**Abstract:** The potential of endoscopic evaluation in the management of inflammatory bowel diseases (IBD) has undoubtedly grown over the last few years. When dealing with IBD patients, histological remission (HR) is now considered a desirable target along with symptomatic and endoscopic remission, due to its association with better long-term outcomes. Consequently, the ability of endoscopic techniques to reflect microscopic findings *in vivo* without having to collect biopsies has become of utmost importance. In this context, a more accurate evaluation of inflammatory disease activity and the detection of dysplasia represent two mainstay targets for IBD endoscopists. New diagnostic technologies have been developed, such as dye-less chromoendoscopy, endomicroscopy, and molecular imaging, but their real incorporation in daily practice is not yet well defined. Although dye-chromoendoscopy is still recommended as the gold standard approach in dysplasia surveillance, recent research questioned the superiority of this technique over new advanced dye-less modalities [narrow band imaging (NBI), Fuji intelligent color enhancement (FICE), i-scan, blue light imaging (BLI) and linked color imaging (LCI)]. The endoscopic armamentarium might also be enriched by new video capsule endoscopy for monitoring disease activity, and high expectations are placed on the application of artificial intelligence (AI) systems to reduce operator-subjectivity and inter-observer variability. The goal of this review is to provide an updated insight on contemporary knowledge regarding new endoscopic techniques and devices, with special focus on their role in the assessment of disease activity and colorectal cancer surveillance.

Received: 23 January 2021; revised manuscript accepted: 8 March 2021.

## Introduction

Endoscopy plays a crucial role in the management of patients with inflammatory bowel diseases (IBD), as it represents the mainstay of both initial diagnostic assessment and evaluation of disease activity.<sup>1,2</sup> To date, endoscopic remission is the main treatment target as mucosal healing (MH) is associated with better long-term efficacy outcomes.<sup>3–5</sup> However, there is growing evidence that, in addition to MH, the objective of attaining histological remission (HR) might result in further improved outcomes.<sup>6,7</sup> In fact, histological

disease activity can be detected in up to 40% of patients with endoscopic remission and is associated with a greater risk of clinical relapse.<sup>8</sup>

It is currently recommended that endoscopic procedures should be performed with high definition white-light endoscopy (HD-WLE) in order to ensure optimal evaluation of the mucosa.<sup>2</sup> Importantly, residual inflammatory activity persists even if HD-WLE identifies a normal-appearing mucosa.<sup>9</sup> Besides the certain discordance between HD-WLE and histopathology, there is a

multitude of histological scoring systems, which makes disease activity estimation more complex.<sup>10</sup> Of note, in recent years, several methods have been introduced to ameliorate the evaluation of the mucosa by endoscopists. New diagnostic devices, such as confocal laser endomicroscopy (CLE), have been developed to better predict histopathology, but their real incorporation in daily practice is not yet well defined.<sup>11</sup> The use of artificial intelligence (AI) systems to standardize operator-subjectivity in IBD and molecular imaging have also come to light as captivating areas of research.<sup>12</sup> In addition, endoscopic surveillance is fundamental in the prevention of colorectal cancer in IBD and the use of modalities such as chromoendoscopy, which involves the spraying of topical dyes to enhance visualization of the mucosa has become the gold standard for dysplasia detection.<sup>13</sup> The Surveillance for Colorectal Endoscopic Neoplasia Detection and Management in Inflammatory Bowel Disease Patients (SCENIC) recommendations highlighted the superiority of HD-WLE over standard definition (SD)-WLE and, most importantly, put emphasis on the preferential use of dye-chromoendoscopy (DCE) over WLE, in guiding targeted biopsies.<sup>14</sup> Despite the authoritative position of the SCENIC consensus, debate is still ongoing, as further research has produced contradictory results, with a recent meta-analysis failing to show a significant superiority of DCE over HD-WLE in dysplasia identification [relative risk (RR) = 1.36; 95% confidence interval (CI): 0.84–2.18].<sup>15</sup> Moreover, long examination time, need for adequate training, and additional costs for dye spraying might limit the wider application of this technique.<sup>16,17</sup> In this context, dye-less chromoendoscopy or virtual chromoendoscopy (VCE) is emerging for its advantageous role in IBD surveillance.<sup>18</sup> In this review, we aim to summarize the current evidence on the most recent endoscopic techniques and devices in two cornerstones of IBD management: evaluation of disease activity and colorectal cancer surveillance. The review also focused on the strengths and limitations of the new advances to provide physicians with an updated insight on what is feasible and effective in a real-life setting.

## Methods

We searched the PubMed, Ovid MEDLINE and EMBASE databases using the following keywords ‘endoscopy’, ‘dye-chromoendoscopy’,

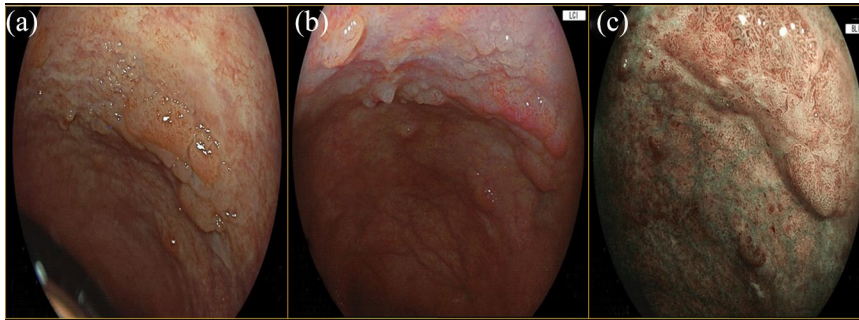

‘virtual chromoendoscopy’, ‘endocytoscopy’, ‘confocal laser endomicroscopy’, ‘capsule enteroscopy’, ‘artificial intelligence’, ‘molecular imaging’ individually or in combination with ‘IBD’, ‘Inflammatory Bowel Disease(s)’, ‘Crohn’s disease’, ‘CD’, ‘Ulcerative Colitis’, or ‘UC’. The search focused on full text papers published in English up to December 2020. Abstracts were selected when relevant. No publication date restrictions were imposed. Finally, articles were included in this review if they were relevant, while additional publications were identified through their reference lists. Ethics approval and informed consent were not required for this review.

## Endoscopic technologies for the assessment of mucosal inflammation

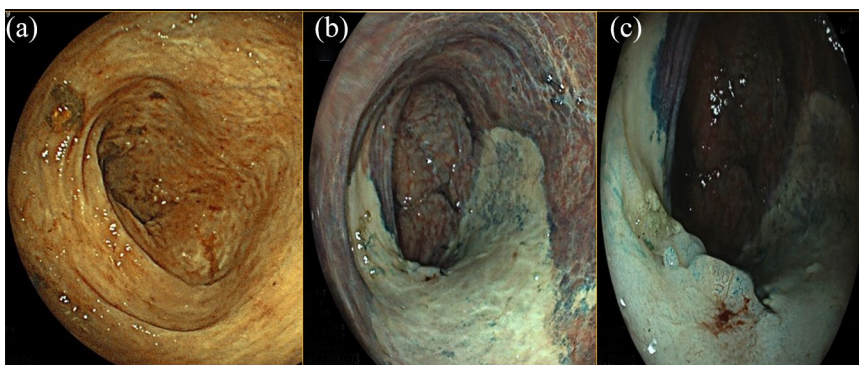

Endoscopy plays a key role in both Crohn’s disease (CD) and ulcerative colitis (UC). However, in patients with CD inflammation is extended to deeper layers and additional cross-sectional imaging techniques are required to assess transmural healing.<sup>19</sup> Rapid advancements in endoscopic technologies including DCE, VCE, endocytoscopy (EC), and CLE have enabled a more precise assessment of mucosal inflammation (Figure 1).<sup>18</sup>

### Dye-chromoendoscopy

DCE was introduced more than a decade ago. In this procedure, dye agents (e.g., methylene blue and indigo carmine) are applied to improve the detection of the mucosal surface and any potential abnormalities.<sup>20</sup> The interest in DCE derives from the clear benefit in the adenoma detection rate (ADR) in the context of IBD surveillance (Figure 2).<sup>21</sup> Several studies have demonstrated the role of this technology in accurately determining mucosal inflammation.<sup>22–24</sup> A paradigmatic trial randomized 263 clinically inactive, UC patients at a 1:1 ratio to undergo conventional colonoscopy or colonoscopy with DCE.<sup>24</sup> A significantly improved correlation between endoscopic assessment of disease extent and histologic data was observed in the group of patients undergoing DCE (89% *versus* 52%,  $p < 0.0001$ ). This technique was also able to better predict the degree of inflammatory activity, as a higher percentage of agreement between endoscopic and histopathologic findings was described in the DCE arm (87% *versus* 54%,  $p < 0.0002$ ).<sup>24</sup>

**Figure 2.** Descending colon flat lesion (IIb according to the Paris classification), pit Patter IIII according to the Kudo classification at the same specific points. (a) WLE. (b) DCE. (c) Detail with DCE. Histologic examination: biopsies on the white area compatible with chronic inflammation; biopsies on the lesion compatible with low grade dysplasia. DEC, dye-chromoendoscopy; WLE, white-light endoscopy.

### *Dye-less chromoendoscopy*

Unlike DCE, which utilizes staining agents and has a long procedure time, dye-less chromoendoscopy or VCE [narrow band imaging (NBI), Fuji intelligent color enhancement (FICE), i-scan, blue light imaging (BLI), and linked color imaging (LCI)] can be performed easily without complex equipment (Table 1).<sup>25</sup>

NBI uses an optic filter that reduces the light spectrum emitted from the endoscope, thus being absorbed by hemoglobin and providing an enhanced image of the mucosal vascularity.<sup>26</sup> FICE and i-scan belong to DCE. A digital post-processing system is used to enhance the real-time vascular and surface images.<sup>25</sup> Among most advanced developments in light emitting technologies, BLI is based on the not-filtered emission of short wavelength blue light, which is selectively absorbed by hemoglobin.<sup>27</sup> By increasing shades

of reddish and whitish tones through the BLI light, an image-enhanced endoscope called LCI, increases slight differences in the red region of the mucosa that are related to inflammation and neoplasia (Figure 3).<sup>28</sup> A prospective study compared structural and vascular alterations of Peyer's paths (PPs) between 60 IBD patients and 23 healthy controls (HC) through the use of NBI.<sup>29</sup> IBD patients had significant abnormalities in the vessels of PPs (e.g., branch-like structures) compared with HC ( $p < 0.001$ ).<sup>29</sup> When compared with conventional HD-WLE, NBI was shown to be more accurate in assessing the mucosal vascular pattern ( $p = 0.0001$ ), which was correlated with the inflammatory histological features in patients with quiescent UC.<sup>30</sup> Danese *et al.*<sup>31</sup> suggested that NBI colonoscopy might be a useful tool for the *in vivo* detection of angiogenesis in IBD.<sup>23</sup> In fact, a significant increase in vessel density in inflamed areas was identified

**Table 1.** Dye-less chromoendoscopy techniques.

Modality	Company	Description	Digital pre-image processing	Digital post-image processing
NBI	Olympus, Japan	It uses an optic filter that reduces the light spectrum emitted from the endoscope, thus being absorbed by hemoglobin and providing an enhanced image of mucosal vascularity	No	No
FICE	Fujinon, Japan	Starting from white-light endoscopic images from the video processor, FICE mathematically processes the image by emphasizing certain ranges of wavelengths (post-image processing)	No	Yes
i-SCAN	Pentax, Japan	It uses digital post-processing to enhance real-time vascular and surface images	No	Yes
i-SCAN OE	Pentax, Tokyo, Japan	It incorporates a pre-processor OE to gain better visualization of mucosal vascular pattern morphology	Yes	Yes
BLI	Fujifilm, Japan	It enhances superficial vascularity through the not-filtered emission of a short wavelength blue light that is selectively absorbed by hemoglobin	No	Yes
LCI	Fujifilm, Japan	By increasing shades of reddish and whitish tones through the BLI light, LCI uses both pre-processing and post-processing technology to increase slight differences in the red region of the mucosa that are related to inflammation and neoplasia.	Yes	Yes

in endoscopically normal NBI-positive areas compared with NBI-negative areas ( $12 \pm 1$  vessels/field versus  $18 \pm 2$  vessels/field, respectively;  $p < 0.05$ ).<sup>31</sup> A more recent study reinforced the previous findings on vascular patterns, by showing a correlation between magnified NBI and

histological disease activity and prognosis.<sup>32</sup> In particular, Sasanuma *et al.*<sup>32</sup> focused on the shapes of capillary vessels with magnifying NBI and reported that patients with vessels shaped like bare branches had a greater risk of recurrence compared with those showing a honeycomb-like

appearance [odds ratio (OR)=14.2, 95% CI: 3.3–60.9]. A randomized study comparing i-scan and HD-WLE in 78 IBD patients reported that i-scan correlated better with histologic findings in terms of extent (92.3% *versus* 48.7%,  $p=0.0009$ ) and degree of disease activity (89.7% *versus* 53.9%,  $p=0.066$ ).<sup>33</sup> Accordingly, Iacucci *et al.* developed and validated a new endoscopic score, the Paddington International Virtual Chromoendoscopy Score (PICaSSO),<sup>34</sup> for assessing the severity of mucosal inflammation in UC by using the i-scan. PICaSSO assesses mucosal (e.g., crypts, erosions, ulcerations) and vascular (e.g., vessels appearance, bleeding) findings and is associated with the HR.<sup>34</sup> Here a particularly positive interobserver agreement was found among experts (kappa=0.92 and 0.89 in the pre and post evaluations, respectively). Furthermore, the correlation between i-scan optical enhancement (OE) magnification and two histological scores has been evaluated recently.<sup>35</sup> The overall i-scan OE score correlated moderately with two histologic scores used in UC: Roberts Histopathology Index (RHI) ( $r=0.61$ ,  $p<0.01$ ) and ECAP (Extent, Chronicity, Activity, Plus additional findings) ( $r=0.70$ ,  $p<0.001$ ).<sup>35</sup> Notably, a strong correlation between magnification endoscopy with i-scan OE and histological inflammation was established also in CD patients.<sup>36</sup> In this population, i-scan OE plus magnification endoscopy demonstrated to precisely identify histological inflammation, defined by the modified Riley score ( $r=0.74$ , 95% CI: 0.58–0.85;  $p<0.05$ ).<sup>36</sup> The first study using LCI in UC patients showed that endoscopic assessment with LCI strongly correlated with Matts histopathological grade ( $p=0.001$ ).<sup>37</sup> The interobserver agreement for LCI was excellent (kappa > 0.8) between experts and non-experts.<sup>37</sup> Furthermore, LCI is a promising tool for the prediction of clinical relapse in UC, as the average of the LCI-index (based on the redness of the lesion in the region of interest) in relapsing patients was statistically higher than that in non-relapsing (47.23 *versus* 31.91,  $p=0.0003$ ).<sup>37</sup>

### Endocytoscopy

Endocytoscopy (EC) is an endoscopic imaging technique that allows histological analysis of *in vivo* optical biopsies during the endoscopic procedure itself, in order to evaluate inflammatory disease activity.<sup>18</sup> In EC, the microscopic visualization of the superficial mucosal layer can extend

up to 50  $\mu\text{m}$  in depth. In a pilot study involving 40 IBD (UC = 21, CD = 19) subjects, a concordance of 100% between EC and histopathology assessment (Riley score) of bowel disease activity was found and the intraobserver agreement between two investigators was almost perfect (kappa = 0.76–0.88).<sup>38</sup> Nakazato *et al.* hypothesized that EC was able to differentiate among patients in endoscopic remission, those in HR (defined as Geboes score  $\leq 2$ ) from patients with histologically active disease.<sup>39</sup> The agreement between EC remission and HR was substantial in patients with a Mayo endoscopic score of 0 (kappa = 0.72). The authors therefore suggested considering the possibility of evaluating histological activity through EC without collecting biopsy specimens.<sup>39</sup> Ueda *et al.* recently stratified EC appearance into four groups (A, B, C, and D), according to crypt alterations in UC patients.<sup>40</sup> They found significant differences in terms of relapse among the different groups, since patients with disruptive or hidden pits (group D) had higher recurrence rates compared with individuals without crypt abnormalities or with milder EC appearance (75% *versus* 0, 50% and 40% in group A, B, and C respectively;  $p<0.005$ ).<sup>40</sup> Interestingly, a pilot study combined the EC system with the dye-less chromoendoscopy NBI (EC-NBI).<sup>41</sup> A strong correlation between EC-NBI capillary appearance and histological activity according to Geboes index was found ( $r=0.871$ ,  $p<0.01$ ).<sup>41</sup>

### Confocal laser endomicroscopy

Confocal laser endomicroscopy (CLE) is an additional endomicroscopic technique that allows for tissue analysis with a maximum depth of imaging of 250  $\mu\text{m}$ .<sup>42</sup> In UC patients in remission, CLE revealed a significant rate of mucosal pathologic abnormalities such as impaired and distorted crypt regeneration, sustained inflammation, and abnormal vascular patterns (all  $p<0.001$ ).<sup>43</sup> Interestingly, the Erlangen group investigated the ability of CLE to evaluate and define MH during biological therapy with anti-TNF, aiming at validating the first CLE MH score for UC.<sup>44</sup> The endomicroscopic MH score (eMHs), which includes number of crypts, lumen deformity and leakage, and vascular endothelial permeability, showed high sensitivity, specificity, and accuracy values (100%, 93.75%, and 94.44%, respectively) and a good correlation with the histological Gupta score ( $r=0.82$ ,  $p<0.0001$ ) and the

endoscopic Mayo subscore ( $r=0.81\%$ ,  $p<0.0001$ ).<sup>44</sup> All patients with an eMHs score  $<1$  were in remission (Partial Mayo score 0) after 3 years, suggesting that CLE and eMHs were valuable tools for prediction of a deep sustained remission.<sup>44</sup> The above-mentioned PICaSSO score and a new probe-based CLE (pCLE) grading system have been tested recently for their ability to approximate histopathologic results and therefore predict HR (defined as  $RHI \leq 6$ ).<sup>45</sup> Preliminary results found that a PICaSSO of  $\leq 4$  and a pCLE of  $\leq 10$  predicted HR with accuracy of 92.7% (95% CI: 84.8–97.3) and 95.1% (95% CI: 88.0–98.7), respectively.<sup>45</sup> A recent prospective observational study focusing on CD patients evaluated the role of CLE in predicting clinical outcomes.<sup>46</sup> The presence of both discontinuous crypt architecture and focal cryptitis was described in 63.3% of patients ( $n=31$ , CLE+ group).<sup>46</sup> After 12 months of follow up, the CLE+ group showed an increased incidence of medical treatment escalation ( $RR=3.27$ ,  $p<0.001$ ) and transmural lesions ( $RR=1.70$ ,  $p=0.025$ ) compared with CLE-, suggesting that CLE might represent an attractive prognostic tool.<sup>46</sup> The most relevant studies on available techniques for the evaluation of IBD activity are summarized in Table 2.

### Endoscopic technologies for the detection of dysplasia

Patients with longstanding colonic IBD have an increased risk of developing colorectal cancer (estimated prevalence is approximately 3.5% in both longstanding UC and CD).<sup>49,50</sup> Subsequently, 8–10 years after disease onset, IBD patients are enrolled in surveillance colonoscopy programmes.<sup>2</sup>

At the moment DCE is recognized as the gold standard method for dysplasia surveillance in IBD, as it was demonstrated to be superior to WLE for dysplasia detection.<sup>14</sup>

#### Dye-chromoendoscopy

A prospective study by Picco *et al.* reported that indigo carmine CE for UC surveillance resulted in higher rates of dysplasia detection as compared with WLE (21.3% versus 9.3%,  $p=0.007$ ).<sup>51</sup> The superiority of DCE over HD-WLE for identifying dysplasia was confirmed by a recent trial that assigned IBD patients randomly to HD-DCE with indigo carmine ( $n=152$ ) or HD-WLE ( $n=153$ ).<sup>52</sup> Dysplastic lesions were identified in a

more significant number of patients with HD-DCE (17 versus 7, respectively;  $p=0.032$ ).<sup>52</sup> However, there is contradictory evidence concerning superiority of DCE over HD-WLE ( $RR=1.36$ ; 95% CI, 0.84–2.18), and additional studies are needed to support these data.<sup>15</sup>

#### Dye-less chromoendoscopy

The first results from studies evaluating the effectiveness of VCE in revealing dysplastic lesions in IBD are now becoming available.<sup>15</sup> To compare the performance of DCE with NBI for the detection of neoplastic lesions in patients with longstanding UC, a multicenter prospective study randomized 1:1 131 patients to DCE ( $n=66$ ) or NBI ( $n=65$ ).<sup>53</sup> After targeting suspicious lesions and surrounding mucosa, no significant difference was found in neoplasia detection between NBI and DCE with a mean number of neoplastic lesions per colonoscopy of 0.47 and 0.32, respectively.<sup>53</sup> In addition, per lesion analysis revealed a neoplasia detection of 17% and 16% for NBI, respectively.<sup>53</sup> The authors concluded that, given the longer withdrawal time for DCE, the gold standard might be replaced by NBI.<sup>53</sup> A meta-analysis included 10 randomized controlled trials with the aim of comparing DCE with other endoscopic techniques (SD-WLE, HD-WLE, NBI).<sup>54</sup> DCE was able to identify more dysplastic lesions compared with SD-WLE ( $RR=2.12$ ; 95% CI: 1.15–3.91).<sup>54</sup> No significant difference was found between DCE and HD-WLE ( $RR=1.42$ ; 95% CI: 0.80–2.52) or NBI ( $RR=1.05$ ; 95% CI: 0.64–1.71).<sup>54</sup> The advantages of new VCE techniques are sustained by yet another meta-analysis that confirmed no significant differences among DCE, HD-WLE, NBI, and FICE in detecting neoplasia during IBD surveillance, and also supported the use of Full spectrum HD-WLE.<sup>55</sup> Full-spectrum endoscopy is characterized by supplementary lateral camera lenses in addition to the standard forward-viewing camera. According to Iannone *et al.*,<sup>55</sup> this new colonoscope showed higher odds of detecting neoplastic ( $OR=3.22$ , 95% CI: 0.55–18.98) and non-polypoid lesions ( $OR=18.04$ , 95% CI: 0.49–668.36) in IBD patients.

Two studies by Hoffman *et al.*<sup>56,57</sup> demonstrated that i-scan imaging was superior to standard colonoscopy (neoplasia detection rate: 38 % versus 13 %,  $p<0.0001$ ) and equal to DCE in identifying neoplastic lesions (number of neoplastic lesions:

**Table 2.** Most relevant studies on available techniques for the assessment of mucosal inflammation.

Author	Study design	Population	Endoscopic technique	Outcome	Results	Authors' conclusions
Matsumoto et al. <sup>22</sup>	Prospective cohort study	41 UC	DCE with indigo carmine	Determination of UC severity	Patients with visible NWP and CO had lower grade of histologic inflammation than those in whom both findings could not be visualized (grade $\leq 2$ versus $\geq 3$ , $p = 0.017$ )	Good estimation of disease activity with DCE
Ibarra-Palomino et al. <sup>23</sup>	Prospective cohort study	25 UC	DCE with indigo carmine or methylene blue	Determination of UC extension and severity, as well as inter-observer variability	Fair agreement among endoscopic and pathologic diagnoses of each observer	DCE increases endoscopic-pathologic agreement for assessment of severity
Kiesslich et al. <sup>24</sup>	RCT	263 UC Randomized 1:1 to conventional colonoscopy or DCE	Blue-aided DCE	Prediction of inflammation extent and severity between the two groups	DCE group showed better correlation between the endoscopic assessment of degree ( $p < 0.001$ ) and extent (89% versus 52%; $p < 0.001$ ) of colonic inflammation and the histopathologic findings	DCE permits more accurate diagnosis of the extent and severity of the inflammatory activity compared with conventional colonoscopy
Hiyama et al. <sup>29</sup>	Prospective cohort study	17 CD, 43 UC, 23 HC	NBI-ME	Evaluation of endoscopic changes of PPs	IBD patients had a high prevalence of having branch-like structures ( $p < 0.001$ ) and significantly higher vascularity lesions ( $p < 0.05$ ) than HC	NBI-ME demonstrates microstructure and microvascular alterations of PPs
Kudo et al. <sup>30</sup>	Prospective cohort study	30 inactive or mildly active UC	NBI	Significance of MVP classification and possible correlation between MVP and the histologic grade of inflammation	MVP determination was significantly different between conventional colonoscopy and NBI colonoscopy ( $p = 0.001$ ). Histologic inflammation was more frequently observed in segments with an obscure MVP than in those with a clear MVP	NBI valuable for determining inflammation grade
Danese et al. <sup>31</sup>	Prospective cohort study	8 UC, 6 CD	NBI	Investigation whether NBI colonoscopy could detect <i>in vivo</i> angiogenesis in IBD patients with colonic inflammation	Endoscopically normal areas NBI+ showed a significant increase in angiogenesis ( $12 \pm 1$ vessels/field versus $18 \pm 2$ vessels/field, $p < 0.05$ ) compared with NBI-	NBI may allow <i>in vivo</i> imaging of intestinal angiogenesis

Author	Study design	Population	Endoscopic technique	Outcome	Results	Authors' conclusions
Ueda et al. <sup>40</sup>	Prospective cohort study	32 UC	EC	Evaluation of the association of an EC classification with microscopic features and disease relapse	Patients with disruptive or disappeared pits (group D) had higher recurrence rates (75% versus 0, 50% and 40% in group A, B and C respectively, $p < 0.005$ ) during the follow-up period	EC is reliable for the assessment of microscopic inflammatory features. An EC stratification can predict the disease relapse
Maeda et al. <sup>47</sup>	Retrospective cohort study	52 UC	EC-NBI	Assessment of the efficacy of EC-NBI for evaluating the severity of inflammation	Strong correlation between the EC-NBI findings and the histological assessment ( $r = 0.871$ , $p < 0.01$ )	EC-NBI findings can be effective in the on-site evaluation of inflammatory activity
Macé et al. <sup>43</sup>	Prospective cohort study	6 UC-IR, 6 HC	CLE	Feasibility of measurements of mucosal microvascular permeability using CLE in patients with UC-IR	CLE detected mucosal pathologic abnormalities such as impaired and distorted crypt regeneration, persistent inflammation, and abnormal vascular patterns when compared with controls (all $p < 0.001$ versus normal mucosa)	CLE may serve as a new gold standard for the assessment of MH in UC
Hundorfean et al. <sup>44</sup>	Prospective cohort study	23 UC	CLE	Establishment and validation of an eMHs based on CLE	The eMHs showed high sensitivity, specificity, and accuracy values (100%; 93.75% and 94.44%, respectively) and good correlation with the histological Gupta score ( $r_s = 0.82$ , $p < 0.001$ )	CLE can assess MH accurately based on the newly developed and validated eMHs
Iacucci et al. <sup>48</sup>	Prospective cohort study	82 UC	VCE and CLE	Evaluation of the ability of PICaSSO and a pCLE grading system to predict HR (RHI $\leq 6$ )	A PICaSSO of $\leq 4$ and pCLE of $\leq 10$ predicted HR with accuracy of 92.7% (95% CI: 84.8–97.3) and 95.1% (95% CI: 88.0–98.7), respectively	The new VCE PICaSSO score and pCLE score can predict HR accurately
Tontini et al. <sup>46</sup>	Prospective cohort study	49 CD	CLE	Evaluation of the value of CLE for prediction of clinical outcomes	CLE+ group showed an increased incidence of medical treatment escalation (RR = 3.27, $p < 0.001$ ) and transmural lesions (RR = 1.70, $p = 0.025$ ),	CLE reveals CD-related features of mucosal inflammation and allows for early prediction of relevant clinical outcomes

BV-BB, blood vessels shaped like bare branches; BV-H, honeycomb-like blood vessels; CD, Crohn's disease; CI, confidence interval; CLE, confocal Laser endomicroscopy; CO, cryptal opening; DCE, dye-chromoendoscopy; EC, endocytoscopy; ECAP, Extent; Chronicity; Activity; Plus additional findings; eMHs, endomicroscopic MH score; HC, healthy controls; HR, histological remission; IBD, inflammatory bowel diseases; IR, in remission;  $\kappa$ , kappa; LCI, linked color imaging; ME, magnifying endoscopy; MH, mucosal healing; MPV, mucosal vascular pattern; mRI, modified Riley index; NHI, Nancy histology index; NWP, network pattern; OE, optical enhancement; pCLE, probe-based CLE; PICaSSO, Paddington International Virtual Chromoendoscopy Score; PP, Peyer paths; RHI, Roberts histopathology index; RCT, randomized controlled trial; RR, relative risk; UC, ulcerative colitis; WLE, white light endoscopy.

11 versus 11). More recently, a comparative study by Iacucci *et al.*<sup>48</sup> proved that i-scan and HD-WLE were not inferior to DCE in detecting neoplastic lesions. Adenoma, dysplasia (polypoid and non-polypoid), and adenocarcinoma detection rates were similar in the three-arms study (number of total lesions: 42 versus 27 versus 23 with HD, DCE, and VCE, respectively;  $p=0.84$ ).<sup>48</sup> Along these lines, the VIRTUOSO trial randomized 188 longstanding IBD patients (>8 years after disease onset) to VCE with i-scan OE or HD-WLE during colorectal cancer surveillance.<sup>58</sup> The neoplasia detection rate was not statistically different between the two groups (14.9% versus 23.4% with i-scan OE and HD-WLE, respectively,  $p=0.14$ ).<sup>58</sup>

In addition, an updated meta-analysis conducted by El-Dallal *et al.* strengthened the concept that dye-less chromoendoscopy, including both NBI and i-scan, was not statistically different in colorectal cancer screening compared with DCE (RR=0.77; 95% CI: 0.55–1.08) or HD-WLE (RR 0.72; 95% CI: 0.45–1.15).<sup>59</sup>

A new classification of lesions discovered during IBD surveillance, FACILE, (Frankfurt Advanced Chromoendoscopic IBD LEsions classification) was recently proposed.<sup>60</sup> It integrates four endoscopic findings (e.g., morphology, surface and vessel pattern, and inflammation), focusing on predictors of dysplasia (e.g., flat shape, irregular vessel and surface pattern, and signs of inflammation).<sup>60</sup> Finally, data about the use of BLI or LCI to identify neoplastic lesions in patients with IBD are not available yet. However, these newer-generation endoscopic devices proved to be promising in gastrointestinal tumor surveillance in the general population.<sup>61–63</sup> A prospective randomized study including 245 patients proved that BLI was more accurate in predicting the histopathology of colon polyps when compared with HD-WLE (92% versus 84%,  $p=0.011$ ).<sup>61</sup>

#### Endocytoscopy and CLE

At the moment, consistent evidence from using EC and CLE for dysplasia detection is lacking, probably due to the intrinsic difficulties of obtaining clear images during breathing and cardiac motion.<sup>64</sup> A prospective pilot study in 2011 aimed to evaluate feasibility and diagnostic accuracy of pCLE in UC surveillance.<sup>65</sup> Even though accuracy, specificity, and sensitivity of pCLE were

81%, 82%, and 65%, respectively, these performance measures were inferior to those provided by NBI/HD-WLE in real time (92%, 89% and 100%, respectively).<sup>65</sup> In line with these findings, a study assessing the diagnostic value of CE combined with integrated CLE (iCLE) reported a relatively good accuracy (86.7%, 95% CI: 78.1–95.3 versus 80.3%, 95% CI: 70.7–89.9), but a very poor sensitivity (42.9%, 95% CI: 11.8–79.8 versus 28.6%, 95% CI: 5.1–69.7).<sup>11</sup> The most relevant studies on available technologies for cancer surveillance in IBD are summarized in Table 3.

### What is next: capsule endoscopy, artificial intelligence, and molecular imaging

#### Capsule endoscopy

Small bowel capsule endoscopy (SBCE) is a particularly sensitive instrument used to detect mucosal alterations in the small bowel.<sup>2</sup> It should be considered for patients with clinical suspicion of CD who have already undergone an endoscopy, as stated in more recent guidelines.<sup>2</sup> Since the introduction of the first wireless capsule endoscopy (CE) in the 2000s, several advances, such as improved resolution systems and new types of capsules, have been made to further increase diagnostic yield.<sup>66</sup> Several clinical trials have investigated the potential role of SBCE in MH assessment.<sup>67,68</sup> A prospective, multicenter, case-series included 40 patients who underwent SBCE before therapy initiation and after achievement of clinical response.<sup>67</sup> The number of large ulcers detected through SBCE was significantly reduced after treatment ( $8.3 \pm 1.4$  versus  $5 \pm 0.8$ ; respectively,  $p=0.01$ ), suggesting that SBCE was a valuable method not only for CD diagnosis, but also for disease activity assessment.<sup>67</sup> Another study demonstrated the effectiveness of SBCE in assessing small bowel treatment response in CD patients with active disease. At week 52, 42% of subjects achieved complete mucosal healing (absence of ulcers) and deep remission (Harvey–Bradshaw Index  $\leq 5$  + C-reactive protein  $\leq 5$  mg/l or fecal calprotectin  $\leq 50$   $\mu$ g/g).<sup>68</sup> More recently Ben-Horin *et al.* supported the use of CE for the monitoring of quiescent CD patients,<sup>69</sup> as CE was able to predict disease flares within 6 months in a cohort of 61 patients [area under the curve (AUC) of 0.79, % 95 CI: 0.65–0.89;  $p=0.011$ ]. In this context, the pan-enteric video capsule system through Pillcam Crohn's Capsule (Medtronic) constitutes a very promising innovation.<sup>70</sup> In a

**Table 3.** Most relevant studies on available techniques for dysplasia detection in IBD.

Author	Study design	Population	Endoscopic technique	Outcome	Results	Authors' Conclusions
Picco <i>et al.</i> <sup>51</sup>	Prospective cohort study	586 images (266 WLE and 320 DCE) from 75 UC	WLE and DCE	Interobserver variability in the detection of dysplastic lesions, dysplasia detection rates	Interobserver agreement for lesions was high ( $\kappa=0.91$ and $0.86$ for WLE and CE, respectively). Dysplasia was found in 9.3% with WLE compared with 21.3% with WLE and DCE ( $p=0.007$ )	Adoption of DCE into general endoscopic practice should be encouraged
Alexandersson <i>et al.</i> <sup>52</sup>	RCT	186 UC, 116 CD, 3 indetermined colitis randomized 1:1 to HD-DCE group or HD-WLE group	HD-DCE vs. HD-WLE	To compare the detection rates of dysplasia using HD-DCE plus random biopsies vs. HD-WLE plus random biopsies	Dysplastic lesions were detected in 17 patients with HD-DCE vs. 7 patients with HD-WLE ( $p<0.032$ )	HD-DCE with random biopsies is superior to HD-WLE with random biopsies
Feuerstein <i>et al.</i> <sup>15</sup>	Meta-analysis of 10 studies (6 RCTs)	494 IBD	DCE compared with SD and HD-WLE	To compare the number of patients in whom dysplasia was identified using a per patient analysis in RCTs and analyzed separately for non-RCTs.	DCE was more effective at identifying dysplasia than SD-WLE (RR, 2.12; 95% CI: 1.15–3.91), but it was not more effective compared with HD-WLE (RR, 1.36; 95% CI: 0.84–2.18)	DCE appears superior to non-chromoendoscopy only when compared with SD-WLE and in non-RCT studies
Bisschops <i>et al.</i> <sup>53</sup>	RCT	131 UC randomized to DCE or VCE with NBI	DCE vs. NBI	To compare the performance of DCE to VCE for the detection of neoplastic lesions	Mean number of neoplastic lesions per colonoscopy [0.47 versus 0.32 for DCE and NBI, respectively; $p=0.992$ ]. Neoplasia detection rate was not different between DCE (21.2%) and NBI (21.5%) (OR = 1.02, $p=0.964$ ).	NBI may replace DCE for surveillance
Iannone <i>et al.</i> <sup>54</sup>	Meta-analysis of 10 RCTs	1500 IBD	DCE vs. SD-WLE/HD-WLE/NBI	To review current evidence on the comparative benefits and harms of DCE vs. all other endoscopic techniques in dysplasia surveillance	Likelihood of detecting patients with dysplasia with DCE was higher compared with other techniques (RR, 1.37; 95% CI: 1.04–1.79). Subgroup analyses confirmed this effect only when DCE was compared with SD-WLE (RR, 2.12; 95% CI: 1.15–3.91).	Data from existing RCTs show no difference between DCE and HD-WLE, NBI
Iacucci <i>et al.</i> <sup>50</sup>	RCT	129 UC, 136 CD, 5 indeterminate colitis	HD-WLE vs. DCE vs. and VCE (i-scan)	To compare HD-WLE, DCE and VCE (i-scan) for surveillance to detect colonic neoplastic lesions	Adenoma, dysplasia and adenocarcinoma detection rates were similar in the three-arms study (number of total lesions: 42 vs. 27 vs. 23 with HD, DCE and VCE, respectively, $p=0.84$ )	VCE or HD-WLE is not inferior to DCE for detection of colonic neoplastic lesions

(Continued)

Table 3. (Continued)

Author	Study design	Population	Endoscopic technique	Outcome	Results	Authors' Conclusions
Kandiah <i>et al.</i> <sup>58</sup>	RCT	188 IBD randomized to HD-WLE or VCE with i-scan OE	HD-WLE vs. VCE (i-scan)	To compare HD-WLE with i-scan OE for detection of neoplasia	NDR was not significantly different for HD-WLE (24.2%) and VCE with i-scan (14.9%) ( $p=0.14$ )	VCE with i-scan and HD-WLE do not differ significantly in the detection of neoplasia
El-Dallal <i>et al.</i> <sup>59</sup>	Meta-analysis of 11 RCTs	1328 IBD	VCE vs. HD-WLE/DCE	To compare the efficacy of VCE vs. HD-WLE or DCE through a meta-analysis and rating the quality of evidence	VCE, including both NBI and i-scan, was not statistically different compared with DCE (RR=0.77; 95% CI: 0.55–1.08) or HD-WLE (RR 0.72; 95% CI: 0.45–1.15) in detecting dysplasia	VCE or only HD-WLE might be considered for CRC screening
Iannone <i>et al.</i> <sup>55</sup>	Systematic review with network meta-analysis of 18 RCTs	2638 IBD	SD-WLE, HD-WLE, DCE, NBI, i-scan, autofluorescence, FICE and FUSE	To compare endoscopic techniques for dysplasia surveillance	Full spectrum HD-WLE showed higher odds of detecting patients with both neoplastic (OR=3.22) and non-polypoid lesions (OR=18.04)	DCE, HD-WLE, NBI, FICE and Full spectrum HD-WLE may be comparable for dysplasia surveillance. Full spectrum HD-WLE may represent the first-line approach.
Van Den Broek <i>et al.</i> <sup>65</sup>	Prospective cohort study	22 UC	pCLE	To evaluate feasibility and diagnostic accuracy of pCLE in UC surveillance	The sensitivity, specificity, and accuracy of blinded pCLE were 65%, 82%, and 81%, respectively compared with 100%, 89%, and 92% for real-time endoscopic diagnosis with NBI and HD-WLE endoscopy	pCLE is feasible with reasonable diagnostic accuracy, but there is little possible gain as an add-on test alongside NBI/HD-WLE endoscopy
Wanders <i>et al.</i> <sup>11</sup>	Prospective cohort study	61 CD	DCE plus iCLE	To evaluate diagnostic accuracy of DCE plus iCLE for differentiating dysplastic vs. non-dysplastic lesions	DCE plus iCLE for differentiating lesions had good accuracy and specificity (86.7% and 92.4, respectively), but poor sensitivity (42.9%)	iCLE has limited applicability in daily practice as a surveillance strategy

CD, Crohn's disease; CLE, confocal laser endomicroscopy; CRC, colorectal cancer; DCE, dye-chromoendoscopy; FICE Fujinon intelligent color enhancement; FUSE, full-spectrum endoscopy; HD, high definition; IBD, inflammatory bowel diseases; iCLE, integrated CLE; ns, not significant; NDR, neoplasia detection rate; OE, optical enhancement; OR, odds ratio; pCLE, probe-based CLE; RCT, randomized controlled trial; RR, relative risk; SD, standard definition; UC, ulcerative colitis; VCE, virtual chromoendoscopy; WLE, white light endoscopy.

pilot study including 41 patients with suspected or established CD, the Pillcam Crohn's Capsule was performed successfully in all 41 videos, allowing for an overall evaluation of the whole intestine without risk of capsule retention.<sup>70</sup> Moreover, thanks to a new integrated reading system, this video capsule permitted the recording and further comparison of patients' images over time, thus monitoring disease activity and extent under treatment.<sup>71</sup> It is particularly relevant in the pediatric population, where this type of "pan-endoscopy" was shown to effectively monitor mucosal inflammation and successfully guide a treat-to target strategy (twofold increase in the rate of MH and deep remission from baseline to week 54;  $p < 0.05$ ).<sup>72</sup>

### Artificial intelligence

The broad term AI generally refers to the ability of a computer to perform functions and reasoning that are typical of the human mind.<sup>73</sup> AI tools are used in the field of endoscopy, and studies evaluating AI systems for endoscopic support have shown good results.<sup>74,75</sup> This can be highly valued also in IBD, where the endoscopic assessment can be influenced by operator subjectivity.<sup>76</sup> A computer-aided diagnosis (CAD) system in use with EC was developed to predict persistent histologic inflammation in UC patients.<sup>47</sup> CAD provided good performance measures, showing sensitivity, specificity, and accuracy of 74% (95% CI: 65–81%), 97% (95% CI: 95–99%), and 91% (95% CI: 83–95%), respectively.<sup>47</sup> A CAD system based on GoogLeNet architecture was applied to identify normal mucosa (Mayo endoscopic sub-score 0) and MH (Mayo endoscopic sub-score 0–1) in an independent test set of 3981 images from 114 UC patients.<sup>77</sup> This new system performed well, with AUCs of 0.86 and 0.98 in the two groups, respectively.<sup>77</sup> Moreover, a computer algorithm based on the integration of pixel color data from the redness map and vascular pattern recognition, called red density (RD), was tested in a validation cohort of 29 UC patients.<sup>78</sup> In this latter study, Bossuyt *et al.* found a correlation between RD score and endoscopic (Mayo endoscopic subscore and UC Endoscopic Index of Severity scores with  $r = 0.76$ ,  $p < 0.0001$  and  $r = 0.74$ ,  $p < 0.0001$ , respectively) and histological scoring systems (RHI,  $r = 0.74$ ,  $p < 0.0001$ ),<sup>78</sup> suggesting that this tool might overcome interobserver variability and subjectivity for disease activity assessment. Deep learning convolutional neural networks (DCNN) belong to the AI field

aiming to obtain automatically detailed imaging features, by using multiple network layers without human perceptual biases.<sup>79</sup> Given input data, DCNN manage to autonomously classify images and find the most relevant and useful ones for solving problems.<sup>73</sup> Su *et al.* conceived of an automatic quality control system (AQCS) based on DCNN and investigated whether it could improve the identification of abnormal lesions such as adenomas and polyps in a large cohort of 659 non-IBD patients.<sup>80</sup> The ADR (0.289 *versus* 0.165,  $p < 0.001$ ) and the mean number of adenomas (0.367 *versus* 0.178,  $p < 0.001$ ) were significantly higher in the AQCS group when compared with the control.<sup>80</sup>

Taking advantage of convolutional neural networks, a fully automated video analysis system was developed recently, aimed at generating Mayo endoscopic scores automatically.<sup>81</sup> The analysis of 264 videos from a multicenter clinical trial proved that this system was able to distinguish remission from endoscopic activity in more than 80% of videos reviewed, with a positive level of agreement with gastroenterologist scoring ( $\kappa = 0.84$ ).<sup>81</sup>

### Molecular imaging

Molecular imaging is based on the topical or intravenous administration of specific and label structures and the subsequent visualization of targeted structures through simultaneous confocal imaging.<sup>82</sup> Molecular imaging with fluorescent labeled antibody for membrane-bound TNF (mTNF) in conjunction with CLE can be used for *in vivo* assessment of mTNF-expressing cells in CD inflamed mucosa.<sup>83</sup> In a single-arm clinical study including 25 CD patients, subjects with high numbers of mTNF(+) cells had significantly higher short-term response rates (92%) after 12 weeks of an anti-TNF therapy when compared with patients in the low-mTNF group (15%).<sup>83</sup> Moreover, the clinical response in the high-mTNF group was sustained over a 1-year follow-up period, and was associated with MH at follow-up endoscopy.<sup>83</sup> Similarly, the topical application of fluorescein-labeled antiadhesion ( $\alpha 4\beta 7$ ) molecule antibody was tested in five CD patients with active disease.<sup>84</sup>  $\alpha 4\beta 7+$  cells were observed during *ex vivo* confocal microscopy in only two patients responding to vedolizumab (VDZ). On the contrary, no  $\alpha 4\beta 7+$  were detected in the three non-responders to VDZ.<sup>84</sup>

Multiphoton imaging is a molecular imaging technique that provides both high cellular resolution and great depth of penetration into the tissue without the need for labels.<sup>85</sup> An endoscopic application of this system, named multiphoton endomicroscopy (MPEM), has recently been proven to yield label-free *in vivo* histopathologic results in experimental colitis models.<sup>86</sup>

### Discussion

Progress in endoscopy has paved the way for a more accurate approximation of histopathologic results. Histological modifications, inflammation, and healing are well reflected by endoscopic images provided by cutting-edge techniques. Furthermore, with the introduction of new advanced endoscopic modalities, such as VCE, most dysplastic lesions are visible and a smaller number of biopsy specimens is required, making surveillance less cumbersome for both patients and clinicians.<sup>53,87</sup> Among image enhancement techniques, the available evidence suggests that dye-less chromoendoscopy is not inferior to the gold standard DCE in terms of neoplastic lesions detection.<sup>48,53,54,59</sup> Moreover, dye-less chromoendoscopy modalities offer the advantage of requiring less procedure time without additional spray-agent costs (median withdrawal time: 15 *versus* 20 min with VCE and DCE, respectively).<sup>53,88</sup> To date, no comparative studies are available between the different VCE techniques and there is no standardized training to evaluate the expertise of operators. The use of one method rather than another is currently linked to cost and the preferences of individual centers. Head-to-head trials between the different VCE modalities are necessary to define whether one approach is in fact superior to the other. Future data well may result in this modern methodology becoming the routine approach for MH assessment and colorectal cancer screening in IBD.

EC and CLE are also available, and they provide the clear advantage of allowing *in vivo* estimation of inflammatory activity.<sup>38,89</sup> These methods could make endoscopic examinations less invasive by reducing the risk of complications related to biopsies. However, they are not yet widely adopted in clinical practice due to the associated costs and the prolonged time required by the procedure (an average increase of approximately 30–40 min).<sup>65</sup> Less expensive confocal probes and economic analyses are eagerly awaited to overcome this significant disadvantage. Moreover, there is no standardized

training and the level of expertise among operators is not high, so further studies are needed to increase the use of these techniques in clinical practice.

In addition, SBCE might be seen not only as a diagnostic tool in patients with suspected small bowel CD and normal endoscopy and magnetic resonance enterography (MRE), but also as an accurate investigation method to evaluate MH in small-bowel CD patients. Capsule retention leading to an urgent endoscopic or surgical intervention remains one of the main concerns of this device; as a result, it is not considered in patients with known or suspected stenotic disease or with a history of bowel obstruction. Of note, the new Pillcam Crohn's capsule with a pan-enteric video system is a promising and safe tool for the assessment of MH in selected populations such as pediatric patients in order to avoid endoscopy deep sedation and biopsy-related complications. The use of pan-enteric CE for activity monitoring should be encouraged in centers where video capsule is a routine examination, and the staff are adequately trained to read images. Due to its likely cost-effectiveness (mean total 20-year cost per patient: £38,043 *versus* £42,266 with pan-enteric CE and colonoscopy ± MRE, respectively) it may well represent a valid alternative to colonoscopy combined with MRE.<sup>90</sup>

AI represents a revolutionary technique in the endoscopy field, providing an objective and accurate evaluation of disease severity. AI offers enormous potential to improve the quality of endoscopic procedures and ultimately to reduce the number of biopsy specimens.<sup>91</sup> The use of AI in endoscopy is also expected to increase the ADR and help non-expert endoscopists in the challenging differentiation between inflammatory and neoplastic lesions, although this will need to be confirmed in studies involving IBD patients. Finally, implementing molecular imaging in endoscopy could provide physicians with a real-time *in vivo* view of targeted biomarkers, but it is still a research field that requires further validation [ClinicalTrials.gov identifier: NCT02852850].

### Conclusion

The goal of HR in IBD management has certainly influenced new advances in the endoscopic field. Endoscopy is now asked to accurately describe inflammatory disease activity and promptly identify suspected lesions during

the ongoing procedure, thus getting as close as possible to microscopic findings. Dye-less chromoendoscopy has already demonstrated to be feasible and cost-effective in a real-life setting, whereas endomicroscopy systems still appear as complex and costly techniques. New pan-enteric video capsules might enrich the endoscopic armamentarium for monitoring disease in specific populations. Further clinical studies are expected to confirm the great expectations placed on AI tools and molecular imaging.
