

Sex-Based Differences in Prevalence, Outcomes, and Complications of Hip Arthroscopy for Femoroacetabular Impingement

A Systematic Review and Meta-analysis

Madeline M. Owen,^{*†} BS, Chetan Gohal,[‡] MD, FRCSC, Hunter S. Angileri,[†] BA, Matthew J. Hartwell,[‡] MD, Mark A. Plantz,[‡] MD, Vehniah K. Tjong,[‡] MD, FRCSC, and Michael A. Terry,[‡] MD

Investigation performed at Northwestern University Feinberg School of Medicine, Chicago, Illinois, USA

Background: Trends between the sexes have been reported regarding prevalence, patient-reported outcomes (PROs), and complications of hip arthroscopy (HA) for femoroacetabular impingement syndrome (FAIS), yet current results lack consensus.

Purpose: To evaluate sex-based differences after HA for FAIS in (1) prevalence of cam and pincer morphology in FAIS and (2) PROs, pain scores, and postoperative complication rates.

Study Design: Systematic review; Level of evidence, 4.

Methods: The EMBASE, PubMed, and Ovid (MEDLINE) databases were searched from establishment to February 28, 2022, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. Included studies had sex-based data on prevalence, outcomes, and complications of HA for FAIS. Reviews and commentaries were excluded. Data were combined, and between-sex differences were analyzed. Meta-analyses using random-effects models were performed when possible. Pooled risk ratios (RRs) and standardized mean differences were calculated.

Results: A total of 74 studies were included (213,059 patients; 132,973 female hips [62.4%] and 80,086 male hips [37.6%]). The mean age was 30.7 ± 7.7 years among male patients and 31.1 ± 7.8 years among female patients. Male patients experienced mixed-type impingement significantly more often (39.4% vs 27.2% for female patients; RR = 0.69 [95% confidence interval [CI], 0.58-0.81]; $P < .001$), whereas female patients experienced pincer-type impingement more often (50.6% vs 30.8% for male patients; RR = 2.35 [95% CI, 1.14-4.86]; $P = .02$). Male patients had higher likelihoods of undergoing femoroplasty (89.8% vs 77.4% for female patients; RR = 0.90 [95% CI, 0.83-0.97]; $P = .006$), acetabuloplasty (67.1% vs 59.3% for female patients; RR = 0.87 [95% CI, 0.79-0.97]; $P = .01$), or combined femoroplasty/acetabuloplasty (29.2% vs 14.5% for female patients; RR = 0.63 [95% CI, 0.44-0.90]; $P = .01$). Although female patients showed greater improvements in Hip Outcome Score–Sport-Specific subscale ($P = .005$), modified Harris Hip Score ($P = .006$), and visual analog scale pain ($P < .001$), both sexes surpassed the minimal clinically important difference at 1, 2, and 5 years postoperatively. Female patients had higher complication rates ($P = .003$), although no sex-based differences were found in total hip arthroplasty conversion rates ($P = .21$).

Conclusion: Male patients undergoing HA for FAIS had a higher prevalence of mixed-type FAIS while female patients had more pincer-type FAIS. Female patients gained greater improvements in PROs, although both sexes exceeded the minimal clinically important difference, suggesting that both male and female patients can benefit from HA.

Keywords: femoroacetabular impingement; sex; hip arthroscopy; labral tear

Femoroacetabular impingement syndrome (FAIS), which results from abnormal contact between the acetabular rim and femoral head-neck junction, causing morphological changes that create an aspherical joint, is a leading cause

of hip pain in young adults.^{5,18,27} Three basic subtypes have been established in the literature with varying hip morphology that leads to impingement: cam-, pincer-, and mixed-type FAIS.

Hip arthroscopy (HA) has been established as an effective procedure that improves patient-reported outcomes (PROs) in the treatment of FAIS, with impingement and labral tears being the leading indications.^{11,14,59} Studies suggest that nonmodifiable factors, such as age and sex, impact outcomes of HA; however, there is conflicting evidence as to whether sex differences exist and the magnitude of those differences. Salvo et al⁷⁷ reported a significant difference in preoperative hip function, morphology, and self-reported functional deficits between male and female patients. Beck et al³ found that female patients achieved postoperative improvements on certain PROs at higher rates than male patients after HA for FAIS, whereas Cvetanovich et al¹⁶ found that male and female patients achieved similar improvements on PROs and low complication rates. Some studies have found sex-based differences in HA rates regardless of FAIS diagnosis,⁸ whereas others have reported no such differences.⁶²

The aim of this systematic review was to compare sex-based differences in the prevalence of cam and pincer morphology in FAIS, and to evaluate such differences in PROs, pain scores, and postoperative complication rates after HA for treatment of FAIS. The hypothesis was that, whereas male patients may more frequently undergo HA for cam-type FAIS and female patients for pincer-type, similar improvements in PROs and no difference in complication rates would be expected between sexes.

METHODS

Search Strategy

Three online databases (Embase, PubMed, and Ovid [MEDLINE]) were searched from database inception until February 28, 2022, for studies investigating patient-reported or sex-specific outcomes after HA for FAIS. Search terms included “hip arthroscopy,” “femoroacetabular impingement,” “labrum tear,” “labral tear,” “gender,” “sex,” “male,” and “female,” and were limited to English and human studies (Appendix Table A1).

Of note, a distinction between *gender* and *sex* was not incorporated into the reviewed studies. Results were analyzed as a dichotomous assigned-male-at-birth versus assigned-female-at-birth comparison due to the literature suggesting that sex-based differences in FAIS are due to anatomic differences in hip joint and pelvic

anatomy, including females having smaller alpha angles and increased acetabular and femoral anteversion.³⁴

Study Screening

Two reviewers (H.A. and M.O.) screened titles, abstracts, and full-text articles independently and in duplicate in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. A third reviewer (M.H.) reconciled any discrepancies. References of included articles were searched manually to identify studies that may have eluded the initial search, from which 1 article was identified and included in the analysis.⁵⁵ The interreviewer agreement for the title, abstract, and full-text screenings was assessed using the kappa (κ) statistic.

Assessment of Study Eligibility

The research question and criteria for study inclusion were established a priori. Inclusion criteria were as follows: English-language studies, human studies, studies with sex-specific data, and studies investigating HA or FAIS prevalence, outcomes, or complications. Exclusion criteria were review articles, commentaries, case reports or studies with a sample size of $n = 1$, and studies that lacked strong sex-specific data (either direct sex comparisons or sample sizes large enough where sex data could be extracted for comparison).

Data Abstraction

A single reviewer collected and recorded data via Microsoft Excel (Version 16.59). Abstracted data included study year and type, Methodological Index for Non-Randomized Studies (MINORS) score, number of male and female hips, male and female mean ages, time of follow-up measurements, sex-specific outcomes for each reported PRO, and complication types and rates.

Quality Assessment

MINORS criteria were utilized to assess the methodological quality of included studies. MINORS is an instrument used to assess the quality of both comparative and noncomparative, nonrandomized surgical studies.⁸³ Noncomparative studies are scored out of 16, while comparative studies are scored out of 24. The screening process did not yield any randomized control trials; therefore, MINORS was the sole quality assessment tool used.

Outcome Measures

To assess for potential sex differences in prevalence, outcomes, and complications of HA for FAIS, demographic data were analyzed to determine the number of male and female hips undergoing HA, HA for FAIS, HA for a cam diagnosis, HA for a pincer diagnosis, HA for a mixed cam/pincer diagnosis, femoroplasty, acetabuloplasty, and combined femoroplasty/acetabuloplasty.

With respect to the standardized mean differences (SMDs) between male and female patients, 5 validated PROs were analyzed: modified Harris Hip Score (mHHS), Hip Outcome Score–Activities of Daily Living subscale (HOS-ADL), Hip Outcome Score–Sport-Specific subscale (HOS-SS), International Hip Outcome Tool-12,²⁹ and visual analog scale (VAS) for pain.^{1,32,38,58}

When evaluating complication rates, the following postoperative conditions were considered: deep venous thrombosis, pulmonary embolism, venous thromboembolism, persistent paresthesia, weakness of function or muscle strength, other undefined nerve injury, heterotopic ossification, emergency department or hospital admission, chondral injury, revision arthroscopy, or failure to return to the same level of sport.

Statistical Analysis

A meta-analysis was performed to compare several different diagnostic and outcome metrics between male and female cohorts: (1) prevalence of FAIS, (2) type of hip pathology (cam, pincer, or mixed), (3) type of procedure (femoroplasty, acetabuloplasty, or combined femoroplasty/acetabuloplasty), (4) the overall complication rate, (5) the conversion to total hip arthroplasty (THA) rate, and (6) the mean improvement in various PROs (HOS-ADL, HOS-SS, mHHS, VAS).

For type of hip pathology, type of procedure, overall complication rate, and conversion to THA, risk ratios (RRs) for male versus female patients were calculated for each study that reported these data. A pooled RR, weighed by the sample size of each study, was then calculated. RRs <1 indicated favoring male patients and thus having a higher frequency among male patients, and RRs >1 indicated favoring female patients and thus having a higher frequency among female patients. RRs = 1 indicated no frequency difference between sexes.

For continuous variables (eg, the mean increase in PRO scores), the SMD of each outcome measure was compared between male and female patients for each study that reported these data. A pooled SMD, weighed by the sample size of each study, was then calculated.

Heterogeneity of the pooled data was quantified with the I^2 statistic. If $I^2 \leq 50\%$, the studies were assumed to be homogeneous, and a fixed-effects model was used. If $I^2 > 50\%$, the studies were assumed to be heterogeneous, and a random-effects model was used. Statistical significance was defined as an α error less than 5.0% (ie, $P < .05$) for the overall effect size.

All meta-analyses were completed using the publicly available software Cochrane ReviewManager Version 5.4 (Cochrane Collaboration). All other statistical analyses were completed using SPSS Version 24.0 (IBM Corp).

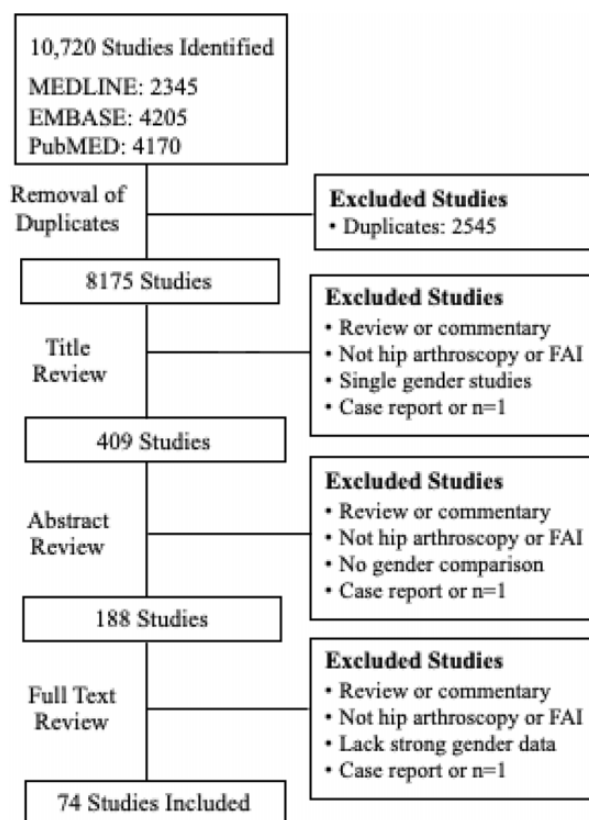

Figure 1. PRISMA flow diagram demonstrating the systematic screening of the literature for sex difference outcomes after HA for FAIS. FAI, femoroacetabular impingement; FAIS, femoroacetabular impingement syndrome; HA, hip arthroscopy; PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

RESULTS

Search Strategy

The initial online database search resulted in 10,720 studies, with a total of 8,175 studies once duplicates were removed. The entire screening process resulted in 74 full-text articles being included for analysis (Figure 1). Interreviewer agreement was found to be 0.43 for the title screening (moderate agreement), 0.64 for the abstract screening (substantial agreement), and 0.36 for the full-text screening (moderate agreement).

Study Quality

The 74 included studies consisted of 17 case series,[§] 6 case-control studies,^{3,7,19,37,51} 32 cohort studies,^{||} and 19 cross-sectional studies.[¶] A summary of the characteristics of each

[§]References 2, 10, 14, 16, 21, 30, 35, 40, 45, 47, 48, 65, 68, 70, 73, 78, 87.

^{||}References 6, 13, 17, 19, 20, 22, 23, 25, 28, 33, 39, 41, 42, 44, 46, 52, 53, 56, 60, 61, 64, 66, 69, 72, 74, 76, 79, 81, 82, 88–90.

[¶]References 8, 9, 12, 15, 24, 34, 36, 43, 50, 54, 57, 62, 63, 75, 77, 80, 84, 85, 91.

study is given in Appendix Table A2. The mean MINORS score for the noncomparative studies was 10.8 (range, 7-12), and the mean MINORS score for the comparative studies was 17 (range, 11-22). All studies had a clearly stated aim and endpoints appropriate for the aim. Moreover, 82.4% had an appropriate follow-up period, which was defined as "sufficiently long to allow the assessment of the main endpoint and possible adverse events."⁸³ All remaining studies did not report a follow-up period, except one study where follow-up was reported but inadequate to assess for possible adverse events. A total of 75.7% of studies had a loss of follow-up less than 5%. Only 2.7% of studies had prospective collection of data, and 9.5% had unbiased assessment of endpoints. Of the comparative studies, 44.7% had adequate control groups, and 55.4% had baseline equivalence of groups with respect to criteria other than the endpoints in question.

Study Characteristics

A total of 236,604 patients were included across all studies, with sex data stratified in a portion of these and identifying 80,002 (37.6%) male patients and 132,962 (62.4%) female patients (Appendix Table A2). From studies where number of hips were recorded and stratified by sex, a total of 80,086 (37.6%) male hips and 132,973 (62.4%) female hips were identified. Mean age among male patients was 30.7 ± 7.7 years, and mean age among female patients was 31.1 ± 7.8 years. Follow-up time ranged from 7 days to 10 years, with 60.8% of studies having a minimum of 1-year follow-up. Studies with perioperative data were included as well. Heterogeneity related to follow-up time is included in the I^2 statistic.

Prevalence Data

Studies lacked consistency in reporting FAIS type when patients underwent HA; therefore, results are displayed only for those studies where specific FAIS types were identified.

Among studies where prevalence of cam impingement was recorded by sex, 61.5% (740/1204) of male hips had a diagnosis of cam-type FAIS, versus 41.6% (586/1410) of female hips (RR = 0.85 [95% CI, 0.69-1.04]; $P = .11$) (Appendix Figure A1). In studies where prevalence of pincer impingement was recorded by sex, 30.8% (376/1219) of male hips had a diagnosis of pincer-type FAIS, versus 50.6% (385/761) of female hips (RR = 2.35 [95% CI, 1.14-4.86], $P = .02$) (Appendix Figure A1). Among studies where prevalence of mixed-type impingement was recorded by sex, 39.4% (388/984) of male hips had a diagnosis of mixed-type FAIS, versus 27.2% (330/1214) of female hips (RR = 0.69 [95% CI, 0.58-0.81], $P < .001$) (Appendix Figure A1).

In studies where prevalence of femoroplasty was recorded by sex, 89.8% (1456/1621) of male hips underwent femoroplasty for FAIS, versus 77.4% (1926/2490) of female hips (RR = 0.90 [95% CI, 0.83-0.97], $P = .006$) (Appendix Figure A2). Among studies where prevalence of acetabuloplasty was recorded by sex, 67.1% (1051/1566) of male hips underwent acetabuloplasty for FAIS, versus 59.3% (1436/

2423) of female hips (RR = 0.87 [95% CI, 0.79-0.97], $P = .01$) (Appendix Figure A2). In studies where prevalence of combined femoroplasty/acetabuloplasty was recorded by sex, 29.2% (119/407) of male hips underwent combined femoroplasty/acetabuloplasty for FAIS, versus 14.5% (56/386) of female hips (RR = 0.63 [95% CI, 0.44-0.90], $P = .01$) (Appendix Figure A2).

PRO Measures

HOS-ADL

Seven studies^{3,14,23,34,52,68,77} reported HOS-ADL scores, totaling 1054 male hips and 1443 female hips. Among these studies, the average HOS-ADL score after HA for FAIS for male patients was 79.4, and for female patients was 77.8. Two studies provided sufficient data to compare pre- and postoperative HOS-ADL scores for both male and female patients,^{3,23} with the average increase in HOS-ADL scores being 17.7 for male and 24.4 for female patients (SMD = 2.18 [95% CI, -1.26 to 5.62], $P = .21$, $I^2 = 99%$) (Appendix Figure A3 and Table A3).

HOS-SS

Nine studies reported HOS-SS scores,[#] totaling 1593 male hips and 2376 female hips. Among these studies, the average HOS-SS score for male patients was 68.6, and that for female patients was 64.8. Four studies reported pre- and postoperative HOS-SS scores for both male and female patients,^{3,23,28,55} with the average increase in HOS-SS scores being 32.9 for male patients and 34.8 for female patients (SMD = 2.34 [95% CI, 0.69-3.98], $P = .005$, $I^2 = 99%$) (Appendix Figure A3 and Table A3).

mHHS

A total of 18 studies reported mHHS scores, totaling 2041 male hips and 2724 female hips.^{**} Among these studies, the average mHHS score for male patients was 81.8, and that for female patients was 77.8. Seven studies^{3,22,23,28,55,76,81} reported pre- and postoperative mHHS scores for both male and female patients, with the average increase in mHHS scores being 22.2 for male and 23.2 for female patients (SMD = 0.78 [95% CI, 0.23-1.34], $P = .006$, $I^2 = 96%$) (Appendix Figure A3 and Table A3).

VAS Pain

Nine studies reported VAS pain scores,^{††} totaling 1619 male hips and 2375 female hips. Among these studies, the average preoperative VAS pain score for male patients was 16.4, and for female patients was 19.9. Five studies^{3,22,28,55,76} reported pre- and postoperative VAS pain

scores for both male and female patients, with the average decrease in VAS pain scores being 8.66 for males and 10.51 for females (SMD = 2.68 [95% CI, 1.23-4.14], $P < .001$, $I^2 = 99%$) (Appendix Figure A3 and Table A3).

Complications

A total of 14 studies reported data with respect to postoperative complications of HA for FAIS,^{‡‡} with a total of 24,912 male hips and 41,760 female hips included in the studies where postoperative complications were recorded. Time of follow-up for evaluating complications ranged from 2 days to 2 years postoperatively. Recorded complications were heterogeneous across studies but included the following: deep venous thrombosis, pulmonary embolism, venous thromboembolism, paresthesia, weakness of function or muscle strength, other undefined nerve injury, heterotopic ossification, emergency department visit, hospital readmission, chondral injury, revision arthroscopy, or failure to return to the same level of sport. Ten studies reported overall postoperative complication rates for both male and female patients,^{§§} with the average complication rate for male patients being 3.4% (845/24,840) and for female patients 5.3% (2228/41,710) (RR = 2.34 [95% CI, 1.33-4.10], $P = .003$, $I^2 = 88%$) (Table 1 and Appendix Figure A4).

Seven studies^{8,12,22,53,55,60,76} reported THA conversion data after HA for FAIS, totaling 42,768 male hips and 75,753 female hips. Time of follow-up for evaluating THA conversion ranged from 1 to 10 years postoperatively. All 7 studies reported THA conversion rates for both male and female patients, with average rates being 5.2% (2232/42,768) for male patients and 4.9% (3727/75,753) for female patients (RR = 0.87 [95% CI, 0.71-1.08], $P = .21$, $I^2 = 83%$) (Appendix Table A4).

Both men and women achieved score improvements for HOS-SS and mHHS far above those needed to confirm a minimal clinically important difference (MCID) at 1, 2, and 5 years postoperatively (Table 2).

DISCUSSION

The findings of this review suggest that sex differences exist for FAIS morphologies, with male patients having a significantly higher prevalence of mixed-type FAIS (39.4% [388/984] of male patients, 27.2% [330/1214] of female patients; RR = 0.69 [95% CI, 0.58-0.81]; $P < .001$) and female patients of pincer-type FAIS (50.6% [385/761] of female patients, 30.8% of male patients [376/1219]; RR = 2.35 [95% CI, 1.14-4.86]; $P = .02$). This prevalence difference was identified among a smaller subset of the initial 236,604 hip cohort due to inconsistency in reporting sex-specific FAIS diagnoses and HA outcomes, highlighting the larger issue of poor reporting after HA for FAIS.

The significantly higher prevalence of mixed cam/pincer impingement among male patients and pincer impingement among female patients reflected clinical expectations and previously reported trends.^{26,46} While sex differences were found for mixed-type and pincer-type FAIS, no significant difference was found for the prevalence of cam-type FAIS. The lack of studies reporting cam incidence by sex limited the cohort to a smaller size, which was made up largely of patients from the study by Salvo et al.⁷⁷ Therefore, cam prevalence reported here may be less representative of population trends and more reflective of the few studies dominating sex-stratified cam results. However, Laurito et al⁴⁶ did find a similar result for cam prevalence, with a higher male prevalence of cam among a cohort of 230 patients with FAIS undergoing HA. Ganz et al²⁶ stated that cam-type impingement was more common among young men, but that most hips overall showed a mixed-type

impingement. Given that the concept of mixed-type impingement as a diagnosis developed after the diagnoses of isolated cam and isolated pincer impingement, it is possible that male patients experience cam impingement more often than female patients, but that they concurrently experience pincer impingement and thus are categorized as having mixed-type FAIS. This reconciles with the results of the present study that men underwent femoroplasty and combined femoroplasty/acetabuloplasty more often than women.

Regarding procedure type, the higher prevalence of combined femoroplasty/acetabuloplasty in male patients was expected given their significantly higher prevalence of mixed cam/pincer impingement. The higher rate of acetabuloplasty among male patients can be explained by their higher prevalence of mixed cam/pincer impingement as well, given that acetabuloplasty is an indicated procedure

for mixed-type impingement, and not just for isolated pincer-type impingement. While female patients had a higher prevalence of isolated pincer-type impingement, the higher prevalence in male patients of mixed cam/pincer impingement, and thus of undergoing both femoroplasty and acetabuloplasty, contributed to their higher rates across all operative procedures.

Regarding PRO improvements, female patients outperformed male patients for HOS-SS, mHHS, and VAS pain scores. However, HOS-SS and mHHS scores of both male and female patients improved far beyond MCID thresholds (Table 2).⁶⁷ This aligned with results from other studies, which suggested that sex does not significantly impact potential clinical benefits of undergoing arthroscopy for FAIS.^{16,22,23,53,55} In light of the current literature, and given the MCID findings of this study, the clinical impact of statistical differences was likely minimal. Considered alongside the comparable THA conversion rates between sexes, this suggests that operative treatment for FAIS can be beneficial and worth the minimal risks it presents, regardless of sex.

For VAS pain improvements (male patients: 8.66, female patients: 10.51), both sexes experienced improvements far below those required to achieve substantial clinical benefit as defined by Beck et al⁴ (minimum 25.5-point improvement). Similarly, average VAS pain score improvements did not meet the MCID threshold set by Beck et al⁴ (a decrease of 14.8) for male or female patients. VAS, however, is one of many metrics of pain measurement. Thus, these results should not limit one's decision to pursue HA for FAIS given that overall clinical outcomes still improved for both sexes after surgical intervention.

Male patients had significantly lower rates of postoperative complications compared with female patients. Due to the heterogeneity of postoperative complications that studies chose to report, it was not feasible to compare male versus female rates for individual outcomes. However, postoperative complications that studies did report suggested that arthroscopy for FAIS may be riskier for female patients with respect to achieving ideal outcomes, although their potential benefits in PROs may be greater than that of male patients. Other studies reported similar trends of female patients being at greater risk for less desirable outcomes after HA for FAIS.^{20,45,47,71} Given that this study found that female patients experienced pincer-type impingement more frequently, it was possible that the difference in postoperative complication rates was due to higher complication rates for acetabuloplasty rather than sex differences. However, other studies reported either no significant differences in complication rates between acetabuloplasty, femoroplasty, and combined femoroplasty/acetabuloplasty³¹ or higher complication rates for femoroplasty and combined femoroplasty/acetabuloplasty.⁸⁶ Thus, the effects of operative procedure on postoperative complication rates could not solely account for trends observed in this study.

Larson et al⁴⁵ identified a significantly higher rate of postoperative complications after HA for female patients compared with male patients. Similarly, Dooley et al²⁰ reported that female patients are significantly less likely

to return to sport after HA for treatment of FAIS. Therefore, patient-specific risks versus benefits of undergoing arthroscopy for FAIS may be particularly important to consider for female athletes. Despite differences in postoperative complication rates, the lack of a sex differences in THA conversion rates suggested that postoperative risks did not progress to requiring total hip replacements. Along with current literature,¹⁶ this suggests that HA for FAIS can offer clinically significant benefits with minimal long-term risks for both male and female patients.

Limitations

This study has several limitations. There was a lack of consistency in the type and method of outcomes reported for FAIS and HA. For instance, many PRO measures exist, yet not all studies reported each PRO. In addition, functional outcomes such as hip strength and range of motion were commonly underreported and thus omitted from data extraction. Clinical criteria for defining FAIS have evolved over time, introducing variation in the way studies defined, reported, and measured FAIS-related outcomes. In addition, there is inconsistency in reporting sex-specific outcomes for HA after a diagnosis of FAIS - out of 236,604 total patients in the present study, only 212,964 had sex-stratified data. Furthermore, prevalence data can be skewed by the small number of studies reporting these values.

CONCLUSION

Male patients who underwent HA for FAIS had a higher prevalence of mixed-type FAIS while female patients had more pincer-type FAIS. Female patients gained greater improvements in PROs, though both sexes exceeded the MCID, suggesting that male and female patients can each benefit from HA. Large, high-quality, directly comparative studies are needed to confirm any sex differences in the prevalence and outcomes of HA for FAIS.

^aF, female; LOE, level of evidence; M, male; MINORS, methodological index for nonrandomized studies; NR, not reported; RTP, return to play.

^bNoncomparative studies are scored out of 16; comparative studies are scored out of 24.

^cNoncomparative studies.

^dAll values are minimum postoperative follow-up in months, unless range or mean is otherwise noted (time measurements not in months are noted).

^eFollow-up days in parentheses as the column is defined in units of months – any follow-up periods <1 month are written in units of 'days' and set-off from the other units of months with parentheses.

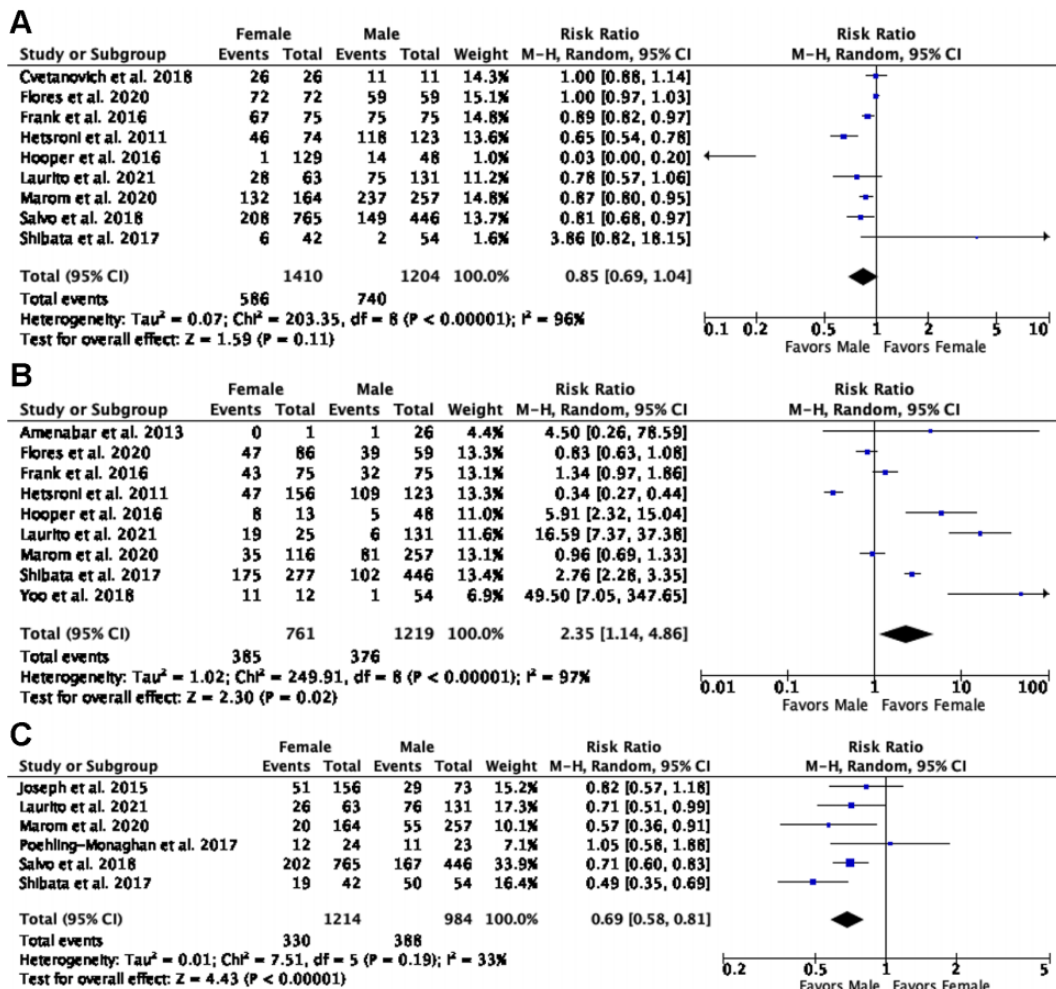

Figure A1. Forest plot demonstrating sex-based differences in the prevalence of (A) cam hips, (B) pincer hips, and (C) mixed cam/pincer hips among patients with FAIS. FAIS, femoroacetabular impingement syndrome; M-H, Mantel-Haenszel.

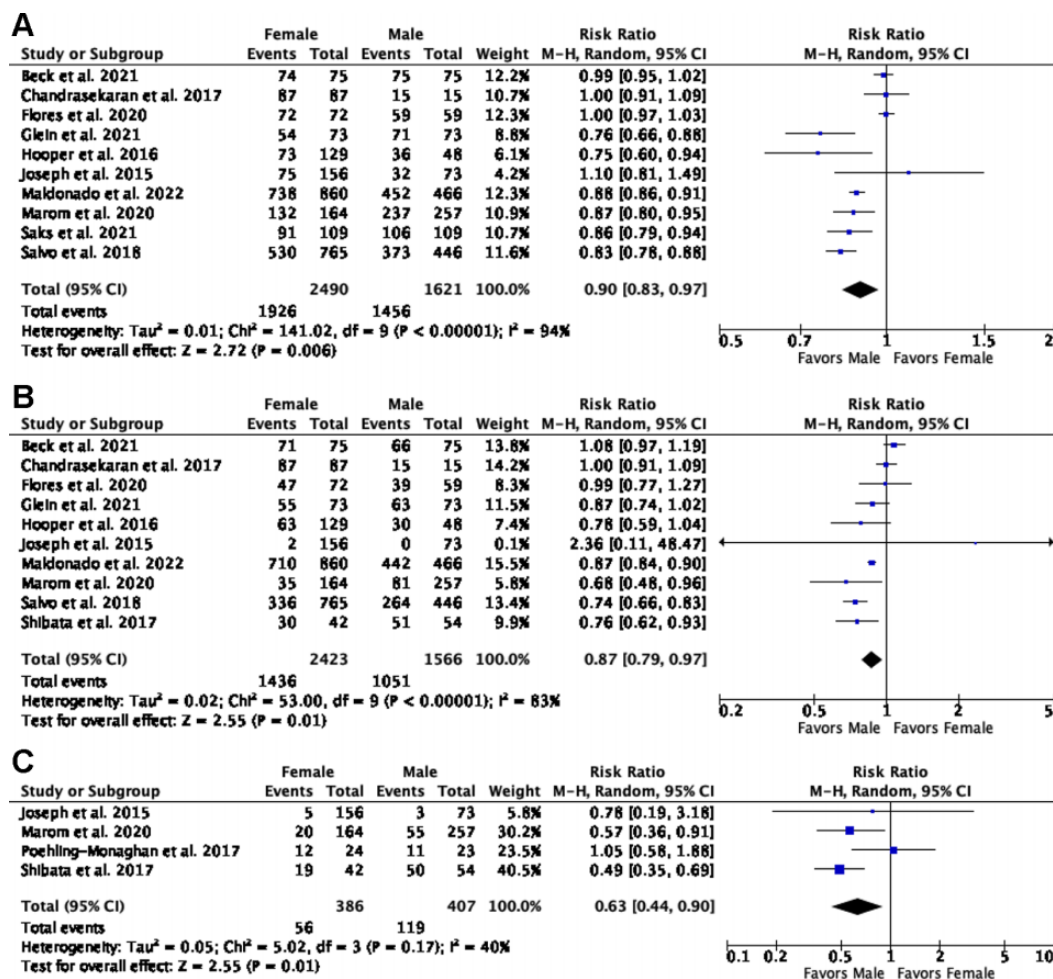

Figure A2. Forest plot demonstrating sex-based differences in the prevalence of (A) femoroplasty, (B) acetabuloplasty, and (C) combined femoroplasty/acetabuloplasty among patients with FAIS. FAIS, femoroacetabular impingement syndrome; M-H, Mantel-Haenszel.

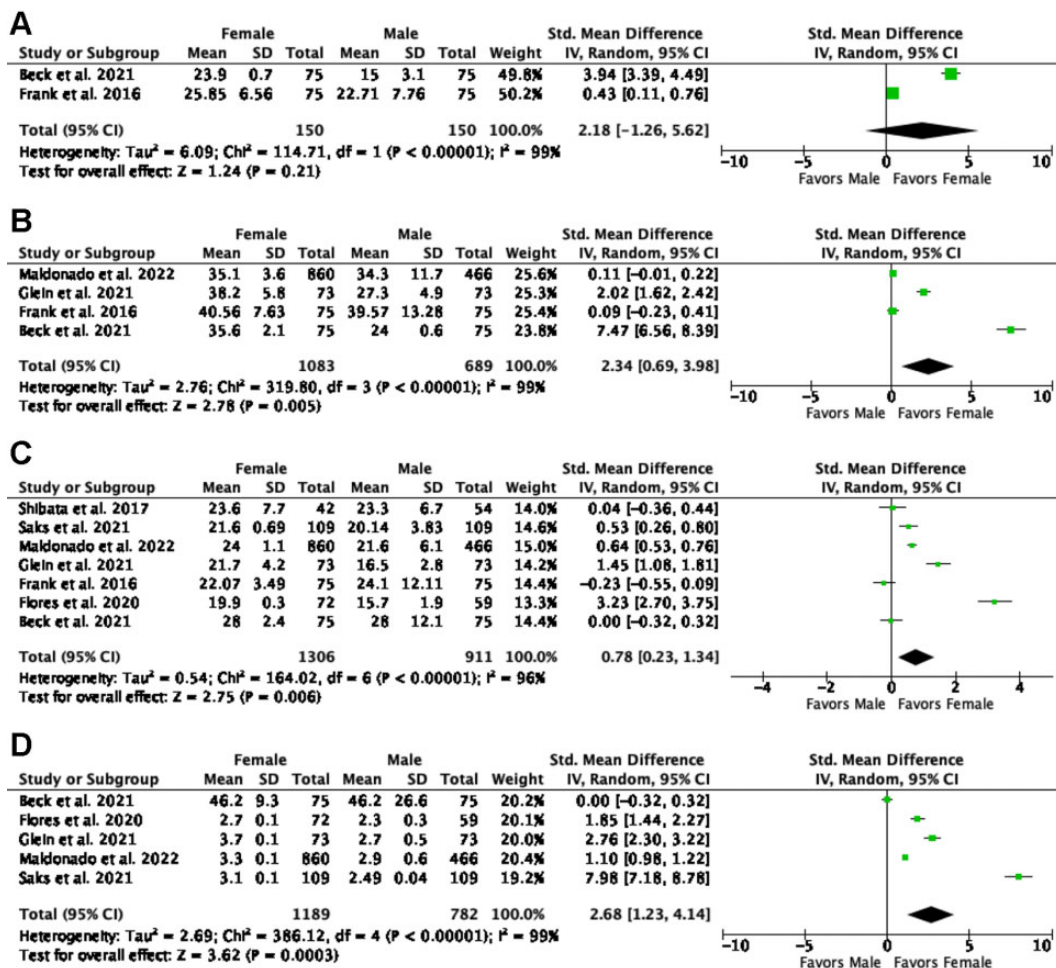

Figure A3. Forest plot demonstrating changes in (A) HOS-ADL, (B) HOS-SS, (C) mHHS, and (D) VAS for pain for male versus female patients after HA for FAIS. FAIS, femoroacetabular impingement syndrome; HA, hip arthroscopy; HOS-ADL, Hip Outcome Score-Activities of Daily Living subscale; HOS-SS, Hip Outcome Score, Sport-Specific subscale; IV, inverse variance; mHHS, modified Harris Hip Score; Std., standardized; VAS, visual analog scale for pain.

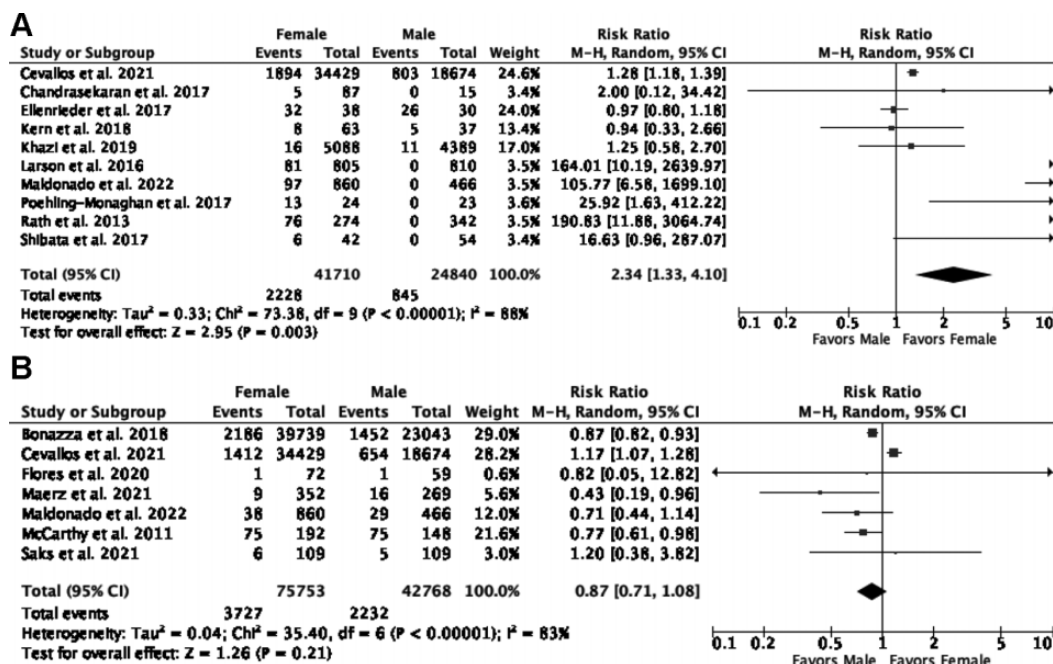

Figure A4. Forest plot demonstrating (A) complication rates and (B) conversion rates to THA for male versus female patients after HA for FAIS. FAIS, femoroacetabular impingement syndrome; HA, hip arthroscopy; M-H, Mantel-Haenszel; THA, total hip arthroplasty.

TABLE A3
Sex-Specific Differences After HA for FAIS According to PROs^a

Lead Author (Year)	Pre- to Postop Differences? (M/F)	Sex-Specific Outcomes
HOS-ADL		
Beck (2021) ³	Yes/Yes	No significant sex difference in achieving MCID, but significant pre- to postop improvements for both sexes
Chandrasekaran (2017) ¹⁴	Yes/Yes	Female patients had significantly lower baseline scores, but showed significantly greater improvements postop vs male patients
Frank (2016) ²³	Yes/Yes	Both male and female patients showed significant improvements in pre- vs postop scores at 2-y follow-up
Hetsroni (2013) ³⁴	NR/NR	Female patients had a significantly lower baseline mean vs male patients (68.3 ± 16.4 vs 75.7 ± 14.9, P = .004)
Lindner (2014) ⁵²	NR/NR	Female patients had significantly lower preop scores vs males (60.7 vs 64.3, P = .03)
Nwachukwu (2017) ⁶⁸	NR/Yes	Only female patients enrolled (mean pre- vs postop scores: 66.9 ± 18.8 vs 86.8 ± 15.8)
Salvo (2018) ⁷⁷	NR/NR	Significantly lower baseline scores for female vs male patients (60.9 vs 67.1, P < .001)
HOS-SS		
Beck (2021) ³	Yes/Yes	Females achieved MCID and PASS at significantly higher rates vs males (P < .05)
Chandrasekaran (2017) ¹⁴	Yes/Yes	Females had significantly lower postop scores vs males (78.6 vs 91.0)
Frank (2016) ²³	Yes/Yes	Both sexes had significant improvements at 2-y follow-up (M: 46.72 ± 26.29 to 86.29 ± 11.55; F: 40.62 ± 22.11 to 81.18 ± 14.48; P < .0001 for both)
Glein (2021) ²⁸	Yes/Yes	Females achieved MCID at significantly higher rates vs males (85.1% vs 70.0%, P = .035)
Hetsroni (2013) ³⁴	NR/NR	Females had significantly lower preop scores vs males (42.7 ± 23.8 vs 52.3 ± 22.9, P = .016)
Lindner (2014) ⁵²	NR/NR	Females had nonsignificantly lower baseline scores vs males (38.6 vs 42.3, P = .06)
Nwachukwu (2017) ⁶⁸	NR/Yes	Only female patients enrolled (pre- vs postop scores: 43.9 ± 23.6 vs 70.4 ± 32.8)
Maldonado (2022) ⁵⁵	Yes/Yes	Both sexes showed significant improvements at 2- and 5-y follow-up (P < .001)
Salvo (2018) ⁷⁷	NR/NR	Female patients had significantly lower baseline scores vs male patients (39.37 ± 20.80 vs 45.15 ± 22.15, P < .001)

(continued)

TABLE A3 (Continued)

Lead Author (Year)	Pre- to Postop Differences? (M/F)	Sex-Specific Outcomes
mHHS		
Amenabar (2013) ²	Yes/NR	Only male patients enrolled; significant improvement at 2-y follow-up after HA (83.6-98, $P < .05$)
Beck (2021) ³	Yes/Yes	Female patients achieved MCID and PASS at significantly higher rates vs male patients ($P < .05$)
Chandrasekaran (2017) ¹⁴	Yes/Yes	Both sexes showed significant improvement ($P < .01$), but female patients had lower pre- and postop scores vs male patients (F: 63.4-88.8, M: 71.0-94.3)
Domb (2021) ¹⁹	Yes/Yes	Both sexes had significant improvement in scores from preop (F: 63.5 ± 14.4; M: 67.5 ± 15.5) to 5-y follow-up (F: 87.7 ± 14.8; M: 90.1 ± 13.1) ($P < .001$), with no significant difference at final follow-up ($P = .079$)
Flores (2020) ²²	Yes/Yes	Both sexes achieved PASS for mHHS at similar rates (F: 76.4% vs M: 77.2%, $P = .915$)
Frank (2016) ²³	Yes/Yes	Both sexes had significant improvements at 2-y follow-up (M: 59.27 ± 11.99 to 83.37 ± 7.15; F: 58.36 ± 12.29 to 80.43 ± 8.80; $P < .0001$ for both)
Glein (2021) ²⁸	Yes/Yes	Female patients had significantly lower preop scores vs male patients (63.9 ± 12.6 vs 72.5 ± 13.7, $P < .001$), and both sexes significantly improved at 2-y follow-up (Δ M: 16.6 ± 19.5, $P < .001$; Δ F: 22.9 ± 19.9, $P < .001$), with no significant sex-based difference in postop scores ($P = .490$)
Hetsroni (2013) ³⁴	NR/NR	Female patients had significantly lower baseline score vs male patients (63.8 ± 11.9 vs 72.5 ± 14.1, $P < .001$)
Lee (2015) ⁴⁸	NR/NR	No statistically significant difference in scores between sexes
Lindner (2014) ⁵²	NR/NR	Female patients had significantly lower baseline score vs male patients (59.9 vs 62.6, $P = .033$)
Nepple (2014) ⁶⁴	NR/NR	Female patients had significantly lower baseline mHHS vs male patients (54.4 ± 14.8 vs 63.7 ± 16.6, $P = .004$)
Nwachukwu (2017) ⁶⁸	NR/Yes	Only female patients enrolled; most patients achieved MCID at 1-y follow-up (preop vs postop: 57.2 ± 15.3 vs 79.5 ± 19.0)
Philippon (2010) ⁷⁰	Yes/NR	Only male patients enrolled; average score improved from 70 (range: 57-100) to 95 (range: 74-100) at 2-y follow-up
Ramos (2020) ⁷²	Yes/NR	Only male patients enrolled; increase in median scores at 1.6-y follow-up (66.0 ± 7.9 to 89.5 ± 3.2) after HA for FAIS
Saks (2021) ⁷⁶	Yes/Yes	Both sexes achieved significant improvement at 2-y follow-up (Δ M: 20.14 ± 18.69; Δ F: 21.61 ± 15.99; $P < .001$ for both)
Salvo (2018) ⁷⁷	NR/NR	Female patients had significantly lower scores and therefore self-reported functional deficits vs male patients (53.40 vs 57.83, $P < .001$)
Shibata (2017) ⁸¹	Yes/Yes	Both sexes had significant pre- to postop improvement in scores (F: 74.3 ± 12.1 to 97.9 ± 4.4, M: 73.0 ± 16.6 to 96.3 ± 20.2; $P < .001$ for both)
Yoo (2018) ⁸⁹	Yes/NR	Both the study group (male military population) and control group showed significant increases at final follow-up (63.5 to 89.9 for study group, $P < .001$ for both study and control groups)
iHOT-12		
Robinson (2020) ⁷⁴	NR/NR	Female patients had a significantly lower median postop score vs male patients after HA (70.0 vs 76.0, $P = .05$)
Salvo (2018) ⁷⁷	NR/NR	Female patients had significantly lower baseline scores vs male patients (31.2 vs 38.5, $P = .001$)
VAS Pain		
Beck (2021) ³	Yes/Yes	Both sexes had significant decreases in pain at 5-y follow-up (F: 70.9 ± 19.6 to 24.7 ± 28.9; M: 70.9 ± 19.6 to 24.7 ± 28.9, $P < .001$ for both)
Chandrasekaran (2017) ¹⁴	Yes/Yes	Both sexes had significant improvement in pain at 2-y follow-up after HA (M: 4.77 to 1.85, F: 6.29 to 2.21, $P < .01$), although female patients had higher preop and postop pain scores
Flores (2020) ²²	Yes/Yes	No significant difference between sexes in preop (M: 4.2 ± 2.6, F: 4.7 ± 2.4, $P = .292$) or postop (M: 1.9 ± 2.3, F: 2.0 ± 2.5, $P = .877$) pain at 2-y follow-up after HA for FAIS

(continued)

TABLE A3 (Continued)

Lead Author (Year)	Pre- to Postop Differences? (M/F)	Sex-Specific Outcomes
Glein (2021) ²⁸	Yes/Yes	Female patients had significantly higher baseline pain scores vs male patients (5.8 ± 2.3 vs 4.6 ± 2.2 , $P < .001$), no significant sex-based difference at 2-y follow-up (F: 2.1 ± 2.4 , M: 1.9 ± 2.4 , $P = .677$). Both sexes had significant decreases in pain at follow-up (Δ F: 3.8 ± 3.1 ; Δ M: 2.7 ± 3.2), female patients had larger improvements vs male patients ($P = .031$)
Lindner (2014) ⁵²	NR/NR	Similar preop pain scores for both sexes (M: 5.7, F: 5.9, $P = .43$)
Maldonado (2022) ⁵⁵	Yes/Yes	Both sexes achieved MCID for VAS pain at similar rates ($P = .087$), and both sexes showed significant improvement from preop to 5-y follow-up (F: 5.3 ± 2.2 to 2.0 ± 2.2 ; M: 4.6 ± 2.3 to 1.7 ± 2.1 , $P < .001$ for both)
Saks (2021) ⁷⁶	Yes/Yes	No significant difference between sexes in preop (M: 4.69 ± 2.45 , F: 5.32 ± 2.28 , $P = .068$) or postop (M: 2.20 ± 2.38 , F: 2.22 ± 2.38 , $P = .778$) pain, but both sexes showed significant improvement in at 2-y follow-up after HA ($P < .001$)
Salvo (2018) ⁷⁷	NR/NR	Female patients had significantly higher average preop pain scores vs male patients (55.42 ± 19.72 vs 50.40 ± 21.72 , $P < .001$)
Yoo (2018) ⁸⁹	Yes/NR	In a male military population, pain improved from 7.6 to 2.6 vs 7.0 to 2.2 for controls ($P < .001$) at 2-y follow-up after HA

^aF, female; FAIS, femoroacetabular impingement syndrome; HA, hip arthroscopy; HOS-ADL, Hip Outcome Score—Activities of Daily Living subscale; HOS-SS, Hip Outcome Score—Sport-Specific subscale; iHOT-12, International Hip Outcome Tool—12; M, male; MCID, minimal clinically important difference; mHHS, modified Harris Hip Score; NR, not reported; PASS, Patient Acceptable Symptom State; postop, postoperative; preop, preoperative; PRO, patient-reported outcome; VAS, visual analog scale.
