

High-throughput sequencing of infectious pathogens (® PIM)

## Test report: TEST REPORT

Patient name: Patient 1

Report number: 24JS01517

Date of inspection: 12-28, 2023

surveillance project: Pathogenic microorganism detection-DNA detection

We only serve the infection di-  
agnosis career [www.genskey.com](http://www.genskey.com)

Case No.:

24JS01517

Name: Patient 1

## 1. Sample information

### Information about the subject

\*\* surn-  
 ame and  
 personal  
 name: Patient 1

\*\* sex: Man

\*\* age: 6 year

\*\* tele-  
 phone: -

Admission nu-  
 mber: -

Bed number: -

### Sample information

Inspectio  
 n hospi-  
 tal: A children's hospital

Inspection physic-  
 ian: -

Departmen  
 t wa-  
 rd: Paediatrics ICU

Sampling  
 date: 2023-12-28

Date of collecti-  
 on: 2023-12-28

Report  
 date: 2023-12-29

Case  
 No.: 24JS01517

Sample Type: The alveo-  
 lar lavage  
 fluid

### Clinical information

White blood cell count (WBC) (10<sup>9</sup> / L): 4.69

Neutrophil ratio (%): 59.6

Lymphocyte ratio (%): 21.7

Procalcitonin (PCT) (ng/ml): -

C-reactive protein (CRP) (mg/L): 23.58

Results of the culture identification: -

Chief complaint: polydipsia, polyuria, more eating for 1 month. Cough for 2 weeks and fever for 6 days

Clinical diagnosis: diabetes mellitus, pneumonia

Clinical attention is high on the pathogen type: Mycoplasma or chlamydia, mycobacteria, parasites, fungi, viruses, and bacteria

Anti-infective drugs are timely and long: -

### Sample status

Color: yellow

Character: severe turbidity with  
 thin film

Cell count (cells / ml): 6,5,60,000

\* Note: When the sample is liquefied with a clot, Cell count results could not be obtained

### Review of test results

Bacteria: 47 Mycoplasma pneumoniae, common colonizing bacteria detected in human body (see list of suspected microecology for details)

Fungi: 15857 A. sparus, common colonization bacteria detected in human body (see suspected microecological list)

Virus: Human herpesvirus type 6B type 3

Parasites: No suspected pathogen was detected

## 2. Results of the DNA detection test

## Pathogen explanation and sequence distribution map \*

1, *Mycoplasma pneumoniae* (*Mycoplasma pneumoniae*):

The *Mycoplasma* family, *Mycoplasma* sp. This bacterium is an aerobic caustic strain without a cell wall and a common pathogen of atypical pneumonia. It can cause upper respiratory tract infection, about 5% -10% of patients will develop tracheobronchitis or pneumonia, can also lead to meningoencephalitis, arthritis and other diseases. The bacteria infection is high in late summer or autumn, children, young adults, the elderly can be infected, can be in schools or military camps outbreak epidemic.

The total number of bases in the genome of this species is 817207 (bp), and the measured total length of sequence coverage for this species is 2313 (bp), with a coverage of 0.283% and an average depth of 1.015 X.

2, *M. root* (*Rhizopus arrhizus*):

Also known as Malaria, Mucoraceae, Rhizaria sp. *T. oligogenum* is one of the causative agents of mucormycosis. Among the hairy mold orders, *A. oligogenes* is currently the most common infectious agent in the western hemisphere. *A. sparum* is an opportunistic pathogen. Immunocompromised patients are most susceptible to infection, especially in patients with chronic wasting diseases such as diabetes, leukemia, long-term chemotherapy, and corticosteroid hormones. Clinically common is the orbital and central nervous system mucormycosis. In addition, it can also occur in the lungs, gastrointestinal tract, skin and other places. *A. oligatum* is responsible for 60% of mucormycosis and nearly 90% of nasal-brain infections in humans.

The total number of genome bases in this species is 40416424 (bp), and the total length of the measured sequence coverage for this species is 1065018 (bp), with a coverage of 2.6351% and an average depth of 1.054 X.

### 3, *human herpes virus type 6B* (*Human betaherpesvirus 6B*):

It belongs to the subfamily herpesviruses, a member of the rose herpesvirus genus. Enveloped, double-stranded DNA viruses. Can cause infant infection and adult infection. HHV-6 infection is usually asymptomatic, and primary infection in infants and young children or immunocompromised patients can develop obvious symptoms. Severe cases, high fever (40 °C), red maculopapular rash. Adult primary infection with HHV-6 is rare, and patients undergoing organ transplantation or immune deficiency (e. g. AIDS) can develop severe infections, such as encephalitis and interstitial pneumonia. Has a wide range of tissue sex, in human can lifelong recessive infection, is a conditional pathogen, often present pathogenic effect in immune suppression, can cause serious disease, in hematopoietic stem cell transplantation, organ transplantation and acquired immune deficiency syndrome patients can lead to the central nervous system, bone marrow, lung, digestive tract, skin and liver serious damage. The total number of genome bases in this species is 162114 (bp), and the total length of sequence coverage for this species is 150 (bp), with a coverage of 0.0925%, and an average depth of 1.0 X.

\* Sequence distribution map: This section only shows the sequence distribution map of the species with three non-repeat-specific sequences detected.

## 2. Results of drug-resistance phenotype testing

not detected

### Results of drug resistance phenotyping:

- 1) , "ND" means that no resistance gene is detected, "-" means that the information is unknown, and "/" means that the prediction is currently impossible to give a conclusion.
  - 2) The column of drug resistance genes is the information of drug resistance characteristics of the corresponding antibiotic drugs, including drug resistance genes, drug resistance gene families or drug resistance mutations.
  - 3) The drug sensitivity phenotype prediction column is the predicted drug sensitivity phenotype results obtained based on the relevant drug resistance characteristics information of the drug detected, which are divided into "resistant", "sensitive" or "/". "/" means that the drug sensitivity phenotype results cannot be predicted at present.
- The above test results are for clinical reference only, and the final diagnosis should be comprehensively judged by combining other clinical test results.

### 3. Results of the virulence gene testing results

not detected

### Results of the virulence gene test indicate that:

- 1) Virulence genes are related to the disease process, and the virulence genes detected in the report are for clinicians' reference only;
- 2) More virulence genes information is available for <http://www.mgc.ac.cn/VFs/>.

### 4. Suspected microecological test results

#### List of suspected microecology

★Compared with other microecological species, the pathogen is more prominent in the relative abundance of the genus accounting for more than 50%, and a single species accounts for more than half of the genus, which should be paid attention to. Please consider the clinical symptoms.

### Explanation of the suspected microecological species

#### 1) Oral Prevotella species (Prevotella oris):

Gram-negative obligate anaerobes, Prevotella spp. It is the normal human body of the oral cavity, female reproductive tract and other parts of the normal flora, but also can cause the endogenous infection of these parts. There have been reports of Prevotella species isolated in the blood of tumor patients.

#### 2) Oral Streptococcus (Streptococcus oralis):

Gram-positive cocci, Streptococcus genus, belong to one of the slow streptococcus groups. Most delayed streptococcus groups are commonly colonized by oral cavity, digestive tract and female reproductive tract. This group of streptococci can instantly colonize normal skin, and such bacteria isolated from blood cultures may be contaminating bacteria. At the same time, these bacteria are also the most common pathogens found in bacterial endocarditis. In patients with granulocytosis, where immunosuppression occurs after chemotherapy, the delayed streptococcal species can often cause pathogenic sepsis and pneumonia in such patients.

#### 3) Streptococcus infantis (Streptococcus infantis):

The Gram-positive cocci, Streptococcus sp. Belongs to one of the slow disease streptococcus group. Most delayed streptococcus groups are commonly colonized by oral cavity, digestive tract and female reproductive tract. This group of streptococci can instantly colonize normal skin, and such bacteria isolated from blood cultures may be contaminating bacteria. At the same time, these bacteria are also the most common pathogens found in bacterial endocarditis. In patients with granulocytosis, where immunosuppression occurs after chemotherapy, the delayed streptococcal species can often cause pathogenic sepsis and pneumonia in such patients.

#### 4) Rhoxi (Rothia mucilaginosa):

Gram-positive cocci, Rhodella sp. It is a normal flora existing in the oral cavity, which can be isolated from the nasopharyngeal cavity and bronchial secretions. It is also a conditional pathogen. For isolates from blood, deep tissues, it is usually considered to be pathogenic bacteria and can cause a variety of human infections, such as endocarditis, bacteremia,

peritonitis, sepsis, etc.

5) *S. coccus* (*Veillonella dispar*):

Gram-negative micrococcus, and *Veronella* sp. It is the normal flora of the oral cavity, pharyngeal region, gastrointestinal tract and female reproductive tract. Is a conditional pathogen (not strong). Reported that it can cause artificial joint infection and endocarditis.

#### 6) *Adjacent to let (Granulicatella adiacens):*

Gram-positive cocci, *Streptococcus* spp. It is a normal flora in the human pharynx, reproductive system and intestinal tract. It is an opportunistic pathogen. It can cause infective endocarditis and other diseases, and the incidence and mortality of infection can exceed the grass green streptococcus and *Enterococcus*. If sterile sites such as blood, deep tissue, implanted prosthetic devices, abscess pus, especially in immunocompromised patients, drug susceptibility test should be performed.

#### 7) *Granular carbon 2 dioxide (Capnocytophaga granulosa):*

Gram-negative elongbacter, carbon 2 fibroia sp. It is the normal flora of human oral cavity, an opportunistic pathogen, related to periodontitis, which can cause sepsis and other infections in patients with normal immunity or immune deficiency (mainly granulocytopenia), such as endocarditis, endometritis, osteomyelitis, abscess, peritonitis and keratitis. Carbon CO can cause periodontitis in adults.

#### 8) *Caries, Actinobacteria (Schaalia odontolytica):*

Also named *Actinomyces odontolyticus*, Gram-positive branching or club bacteria, *Actinomyces* sp. Actinomycetes are a major component of the dental plaque community in the healthy population and are also associated with infections such as dental caries, pulpitis, odontogenic abscesses, and dental implants. Actinomycetes and associated bacteria usually cause mixed infections. Actinomycosis can cause chronic granulomatous diseases in the head and neck, lung, abdominal and cavity and pelvic cavity, mainly caused by various actinobacteria, especially yi, gi and Gravenni, which are also reported to be associated with *Propionibacterium*. The bacterium was initially isolated from the teeth and saliva. Foreign cases reported that it can cause systemic severe infections such as peritonitis, brain abscess and lung disease. However, because it is difficult to accurately distinguish actinomycetes at the level of species, rare related cases were reported in China.

#### 9) *Concise Campylobacter (Campylobacter concisus):*

*Campylobacter*. Mainly cause intestinal infection, can cause periodontal disease and head, neck, internal deep infection and sepsis.

#### 10) *Prevotella tanans (Alloprevotella tanneriae):*

*Prevonoides* spp. Obligate rod-shaped anaerobes. Isolation from plaque in the human gingival crevice can cause periodontitis. No report of infection caused by this bacterium in China.

#### 11) *Candida albicans (Candida albicans):*

*Candida*, a yeast-like species, also known as *Candida albicans*. *Candida albicans* is widely distributed in nature, and can also be isolated from the normal oral cavity, skin, gastrointestinal tract, and urogenital tract. It is usually not pathogenic, and it is an important opportunistic pathogen. The use of antimicrobial drugs, immunosuppression (blood tumor, solid organ or hematopoietic stem cell transplantation, chemotherapy), tumor, diabetes and so on are the risk factors of the bacterial infection. It can lead to oral candidiasis and candida vaginitis, it is often difficult to distinguish invasive infection from asymptomatic colonization, and the clinical manifestations can be from local mucosal lesions (local excessive proliferation and invasive infection) to disseminated infection (blood-borne infection).

#### explanation of nouns:

® Number of sequences: the number of sequences matching to the pathogen is related to the load load

of the pathogen itself, the amount of nucleic acid extraction, and the proportion of human sequences. A higher number of sequences indicates the higher confidence of the pathogen detected in the specimen.

- ® Relative abundance: the proportion of the microorganism in the same type of microorganisms detected in the whole specimen, the higher the abundance, the higher the proportion in the same type of microorganisms.

- ® Coverage: indicates the ratio of the detected nucleic acid sequence of the microorganism covering the entire gene sequence of the microorganism, and the high coverage indicates the high ratio detected by the whole genome of the microorganism.
- ® Multiple Mapping: Multiple alignment, which can compare reads to two or more species.
- ® Unique Mapping: only alignment, only alignment of reads to a species.

## 5. Description of test results

This method, just like other detection methods, has its own detection capability and detection range. The microorganisms not reported in the test results do not mean that they must not exist in the sample. The reasons include but are not limited to:

- 1) The proportion of human nucleic acid in the sample is too high, and the load of the tested pathogen in the sample is lower than the product detection limit;
- 2) For new pathogens or rare pathogens, the database may not be included;
- 3) The use of anti-infective drugs before sampling will lead to a decrease in the microbial content, which may affect the detection of pathogens;
- 4) Sample transportation conditions are not appropriate, resulting in nucleic acid degradation and sample loss;
- 5) Infection caused by the RNA virus, the DNA process cannot be effectively detected, please pay attention to the RNA process test results;

There are many causes of clinical fever (refer to the following table below), among which infectious fever accounts for about 40% and non-infectious fever accounts for about 60%. Clinicians are requested to make comprehensive judgment based on other clinical diagnoses and symptoms.

| Fever nature                | Cause of disease   | Di sease   |
|-----------------------------|--|--|
| Infectious fever (~40%)     | Various pathogens (bacteria, viruses, mycoplasma, chlamydia, spirochetes, rickettsia, and parasites, etc.) | Acute and chronic systemic or focal infections   |
|                             | Blood disease  | Lymphoma, malignant histiocytosis, hemophagocytic syndrome, acute myeloid leukemia, multiple myeloma, etc  |
| Non-infectious fever (~60%) | Allergy reaction and connective tissue disease   | Rheumatic fever, drug fever, systemic lupus erythematosus, dermatomyositis, Behc-uccet's disease, ankylosing spondylitis, autoimmune hepatitis, reactive arthritis, adult Still disease, etc |
|                             | Solid tumor  | Liver and central nervous system metastases, renal cell cancer, liver cancer, colon cancer, pancreatic cancer, etc   |

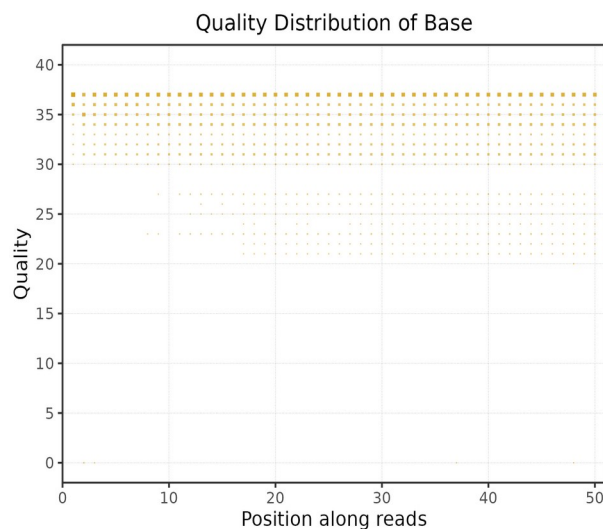

### 3. Cell count results

| Metric                                | Sample data | Host background distribution of the same-type samples |
|---------------------------------------|-------------|---|
| Human cell concentration (cells / ml) | 6560000     | 83.66%  |

#### 4. Sequencing quality

| Quality control parameters      |   | Sample data |
|---------------------------------|---|-------------|
| Experimental<br>quality control | Internal reference                                      | Qualified   |
|                                 | Nucleic acid extraction concentration<br>(ng / $\mu$ L) | 0.262       |
|                                 | Library Concentration (ng / $\mu$ L)                    | 60.4        |
|                                 | Yin control   | Qualified   |
|                                 | Whether to go to the host                               | Yes         |

disclaimer:

- 1) The results of this report are only responsible for the samples submitted for inspection at this time. If you have any doubt, please contact us within 7 working days after receiving the report;
- 2) The test results are available for clinical reference only, and the final clinical diagnosis and treatment plan need to be combined with the comprehensive clinical information of the subject person

The doctor came to;

- 3) Because the subject is aware of the possible mental pressure and psychological burden of the result, the testing institution shall not bear joint and several liability;
- 4) The test shall keep the results confidential and protect the privacy of the subject according to law, but the testing institution shall not bear the corresponding responsibility for the information leakage occurring due to the personal reasons of the subject.

Electronic report query method:

Way one:

Wechat scan code report QR code, input the name of the subject and the reserved mobile phone number, obtain the SMS verification code, you can query;

Way two:

Search for "Golden Medical Laboratory", click "Pathogen Detection-Metagenomic Report Query", enter the name of the subject and the reserved mobile phone number, obtain the SMS verification code, you can query.

## 5. Methodological introduction

The high-throughput detection product of <sup>®</sup> infection was tested based on nucleic acids in the sample to identify the suspected pathogenic microorganisms in the sample. The detectable range includes 12895 bacteria, 11120 viruses, 1582 fungi, 312 parasites, and 177 common pathogenic bacteria and 184 mycoplasma / chlamydia in the mycobacterium complex group. Meanwhile, detect the suspected resistance genes present in the identified samples, thus predicting the possible resistance of the bacteria in the samples based on the resistance genes. This test report provides all microorganisms with valid data detected in the sample and assists the clinician by interpreting the report. It is suitable for patients with unexplained fever, difficulty and immune deficiency.

We used high-throughput sequencing technology to analyze the microbial nucleic acid sequences in the samples and identify the microorganisms by comparing them with the nucleic acid sequences of the existing microorganisms in the database. Using machine learning (machine learning), synchronous error exploration (error modeling), background clearing (denoising) and exact sequence inference (exact sequence inference), and strict quality control system automatically eliminate false positive results.

The above data are based on treatment guidelines and recommendations, in vitro susceptibility results, major sensitivity and resistance mechanisms, and exact clinical efficacy, and are recommended as routine guidance for antimicrobial therapy. Methods of bacterial resistance vary by region and by the site of infection (e. g., community acquired infection, ICU acquired infection). These differences should be taken into account when applying the table above, and the activities of some drugs may be very different from those listed in the table.
