**Abstract:** A 56-year-old woman had an yellow-white retinal lesion superior to the optic disc. Optical coherence tomography demonstrated the mass with a snowball configuration and smooth surface. Autofluorescence disclosed revealed moderate hypoautofluorescence. Ultrasonography showed no calcification. Visual field examination showed an enlargement of the blind spot corresponding to the predominantly superotemporal juxtapapillary extension of the lesion. Eight months later, the lesion spontaneously resolved. Presumed solitary circumscribed retinal astrocytic proliferation (PSCRAP) is a benign stable retinal tumor, but PSCRAP has been reported to resolve spontaneously here. It differs from other white or yellow-white lesions of the retina in important ways that enable the ophthalmologist to reassure the patient as to its benign prognosis. **Keywords:** presumed solitary circumscribed retinal astrocytic proliferation, benign lesion, astrocytes, acquired retinal astrocytoma, astrocytic hamartoma, spontaneous regress

## Introduction

The retina is made up of specialized neurons and glial cells.<sup>1</sup> In cases of retinal injuries, the glial cells become reactive and form a glial scar so clinically significant that involves multiple differential diagnoses and is associated with changes in the retinal architecture.<sup>1</sup> Massive retinal gliosis is rare and develops in long-standing eye diseases or trauma, but normally not assume tumor proportions and is generally not considered in the differential diagnosis of glial tumors.<sup>1,2</sup> Recently, a rare retinal lesion has been described, known as the presumed circumscribed solitary proliferation of retinal astrocytes (PSCRAP), with its own characteristics that make it unique and that usually remains stable in size since diagnosis.<sup>4</sup> We report a clinical case of PSCRAP that experienced spontaneous regression 8 months after it was detected, leaving normal retina at the site of the lesion.

## Clinical case

A 56-year-old woman was referred for an incidental retinal lesion in the left eye. She had no history of tuberous sclerosis complex (TSC) or neurofibromatosis type 1. She had no ocular symptoms. On examination, her visual acuity was 20/20 in both eyes. No significant finding was observed on anterior segment examination. Intraocular pressure was 12 mmHg bilaterally. She had no afferent pupillary defect and had normal color vision in both eyes. Ophthalmoscopy revealed a yellow-white lesion of one-fourth of papillary diameter and the edges slightly blurred located between the superior temporal vein and artery blood vessels close to the optic nerve (Figure 1A and B). Neither feeder nor draining vessels were observed and there were no network vessels in the lesion. Fundus examination of the right eye was normal. The patient refused fluorescein angiography.

**Figure 1** (A) Fundus photo on presentation showing a yellow-white mass in the retina, abruptly elevated without vessels distributed amongst the lesion. (B) High magnification image of (A). We can see details of the shape and boundary features of the lesion. (C) OCT-SD: hyperreflective smooth surface elevated retinal mass with optical shadow posterior to the lesion. (D) Ultrasound shows a mass without calcifications (arrow). (E) Fundus autofluorescence shows mild hypoautofluorescence with a small nidus of hyperautofluorescence. (F) Visual fields analysis showed an enlarged blind spot because the lesion is almost attached to the optic nerve. The visual field shows a large scotoma away from the blind spot not related to PSCRAP (encircling).

Optical coherence spectral tomography (SD-OCT) showed a hyperreflective mass on the RPE with a smooth, well-defined border in form of a snowball and a slight optical acoustic shadow (Figure 1C). B scan ultrasonography showed an elevated mass without calcifications (Figure 1D). Fundus autofluorescence showed mild hypoautofluorescence with a small nidus of hyperautofluorescence (Figure 1E). Visual field examination showed an enlargement of the blind spot corresponding to the predominantly superotemporal juxtapapillary extension of the lesion (Figure 1F). Eight months after the first visit, the lesion spontaneously regressed leaving a retina of normal appearance (Figure 2). The authors confirm that written informed consent has been provided by the patient to have the case details and any accompanying images published and institutional approval was required to publish the case details.

**Figure 2** Fundus image showing spontaneous PSCRAP regression 8 months after diagnosis, leaving normal-appearing retina.

## Discussion

Presumed circumscribed solitary proliferation of retinal astrocytes has recently been described as a small, solitary, well-defined lesion described in the middle ages of life and more frequent in males.<sup>3</sup> The lesion is opaque and is a benign retinal tumor abruptly elevated. It is not associated with exudation and lack of intrinsic or perilesional vascular flow.<sup>3</sup> This report describes an unusual case which demonstrates disappearance of typical PSCRAP 8 months after diagnosis, leaving a normal appearance of the retina. Only in one patient described by Shields et al,<sup>3</sup> the lesion disappeared spontaneously within 1 year. This case was described as the spontaneous

disappearance of hyperplasia of astrocytes, before the use of the term presumed circumscribed solitary proliferation of retinal astrocytes.<sup>3,4</sup> Shields et al<sup>5</sup> consider that the PSCRAP derived from the RPE or deep retina and not in the inner layers as they thought in the first description.<sup>3,5</sup> Goldberg and Raja<sup>6</sup> also consider that the lesion arises from the deep retina or RPE, whereas with OCT angiography characteristics of the lesion show a lack of intrinsic or paralesional vascular flow, indicating that this lesion is fibrous and likely derived from the RPE or

**Table 1** Showing differences between PSCRAP and AH

	<b>PSCRAP</b>	<b>AH</b>
Medical history	Negative	TSC/NF (personal/family history) or Negative (spontaneous)
Age	≥ Middle-aged	Children
Color	White	Yellow-white
	Opaque	Opaque/translucent
Number	Solitary	Multiple
Eye	Unilateral	Bilateral/ Unilateral (normal patients)
Vessels	None	Intrinsic vessels
Glial proliferation	None	Adjacent gliosis
Calcification	None	Yes
OCT	Dome-Shape (optical shadowing)	Flat (hazy area) Slight elevation+traction Moth-eaten (multinodular) Empty cavities
Autofluorescence	Mild hypo-hiper	Hypo (hyper calcification)
Fluorescein angiography (early/late)	Hypo and moderate hyper	Hypo/hyper
Ecography	No calcification	Calcification Not imaged (type1)
Clinical course	Stable	stable or mild progression
Ocular complications	None	Retinal exudation, Subretinal fluid, Vitreous hemorrhage, Tractional detachment
Origen	Deep retina or RPE <sup>6</sup>	Nerve fiber layer

**Abbreviations:** PSCRAP, presumed solitary circumscribed retinal astrocytic proliferation; AH, astrocytic hamartoma; TSC/NF, tuberous sclerosis complex/neurofibromatosis; RPE, retinal pigment epithelium.

deep retina and not the retinal astrocytes.<sup>6</sup> The differential diagnosis includes true tumors of astrocytic as astrocytic hamartoma (AH) and acquired retinal astrocytoma, and diagnosis as retinoblastoma, retinocytoma, simple congenital RPE hamartoma, myelinated fibers, granuloma and reactive gliosis.<sup>1,7</sup> AH is a benign tumor that is composed of a proliferation of well-differentiated astrocytes, which is usually diagnosed at early ages of life associated with tuberous sclerosis or as isolated case. It can occur as a calcified or non-calcified variety, and often a combination of the two. The lesions are usually multiple or bilateral and tend to be located peripapillary.<sup>1,7,8</sup> Our patient did not have any personal or family sign of tuberous sclerosis complex. An identical tumor is occasionally seen in patients with neurofibromatosis type 1.<sup>1</sup> Although AH is considered a stable lesion, spontaneous regression has been described.<sup>9</sup> AH presents a diagnostic challenge because of the variable clinical presentation. Four

types of AH on SD-OCT have been well described: type 1, flat and within the nerve fiber layer. Type 2 slight elevation with retinal traction. Type 3 typical “moth-eaten” areas caused by calcification, and type 4 with optically empty intralaminar cavities (Table 1).<sup>10</sup> None of them were similar to our case. Acquired astrocytoma of the retina typically appears as a solitary mass with abundant intrinsic vessels, tends to be progressive, and may be associated with exudation or exudative retinal detachment.<sup>1,8</sup> Diffuse or nodular glial proliferation can appear with chronic inflammation, ocular trauma, Coats’ disease, retinal hemangioblastoma, or congenital malformations.<sup>1</sup> Reactive gliosis can occur in a chronic retinal detachment area or with a scleral buckling in retinal detachment surgery and the gliosis can be extensive simulating tumors.<sup>1,2</sup> The immature retina in preterm infants may predispose to the formation of reactive nodular hyperplasia of astrocytes that regress in about 6 months.<sup>11</sup>

Myelination of the nerve fiber layer is benign, idiopathic, and appears as a chalk-white, sharply demarcated patches on the superficial retina. SD-OCT shows a thickened nerve fiber layer with hyperreflectivity likely due to myelin.<sup>12</sup> In summary, PSCRAP is a benign lesion that can regress without visual loss or other alterations. The main importance lies in its differentiation from lesions that can have serious ocular and systemic implications.

### Publish your work in this journal

The International Medical Case Reports Journal is an international, peer-reviewed open-access journal publishing original case reports from all medical specialties. Previously unpublished medical posters are also accepted relating to any area of clinical or preclinical science. Submissions should not normally exceed 2,000 words or 4

published pages including figures, diagrams and references. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
