ABSTRACT

Severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) is a serious threat to global health. One attractive antiviral target is the membrane fusion mechanism employed by the virus to gain access to the host cell. Here we report a robust protein-based fluorescent polarization assay, that mimicking the formation of the six-helix bundle (6-HB) process during the membrane fusion, for the evaluation and screening of SARS-CoV-2 fusion inhibitors. The IC₅₀ of known inhibitors, HR2P, EK1, and Salvianolic acid C (Sal-C) were measured to be 6.1 nM, 2.5 nM, and 8.9 μM respectively. In addition, we found Sal-A has a slightly lower IC₅₀ (3.9 μM) than Sal-C. Interestingly, simple caffeic acid can also disrupt the formation of 6-HB with a sub-mM concentration. Pilot high throughput screening (HTS) of a small marine natural product library validates the assay with a Z' factor close to 0.8. We envision the current assay provides a convenient way to screen SARS-CoV-2 fusion inhibitors and assess their binding affinity.

1. Introduction

As of Feb 2021, the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) [1–2] has infected more than 100 million people and cause two million lives. Although several drugs have been “repurposed” for the treatment of SARS-CoV-2 infection, [3–4] there is still a pressing need to identify novel anti-SARS-CoV-2 therapeutics.

Both SARS-CoV-1 and SARS-CoV-2 virus use their surface homotrimeric spike protein (S protein) to enter the host cells (Fig. 1) [5]. The S protein encodes two subunits: S1 and S2. The receptor-binding domain (RBD) from the S1 subunit has a strong binding affinity with the cell surface receptor, angiotensin-converting enzyme II (ACE2), and is responsible for the initial attachment [5]. This binding event triggers a conformational change of S2 subunit and the previously buried hydrophobic fusion peptides are exposed and insert into the host cell membrane. Subsequently, two heptad repeats (HR1 and HR2) form a thermodynamically favorable six-helix bundle (6-HB) postfusion structure to fuse the viral and cellular membranes together [6].

The formation of 6-HB structure is a conserved fusion mechanism shared by many viruses besides coronavirus, including influenza virus, human immunodeficiency virus (HIV), and respiratory syncytial virus (hRSV) [7,8]. It has been shown that peptides derived from the heptad repeats region are potent fusion inhibitors, and such a peptide, Enfuvirtide, has been approved for HIV-1 treatment for almost 20 years [9].

The HR2 peptide of SARS-CoV-1 and SARS-CoV-2 are 100% conserved, and also displayed potent inhibition activities in cell-based assays. [10–13]. Recently, the Lu group reported that a novel HR2-derived peptide, EK1, can disrupt the protein–protein interaction (PPI) during the formation of 6-HB, and inhibit multiple human coronaviruses at sub-nM concentration [11,12]. Thus, fusion inhibitors could potentially be developed as broad-spectrum anti-coronavirus therapeutics [14].

It is well-known that PPI is hard to be disrupted by conventional small molecules [15]. Natural products are privileged structures in the drug discovery process, and it might be easier to find PPI modulators from natural products [16]. Recently, the Liu group identified a potent anti-SARS-CoV-2 fusion inhibitor, Salvianolic acid C (Sal-C, IC₅₀ 3.85 μM) from a natural product library using a cell–cell fusion assay mediated by S protein of SARS-CoV-2 [17]. Deconvolution of the activity by native-polyacrylamide gel electrophoresis (N-PAGE) assay indeed suggested that Sal-C inhibits the formation of 6-HB in a dose-dependent manner.

Cell-based phenotypic screening assays can be expensive and the resulting activities sometimes can be hard to deconvolute. Thus, a robust *in vitro* high-throughput evaluation and screening platform for SARS-CoV-2 fusion inhibitors is highly needed. Here we present our effort on the development of such a platform using fluorescence polarization (FP) techniques and apply it for the evaluation of the binding potency of HR2, EK1, and several Sal family natural products. We found Sal-A has

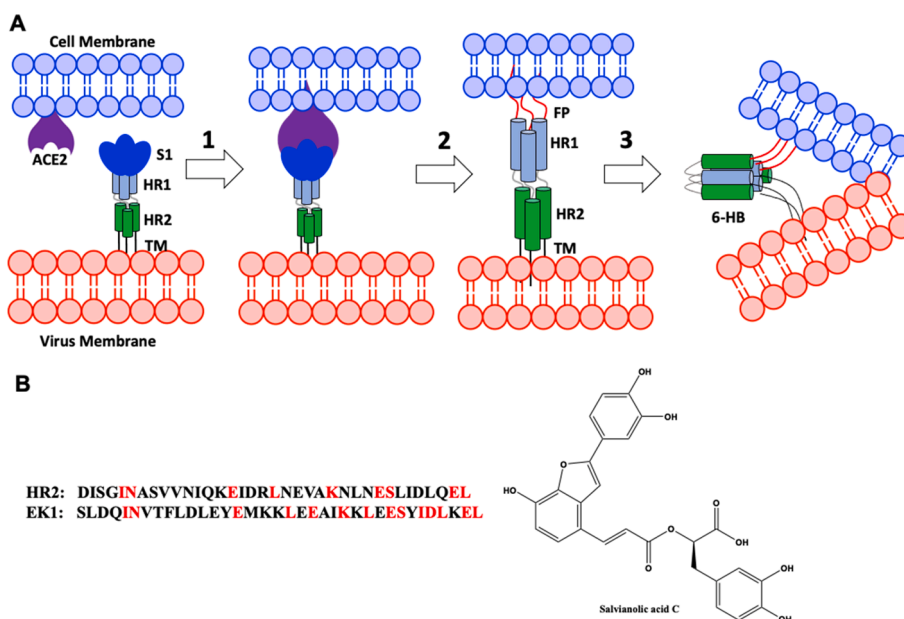

Fig. 1. A) SARS-CoV membrane fusion mechanism. Abbreviations: FP, fusion peptide; HR, heptad repeat; TM, transmembrane anchor. B) Known SARS-CoV-2 fusion inhibitors.

similar binding potency as Sal-C. In addition, we found that the precursor of natural product family of Sal which possesses a simple chemical structure as caffeic acid does, can inhibit the 6-HB formation with a IC_{50} of about 638 μ M. Despite the relatively low potency, such a simple structure could potentially serve as a starting fragment for the fragment growing strategy [18] to increase the potency.

2. Material and methods

2.1. Gene, plasmid, and materials

The codon-optimized gene of 5-HB (the sequence was shown in **Table S1**) was synthesized by Tsingke Co., Ltd (Guangzhou, China) and inserted into plasmid pET-44b(+) and pET-28a(+), respectively. The pCold-NusA plasmid was maintained in our laboratory.

The HR1P (CANQENSAIGKIQDSLSSTASALGKLQDVVNQNQA LNTLVKQ) and HR2P (ELGDISGINASVVNIQKEIDRLNEVAKNLSLIDLQELC) peptides were ordered from APeptide Co., Ltd (Shanghai, China). EK1 (SLDQINVTFDLEYEMKKLEEAIAIKLEESYIDLKEL) peptide was a gift from Prof. Lu Lu (School of Basic Medical Sciences, Fudan-Jinbo Joint Research Center, Fudan University, Shanghai 200032, China). Salvianolic acid A, Salvianolic acid B, Lithospermic acid, Rosmarinic acid, and Caffeic acid were purchased from Aladdin Reagents Co. Ltd (Shanghai, China). Salvianolic acid C was purchased from MACKLIN Reagent Co. Ltd (Shanghai, China). All other chemicals and reagents were chemically pure and obtained commercially.

2.2. Protein expression and purification

The plasmids pET-44b-NusA-5HB, pET-28a-5HB, and pCold-NusA containing the gene encoding NusA-5HB, 5-HB and NusA (with *N*-terminal His-tag) were transformed into competent *E. coli* BL21 (DE3) cells (Invitrogen) respectively. The recombinant *E. coli* was cultivated in LB medium with antibiotic (50 mg/L Kan for pET-28a-5HB; 100 mg/L Amp for pET-44b-NusA-5HB and pCold-NusA) at 37 °C and rotary shaking at 200 rpm. For protein expression, cells were induced with isopropyl- β -D-thiogalactopyranoside (IPTG) at a final concentration of 0.5 mM until OD_{600} reached 0.6–0.8, and then further cultured at 15 °C for 24 h.

The collected cells were washed and resuspended in buffer A (20 mM sodium phosphate, pH 7.4, containing 500 mM NaCl and 20 mM

imidazole). Resuspended cells were disrupted by ultrasonication in an ice bath, followed by centrifugation at 12000 \times g for 30 min to remove cell debris. The supernatant was loaded onto a Ni-NTA column (Thermo Scientific, USA) pre-equilibrated with buffer A, and the proteins were eluted by an increasing gradient of imidazole (from 50 to 250 mM). The purities of the collected fractions were analyzed by SDS-PAGE. Fractions containing the pure target protein were gathered and then desalted by ultrafiltration. The purified proteins were concentrated and stored in 20% (v/v) glycerol at -80 °C until further use. The expression and purification of the proteins were analyzed by sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE, 4 ~ 20%) (**Figure S1**). Protein concentrations were determined using a Bradford protein assay kit (Quick Start™, Bio-Rad, USA).

2.3. HR2P-FL preparation

Dissolving HR2P with 20 mM pH 7.5 phosphate buffer (5 mM EDTA) to a concentration of 100 μ M. A 25-fold molar excess of fluorescein-5-maleimide (2.5 mM) was added and then incubated at 25 °C for 2 h. After incubation, nonreacted fluorescein was removed by ultrafiltration using a 3 kDa molecular-weight cutoff, and HR2P-FL was then purified by HPLC. The purified HR2P-FL was stored from light in single-use aliquots at -20 °C.

2.4. Fluorescence native polyacrylamide gel electrophoresis (N-PAGE)

10 μ M of HR2P-FL was incubated with 10 μ M of HR1P, 5-HB or NusA-5HB in pH 7.5 20 mM PBS at 37 °C for 30 min. After incubation, the sample was mixed with Tris-glycine native sample buffer (Invitrogen, Carlsbad, CA) at a ratio of 1:1 and was then loaded to 4%~20% pre-cast gel (20 μ L each well). Gel electrophoresis was carried out with 100 V constant voltages at room temperature for 1.5 h. The gel was imaged with a Tanon 1220 Gel Imaging System (Shanghai, China).

2.5. FP assays

All reported concentrations represent the final assay conditions unless otherwise specified. Fluorescent polarization measurements were performed on a Spark® multimode microplate reader (Tecan, Switzerland), with an excitation filter at 485 nm, and an emission filter

at 535 nm. The G-Factor was set at 1.06 (Note: The calibration is performed by measuring a 1 nM fluorescein solution at room temperature and adjusting the G-factor to achieve a value of 27 mP; different microplate readers might need a different setting) [19]. Peptides were directly dissolved in water to make a 500 μ M stock solution and then stored at -80 $^{\circ}$ C.

2.5.1. Binding assays of HR2P-FL with NusA-5HB/5-HB

Assays were performed manually in black 96 microplates (Cat. No. 3694, Corning, USA). Each reaction (100 μ L) contained 10 nM of HR2P-FL and 1 μ M of NusA-5HB, 5-HB or NusA in FP buffer (25 mM pH 7.5 PBS, 0.025% NP-40). The FP values were measured after 1 h incubation at 37 $^{\circ}$ C 200 rpm. All experiments were performed in duplicate.

2.5.2. Saturation binding FP measurement

Assays were performed manually in black 96 microplates (Cat. No. 3694, Corning, USA). Each well (100 μ L) contained 5 nM HR2P-FL and increasing concentrations (0 ~ 128 nM) of NusA-5HB in FP buffer (25 mM pH 7.5 PBS, 0.025% NP-40). The FP values were measured after 1 h incubation at 37 $^{\circ}$ C 200 rpm. The binding fraction (f) of HR2P-FL with different NusA-5HB concentrations was calculated using the Eqs. (1) and (2). [20]. The obtained f values were analyzed and plotted using GraphPad Prism 8 to calculate the binding dissociation constant (K_d) by fitting the experimental data using a one-site specific binding model. All experiments were performed in duplicate.

$$A = \frac{2P}{3 - P} \quad (1)$$

$$f = \frac{A - A_f}{(A_B - A)Q + A - A_f} \quad (2)$$

P is the fluorescence polarization values, A is the fluorescence anisotropy values; A_B and A_f denote fluorescence anisotropies of fully bound and free HR2P-FL, respectively; Q is the ratio of fluorescence intensities of bound and free species measured under the same experimental conditions. In our assay, Q is found to be close to 1.

2.5.3. Competitive FP assays of peptides

Assays were performed manually in black 96 microplates (Cat. No. 3694, Corning, USA) contained 8 nM NusA-5HB and increasing concentrations of peptides (0, 0.31, 0.625, 1.25, 2.5, 5, 10, 20, 40, 80, 160, 320 nM) in FP buffer (25 mM pH 7.5 PBS, 0.025% NP-40) in a final volume of 90 μ L. After 1 h incubation at 37 $^{\circ}$ C 200 rpm, 10 μ L HR2P-FL (5 nM) was added and additional 1 h incubation was followed at 37 $^{\circ}$ C 200 rpm. The FP signal was measured. The binding fraction (f) of HR2P-FL with NusA-5HB at different concentrations of peptide was calculated

using the Eqs. (1) and (2). The obtained f values were plotted using GraphPad Prism 8 to calculate the IC_{50} . All experiments were performed in duplicate.

2.5.4. Competitive FP assays of small molecules

Assays were performed manually in black 96 microplates (Cat. No. 3694, Corning, USA) contained 8 nM NusA-5HB and increasing concentrations of small molecules (0, 0.001, 0.01, 0.1, 1, 10, 100, 1000 μ M) in FP buffer (25 mM pH 7.5 PBS, 0.025% NP-40, 4% DMSO) in a final volume of 90 μ L. After 1 h incubation at 37 $^{\circ}$ C 200 rpm, 10 μ L of HR2P-FL (5 nM) was added and additional 1 h incubation was followed at 37 $^{\circ}$ C 200 rpm. In order to eliminate the fluorescence interference of small molecules, fluorescence intensities parallel (I_{\parallel}), and perpendicular (I_{\perp}) to the plane of exciting light were measured after incubation and the real FP values were calculated using the Eq. (3). The binding fractions (f) of HR2P-FL with NusA-5HB at different concentrations of small molecules were calculated using the Eqs. (1) and (2). The obtained f values were plotted using GraphPad Prism 8 to calculate the IC_{50} . All experiments were performed in duplicate.

$$P = \frac{(I_{\parallel} - I_{\perp}^*) - G^*(I_{\perp} - I_{\perp}^*)}{(I_{\parallel} - I_{\perp}^*) - G^*(I_{\perp} - I_{\perp}^*)} \quad (3)$$

I_{\parallel}^* and I_{\perp}^* are fluorescence intensities of same concentration small molecules parallel, and perpendicular to the plane of exciting light. G is the G-Factor (1 nM fluorescein solution at room temperature and adjusting the G-factor to achieve a value of 27 mP).

2.6. Molecular docking

The solved post-fusion core of SARS-CoV-2 6-HB was selected as the docking structure (PDB code: 6LXT) [11]. In this structure, one of the HR2 chains was removed and the channel occupied by this HR2 was defined as the docking grid. Ligands were prepared using MGLTools 1.5.4 and docking was performed with auto-dock vina. The molecular docking poses were ranked according to calculated binding affinity and the top one was selected for further analysis. PyMOL (Version 1.5, Schrödinger, LLC) was used to prepare figures of the complexes.

2.7. Screening the marine natural product library

The marine natural product library (10 mM dissolved in 100% DMSO) in 96-well format was maintained in our laboratory. A daughter library (100 times dilution) was created by transferring 1 μ L of the stocks into 99 μ L of 40% DMSO. To black 96-well microtiter plates were added 80 μ L of a premix containing 8 nM NusA-5HB, buffer (25 mM pH 7.5

Fig. 2. The FP-based assay for SARS-CoV-2 fusion inhibitor. A) 5-HB expression construct. B) FP assay. Upon 5-HB binding to HR2P-FL, the FP reading of HR2P-FL increases. If inhibitors can disrupt the binding between 5-HB and HR2P-FL, the FP reading decreases.

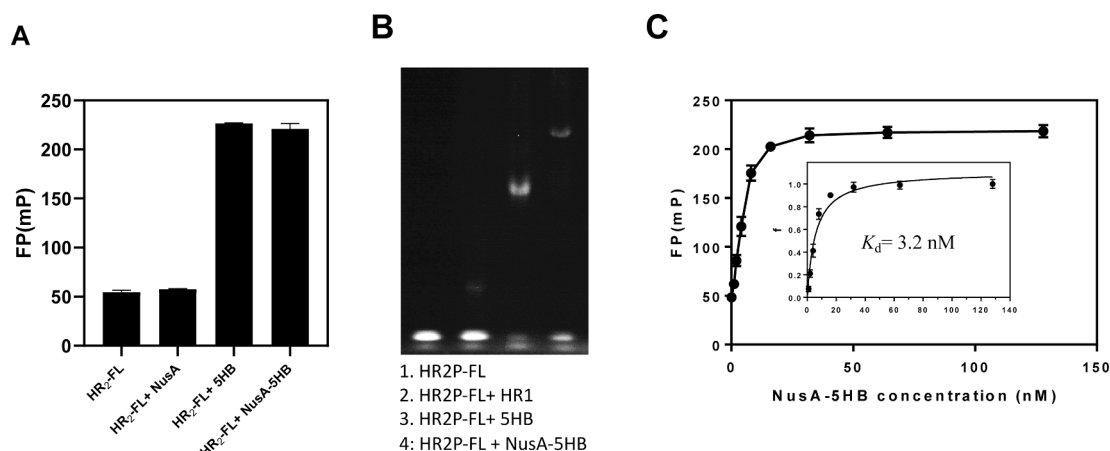

Fig. 3. Validation of the FP assay. A) FP readings of 10 nM of HR2P-FL; 10 nM of HR2P-FL with 1 μ M of NusA, 5-HB, or NusA-5HB. B) Determination of the six-helix bundle formation between HR2P-FL and 5-HB/NusA-5HB by fluorescence *N*-PAGE. Lane 1: 10 μ M HR2P-FL; Lane 2: 10 μ M HR2P-FL + 10 μ M HR1P; Lane 3: 10 μ M HR2P-FL + 10 μ M 5-HB; Lane 4: 10 μ M HR2P-FL + 10 μ M NusA-5HB. C) Saturation binding FP experiments. The FP readings were converted to fraction bounded (*f*), and then plotted against the NusA-5HB concentration to get $K_d = 3.2$ nM. All experiments were performed in duplicate.

PBS, 0.025% NP-40). 10 μ L daughter library solution was added (10 μ M) and incubated at 37 $^{\circ}$ C for 1 h. Then, 10 μ L of HR2P-FL (5 nM) was added and additional 1 h incubation was followed at 37 $^{\circ}$ C 200 rpm. FP signal was measured after incubation. (Note: All concentrations represent the final assay conditions).

For quality assessment of the FP assay, positive and negative controls were set in the same 96-well microtiter plates and subjected to identical conditions described in the above screening procedure. Positive controls refer to the reactions in the absence of inhibitors while negative controls refer to the reactions in the absence of NusA-5HB. *Z'* score was calculated according to the equation as follows [21]:

$$Z' = 1 - \frac{3(\sigma_p + \sigma_n)}{|\mu_p - \mu_n|} \quad (4)$$

The σ_p and σ_n are the standard deviations of the FP signals of positive and negative controls; μ_p and μ_n are the mean of FP signals of positive and negative controls.

3. Results

3.1. FP-based assays for fusion inhibitors.

FP is a powerful technique for the investigation of ligand-receptor interactions in homogenous solutions and has been widely used in the drug discovery process [19,22]. The basic concept is to link a fluorophore to the ligand and the fluorophore-ligand conjugate has a low molecular weight, thus freely rotating in the solution to give a low FP signal. Upon the addition of the receptor (typical an enzyme with higher molecular weight), the binding between receptor-ligand would non-covalently link the fluorophore to a large object, and the rotation is restricted to give a high FP signal.

The Kim group previously design a small protein, 5-HB, by connecting the five of the 6-HB of HIV-1 with short linkers [23]. The resulting 5-HB has a strong binding affinity with the HR2 region of HIV-1 and displaced a strong fusion inhibition activity. Subsequently, such a 5-HB construct was used in an *in vitro* FP assay for screening HIV fusion inhibitors [24]. Inspired by those results, we developed an FP-based assay for SARS-CoV-2 fusion inhibitors as shown in Fig. 2. An expression plasmid with short linkers to link three HR1 and two HR2 of SARS-CoV-2 was constructed. The resulting 5-HB construct would be expected to have a high binding affinity with fluorescence-labeled HR2 peptides (HR2P) to increase the FP signal. An extra cysteine is included in the synthetic HR2P (there is no cysteine in the native sequence) to facilitate

the labeling with fluorescein-5-maleimide to get HR2P-FL.

We found 5-HB is mostly expressed in *E. coli* as inclusion body and the yield of soluble 5-HB fraction is very low. We envision that a solubilization protein tag would aid the expression. Here we chose the *E. coli*-derived NusA tag (55 kDa) [25–26] as it has high intrinsic solubility and its large size can potentially increase the FP signal. Indeed, NusA tag has been employed to help the expression of HIV-5HB [27]. We are glad to found that NusA-5HB construct gave a very high expression yield, and about 30 mg-50 mg/L of soluble NusA-5HB can be obtained after purification.

3.2. Validation of the FP-based assays

With the HR2P-FL, NusA-5HB, and 5-HB in hand, we first mixed 10 nM of HR2P-FL and excess of NusA-5HB and 5HB (1 μ M). After incubation for 1 h, the FP reading was measured by a plate reader. HR2P-FL gave a relatively low FP reading of 50 mP, while NusA-5HB and 5-HB raise the FP reading to 220 and 230 mP, respectively (Fig. 3A). Although NusA-5HB (100 kDa) is significantly larger than 5-HB (35 kDa), comparable FP readings were obtained. This may be because the internal linker between NusA and 5-HB is flexible and the NusA can not restrict the rotation of 5-HB [28–29]. To rule out that NusA itself would bind to HR2P-FL to increase the FP reading, we also expressed the NusA protein, and we found NusA did not change the FP reading, suggested NusA does not bind to HR2P-FL.

To further validate the binding between HR2P-FL and 5-HB, we performed native-polyacrylamide gel electrophoresis (*N*-PAGE) analysis [12]. As shown in Fig. 3B, we found HR2P-FL and HR1P only formed a small amount of 6-HB, while HR2P-FL can form 6-HB effectively with either 5-HB and NusA-5HB. Since both experiments suggest HR2P-FL could bind to NusA-5HB to form NusA-6HB, we subsequently focused on the assay optimization with NusA-5HB.

3.3. Saturation binding FP experiments.

To develop a successful FP-based assay, the K_d between fluorescent ligand and receptor need to be determined by saturation binding experiment [20,30]. The concentrations of fluorescent ligand and receptor in the subsequent competitive FP assay need to be adjusted according to the saturation binding experiment: the fluorescent ligand concentration needs to be less than 2 K_d to avoid stoichiometric titration; while the concentration of receptor needs to be adjusted so that the initial fraction of fluorescent ligand bound to receptor (f_0) is between 0.5 and 0.8.

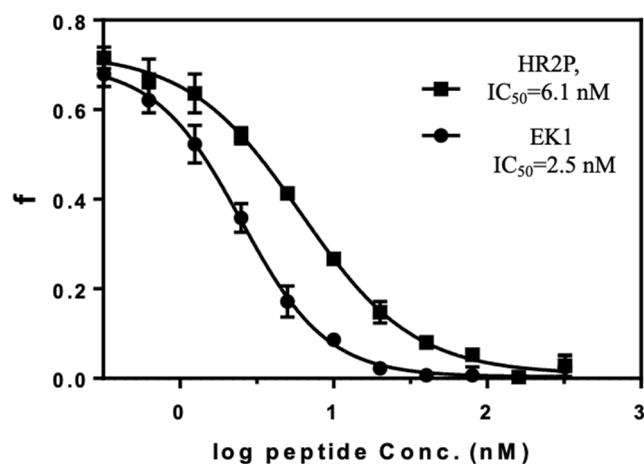

Fig. 4. Competitive FP assays with HR2P and EK1. The FP readings were converted to fraction bounded (f), and then plotted against the HR2P and EK1 concentration to get $IC_{50} = 6.1$ nM for HR2P and $IC_{50} = 2.5$ nM for EK1, respectively. All experiments were performed in duplicate.

To determine the binding constant between NusA-5HB and HR2P-FL, increasing concentrations of NusA-5HB was added to the solution containing 5 nM of HR2P-FL, and after incubate for 1 h, FP signals were measured (Fig. 3C). As FP signals are not linear with the binding strength, [20] the anisotropy data were used to calculate the fraction bounded ratio (f), which were then plotted against the NusA-5HB concentrations to get the $K_d = 3.2$ nM.

3.4. Competitive FP assays with HR2P and EK1

With the saturation binding experiment data in hand, we set the

HR2P-FL and NusA-5HB concentrations to be 5 nM (less than $2K_d$) and 8 nM (f_0 is about 0.7) respectively in the competitive FP assays. As shown in Fig. 4, IC_{50} of HR2P and EK1 is 6.1 and 2.5 nM respectively, suggesting that EK1 has a slightly higher binding toward 5-HB. However, it has been shown that HR2P has better activity than EK1 in cell-based pseudovirus infection assay (0.98 μ M vs 2.38 μ M) [12]. It is possible that the cell-based assay does not reflect the true binding affinity as peptides might have different cell-penetration abilities. Indeed, the Lu group recently reported that cholesterol or palmitic acid conjugated EK1 have much better *in vivo* activity than EK1, and the IC_{50} of both labeled peptides are in nM range [11].

3.5. Evaluation of Sal family natural products with FP assays

The Liu group reported that the nonpeptic natural product Sal-C is a potent SARS-CoV-2 fusion inhibitor with a IC_{50} of 3.85 μ M with an ACE2-expressing HEK293T cell, and a EC_{50} of 3.41 μ M with native SARS-CoV-2 virus [17]. The mode of action of Sal-C was elucidated by N-PAGE, and it was observed that Sal-C inhibits the formation of 6-HB between HR1P and HR2P in a dose-dependent manner. However, the binding affinity between Sal-C and SARS-CoV-S2, SARS-CoV-2-S2 (405 μ M and 284.3 μ M respectively) is relatively low, possibly because S2 unit is not in the prefusion state. Our current assay has the potential to evaluate the true binding strength between Sal-C and spike protein in its prefusion state. In a competitive bind experiment, we obtained the IC_{50} of Sal-C to be 8.9 μ M (Fig. 5), comparable to that determined in the cell-based assay, suggest that Sal C possibly interacts at the interface of 5HB and HR2P. This result strongly suggested that our assay can be used to evaluate the potency of SARS-CoV-2 fusion inhibitors.

With these encouraging results in hand, we tested several Sal-C analogs that are commercially available: Sal-A, Sal-B, lithospermic acid, and rosmarinic acid (Fig. 5). The IC_{50} of Sal-A is about 3.9 μ M, slightly better than Sal-C, suggesting the furan ring of Sal-C is not necessary. The

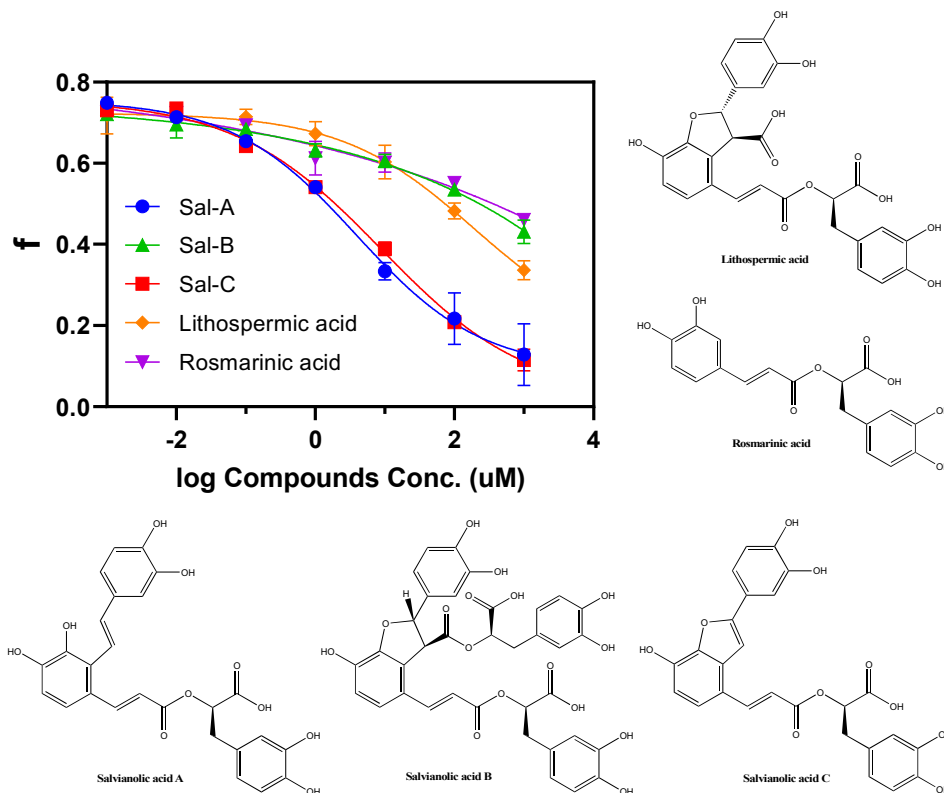

Fig. 5. Evaluation of Sal family natural products. The FP readings were converted to fraction bounded (f), and then plotted against the respective natural product concentrations. All experiments were performed in duplicate.

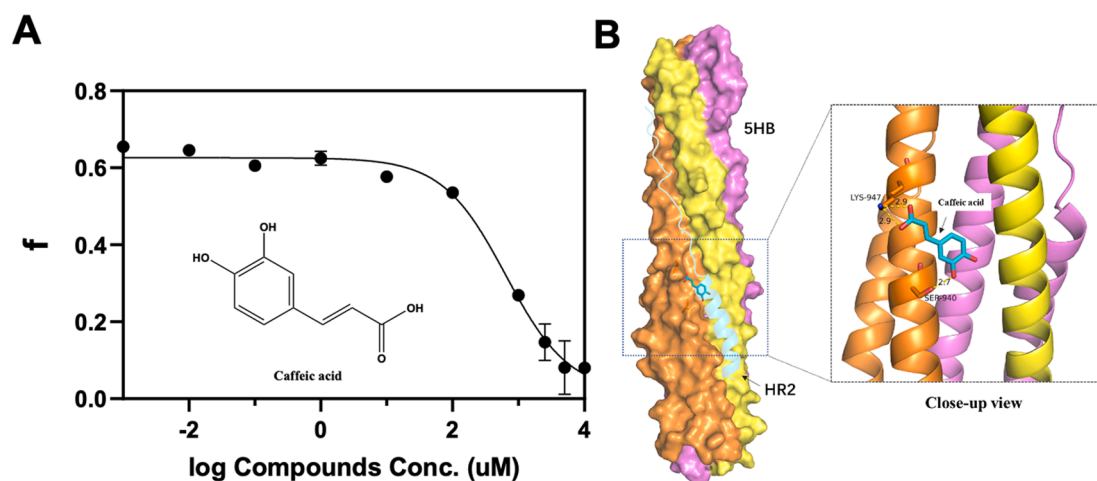

Fig. 6. Evaluation of the caffeic acid activity. A) IC_{50} of caffeic acid. The FP readings were converted to fraction bounded (f), and then plotted against the respective natural product concentrations. All experiments were performed in duplicate. B) Docking structure between caffeic acid and 6-HB without one of HR2 (PDB code:6LXT).

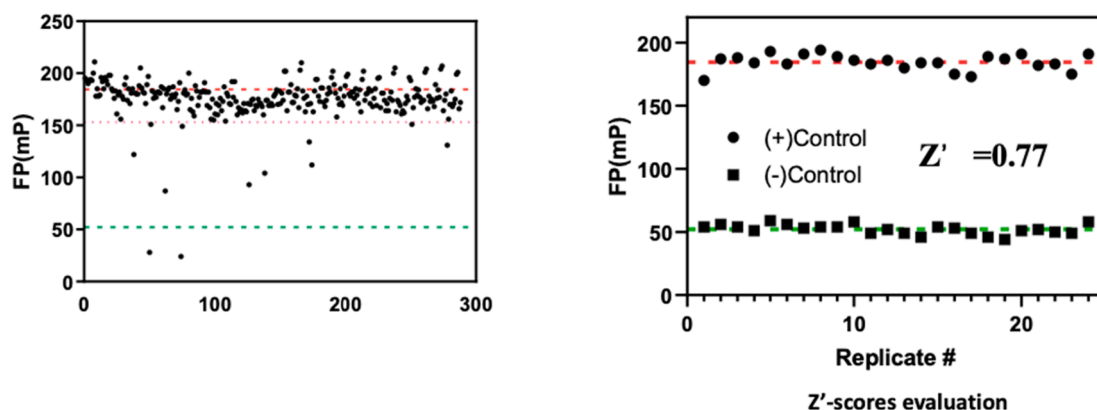

Fig. 7. Evaluation of the FP assay in HTS formats. A) Pilot HTS of marine natural product library. B) Z' scores evaluation.

other three natural products all have very weak activities, and because of solubility issues, the IC_{50} values can not be obtained. Those results suggest although the furan ring is not necessary, the double bond of the furan ring is crucial for the activities.

Since Sal family natural products are oligomers of caffeic acid, we are curious that caffeic acid can also bind to 5-HB. As caffeic acid is much more soluble, we successfully obtained a IC_{50} of 638 μ M (Fig. 6A). PPI does not have a binding pocket, and usually it is hard to find binders with simple structures. It is pretty remarkable a simple structure such as caffeic acid could disrupt the interaction between 5-HB and HR2P in less than mM concentration. We then performed docking studies with the solved 6-HB crystal structure (PDB code:6LXT) [11], and it suggests that the carboxyl group of caffeic acid forms hydrogen bonding with Lys947, and para phenolic OH might interact with Ser940 (Fig. 6B). We envision that caffeic acid could potentially serve as a starting fragment in fragment-based drug discovery to increase the binding with 5-HB.

3.6. High-throughput screening (HTS) of marine natural product library.

As a marine natural product research group, we have a long-term interest to find bioactive molecules from the marine environment, and indeed we have previously successfully identified several potent inhibitors from marine natural product libraries with FP-based assays [31–32]. Therefore, we performed a pilot HTS with a small marine natural product library (about 300 compounds) at 10 μ M (Fig. 7A). Unfortunately, we did not find any active natural products from this

small library after ruling out the fluorescent interfering compounds. However, we found the assay itself is very robust with a Z' at 0.77 (Fig. 7B), which suggested that this assay can be applied to screen large-size commercial compound libraries.

4. Discussion and conclusions

SARS-CoV-2 continues to be a big threat to public health after the initial outbreak a year ago. The membrane fusion process employed by SARS-CoV-2 to enter the host cell is a highly conserved mechanism shared by many different types of viruses, suggesting that it is an attractive target to develop broad-spectrum antivirals.

Currently, research mainly relies on cell-based phenotypic assays to screen and evaluate the SARS-CoV-2 fusion inhibitors. Cell-based assays have advantages such as cell permeability factor already included, however, an economical, robust, and high-throughput *in vitro* assay is also an important complementary tool for screening and evaluation of binding potency of novel fusion inhibitors, and the further structure–activity relationship studies. In this study, we developed an *in vitro* assay to evaluate the inhibition of 6-HB by determining the binding between 5-HB and fluorescently labeled HR2P with FP techniques.

FP-based assays typically required a large amount of protein, and we solved the 5-HB production problem by fusing it to a highly soluble NusA tag, and the resulting NusA-5HB construct can be produced in large quantities in *E. coli* (30–50 mg/L). In competitive FP experiments, the IC_{50} of HR2P and EK1 peptides were determined to be 6 and 2.5 nM

respectively. Five Sal family natural products were evaluated with our assay, and we found Sal-A has a comparable activity with Sal-C, while the other three analogs have much lower activities. Interestingly, the simple monomer, caffeic acid also has a sub-mM activity, thus could potentially serve as a starting fragment for “fragment-based drug design”.

Although our attempt to find fusion inhibitors from a small marine natural product library is not successful, the assay itself did demonstrate robustness with a Z' factor close to 0.8 in HTS formats. We envision that this assay could be applied to screen large commercial compound libraries as the production of large quantities of NusA-5HB and HR2P-FL is very straightforward. Another potential application of this assay is to screen fragment library as our assay can pick up sub-mM week activities, and the resulting fragment can be further optimized to increase the binding affinity with the aid of this assay.
