Aim: The aim of this study was to evaluate the effects of irisin in a murine model of hind limb ischemia reperfusion (I/R).

Methods: The mice were divided into four groups (n = 6 in each group): control, irisin, ischemia reperfusion (I/R), and irisin-ischemia reperfusion (I-I/R). Irisin (0.5 µg.g⁻¹, intraperitoneally [i.p.]) was administered 30 min before the I/R procedure. After 2 h of ischemia and 2.5 h of reperfusion, blood and tissue samples were taken for biochemical and histopathological analysis. The results were analyzed by Kruskal–Wallis and Mann–Whitney *U*-tests.

Results: There was a statistically significant difference in the total antioxidant status (TAS) and total oxidant status (TOS) levels in all the groups. The TAS level in the I/R group was significantly lower than that in the control, irisin, and I-I/R groups, whereas the TOS level was significantly higher in the I/R group as compared with that in the other groups. Caspase-3 activity and caspase-8 activity, indicators of inflammation, were significantly higher in the I/R and I-I/R groups as compared with those in the control and irisin groups.

Conclusion: Irisin may have protective effects in skeletal muscle ischemia reperfusion injury.

Keywords: irisin, ischemia reperfusion, caspase-3, caspase-8, mice

Introduction

Ischemia is the occurrence of cell death as a result of inadequate perfusion due to a decrease in the tissue blood supply. Reperfusion is the resumption of blood flow. In this period, secondary metabolites, such as oxygen free radicals, are produced.¹ Oxygen free radicals are toxic under various clinical conditions.² The production of oxygen free radical during reperfusion can lead to multiorgan failure, followed by local edema and muscle necrosis.^{3–5} Irisin is a recently identified hormone with 112 amino acids (12,587 kDa).⁶ It is a product of type I membrane protein cleavage encoded by the fibronectin type III domain containing 5 (FNDC5) gene.⁷ Irisin is secreted mainly in skeletal muscle and cardiac muscle. Irisin has several pharmacological effects, such as antioxidant,⁸ antiapoptotic,^{9,10} anti-inflammatory,^{11,12} neuroprotective,¹³ and hepatoprotective.¹⁴ It also has bone loss prevention effects.¹⁵

After reperfusion of ischemic tissues, cellular damage is a common and critical clinical incident. Caspases, especially caspase-8, are proteases that initiate and execute apoptotic cell death.¹⁶ In the presence of increased inhibition of caspase-8, sensitivity to death receptors increases. Caspase-3 is another protease that interacts with caspase-8 and caspase-9 in apoptosis.

The aim of the study was to investigate the effect of irisin in a rodent model of hind limb muscle ischemia/reperfusion (I/R) injury.

Materials and Methods

This study was performed in accordance with the guidelines of the National Institutes of Health on animal research, and it was approved by the animal experiments local ethics committee of Gazi University.

This study used 24 mice weighing 35–45 g. The animals were housed in polycarbonate cages and maintained at 24° C under a 12-h light/12-h dark cycle. Access to food was restricted 2 hours before the anesthesia procedure.

The animals were assigned to four groups (n = 6 in each group): control, irisin, I/R, and irisin-I/R (I-I/R). In the control group, a midline laparotomy was performed without any additional surgical interventions. In the irisin group, the same procedures were applied as in the control group. %0.9 saline was used to prepare a 1% solution of irisin. Thirty minutes before ischemia, 0.5 µg.g⁻¹ irisin (Sigma-Aldrich Co. Ltd.) was administered intraperitoneally (i.p.). A midline laparotomy was performed in the same way in the I/R group. During the ischemic period, the infrarenal aorta was clamped for 2 h. The clamp was then removed, and the tissue was reperfused for 2.5 h. In the I-I/R-group, irisin was administered 30 min before ischemia. The group was then subjected to 2 h of ischemia and 2.5 h of reperfusion as in the other groups.

At the end of the experiments, blood samples and tissue samples were taken for biochemical and histopathological analysis. All the mice were then sacrificed.

Biochemical Analysis

Homogenization of Tissues

The hind limb tissue collected in the Eppendorf tube frozen immediately in liquid nitrogen, and stored at -80° C in a deep freezer until the time of the total antioxidant status (TAS), total oxidant status (TOS), and oxidative stress index analyses. The procedures were done very quickly so the tissues were not allowed to thaw. First, pieces of 80–100 mg weight were cut with 22 lancets (PLUSMED®) from the hind limb tissues weighed on a precision scale. 80–100 mg weighted tissue was smashed in a porcelain bowl in the presence of liquid nitrogen, and powdered tissue was immediately transferred to a homogenization tube (099C S3, Glas-Col). 140 mM KCl solution was added per gram of tissue to achieve a 1/10 (w/v) dilution. In order not to increase the

temperature, the homogenization tube was placed in a flake-ice-filled glass beaker. Glas-Col (K5424®) homogenizer was used at a speed of 50 rpm for 2 min to complete the process (pestle, 099C S21G, Glas-Col). Homogenates were transferred to 1.5 mL Eppendorf tubes and centrifuged at 3000 rpm for 10 minutes (NF 048, NUVE). The supernatants obtained were transferred to new Eppendorf tubes.

Measurements of Total Antioxidant Status/Total Oxidant Status

TAS Measurement

TAS test kit (RelAssay Diagnostic®, Turkey) was used according to the manufacturer's instructions to measure the TAS levels. 30 µL of the sample was mixed with 500 µL of measurement buffer (reagent 1) in an Eppendorf tube. 2 µL of that mixture was used to measure the absorbance at 660 nm (A1) (NanoDrop® ONE, Thermo Scientific). Then, 75 µL of colored 2,2-azino-bis-3-ethylbenzothiazoline-6-sulfonic acid (ABTS) (reagent 2) was added to the mixture, and an incubation performed at 37° C for 5 min (ST 30, NUVE). A2 measurement was evaluated at the absorbance of 660 nm. Trolox Eq solution at a concentration of 1 mmol/L was used instead of samples to obtain the standard values. A1 and A2 measurements were done three times for each of the samples, and the average values were calculated. The absorbance change (ΔAbs) was calculated by subtracting the first absorbance value (A₁) from the second absorbance value (A₂). The TAS level was calculated using the formula given in the kit and expressed as mmol Trolox Eq/L.

$$\text{TAS} = ([\Delta\text{AbsH}_2\text{O} - \Delta\text{Abs sample}]/[\Delta\text{Abs H}_2\text{O} - \Delta\text{Abs standard}])$$

TOS Measurement

TOS test kit (RelAssay Diagnostic®, Turkey) was used according to the manufacturer's instructions to measure the TOS levels. 75 µL of the sample was mixed with 500 µL of measurement buffer (reagent 1) in an Eppendorf tube. 2 µL of that mixture was used to measure the absorbance at 530 nm (A1) (NanoDrop® ONE, Thermo Scientific). Then, 25 µL of Pro-chromogenic solution (reagent 2) was added to the mixture, and an incubation performed at 37° C for 5 min (ST 30, NUVE). A2 measurement was evaluated at the absorbance of 530 nm. A standard solution containing 10 µmol/L of hydrogen peroxide (H₂O₂) equivalent/liter given in the kit was used for standard measurement. A1 and A2 measurements were done three times for each of the

samples, and the average values were calculated. The absorbance change (ΔAbs) was calculated by subtracting the first absorbance value (A_1) from the second absorbance value (A_2). The TOS level was calculated using the formula given in the kit and expressed as mmol H_2O_2 Eq/L.

$$\text{TOS} = \left(\frac{[\Delta\text{Abs sample}]}{[\Delta\text{Abs standard}]} \right) \times \text{standard concentration [10 } \mu\text{mol/L]}.$$

Immunohistochemical Analysis

Following tissue collection, the samples were fixed in formalin, embedded in paraffin blocks, and cut into sections 4 μm thick. The cut tissue samples were then placed on slides coated with poly-L-lysine. The slides were kept in a humid medium at 45° C for one night and then transferred to another medium at 75° for 20 min. Leica Bond-Max auto-stainer was used for deparaffinization after caspase-8 and caspase-3 antibodies were stained. The stained slides were covered with a cover slip with mounting medium and examined under a light microscope. The intensity of cytoplasmic localized caspase-3 and caspase-8 in muscle and endothelial cells were evaluated at 40 and 100 \times magnifications. The slides were evaluated by a pathologist who was blind to the study. The staining was scored as follows: 0 = no staining, 1 = mild staining, and 2 = intense staining. The inclusion and evaluation criteria were to be stained with antibodies at least 50%. Routine staining with hematoxylin-eosin dye, followed by examination under a light microscope was used to detect possible morphological changes.

Statistical Analysis

Statistical analysis was performed using the Statistical Package for the Social Sciences (SPSS, Chicago, IL, USA) 20.0 program. The Kolmogorov–Smirnov test was used for the comparisons of all variable groups. The results were analyzed using the Kruskal–Wallis test, with a Bonferroni-adjusted Mann–Whitney U post hoc test. The results were expressed as the mean \pm standard error (SE). A value of $p < 0.05$ was considered statistically significant.

Results

Biochemical Findings

There was a statistically significant difference in the TAS levels in all the groups ($p = 0.034$). The TAS level in the I/R group was significantly lower than that in the control, irisin, and I–I/R groups (respectively, $p = 0.045$, $p = 0.015$, and $p = 0.011$) (Figure 1).

Similar to the TAS levels, there was a statistically significant difference in TOS levels in all the groups ($p = 0.002$). The TOS level was significantly higher in the I/R group as compared with that in the control, irisin, and I–I/R groups (respectively, $p = 0.007$, $p = 0.008$, and $p = 0.009$) (Figure 1).

Histopathological Findings

There was a statistically significant between-group difference in myositis caspase-8 activity ($p = 0.006$). Myositis caspase-8 enzyme activity was significantly higher in the I/R and I–I/R groups ($p = 0.003$ for both) as compared with those in the control and irisin groups ($p = 0.032$ and $p = 0.032$, respectively) (Figures 2–4).

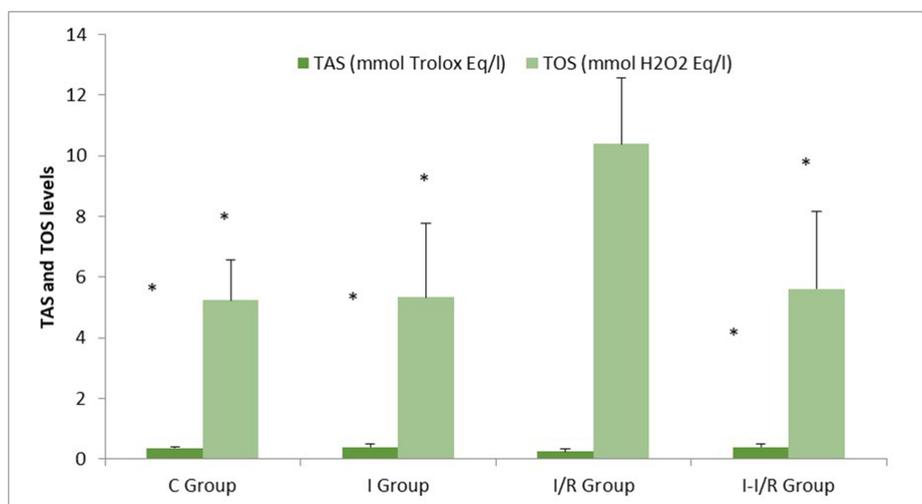

Figure 1 Total antioxidant status (TAS) and total oxidative status (TOS) levels (Mean \pm SE) * $p < 0.05$: Compared with I/R group.

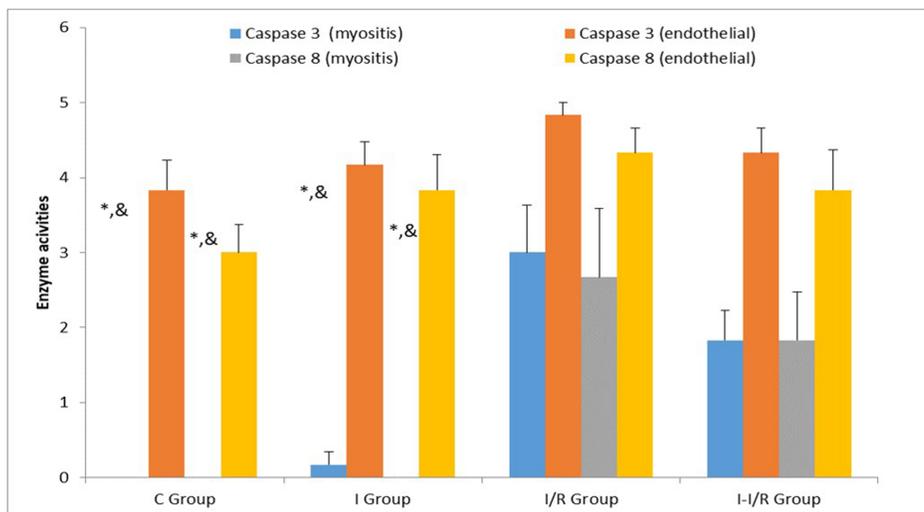

Figure 2 Caspase 3 and 8 enzyme activities (Mean±SE). * $p < 0.05$: Compared with I/R group; ⁸ $p < 0.05$: Compared with I-I/R group.

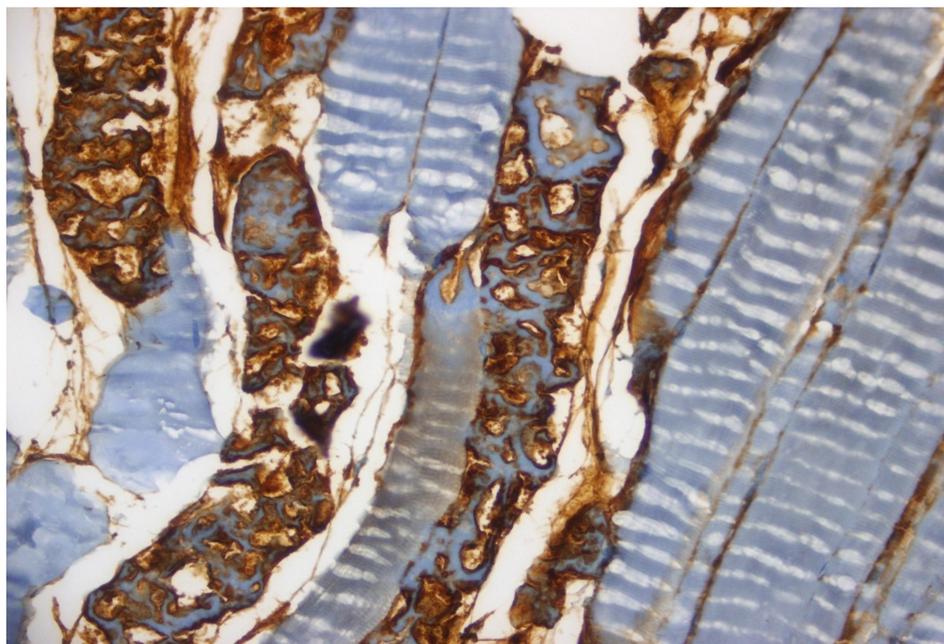

Figure 3 Remarkable caspase-8 staining is seen in muscle fibers and more than fifty percent of the vascular endothelium in I/R group (HE, 40x).

Similarly, there was a statistically significant between-group difference in myositis caspase-3 activity ($p < 0.0001$). Myositis caspase-3 enzyme activity was significantly higher in the I/R and I-I/R groups ($p < 0.0001$ for both) as compared with those in the control and irisin groups ($p = 0.003$ and $p = 0.006$, respectively) (Figure 2).

Inflammation was significantly higher in the I/R group as compared with that in the control, irisin, and

I-I/R groups ($p = 0.007$, $p = 0.037$, and $p = 0.037$, respectively).

Myositis damage was significantly higher in the I/R group as compared with that in the control, irisin, and I-I/R groups (respectively, $p < 0.0001$, $p = 0.022$, and $p < 0.0001$) (Table 1, Figures 5 and 6).

Congestion was significantly higher in the I/R group as compared with that in the control and irisin groups ($p < 0.001$ and $p < 0.0001$, respectively) (Table 1, Figures 5 and 6).

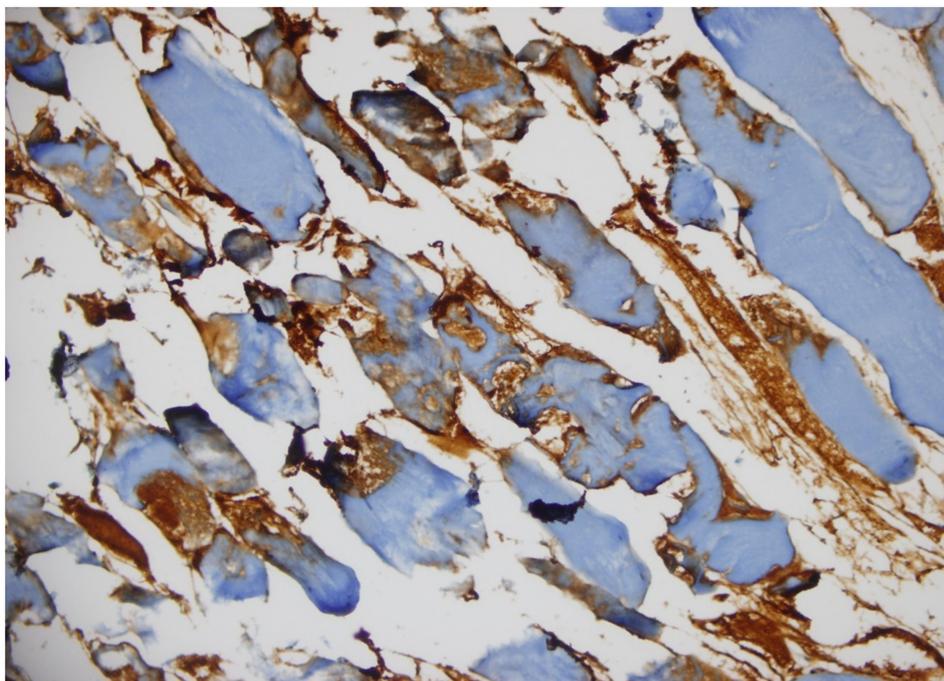

Figure 4 There is a medium caspase-8 staining intensity in some parts of the muscle fibers and in less than half of the vascular endothelial regions in I-/R group (HE, 40x magnification).

Discussion

Irisin is a PGC1- α -dependent myokine, which can transform white adipose tissue into brown adipose tissue.⁷ It is the product of a transmembrane protein transcribed from the *FNDC5* gene^{17,18} and is mainly secreted by skeletal muscle and myocardium during exercise.¹⁹ Previous research reported that irisin reduced oxidative/nitrative stress and protected endothelial cells in type 2 diabetes.⁷ Studies also reported that irisin provided protection against liver, cardiac, and perforator flap I/R.^{8,20–22} In addition, irisin was reported to play an important role in limb remote ischemic preconditioning-mediated lung protection by improving mitochondrial function.²²

Ischemia is the most common cause of irreversible cellular injury. I/R results in the generation of toxic reactive oxygen species (ROS) in organs. Ischemia studies

reported irisin reduced the activity of cellular defense enzymes against ROS and reperfusion and that these oxidative products disturbed the delicate balance of oxidants/antioxidants, leading to intracellular calcium overload, adenosine triphosphate depletion, myocardial apoptosis, and endothelial dysfunction.^{23–27} Research also demonstrated that oxidative products, such as ROS, reactive nitrogen species, lipid peroxides, hydrochloric acid, and malondialdehyde (MDA), formed TOS.¹

In the present study, in light of this information, we investigated whether irisin ameliorated I/R-induced damage by measuring TAS and TOS levels in a murine model of I/R injury. Previous studies showed that measurements of TAS levels provided more valuable information than individual measurements of antioxidants.^{28,29} Thus, in our study, we used TAS as a marker of total

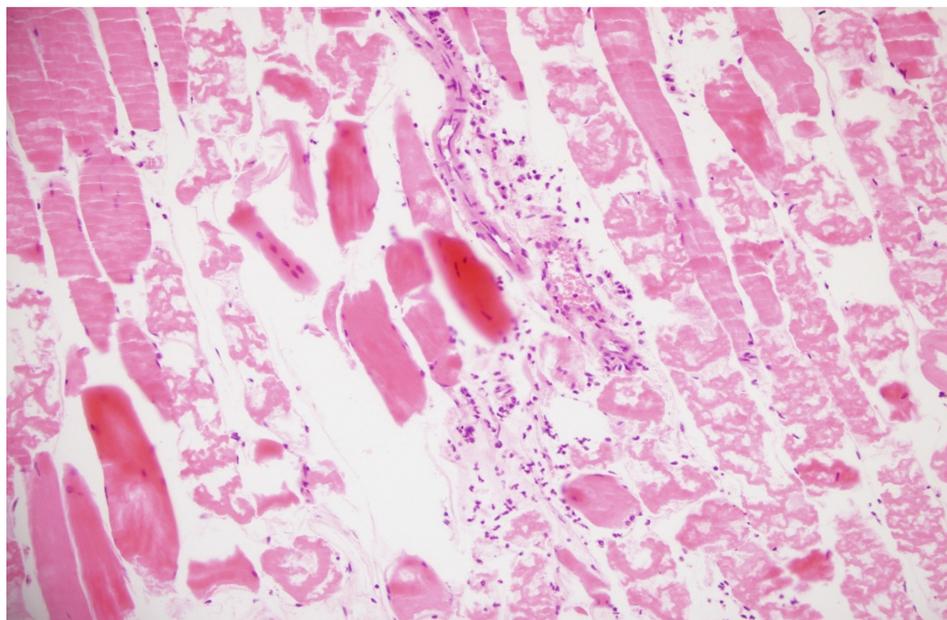

Figure 5 Prominent damage pattern is seen in most of the muscle fibers. There are also inflammatory cell infiltration sites between muscle fibers and significant congestion in veins (HE, 20x).

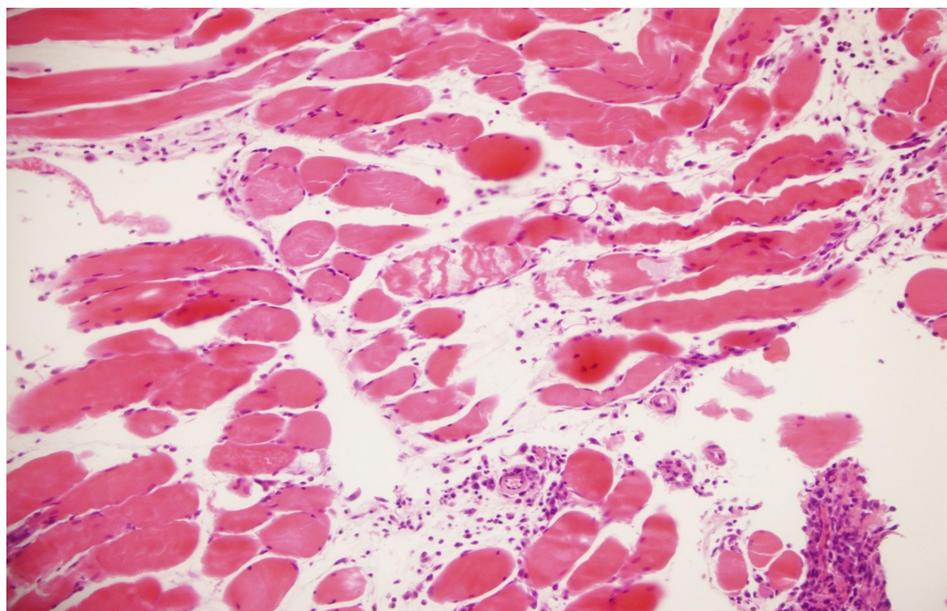

Figure 6 There are prominent focal acute necrotic change sites in muscular tissue sites and diffuse inflammatory cell infiltration (HE, 20x).

antioxidant protection against attack by free radicals and TOS as a marker of total oxidative stress. The TAS level was significantly higher in the I/R group as compared with that in the control and I-I/R groups, which was in accordance with I/R-induced impairment of antioxidant activity, as reported previously. Kim et al³⁰ found that vitamin C treatment at a dose of 2.5 mg for 5 d increased the TAS during and after the treatment period. They found that

TAS levels were decreased in their study and attributed this finding to a decrease in antioxidant stress. The TOS level in the I/R group in the present study was significantly higher than that in the control and I-I/R groups. Oxidative stress, which is the main actor of I/R injury, was lower in the irisin-treated groups according to the TOS level.

Some pathophysiological processes in apoptosis events are related to the severity of I/R.^{31,32} The proportion of

Bax to Bcl-2 reflects the triggering of apoptosis following the initiation process, and caspase-3 antibody signaling is the main factor responsible for the acceleration of the apoptotic event.^{33,34} Previous research reported that irisin effectively decreased the cellular expression level of cleaved caspase-3, which, in turn, indicated that irisin administration may have a protective effect against I/R damage of striated muscle tissue. In our study, we observed that irisin led to a reduction in caspase-3 levels. This finding was in accordance with the previous study.

Significant differences were found between groups in terms of inflammation, myositis injury and congestion. Inflammation and myositis injury were significantly higher in the I/R group than in the control, irisin, and I-I/R groups. The congestion was significantly higher in the I/R group than in the control and irisin groups. In addition, there was a significant between-group difference in the skeletal muscle cross-sections in our study.

In light of these data, we conclude that irisin has a protective effect against hind limb I/R-induced damage in skeletal muscle. To evaluate the protective effects of irisin against I/R-induced damage to various organs, studies are needed to establish different I/R times. Such studies could elucidate the protective effects of irisin, as well as the underlying mechanisms of tissue damage associated with I/R injury.
