Keywords: DFT LUMO energy Cu-β-diketonato complexes

A B S T R A C T

We present data on the computed lowest unoccupied molecular orbital energy (*E_{LUMO}*) of two series of Cu(II)-βdiketonato complexes, calculated via density functional theory (DFT). These are correlated to experimental reduction potential data (*E*pc), obtained by cyclic voltammetry under different experimental conditions (solvent, working and reference electrodes). All calculations were done with the B3LYP functional in the gas phase. Knowledge of the influence of different ligands on the redox potential of copper complexes, as measured by DFT calculated energy data, are very useful. These theoretical correlations are vital in the further design of similar compounds, to be customized for specific applications. The correlations can be used to predict and finetune redox potentials prior to synthesis, saving experimental chemists time and laboratory expenses. Redox potentials influence the catalytic property of bis(β -diketonato)copper(II) compounds. New catalysts can therefore be customized with a specific reduction potential and catalytic activity. Further, the Cu(II/I) redox couple is a potential alternative as electrolyte for dye-sensitized solar cells $[1-3]$. The redox potential of the electrolyte can drastically affect the photovoltage output and should therefore be optimized for efficiency and durability. By adjusting the reduction potential via different ligands on the complex, the properties of copper dyes can be

Specifications Table

Value of the Data

- The relationship between E_{LUMO} and the experimental reduction potential E_{pc} of copper(II)- β -diketonato complexes is important in the field of catalysis, as it allows to predict their catalytic activity.
- E_{DC} vs E_{LUMO} relationships can be used by experimental chemists in the design of customized complexes with a desired reduction potential.
- Calculated LUMO energy data provides insight into the influence of different ligands on the redox potential of copper complexes.
- Redox potentials are important for researchers interested in copper electrolytes under low light conditions, for commercialization of dye sensitized solar cell (DSSC) technology.

1. Data Description

The complexes shown in [Scheme](#page-2-0) 1 have been studied via DFT and their optimized Cartesian coordinates are given in the supporting information. E_{LUMO} data and complex number-ing are listed in [Table](#page-3-0) 1. Linear relationships between experimental E_{DC} and computed E_{LUMO} of the copper (II/I) reduction, are shown in [Figs.](#page-2-0) 1–4. These values were obtained for series of related molecules obtained under the same experimental conditions (solvent, working and reference electrodes). In [Figs.](#page-2-0) 1 and [2,](#page-4-0) the E_{pc} *vs* E_{LUMO} relationships for two different series of [CuII(β-diketonato)2] compounds are shown. For both these series, *E*pc (CuII/I) was obtained in the same solvent $CH₃CN$, but with different working and reference electrodes [4-7]. In [Fig.](#page-4-0) 3 the E_{pc} *vs* E_{LUMO} relationship is shown only for $\left[\text{Cu}^{\text{II}}(\beta-\text{diketonato})_{2}\right]$ compounds, with E_{pc} (Cu^{II/I}) obtained in DMSO as solvent [\[8\].](#page-6-0) [Fig.](#page-5-0) 4 provides the E_{pc} *vs* E_{LUMO} relationship

Scheme 1. Copper(II)-β-diketonato compounds of this study: (a) $\left[\text{Cu}^{\text{II}}(\beta-\text{diketonato})_2\right]$ and (b) $\left[\text{Cu}^{\text{II}}(\beta-\text{diketonato})_2\right]$ diketonato)(dmeen)]⁺ complexes, where dmeen = N,N-dimethyl-N'-ethyl-1,2-diaminoethane. Groups R, R" and R' and complex numbering are indicated in [Table](#page-3-0) 1.

Fig. 1. CH₃CN as solvent and glassy carbon working electrode: Relationship between experimental reduction potentials *E*pc (V *versus* Fc/Fc+) of [CuII(β-diketonato)2] complexes (**2**) - (**14**), and their DFT calculated energy *E*LUMO. Data and complex numbering given in [Table](#page-3-0) 1.

for $[Cu^{II}(\beta$ -diketonato)(dmeen)]⁺ compounds, with E_{pc} (Cu^{II/I}) also obtained in DMSO as solvent [\[8\].](#page-6-0) Experimental *E*pc data is reported either *versus* the redox couple of ferrocene (Fc/Fc⁺ [\[9\]\)](#page-6-0), or against the saturated calomel electrode (SCE) or the saturated salt calomel electrode (SSCE). The reference values used are either E (SCE) = 0.241 V or E (SSCE) = 0.2360 V, *versus* the normal hydrogen electrode (NHE). The catalytic property and application of copper- β -diketonato compounds as redox mediators for dye-sensitized solar cells (DSSC), depends on their redox potential $[1-3,10,11]$. This is why the theoretical prediction of the redox potential of copper-β-diketonato compounds from these existing *E*pc - *E*LUMO relationships, is indispensable.

Table 1

B3LYP/6–311G(d,p) calculated LUMO energies and experimental reduction potentials measured in different solvents and with different reference electrodes. Values are listed both for $[Cu^{II}(\beta$ -diketonato)₂] compounds (**1**) – (**22**) and $[Cu^{II}(\beta$ diketonato)(dmeen)]⁺ compounds (23) – (30), with β -diketonato = (R'COCR"COR)⁻.

2. Experimental Design, Materials and Methods

The optimized geometry of the specified molecules were obtained by DFT calculations, similar to the computations described in our previous publication [\[12\].](#page-6-0) The Gaussian 16 package [\[13\]](#page-6-0) was used, together with the hybrid functional B3LYP [\[14,15\],](#page-6-0) while applying the GTO (Gaussian type orbital) triple- ζ basis set 6–311G(d,p) for all the atoms. The optimization of the molecules was done in the gas phase. The Berny optimization algorithm [\[16\]](#page-6-0) was used, requesting a convergence on energy of 1.0D-8 atomic unit. The input coordinates for the compounds were constructed using Chemcraft software $[17]$. The coordinates and multiplicity (2) were specified in the input files of the DFT calculations. Frequency calculations were done on all

Fig. 2. CH₃CN as solvent and carbon fibres working electrode: Relationship between experimental reduction potentials *E*pc (V *versus* SCE) of [CuII(β-diketonato)2] complexes (**1**), (**5**), (**7**), (**9**), (**12**), (**14**), (**15**) – (**18**), (**20**) - (**22**), and their DFT calculated energy E_{LUMO} . Data and complex numbering given in [Table](#page-3-0) 1. Complex (19) did not fit the trend.

Fig. 3. DMSO as solvent and carbon fibres working electrode: Relationship between experimental reduction potentials E_{pc} (V *versus* SSCE) of $[Cu^{II}(\beta$ -diketonato)₂] complexes (**1**), (**5**) – (**7**), (**9**), (**12**) - (**14**), and their DFT calculated energy *E*LUMO. Data and complex numbering given in [Table](#page-3-0) 1.

molecules to ensure true minimum energy (no imaginary frequency). The LUMO energies were obtained from the output files, searching for "Orbital energies and kinetic energies" from the bottom of the file and identifying the LUMO from the orbital energies and the provided occupations.
