## ABSTRACT

**Background.** *Helicobacter pylori* (*H. pylori*), a bacterium implicated in the development of peptic ulcer and gastric cancer, is estimated to infect around half the world's population. Its prevalence in Australia is unclear. This scoping review aimed to evaluate all Australian literature providing estimates of the prevalence of *H. pylori*.

**Methods.** Australian studies examining *H. pylori* prevalence from 1982 onwards were eligible for inclusion. Medline, Embase and Scopus databases, and grey literature sources, were searched. Two independent reviewers undertook a two-stage screening process. Data were extracted by two independent reviewers using a pre-specified template.

**Results.** Of 444 identified studies, 75 were included in the review. *H. pylori* prevalence in Australian population-based studies ( $n = 8$ ) ranged from 38.0% in 1991 to 15.1% in 2002; however, estimated prevalence across all non-clinical population studies in diverse sub-groups ( $n = 29$ ) has varied dramatically. Decreased prevalence has been more marked in populations with gastrointestinal symptoms and conditions compared to non-clinical populations. Data on *H. pylori* prevalence in vulnerable populations are lacking.

**Conclusions.** This is the first scoping review of Australian studies reporting *H. pylori* prevalence. A wide range of study designs, population groups, geographic regions, and diagnostic methods was included, involving data collected over a 50-year period (1969 to 2018). The summary of *H. pylori* prevalence estimates over time in this review points to a decrease in prevalence in Australia, particularly among populations with gastrointestinal symptoms and illnesses; however, it is unknown whether there is inequity in prevalence trends across vulnerable sub-groups of the Australian population. Future research and interventions supporting the health and wellbeing of vulnerable populations is required to ensure equitable health gains are made for all.

## BACKGROUND

*Helicobacter pylori* (*H. pylori*), a spiral-shaped bacillus, is a major risk factor for the development of peptic ulcers, some forms of gastric cancer and mucosa-associated lymphoid tissue (MALT) lymphoma (Kusters, van Vliet & Kuipers, 2006). There is also

some evidence of an association with conditions such as cardiovascular disease and ischaemic stroke, although this is debated (Jiang et al., 2017). When used alongside standard treatment, *H. pylori* eradication therapy, typically comprising combinations of two to three antibiotics and a proton-pump inhibitor (Chey et al., 2017), can support healing of peptic ulcers and prevent their recurrence (Ford et al., 2016), and can reduce the risk of gastric cancer (Shiotani, Cen & Graham, 2013; Chiang et al., 2021).

*H. pylori* is an important pathogen from a public health perspective. It is estimated that in 2018, around 800,000 new cases of gastric cancer worldwide could be attributed to *H. pylori* infection (de Martel et al., 2020). The 2010 Global Burden of Disease Study estimated that 3.5 deaths per 100,000 population per year were due to peptic ulcer disease (Stewart et al., 2014), for which *H. pylori* is a major risk factor (Kusters, van Vliet & Kuipers, 2006; Kuipers, Thijs & Festen, 1995). In addition, studies of Japanese-American men have found *H. pylori* infection to be associated with 3.0 to 4.7 times the odds of developing peptic ulcer disease compared to those uninfected (Nomura et al., 2002; Nomura et al., 1994).

There is evidence to suggest that *H. pylori* prevalence varies according to place, person and time characteristics. A systematic review of global *H. pylori* prevalence estimated that, in 2015, there were approximately 4.4 billion individuals with *H. pylori* infection worldwide (Hooi et al., 2017). This review of prevalence data from 62 countries reported large differences in *H. pylori* prevalence across geographic regions, with the highest prevalence in Africa (70.1%; 95% CI [62.6–77.7]) and the lowest prevalence in Oceania (24.4%; 95% CI [18.5–30.4]) (Hooi et al., 2017). Another systematic review of global *H. pylori* prevalence reported wide variation in prevalence between countries, from 13.1% in Finland to 90% in Mexico (Peleteiro et al., 2014). Studies have similarly shown variation across sub-populations within countries, typically with higher *H. pylori* prevalence in vulnerable groups such as migrant and Indigenous populations (Jones et al., 2012; Windsor et al., 2005). For instance, the systematic review by Hooi et al. (2017) reported that, in Australia, the general population pooled prevalence was 24.6% (95% CI [17.2–32.1]) compared to 76.0% in a rural Western Australian Indigenous community. The same systematic review reported a pooled prevalence estimate in the United States of 35.6% (95% CI [30.0–41.1]) for the general population, compared to 74.8% (95% CI [72.9–76.7]) in an Alaskan Indigenous population. In addition, there are documented associations between poorer social and environmental contextual factors, for example low socio-economic status and crowded living conditions, and *H. pylori* infection (Mentis, Lehours & Mégraud, 2015; Cheng et al., 2009; Genta, Turner & Sonnenberg, 2017; Lim et al., 2013; Pandeya, Whiteman & Australian Canc Study, 2011), and numerous studies have found that *H. pylori* prevalence increases with age (EUROGAST Study Group, 1993; Lane et al., 2002; Megraud et al., 1989).

With regard to variations in prevalence over time, systematic reviews have reported that the population-wide prevalence of *H. pylori* may have decreased in some, typically more industrialised, countries in recent decades. Hooi and colleagues reported lower period prevalence from 2000–2016 compared to 1970–1999 in Europe, North America and Oceania, whereas similar prevalence across the two time periods was reported for Asia, Latin American and the Caribbean (Hooi et al., 2017). In contrast, Nagy, Johansson & Molloy-Bl (2016) reported a decrease in *H. pylori* prevalence in China from 1983 to 2013

(25 studies; 28 datasets), but no significant trend was observed in prevalence over time for the United States (1990–2006; 11 studies). It has been stated that higher prevalence of *H. pylori* with increasing age is likely due to a cohort effect rather than incremental infection over the life course (Banatvala et al., 1993). Mitchell & Katelaris (2016) have argued that this cohort effect, whereby each birth cohort has a lower overall *H. pylori* prevalence than the cohorts before them, has led to a decrease in the prevalence of infection in Australia over time.

In Australia, estimated population prevalence has ranged from 38% in 1991 (Lin et al., 1998a) to 15% in 2002 and 2005 (Pandeya, Whiteman & Australian Canc Study, 2011; Moujaber et al., 2008). However, these prevalence data represent different population groups and different age ranges. The earlier study from data collected in 1991 (Lin et al., 1998a) included 273 participants aged 20–80 years from the Melbourne metropolitan area; a sample which is unlikely to be representative of the Australian population as a whole. The two later studies included larger samples from across Australia. One utilised a random sample of 2,413 serum samples from 37 major diagnostic laboratories across Australia, collected from people aged from 1 to 59 years (Moujaber et al., 2008). The other study used data from 1,355 community controls aged 18 to 79 years, who were recruited for a nation-wide case-control study of oesophageal cancer (Pandeya, Whiteman & Australian Canc Study, 2011).

There have been no studies published to date which have comprehensively reviewed and reported on studies of the prevalence of *H. pylori* in Australia over time. Given the public health importance of *H. pylori* infection, even in populations with relatively lower prevalence such as Australia, and lack of existing reviews of Australian *H. pylori* prevalence, this scoping review aimed to systematically identify and describe all studies reporting prevalence of *H. pylori* in Australia. In particular, this scoping review aimed to describe the scope of Australian *H. pylori* prevalence studies in terms of study characteristics (e.g., geographic location, population and diagnostic methods), and to describe prevalence estimates according to person (e.g., type of population studied, diagnoses, age, gender) and time characteristics (year(s) of data collection relating to *H. pylori* status).

## METHODS

This review was performed in accordance with the guidelines set out in the PRISMA Extension for Scoping Reviews (Tricco et al., 2018).

### Eligibility criteria

All studies reporting prevalence of *H. pylori* infection in Australian populations from 1982 onwards were eligible for inclusion. The search was limited to studies published from 1982, when *H. pylori* was first identified. Reviews, letters, commentaries or opinion papers were excluded. Studies were also excluded if they reported on a dataset that was published in a more recent or complete study.

### Information sources

Medline, Embase and Scopus were searched for articles published from 1982 onwards on 26/06/2017 (search updated on 29/01/2021 to capture additional studies published

between the original and updated search). Reference lists of the included studies were hand-searched to identify any additional relevant studies. Grey literature was searched using Google, Web of Science for conference presentations, and online government sources including the Australian Bureau of Statistics (ABS), the Australian Institute of Health and Welfare (AIHW) and the State Health Departments. A search was made on websites of all Australian universities to find researchers who conduct *H. pylori* research. These researchers (some of whom were authors of included papers), were contacted by email for information about current research, unpublished studies or studies not identified by previous searches.

### Search strategy

The search strategy was developed in conjunction with an experienced University of South Australia librarian. The search was performed using the following search terms together with relevant Boolean Operators and MeSH terms identified for individual databases: *Helicobacter pylori* (*Helicobacter pylori* \* or *H? pylori* \* or *Campylobacter pylori* \*), Australia (australia\* or tasmania\* or victoria\* or new south wales or queensland\* or northern territory\* or christmas island or canton island or enderbury island or melbourn\* or sydney or adelaide\* or perth or hobart or canberra or brisbane or darwin), Prevalence (prevalen\* or infection rate\* or proportion\* or frequenc\* or occurrence\* or likelihood\* or probabilit\*), Epidemiolog\*, risk factors (“population? at risk” or risk factor?), cohort studies (follow up stud\* or follow?up stud\* or longitudinal stud\* or longitudinal survey\* or prospective stud\* or retrospective stud\* or cohort stud\* or cohort analys?s or con?current stud\* or incidence stud\* or cross?section\* stud\*), population surveillance (Population Surveillance or Sentinel Surveillance or Public Health Surveillance or general population\* or screen\*), asymptomatic infections (a?symptomatic infection\* or sub?clinical infection\*). See [Appendix 1](#) for full search details.

### Study selection

Search results were imported into Endnote (*The EndNote Team, 2013*) where duplicates were removed. The studies were then imported into Covidence (*Covidence, 2022*) and were screened in duplicate by two independent reviewers (JC and KB) through a two-stage process: (1) screening titles and abstracts; and (2) reviewing full text of articles identified in step 1). Any differences were discussed between the reviewers (JC and KB) to reach consensus.

### Charting the data

The data extraction process was completed by two independent reviewers (JC and KB) using a standardised template. Any differences were resolved through discussion among the review team. The following information was extracted from the selected papers: “title”, “authors”, “year of publication”, “location of study”, “study design”, “year(s) of data collection”, “*H. pylori* testing method(s) used”, “description of study population”, “age groups”, “sample size”, and “*H. pylori* prevalence (percentage)”.

## Collating and summarising the results

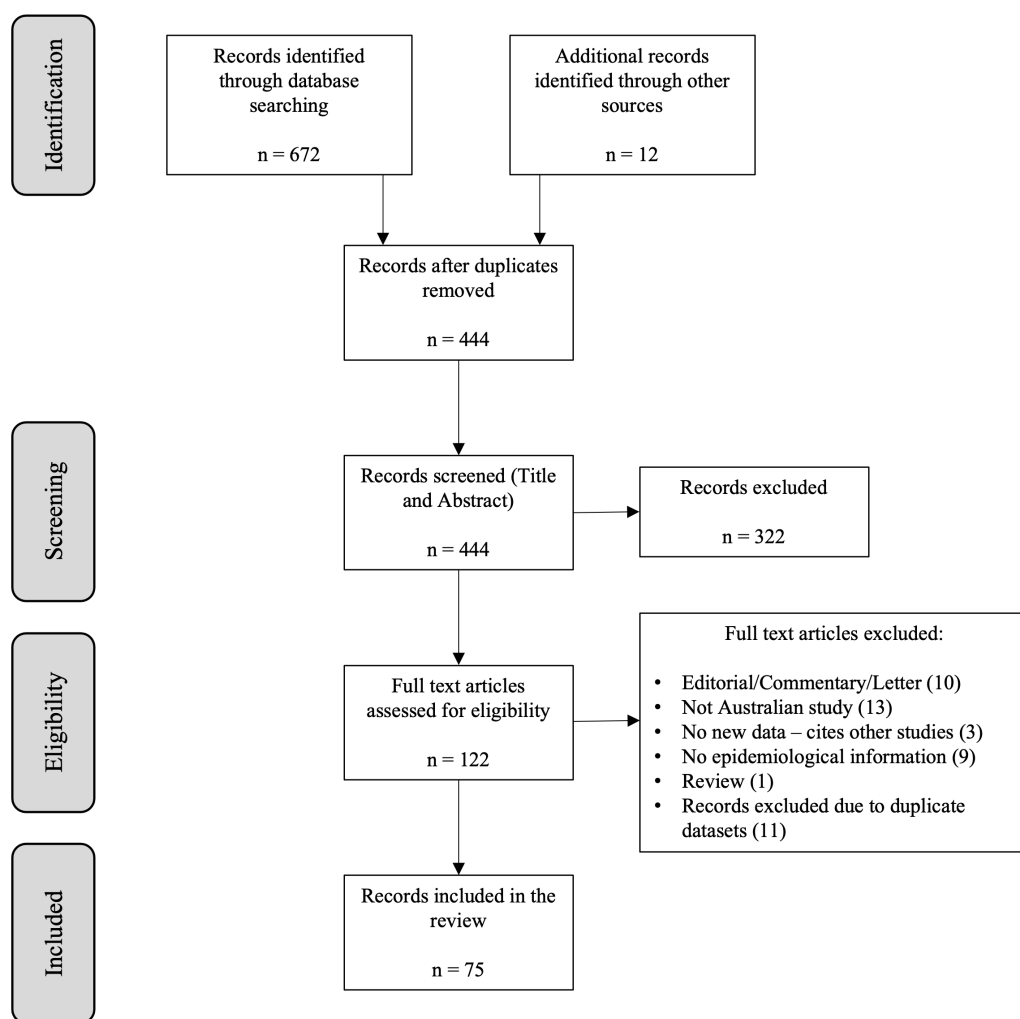

Data were categorised according to study design and then tabulated in chronological order according to the date(s) of data collection. Studies for which no data collection date was available were listed chronologically by date of publication. The data were described in terms of types of populations studied, diagnostic methods used, Australian state and *H. pylori* prevalence. Study results were also analysed using meta-regression to estimate trends in *H. pylori* prevalence over time in clinical populations (those with gastrointestinal symptoms or conditions) and non-clinical populations. Prevalence data organised by clinical and non-clinical populations were plotted using the method described by [Nagy, Johansson & Molloy-Bl \(2016\)](#).

## RESULTS

The search resulted in 86 publications that met the inclusion criteria. Of these, 75 distinct studies were included in the review ([Fig. 1](#)).

The included studies were published between 1988 ([Dwyer et al., 1988a](#); [Dwyer et al., 1988b](#); [Mitchell et al., 1988](#)) and 2020 ([Chamberlain et al., 2020](#); [Endall et al., 2020](#)) and were based on data collected between 1969 ([Cullen et al., 1993](#)) and 2018 ([Sharma & Dowling, 2018](#); [van der Poorten et al., 2018](#)). Although *H. pylori* was identified in 1982, some studies used frozen plasma from earlier studies to determine *H. pylori* prevalence prior to 1982. Eleven of the 75 papers were conference abstracts for which no subsequent published paper was found. The majority of studies used a cross-sectional design. Characteristics of included studies are presented in [Table 1](#).

Studies were performed in all Australian states and in the Northern Territory, with more than 70% of the publications reporting findings from Victorian, New South Wales or Western Australian populations. The number of participants ranged from nine ([Ho et al., 2001](#)) to over 70,000 ([Wise, Lamichhane & Webberley, 2019](#)). Around 50% of the studies included 100–500 participants. Over a third of the studies investigated patients with gastrointestinal (GI) symptoms or conditions. Patients with non-GI related conditions, for example coronary heart disease ([Coles et al., 2003](#)), diabetes ([Schimke et al., 2009](#)), sudden infant death syndrome (SIDS) ([Ho et al., 2001](#)), multiple sclerosis ([Pedrini et al., 2015](#)) and HIV/AIDS ([Edwards et al., 1991](#)) were also commonly investigated. Specific cultural groups studied included both urban and rural Aboriginal populations (8.0% of the included publications) ([Windsor et al., 2005](#); [Dwyer et al., 1988b](#); [Pringle et al., 2015](#); [Mollison et al., 1994](#); [McDonald et al., 2004](#); [Ritchie et al., 2009](#)), newly arrived migrants (10.6% of included studies) ([Dwyer et al., 1988a](#); [Gibney et al., 2009](#); [Chaves et al., 2009](#); [Cherian et al., 2008](#); [Mutch et al., 2012](#); [Johnston, Smith & Roydhouse, 2012](#); [Abdul Rahim et al., 2017](#); [Benson, Rahim & Agrawal, 2017](#)), ethnic groups such as members of the Chinese population of Melbourne (2.6% of included studies) ([Chow et al., 1995](#); [Lin et al., 1991](#)), and institutionalised populations (2.6% of included studies) ([Lambert et al., 1995](#); [Wallace, Webb & Schluter, 2002](#)). Several studies investigated groups of health professionals, hypothesised to be at greater risk of contracting *H. pylori*, including dentists ([Lin et al., 1998b](#)) gastroenterologists ([Lin et al., 1994](#)) and nurses ([Robertson, Cade &](#)

**Figure 1** Flowchart illustrating the process of selection of papers for inclusion in the review.

Full-size  DOI: [10.7717/peerj.13430/fig-1](https://doi.org/10.7717/peerj.13430/fig-1)

*Clancy, 1999*). Fourteen of the included papers (19%) estimated *H. pylori* prevalence in children (*Windsor et al., 2005; Moujaber et al., 2008; Dwyer et al., 1988a; Dwyer et al., 1988b; Mitchell et al., 1993a; Hardikar et al., 1996; Hardikar et al., 1991; Mitchell et al., 1993b; Hardikar & Grimwood, 1995; Ho et al., 2001; Ritchie et al., 2009; Cherian et al., 2008; Mutch et al., 2012; Benson, Rahim & Agrawal, 2017*).

A range of different diagnostic methods were used to determine *H. pylori* presence in the included studies. Histology, rapid urease and culture are invasive tests performed on tissue samples collected by endoscopy. Non-invasive tests include serology, urea breath test (UBT) and faecal antigen (FA) test. Among the studies included in this review, serology was by far the most common method used to detect presence of *H. pylori* infection, used in 56 (75%) studies. Serology and histology have been used throughout the study period. The earliest study using UBT as the diagnostic method was published in 1994 (*Borody et*

## Notes.

\* Data collection date determined by contacting the author.

*al.*, 1994) and FA was first used for *H. pylori* testing in an Australian epidemiological study in 2002 (Wallace, Webb & Schluter, 2002).

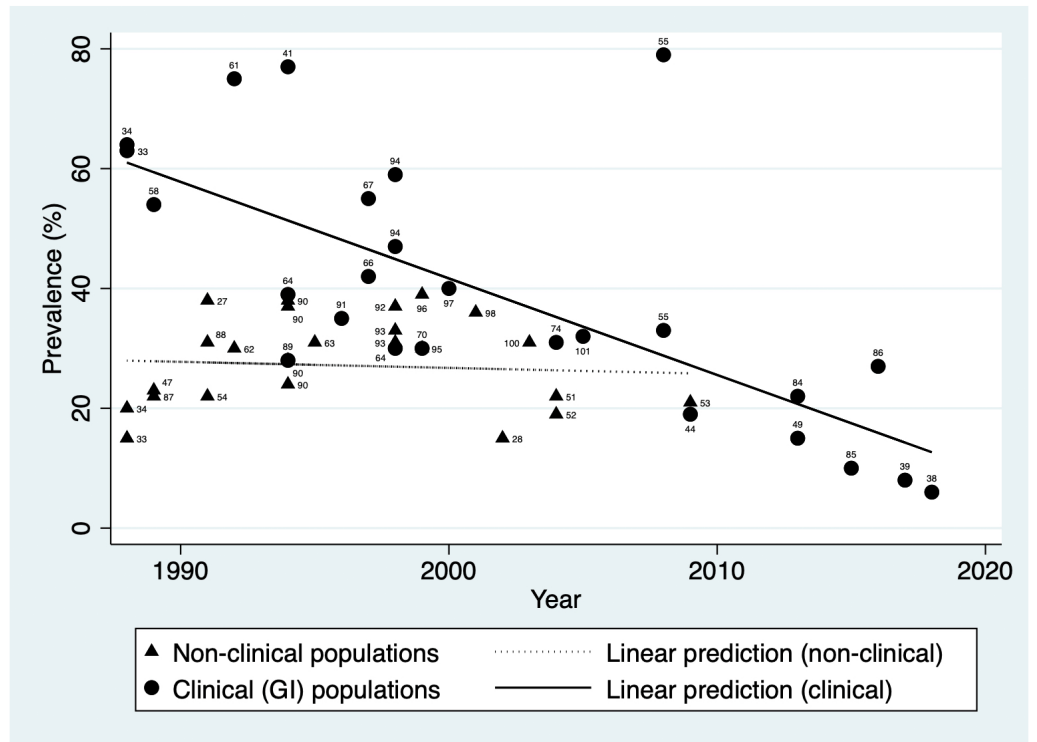

The estimated prevalence of *H. pylori* in included studies was wide-ranging, among diverse populations, from 0% in SIDS babies in 1997–1999 (Ho *et al.*, 2001) to 91% in Aboriginal community members in 2003–2004 (Windsor *et al.*, 2005). Estimated prevalence among children ranged from 0% in SIDS babies (Ho *et al.*, 2001) to 85% in a group of Aboriginal children (Windsor *et al.*, 2005). In 2002, Moujaber and colleagues estimated that the *H. pylori* prevalence was 7.8% among children in the general population aged 1 to 19 years (Moujaber *et al.*, 2008). Prevalence was similarly low among patients with conditions including oesophageal cancer (Whiteman *et al.*, 2010), Barrett's oesophagus (Thrift *et al.*, 2012) and fundic gland polyps (Samarasam, Roberts-Thomson & Brockwell, 2009). Male AIDS patients (Edwards *et al.*, 1991) and females with multiple sclerosis (Pedrini *et al.*, 2015) were also found to have a low prevalence of *H. pylori* infection. Gastric cancer patients (Dugué *et al.*, 2019; Mitchell *et al.*, 2008), institutionalised individuals (Lambert *et al.*, 1995; Wallace, Webb & Schluter, 2002), refugees (Chaves *et al.*, 2009; Cherian *et al.*, 2008; Johnston, Smith & Roydhouse, 2012) and Aboriginal and Torres Strait Islander populations (Windsor *et al.*, 2005; Mollison *et al.*, 1994; McDonald *et al.*, 2004) typically had high prevalence of *H. pylori* infection. Recent prevalence estimates are lacking for vulnerable groups. The most recent prevalence estimates available for these groups are: 60% in an urban Aboriginal population in 2003–2004; 91% in a non-urban Aboriginal population at the same time; 21.5% in a refugee population in metropolitan South Australia in 2010–2013; 86.8% in long-term institutionalised and 79.2% in previously institutionalised adults with intellectual disability in 1999–2000; 31.6% in adults aged over 70 in 2002–2005; and 69.2% in gastroenterologists studied in 1994.

*H. pylori* prevalence estimated in general population studies ranged from 38.0% in 1991 (Lin *et al.*, 1998a) to 15.1% in 2002 (Moujaber *et al.*, 2008). In addition to population-based studies, a number of studies included control groups such as blood donors. Figure 2 illustrates prevalence over time in non-clinical populations (excluding studies that looked only at children) and indicates a stable prevalence between 1988 and 2009 (Coefficient =  $-0.10$ , 95% CI [ $-0.66$ – $-0.46$ ]). This is shown alongside the pronounced downward trend seen in clinical populations with gastrointestinal conditions or symptoms (Coefficient =  $-1.61$ , 95% CI [ $-2.26$ – $-0.97$ ]).

Prevalence estimate ranges by birth decade were determined from the studies that reported prevalence estimates in general populations by age-group (Pandeya, Whiteman & Australian Canc Study, 2011; Lin *et al.*, 1998a; Moujaber *et al.*, 2008; Dwyer *et al.*, 1988b; Mitchell *et al.*, 1988), and are presented in Table 2. Observation of these prevalence ranges across birth decades appears to indicate lower prevalence with successive birth cohorts.

## DISCUSSION

The aim of this review was to describe the scope of studies that have documented the prevalence of *H. pylori* in Australia with regard to study characteristics such as study design, geographic region, population characteristics, and diagnostic methods, and to summarise

**Figure 2** *H. pylori* prevalence over time in populations with gastrointestinal conditions and in non-clinical populations in Australia. Data labels indicate source reference.

Full-size [DOI: 10.7717/peerj.13430/fig-2](https://doi.org/10.7717/peerj.13430/fig-2)

**Table 2** *H. pylori* Australian prevalence estimate ranges by decade of birth.

Decade of birth	Prevalence range (%)
Earlier than 1920	53.0
1920s	20.0–46.0
1930s	26.0–37.0
1940s	16.7–27.0
1950s	11.7–24.0
1960s	18.0–18.4
1970s	5.0–12.4
1980s	4.0–10.0
1990s	4.0–8.3

the estimated prevalence in the included studies according to person characteristics and time. This review has compiled the most comprehensive collection of Australian-based *H. pylori* prevalence data to date.

*H. pylori* prevalence estimated in Australian general population studies ranged from 38.0% in 1991 (Lin et al., 1998a) to 15.1% in 2002 (Moujaber et al., 2008), but prevalence has varied dramatically across population sub-groups. In Australia, it appears from the data summarised from included studies in this review that there may have been a decrease

in prevalence in recent decades, which may be more marked in populations with GI symptoms and conditions than in the general population. Whether this is a true difference is unknown, as this study did not consider the quality of included studies. However, several international studies have similarly claimed a recent decrease in *H. pylori* prevalence in clinical populations. [Leow et al. \(2016\)](#) reported that *H. pylori* prevalence decreased in first-time gastroscopy patients in a single medical centre in Malaysia, from 51.7% in 1989–1990 to 11.1% in 2009–2010. [Kamada et al. \(2015\)](#) collected data from gastric biopsies performed in Honshu, Japan and reported that *H. pylori* prevalence decreased from 74.7% in the 1970s to 35.1% in the 2010s. However, no studies have compared clinical and non-clinical populations in the same country. Our observation of a potentially smaller decrease in prevalence in non-clinical populations is novel. The apparent larger decrease in prevalence among clinical populations may be attributed to greater levels of diagnostic testing and treatment for *H. pylori* infection among those with gastrointestinal symptoms compared to infected individuals who are asymptomatic. [Aro et al. \(2006\)](#) and [Bae et al. \(2018\)](#) reported that peptic ulcer and gastric cancer were present even in asymptomatic populations so a stable prevalence in non-clinical populations may be of concern.

Analysis of the included studies found that while no longitudinal or comparable studies have been performed, some evidence for a decrease in prevalence comes from examining the data from the point of view of prevalence by birth year using the studies that have estimated prevalence by age-group. This indicates a clear cohort effect. Evidence from this review suggests that *H. pylori* prevalence in Australia was much lower in the early 21st century than in the first half of the 20th century. This observation may be explained by a decrease in childhood acquisition rates in line with improvements to living conditions, such as household size (a measure of ‘crowding’), over the 20th century. Information from the Australian Institute of Health and Welfare shows that average household size decreased from 4.5 persons in 1911 to 2.6 persons in 2016 ([Australian Institute of Family Studies, 2021](#)). Interestingly, a plateau in *H. pylori* prevalence has been observed in the early 21st century among children in Holland ([den Hoed et al., 2011](#)). While it appears there may have been a similar plateau in childhood acquisition of *H. pylori* infection in Australia, potentially driving the decrease in prevalence from the first half of the 20th century to the early 21st century, this decrease may not continue into the future if a decrease in adult-acquired infections does not also follow and if further improvements to living conditions are not made. For instance, while data from the Australian Institute of Health and Welfare shows average household size decreased from 4.5 to 2.6 persons between 1911 to 2016, there was no change from 2001 to 2016 ([Australian Institute of Family Studies, 2021](#)). Further, evidence from studies of institutionalised adults ([Lambert et al., 1995](#); [Wallace, Webb & Schluter, 2002](#)), gastroenterologists ([Mitchell, Lee & Carrick, 1989](#); [Lin et al., 1994](#)) and married couples ([Lee, Windsor & Marshall, 2001](#)), indicate that acquisition in adulthood is possible, and there are not sufficient data to determine whether the proportion of adult-acquired infections is decreasing over time and/or whether the proportion of adult-acquired infections has an impact on changes in population prevalence either historically or into the future. However, the potential that overall *H. pylori* prevalence is stabilising in Australia remains a possibility that is not currently being discussed in the

(Australian) literature, with associated issues of anti-microbial resistance in eradication treatment, and risks of peptic ulcers and gastric cancer.

Whether or not the overall prevalence of *H. pylori* has decreased in Australia, it is important to note that high prevalence has been reported in marginalised and vulnerable population sub-groups in Australia such as Indigenous ([Windsor et al., 2005](#); [Pringle et al., 2015](#); [McDonald et al., 2004](#)), migrant ([Chow et al., 1995](#); [Lin et al., 1991](#)), refugee ([Gibney et al., 2009](#); [Chaves et al., 2009](#); [Cherian et al., 2008](#); [Mutch et al., 2012](#); [Abdul Rahim et al., 2017](#); [Benson, Rahim & Agrawal, 2017](#)) and institutionalised populations ([Lambert et al., 1995](#); [Wallace, Webb & Schluter, 2002](#)), the elderly ([Pandeya, Whiteman & Australian Canc Study, 2011](#); [Lin et al., 1998a](#); [Kaffes et al., 2003](#)) and health professionals with higher exposure to *H. pylori* positive patients ([Mitchell, Lee & Carrick, 1989](#); [Lin et al., 1994](#)), consistent with worldwide studies ([Jones et al., 2012](#); [Eusebi, Zagari & Bazzoli, 2014](#); [Fagan-Garcia et al., 2019](#); [Pabla et al., 2020](#); [Kheyre et al., 2018](#)). This review indicates that recent data for these groups in Australia are lacking. As the number and proportion of older Australians increases ([Australian Institute of Health and Welfare, 2021b](#)), it is important to know whether prevalence remains high in this population group. Data from the Australian Institute of Health and Welfare indicate that gastric cancer incidence declined from 9.3–7.5 cases per 100,000 persons between 1998 and 2013 among non-Indigenous Australians, as did gastric cancer mortality (6.1–3.9 deaths per 100,000 persons, 1998–2015). However, rates in Australian Indigenous populations have remained stable over time (gastric cancer incidence: 10.0–14.3 cases per 100,000 persons, 1998–2013; gastric cancer mortality: 6.7–8.8 deaths per 100,000 persons, 1998–2015) ([Australian Institute of Health and Welfare, 2021a](#)). High prevalence of *H. pylori* infection and gastric cancer are also seen in other Indigenous populations, for example in New Zealand ([Signal et al., 2020](#)) and Canada ([Jones et al., 2012](#)). Management of *H. pylori* infection and associated disease in these at-risk groups requires up to date and accurate information. A 2005 report of very high (91%) prevalence within an Aboriginal community ([Windsor et al., 2005](#)) sparked a call for more research by others ([Talley, 2005](#)). As far as we can tell this is yet to eventuate.

Prevalence estimation in the general Australian population is challenging due to the populations recruited to studies included in this review. For instance, blood donors, who are commonly recruited for epidemiological studies, have been shown to poorly represent *H. pylori* prevalence in the general population, particularly in relation to older age groups. A study from Sweden ([Sörberg, Nyrén & Granström, 2003](#)), for example, showed that older participants who were *H. pylori* positive were less likely to be regular blood donors, possibly because blood taking was more likely to make them feel unwell, compared to *H. pylori* negative participants. Also related to age, the sero-surveillance survey included in this review ([Moujaber et al., 2008](#)) only included participants aged up to 59 years, so is likely to have underestimated population prevalence. There is also no information available about the likely socio-economic profile of the sera used in that study. Some research shows that non-participants in control groups are more likely to be of lower socio-economic status than participants ([Pandeya et al., 2009](#)). Since *H. pylori* positivity is inversely associated with socio-economic status, this may also affect prevalence estimation.

With regard to diagnostic testing, serology was the most commonly used test in the studies included in this review, consistent with world-wide epidemiological studies (Zamani *et al.*, 2018). It has been noted that serological tests are commonly used for epidemiological studies (Katelaris *et al.*, 2021), as they are widely available and inexpensive (Tshibangu-Kabamba *et al.*, 2021). However, antibodies to *H. pylori* can remain at high levels for some time after eradication of the infection (Ricci, Holton & Vaira, 2007); thus, using serological data may lead to misclassification of *H. pylori* presence and absence, leading to a lack of confidence in estimates of prevalence in serological studies. This is reflected in Australian clinical guidelines for diagnosis of *H. pylori*, which recommend the use of UBT or FA tests over serology (Mitchell & Katelaris, 2016; Stenström, Mendis & Marshall, 2008).

### Strengths and limitations

This study has followed the rigorous and globally accepted methodologies for scoping reviews. Therefore, we can be confident that every possible effort was made to include all relevant research. The main limitation is that no quality appraisal of the included studies was undertaken. Although this is not strictly necessary for scoping reviews, it does mean that some included studies may be of lower standard.

## CONCLUSION

This scoping review has provided, to our knowledge, the first structured review of studies reporting prevalence of *H. pylori* in Australia. A wide range of studies was reviewed based on data collected over a 50-year period (1969 to 2018), including diverse study designs, population groups, geographic regions within Australia, and diagnostic methods. The summary of *H. pylori* prevalence estimates over time in this review points to a decrease in *H. pylori* prevalence in Australia, particularly among clinical populations; however, it appears that prevalence in the general population without gastrointestinal symptoms or disease has remained relatively stable over time. While this novel study adds to current knowledge, there are several specific population groups for whom further research is warranted. For instance, it is unknown whether there is enduring inequity in patterns of prevalence across vulnerable sub-groups of the Australian population, specifically, older Australians and Aboriginal populations. Given the stable rates of gastric cancer among Australian Aboriginal populations, a decrease in *H. pylori* prevalence over time is unlikely to have occurred; however, without the data to evidence this, interventions to improve infection rates, and morbidity and mortality from resultant illnesses such as gastric cancer, may be limited. A new national survey using UBT or FA would also be a useful addition to our understanding of the prevalence and epidemiology of *H. pylori* in Australia, given the limitations in accuracy of serology tests.
