Received 29 October 2010; accepted 3 November 2010

Key indicators: single-crystal X-ray study;  $T = 295\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$ ;  $R$  factor = 0.050;  $wR$  factor = 0.113; data-to-parameter ratio = 11.4.

In the crystal structure of the title compound,  $\text{C}_{15}\text{H}_9\text{FO}_3$ , inversely oriented molecules form inversion dimers through pairs of  $\text{O}-\text{H}\cdots\text{O}$  hydrogen bonds. The benzene ring is twisted at an angle of  $12.0(1)^\circ$  relative to the  $4\text{H}$ -chromene skeleton of the molecule. Adjacent  $4\text{H}$ -chromene units are parallel in a given column or oriented at an angle of  $50.0(1)^\circ$  in neighboring, inversely oriented, columns, forming a herringbone pattern.

## **2-(4-Fluorophenyl)-3-hydroxy-4*H*-chromen-4-one**

**M. Wera, I. E. Serdiuk, A. D. Roshal and J. Blazejowski**

### **Comment**

3-Hydroxy-2-phenyl-4*H*-chromen-4-one (flavonol) and its derivatives exhibit dual fluorescence in liquid phases originating from the Excited State Intramolecular Proton Transfer (ESIPT) phenomenon (Sengupta & Kasha, 1979). Since the fluorescence of flavonols depends strongly on the properties of the medium, the compounds can be applied as analytical probes in chemistry, biochemistry, biology and medicine (Demchenko *et al.*, 2002). Continuing our investigations into this group of compounds (Roshal *et al.*, 2003; Pivovarenko *et al.*, 2005) we now present the crystal structure of a flavonol derivative – 2-(4-fluorophenyl)-3-hydroxy-4*H*-chromen-4-one.

In the title compound (Fig. 1), the bond lengths and angles characterizing the geometry of the 2-phenyl-4*H*-chromen-4-one (flavone) moiety are typical of this group of compounds (Cantrell & Stalzer, 1982; Etter *et al.*, 1986; Waller *et al.*, 2003). With respective average deviations from planarity of 0.0147 (2)° and 0.0020 (2)°, the 4*H*-chromene and benzene ring systems are oriented at a dihedral angle of 12.0 (1)° (in the case of flavonol this angle is equal to 5.5 (1)° (Etter *et al.*, 1986)).

In the crystal structure, the inversely oriented molecules form dimers through a pair of intermolecular O—H···O (Aakeröy *et al.*, 1992) bonds (Table 1, Fig. 2). Dimers oriented in parallel – linked by C—F···π (Dorn *et al.*, 2005) contacts (Table 2, Fig. 2) – are arranged in columns along the *b* axis which are dispersively stabilized in the crystal lattice. The adjacent 4*H*-chromene moieties are parallel in a given column or oriented at an angle of 50.0 (1) in the two neighboring, inversely oriented, columns, which forms a herringbone pattern. The O11—H11···O12 intramolecular hydrogen bond (Table 1, Figs. 1 and 2) is the one involved in the ESIPT phenomenon, characteristic of flavonols (Sengupta & Kasha, 1979).

### **Experimental**

The title compound was synthesized following the procedure described by Smith *et al.*, 1968. Briefly, 3-(4-fluorophenyl)-1-(2-hydroxyphenyl)prop-2-en-1-one was synthesized first by the condensation of 1-(2-hydroxyphenyl)ethanone with 4-fluorobenzaldehyde in methanol/50% aqueous NaOH (1/1 *v/v*), precipitated by neutralizing the reaction mixture with aqueous HCl and separated by filtration. The product thus obtained was subjected to oxidative cyclization in alkaline methanol/H<sub>2</sub>O<sub>2</sub> to yield 2-(4-fluorophenyl)-3-hydroxy-4*H*-chromen-4-one. The filtered product was purified chromatographically (Silica Gel, chloroform/methanol, 20/1 *v/v*) and yellow crystals suitable for X-ray investigations were grown from absolute ethanol (m.p. = 442–443 K).

### **Refinement**

The H atoms of the C—H bonds were positioned geometrically, with C—H = 0.93 Å, and constrained to ride on their parent atoms with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ . The H atoms involved in O—H···O hydrogen bonds were located on a difference map and refined freely with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{O})$ .

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
