 0.11 , $p < 0.05$, 5.74 ± 0.35 vs 5.49 ± 0.11 , $p < 0.05$). (G) TNF α level in PLT $< 50 \times 10^9/L$ group was significantly higher than that in healthy control group (6.74 ± 0.48 vs 6.33 ± 0.24 , $p < 0.05$). The difference of TNF- α was not statistically significant in PLT $< 50 \times 10^9/L$ and PLT $> 50 \times 10^9/L$ group (6.74 ± 0.48 vs 6.57 ± 0.37 , $p = 0.29$). (H) The levels of IL-10 was not significantly different among different platelet counts (2.35 ± 0.99 vs 1.83 ± 0.92 , $p = 0.16$). Bars represent means \pm SD. $p < 0.05$ was considered significant.

induce helper T cell (CD4+T cell) to generate inflammatory factor storm in ITP through chemotaxis and play an important role in cell-mediated immunity.

PD-1 was reported to be decreased in cITP patients, which suggested the important role of the PD-1 pathway in the pathogenesis of ITP.⁴⁹ However, we found that the PD-1 expression level was significantly increased in cITP in comparison with healthy control. Wan and others found a high level of sPD-1 in the serum of patients with rheumatoid arthritis, and its expression level was closely related to clinical immune detection indexes, which suggested that sPD-1 may be an important factor to maintain the balance between PD-1 and PDL-1.⁵⁰ It can be seen that PD-1/PDL-1 signaling pathway is not enough to explain the mechanism of ITP. PD-1 pathway in the pathogenesis of ITP needs further study.

Conclusions

Taken together, this study suggested that T cell immune dysfunction plays an important role in the pathogenesis of ITP. However, there were shortcomings in the current study; for example, the sample of pITP patients is too small, leading to no significant differences between some

test indicators in the course of the disease. In addition, the above data need to be studied in a longitudinal study.

Acknowledgments

The authors thank the patients, their families, and all doctors who treated the patients.

International Journal of General Medicine

Dovepress

Publish your work in this journal

The International Journal of General Medicine is an international, peer-reviewed open-access journal that focuses on general and internal medicine, pathogenesis, epidemiology, diagnosis, monitoring and treatment protocols. The journal is characterized by the rapid reporting of reviews, original research and clinical studies

across all disease areas. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-general-medicine-journal>
