Abstract: The present study aimed to evaluate the effectiveness of morphine and meperidine (pethidine) as pain relief in opioid-dependent patients with acute pain. A total of 122 opioid-dependent patients with acute pain were included in the study. Their pain severity was assessed, using visual analog scale (VAS) scores ranging from 0 to 10. The patients randomly received intravenous morphine (up to 0.15 mg/kg) or meperidine (up to 1.5 mg/kg) for pain control by patient control analgesia (PCA) pump. The clinical opioid withdrawal scale (COWS) was employed for the assessment of withdrawal symptoms. The pain relief and the emergence of withdrawal symptoms were measured at 15, 30, and 60 minutes after drug administration. The patients who received morphine reported a better pain control compared to those who received meperidine (mean \pm standard deviation [SD] VAS scores 4.11 ± 1.90 vs 5.85 ± 2.08 at the end of the study; $P < 0.001$). On the other hand, the patients who received meperidine indicated prominent withdrawal symptoms (mean \pm SD COWS scores 4.80 ± 2.18 vs 1.98 ± 0.82 at the end of the study; $P < 0.001$). Our findings revealed that morphine can be recommended in acute pain management of opioid-dependent patients. In addition, emergency physicians should ask their patients about any drug dependence before selecting the appropriate drug for their acute pain management.

Keywords: pain management, meperidine, morphine, opioid dependency, withdrawal symptoms

Introduction

Pain is a major medical problem. The physiological and psychological consequences of acute and chronic pain are well-recognized.¹⁻³ Inadequately treated pain can lead to detrimental physiological consequences and may also have psychological, economic, and social adverse effects. Effective pain control is desirable on humanitarian grounds, as well as for its potential to improve patients' recovery, rehabilitation, and outcome.^{2,3} Acute pain can also increase heart rate and blood pressure, suppress immune functioning, and reduce pulmonary function, leading to an increased risk of dangerous complications, including myocardial ischemia, deep vein thrombosis, pulmonary embolism, hypoxia, pneumonia, and stroke.⁴⁻⁶ Current treatment options for the management of acute pain in the emergency department (ED) encompass opioid analgesics such as morphine, hydromorphone, or fentanyl and non-opioid analgesics such as acetaminophen, ketamine, local anesthetics, and non-steroidal anti-inflammatory drugs.²

Opioids have been utilized for thousands of years to treat pain and still continue to be one of the most commonly prescribed medications for acute pain management in the ED.² Morphine is the standard opium-based analgesic with well-known analgesic effects and side effects.⁷ Meperidine (pethidine) is another opioid, but the use

of meperidine is not very popular in countries such as the USA and Canada, however it is still used in Iran for pain management in the ED.^{7,8} In our country, Iran, the only opioids that can be parenterally used in the ED for acute pain management are meperidine, morphine, and fentanyl. There are few studies that have compared the analgesic effects of meperidine and morphine in non-opioid-dependent patients.⁹ However, thus far no study has been conducted to compare the effectiveness and the side effects of morphine and meperidine for acute pain management in the opioid-dependent patients. The present study was designed to clarify this issue.

Materials and methods

Of the 20- to 60-year-old opioid-dependent patients who presented to the ED of Hazrat Valiasr Hospital in Arak, Iran for acute pain control between March 20, 2012 and September 21, 2012, 122 patients were randomly selected. These patients were dependent on methadone, heroin, opium, opium dross, or refined opium dross (Shireh). In case of suspected acute abdomen, hypotension, head trauma, liver diseases, decreased renal function, and earlier administration of any drugs for pain relief prior to the ED presentation, the patients were excluded from our study. Pain severity was assessed, using visual analog scale (VAS) scores ranging from 0 to 10. The patients randomly received intravenous morphine (up to 0.15 mg/kg) or meperidine (up to 1.5 mg/kg) for pain control by patient control analgesia (PCA) pump. Pain relief and emergence of withdrawal symptoms were assessed at 15, 30, and 60 minutes after drug administration. The clinical opioid withdrawal scale (COWS) was employed for the evaluation of withdrawal symptoms in the patients. The study was approved by the local ethical committee of Arak University of Medical Sciences. All of the patients provided written consent forms. The results were analyzed by SPSS software version 16.0 using Student's *t*-test. The statistical significance was set at $P < 0.05$.

Results

A total of 122 patients were assigned into two 61-patient groups. The mean VAS scores of the groups are demonstrated in Table 1. The severity of withdrawal symptoms during the study is illustrated in Table 2. As demonstrated in the tables, the patients who received morphine reported a better pain control compared to those who received meperidine (mean \pm SD VAS scores 4.11 \pm 1.90 vs 5.85 \pm 2.08 at the end of the study; $P < 0.001$). On the other hand, patients who received meperidine showed prominent withdrawal symptoms (mean \pm SD COWS scores 4.80 \pm 2.18 vs 1.98 \pm 0.82; $P < 0.001$).

Table 1 Mean (\pm SD) visual analog scale scores of the studied groups at the start of the study and thereafter

Assessment time	Morphine group	Meperidine group	P-value
Start of the study	7.34 \pm 1.75	8.06 \pm 1.50	0.073
15 minutes after drug therapy	7.12 \pm 1.71	7.50 \pm 1.65	0.065
30 minutes after drug therapy	6.50 \pm 1.84	7.27 \pm 1.61	<0.001
60 minutes after drug therapy	4.11 \pm 1.90	5.85 \pm 2.08	<0.001

Abbreviation: SD, standard deviation.

Table 2 Mean (\pm SD) clinical opioid withdrawal scale scores in the studied groups during the study

Assessment time	Morphine group	Meperidine group	P-value
Start of the study	none	none	–
15 minutes after drug therapy	1.98 \pm 0.82	2.14 \pm 0.83	0.278
30 minutes after drug therapy	1.98 \pm 0.82	3.00 \pm 1.01	<0.001
60 minutes after drug therapy	1.98 \pm 0.82	4.80 \pm 2.18	<0.001

Abbreviation: SD, standard deviation.

Discussion

In addition to methadone that is orally used in methadone maintenance treatment programs and heroin that is intravenously or inhalationally abused, opium, opium dross, and refined opium dross (Shireh) are the opioids commonly abused in Iran orally or inhalationally.^{10,11} Shireh is usually made by boiling opium dross (left in pipes after smoking opium) or a mixture of opium and opium dross with water which is filtered several times. The filtrate is evaporated until a gummy consistency is achieved.¹⁰

It has been stated that acute pain management is a challenge in opioid-dependent patients since they are often undertreated for pain. Therefore, in acute pain management in these patients, an appropriate opioid with an appropriate dosage should be given to them to control the pain and prevent the development of withdrawal symptoms.^{12,13}

The present study compared the effectiveness of morphine and meperidine in the management of acute pain as well as the development of withdrawal symptoms in the patients. The results confirmed that meperidine was less effective in acute pain management compared to morphine. Moreover, it was found that meperidine might produce withdrawal symptoms which complicated the patients' situation more than before.

To date, a number of studies have been performed that have compared the analgesic effects of meperidine and morphine via PCA in non-opioid-dependent patients, indicating that meperidine can only control mild pain in comparison with morphine.⁹ Our study also suggested that pain control was not successful in meperidine group. It was also revealed that patients who received meperidine experienced more withdrawal, while meperidine is a pure agonist and should not cause withdrawal per se.⁷ As mentioned above, insufficient

doses of opioid not only undertreat the pain, but also cannot prevent withdrawal symptoms in opioid-dependent patients.¹² Therefore, pain can affect the COWS parameters and increase this score in the studied population.

According to our findings, we recommend using morphine, rather than meperidine, in acute pain management of opioid-dependent patients. Emergency physicians should query their patients about any drug dependence before selecting the appropriate drug for their acute pain management.
