25 **Abstract**

26 We report a live-attenuated SARS-CoV-2 vaccine candidate with (i) re-engineered viral
27 transcriptional regulator sequences and (ii) deleted open-reading-frames (ORF) 3, 6, 7, and 8
28 (Δ 3678). The Δ 3678 virus replicates about 7,500-fold lower than wild-type SARS-CoV-2 on
29 primary human airway cultures, but restores its replication on interferon-deficient Vero-E6 cells
30 that are approved for vaccine production. The Δ 3678 virus is highly attenuated in both hamster
31 and K18-hACE2 mouse models. A single-dose immunization of the Δ 3678 virus protects
32 hamsters from wild-type virus challenge and transmission. Among the deleted ORFs in the
33 Δ 3678 virus, ORF3a accounts for the most attenuation through antagonizing STAT1
34 phosphorylation during type-I interferon signaling. We also developed an mNeonGreen reporter
35 Δ 3678 virus for high-throughput neutralization and antiviral testing. Altogether, the results
36 suggest that Δ 3678 SARS-CoV-2 may serve as a live-attenuated vaccine candidate and a
37 research tool for potential biosafety level-2 use.

38

39 **Introduction**

40 The pandemic of COVID-19, caused by SARS-CoV-2, has led to over 395 million confirmed
41 infections and 5.7 million deaths (as of February 6, 2022; <https://coronavirus.jhu.edu/>). Different
42 vaccine platforms have been successfully developed for COVID-19 at an unprecedented pace,
43 including mRNA, viral vector, subunit protein, and inactivated virus. Live-attenuated vaccines of
44 SARS-CoV-2 have not been actively explored, even though they may have advantages of low
45 cost, strong immunogenicity, and long immune durability. The SARS-CoV-2 virion consists of an
46 internal nucleocapsid, formed by the genomic RNA coated with nucleocapsid (N) proteins, and
47 an external envelope, formed by a cell-derived bilipid membrane embedded with spike (S),
48 membrane (M), and envelope (E) proteins¹. The plus-sense, single-stranded viral RNA genome
49 encodes open-reading-frames (ORFs) for replicase (ORF1a/ORF1b), S, E, M, and N structural

50 proteins, as well as seven additional ORFs for accessory proteins². Although the exact functions
51 of SARS-CoV-2 accessory proteins remain to be determined, previous studies of other
52 coronaviruses suggest that these proteins are not essential for viral replication but can modulate
53 replication and pathogenesis through interacting with host pathways³⁻⁷. Thus, deletion of the
54 accessory proteins could be used to attenuate SARS-CoV-2.

55 Reverse genetic systems are important tools to engineer and study viruses. In response to
56 the COVID-19 pandemic, three types of reverse genetic systems have been developed for
57 SARS-CoV-2: (i) an infectious cDNA clone⁸⁻¹², (ii) a transient replicon (a self-replicating viral
58 RNA with one or more genes deleted)^{13,14}, and (iii) a *trans*-complementation system (replicon
59 RNAs in cells that express the missing genes in the replicon, allowing for single cycle replication
60 without spread)¹⁵⁻¹⁷. The three systems have their own strengths and weaknesses and are
61 complementary to each other when applied to address different research questions. The
62 infectious cDNA clone requires biosafety level-3 (BSL-3) containment to recover and handle
63 infectious SARS-CoV-2. The transient replicon system requires RNA preparation and
64 transfection for each experiment; cell lines harboring replicons that can be continuously
65 cultured, like those developed for hepatitis C virus and other plus-sense RNA viruses¹⁸⁻²⁰, have
66 yet to be established for SARS-CoV-2. The *trans*-complementation system produces virions that
67 can infect naïve cells for only a single round. Compared with the infectious cDNA clone, both
68 the replicon and *trans*-complementation system have the advantage of allowing experiments to
69 be performed at biosafety level-2 (BSL-2). A new system that combines the strengths of the
70 current three systems (*e.g.*, multiple rounds of viral infection of naïve cells that can be
71 performed at BSL2) would be very useful for COVID-19 research and countermeasure
72 development. Here we report a highly attenuated SARS-CoV-2 (with deleted accessory proteins
73 and rewired transcriptional regulator sequences) that can potentially serve as a live-attenuated
74 vaccine platform and a BSL-2 experimental system.

75

76 **Results**

77 **Attenuation of SARS-CoV-2 by deletion of accessory genes**

78 Using an infectious clone of USA-WA1/2020 SARS-CoV-2, we constructed two mutant
79 viruses containing accessory ORF deletions (**Fig. 1a**), one with ORF 6, 7, and 8 deletions
80 ($\Delta 678$) and another with ORF 3, 6, 7, and 8 deletions ($\Delta 3678$). Besides the ORF deletions, the
81 viral transcription regulatory sequences (TRS) of both $\Delta 678$ and $\Delta 3678$ viruses were mutated
82 from the wild-type (WT) ACGAAC to CCGGAT (mutant nucleotides underlined; **Fig. 1a**). The
83 mutated TRS virtually eliminates the possibility to produce WT SARS-CoV-2 through
84 recombination between the $\Delta 678$ or $\Delta 3678$ RNA and inadvertently contaminating viral RNA^{21,22}.
85 On Vero-E6 cells, the $\Delta 678$ virus developed plaques similar to the WT virus, whereas the $\Delta 3678$
86 virus produced smaller plaques (**Fig. 1b**). Both $\Delta 678$ and $\Delta 3678$ viruses were visible under the
87 negative staining electron microscope (**Extended Data Fig. 1**). Replication kinetics analysis
88 showed that WT and $\Delta 678$ replicated to comparable viral titers on Vero-E6 (**Fig. 1c**), Calu-3
89 (**Fig. 1d**), and primary human airway epithelial (HAE) cultures (**Fig. 1e**). In contrast, the
90 replication of $\Delta 3678$ was slightly attenuated on Vero-E6 cells (**Fig. 1c**), but became significantly
91 more attenuated on Calu-3 (360-fold lower peak viral titer than WT virus at 72 h; **Fig. 1d**) and
92 HAE cultures (7,500-fold lower peak viral titer than WT virus on day 6; **Fig. 1e**). Consistently,
93 the intracellular level of $\Delta 3678$ RNA was about 100-fold lower than that of $\Delta 678$ RNA and WT in
94 HAE cells (**Fig. 1f**). Corroboratively, the $\Delta 3678$ virus caused much fewer cytopathic effects
95 (CPE) than the $\Delta 678$ and WT viruses on both Vero-E6 and Calu-3 cells (**Extended Data Fig. 2**).
96 To further confirm the attenuation of $\Delta 3678$ virus, we engineered the mNeonGreen (mNG) gene
97 into the $\Delta 3678$ and WT viruses²³. When infecting HAE cultures, the mNG $\Delta 3678$ virus
98 developed significantly fewer mNG-positive cells than the mNG WT virus (**Fig. 1g**). Taken
99 together, the results indicate that (i) deletions of ORFs 6, 7, and 8 slightly attenuate SARS-CoV-

100 2 in cell culture; (ii) an additional deletion of ORF3 to the Δ 678 virus significantly increases the
101 attenuation of Δ 3678; and (iii) the Δ 3678 virus is strikingly more attenuated when infecting
102 immune-competent cells than when infecting interferon-deficient cells.

103 **Characterization of Δ 3678 SARS-CoV-2 as a potential live-attenuated vaccine in a** 104 **hamster model**

105 We characterized the attenuation of Δ 3678 virus in a hamster model (**Fig. 2a**). After intranasal
106 infection with 10^6 plaque-forming units (PFU) of Δ 3678, the hamsters did not lose weight (**Fig.**
107 **2b**) or develop disease (**Fig. 2c**). In contrast, the WT virus-infected animals lost weight (**Fig. 2b**)
108 and developed disease (**Fig. 2c**), as observed in our previous studies²⁴⁻²⁶. On day 2 post-
109 infection, viral loads in the Δ 3678-infected nasal washes (**Fig. 2d**), oral swabs (**Fig. 2e**),
110 tracheae, and lungs (**Fig. 2f**) were 180-, 20-, 16-, and 100-fold lower than those in the WT-
111 infected specimens. The Δ 3678 infection elicited robust neutralization with a peak 50%
112 neutralization titer (NT₅₀) of 1,090 on day 21 post-infection, while the WT virus evoked 1.4-fold
113 higher peak NT₅₀ (**Fig. 2g**). The results demonstrate that the Δ 3678 virus is attenuated and can
114 elicit robust neutralization in hamsters.

115 We examined whether the above immunized hamsters could be protected from SARS-CoV-
116 2 challenge. After intranasal challenge with 10^5 PFU of WT SARS-CoV-2 on day 28 post-
117 immunization (**Fig. 2a**), both the Δ 3678- and WT virus-immunized animals were protected from
118 weight loss (**Fig. 3a**) or disease (**Fig. 3b**). Compared with the mock-immunized group, the viral
119 loads in the nasal washes (**Fig. 3c**) and oral swabs (**Fig. 3d**) from the Δ 3678- and WT virus-
120 immunized groups were decreased by >660 (day 2) and >80 folds (day 2), respectively; no
121 infectious viruses were detected in trachea (**Fig. 3e**) and lungs (**Fig. 3f**) from the immunized
122 groups. The challenge significantly increased the neutralization titers (on day 21 post-challenge)
123 in both the Δ 3678- and WT virus-immunized groups (**Fig. 3g**), suggesting that a single infection
124 with the Δ 3678 or WT virus did not elicit sterilizing immunity. Histopathology analysis showed

125 that immunization with attenuated $\Delta 3678$ virus reduced lung pathology score, inflammation,
126 alveolar septa change, and airway damage (**Extended Data Fig. 3**). In contrast, previous
127 infection with WT virus did not exhibit improved lung histopathology after the challenge, possibly
128 because the observed pathologic changes were caused by the initial WT viral infection
129 (**Extended Data Fig. 3**). Collectively, the results demonstrate that immunization with attenuated
130 $\Delta 3678$ virus can protect against WT SARS-CoV-2 challenge in hamsters.

131 Next, we tested whether lower dose immunization could also achieve protection. Hamsters
132 were immunized with 10^2 , 10^3 , 10^4 , or 10^5 PFU of $\Delta 3678$ virus. No weight loss was observed for
133 all dose groups (**Extended Data Fig. 4a**). All dose groups developed equivalent, low lung viral
134 loads (**Extended Data Fig. 4b**). After challenge with WT SARS-CoV-2, all dose groups
135 exhibited protection similar to the 10^6 -PFU-dose group, including undetectable viral loads in the
136 tracheae or lungs and significantly reduced viral loads in the nasal washes and oral swabs
137 (**Extended Data Fig. 4c**). These results indicate a low dose of 10^2 PFU of $\Delta 3678$ immunization
138 is protective in hamsters.

139 Since infectious viruses were detected in the nasal and oral specimens from the $\Delta 3678$ -
140 immunized hamsters after the challenge, we examined whether such low levels of virus could
141 be transmitted to naïve hamsters. On day 1 post-challenge, the $\Delta 3678$ -immunized-and-
142 challenged animals (donor) were co-housed with clean naïve hamsters (recipient) for 8 h, after
143 which the donor and recipient animals were separated (**Fig. 3h**). As expected, after WT virus
144 challenge, no weight loss was observed in the $\Delta 3678$ -immunized donor animals, but weight loss
145 did occur in the mock-immunized donor animals (**Fig. 3i**). After co-housing with $\Delta 3678$ -
146 immunized-and-challenged donor animals, naïve recipient animals did not lose weight (**Fig. 3j**)
147 and did not have infectious viruses in the nasal washes (**Fig. 3k**). In contrast, after co-housing
148 with the mock-immunized-and-challenged donor animals, the recipient animals lost weight (**Fig.**
149 **3j**) and developed high viral loads in the nasal wash (**Fig. 3k**). Altogether, the results indicate

150 that although the Δ 3678-immunized donor animals developed low viral loads in their nasal and
151 oral specimens after the WT virus challenge, they were unable to transmit the virus to clean
152 naïve hamsters.

153 **Attenuation of Δ 3678 SARS-CoV-2 in K18-hACE2 mice**

154 To further characterize the attenuation of Δ 3678, we intranasally inoculated K18-hACE2
155 mice with 4, 40, 400, 4,000, or 40,000 PFU of WT or Δ 3678 virus (**Fig. 4a**). The infected groups
156 were compared for their weight loss, survival rates, and disease signs. The WT viral infection
157 caused weight loss at doses of \geq 400 PFU (**Fig. 4b**), diseases at dose \geq 400 PFU (**Fig. 4d**), and
158 deaths at doses \geq 4,000 PFU (**Fig. 4f**). In contrast, the Δ 3678 virus caused slight (statistically
159 insignificant) weight loss at 40,000 PFU (**Fig. 4c**), transient disease at \geq 4,000 PFU (**Fig. 4e**),
160 and no death at any dose (**Fig. 4g**). Consistently, the lung viral loads from the Δ 3678-infected
161 mice were significantly lower than those from the WT-infected animals (**Fig. 4h**). The results
162 demonstrated that Δ 3678 virus was highly attenuated in the K18-hACE2 mice.

163 **Genetic stability of Δ 3678 SARS-CoV-2 on Vero-E6 cells**

164 Given the potential of Δ 3678 as a live-attenuated vaccine, we examined its genetic stability
165 by continuously culturing the virus for five rounds on Vero-E6 cells. Three independent, parallel
166 passaging experiments were performed to assess the consistency of adaptive mutations
167 (**Extended Data Figure 5a**). The passage 5 (P5) virus developed bigger plaques than the
168 original P0 virus (**Extended Data Figure 5b**). Full-genome sequencing of the P5 viruses
169 identified an H655Y substitution in the spike protein and a 675-679 QTQTN spike deletion from
170 all three passage series (**Extended Data Figure 5c**). The substitution and deletion are located
171 immediately upstream of the furin cleavage site between the spike 1 and 2 subunits. Previous
172 studies showed that culturing of SRAS-CoV-2 on Vero cells expressing serine protease
173 TMPRSS2 could eliminate such mutations/deletions²⁶⁻²⁸. Alternatively, to meet the genetic
174 stability required by regulatory agencies, we can engineer the recovered mutations and

175 deletions into our infectious clone to stabilize the vaccine candidate for large-scale production
176 on Vero-E6 cells.

177 **Contribution of individual ORFs to the attenuation of Δ 3678 virus**

178 To define the role of each ORF in attenuating Δ 3678 virus, we prepared a panel of mutant
179 viruses in the backbone of a mouse-adapted SARS-CoV-2 (MA-SARS-CoV-2) that can robustly
180 infect BALB/c mice²⁹. Each mutant virus contained a single accessory gene deletion, including
181 Δ 3a, Δ 3b, Δ 6, Δ 7a, Δ 7b, or Δ 8. Among all the individual deletion mutants, Δ 3a virus developed
182 the smallest plaques on Vero-E6 cells (**Extended Data Figure 6**). The biological importance of
183 each deleted gene was analyzed by viral replication in the lungs after intranasal infection of
184 BALB/c mice (**Fig. 5a**). On day 2 post-infection, deletion of Δ 3a, Δ 3b, Δ 6, Δ 7b, or Δ 8 reduced
185 viral loads in lungs, among which Δ 3a exhibited the largest reduction (**Fig. 5b**). To further
186 confirm the critical role of Δ 3a in viral attenuation, we compared the replication kinetics of Δ 3a
187 and WT MA-SARS-CoV-2 on Vero-E6 (**Fig. 5c**), Calu-3 (**Fig. 5d**), and HAE cultures (**Fig. 5e**).
188 The replication of Δ 3a was significantly more attenuated in immune-competent Calu-3 and HAE
189 cells than in interferon-deficient Vero-E6 cells (**Fig. 5c-e**). Taken together, the results indicate
190 that Δ 3a played a major role in attenuating the Δ 3678 virus, possibly through the type-I
191 interferon pathway.

192 **ORF3a antagonizes type-I interferon signaling through inhibiting STAT1 phosphorylation**

193 To define the mechanism of Δ 3a-mediated viral attenuation, we infected human lung A549
194 cells, expressing the human ACE2 receptor (A549-hACE2), with Δ 3a or WT MA-SARS-CoV-2.
195 Although the replication of Δ 3a was lower than that of the WT virus, comparable levels of IFN- α
196 RNA were produced (**Fig. 5f**). Significantly higher levels of interferon-stimulating genes (ISGs),
197 such as IFITM1, ISG56, OAS1, and PKR, were detected in the Δ 3a virus-infected cells than in
198 the WT virus-infected cells (**Fig. 5f**), suggesting a role of ORF3a in suppressing type-I interferon
199 signaling. To further support this conclusion, we treated the A549-hACE cells with IFN- α

200 followed by Δ 3a or WT virus infection. Western blot analysis showed that the phosphorylation of
201 STAT1 was less efficient in the Δ 3a-infected cells than the WT-infected cells, whereas no
202 difference in STAT2 phosphorylation was observed (**Fig. 5g**). Thus, the results indicate that
203 ORF3a protein suppresses STAT1 phosphorylation during type-I interferon signaling.

204 **An mNG reporter Δ 3678 virus for neutralization and antiviral testing**

205 The *in vitro* and *in vivo* attenuation results suggest that Δ 3678 virus may serve as a
206 research tool for BSL-2 use. To further develop this tool, we engineered an mNG gene (driven
207 by its own TRS sequence) between the M and N genes of the Δ 3678 genome, resulting in mNG
208 Δ 3678 virus (**Fig. 6a**). For high-throughput neutralization testing, we developed the mNG Δ 3678
209 virus into a fluorescent focus reduction neutralization test (FFRNT) in a 96-well format. When
210 infecting Vero-E6 cells, the mNG Δ 3678 developed fluorescent foci that could be quantified by
211 high content imaging (**Fig. 6b**). **Fig. 6c** shows the FFRNT curves for one COVID-19
212 convalescent positive serum one negative serum. To validate the FFRNT assay, we tested 20
213 convalescent sera against the mNG Δ 3678 virus. For comparison, the same serum panel was
214 tested against the WT SARS-CoV-2 (without mNG) using the gold-standard plaque-reduction
215 neutralization test (PRNT)²³. The 50% reduction neutralization titers (NT₅₀) correlated well
216 between the FFRNT and PRNT assays (**Fig. 6d**). The geometric mean of FFRNT₅₀/PRNT₅₀ ratio
217 was 0.57 for the tested serum panel (**Fig. 6e**). Next, we developed the reporter mNG Δ 3678
218 virus into a high-throughput antiviral assay. Treatment of the mNG Δ 3678 virus-infected A549-
219 hACE2 cells with remdesivir diminished the appearance of mNG-positive cells (**Fig. 6f**). Dose-
220 responsive antiviral curves were reliably obtained for the small molecule remdesivir (**Fig. 6g**)
221 and for a monoclonal antibody (**Fig. 6h**). Overall, the results demonstrate that mNG Δ 3678 virus
222 could be used for high-throughput neutralization and antiviral testing.

223

224 **Discussion**

225 We have developed $\Delta 3678$ SARS-CoV-2 as a potential live-attenuated vaccine candidate.
226 The $\Delta 3678$ virus could replicate to titers $>5.6 \times 10^6$ PFU/ml on interferon-incompetent Vero-E6
227 cells (**Fig. 1c**), making large-scale production feasible in this vaccine manufacture-approved cell
228 line. In contrast, the $\Delta 3678$ virus was highly attenuated when infecting immune-competent cells,
229 as evidenced by the 7,500-fold reduction in viral replication than WT virus on human primary
230 HAE cells (**Fig. 1e**). In both hamster and K18-hACE2 mouse models, the $\Delta 3678$ infection did
231 not cause significant weight loss or death at the highest tested infection dose [10^6 PFU for
232 hamsters (**Fig. 2b**) and 4×10^4 PFU for K18-hACE2 mice (**Fig. 4c, g**)], whereas the WT virus
233 caused weight loss and death at a much lower infection dose ($>4 \times 10^2$ PFU for K18-hACE2
234 mice; **Fig. 4b, f**). Analysis of individual ORF-deletion viruses identified ORF3a as a major
235 accessory protein responsible for the attenuation of the $\Delta 3678$ virus (**Fig. 5b**); this conclusion
236 was further supported by the observation that the addition of $\Delta 3a$ to the $\Delta 678$ virus significantly
237 increased the attenuation of $\Delta 3678$ replication (**Fig. 1c-g**). Our results are supported by a recent
238 study reporting that $\Delta 3a$ SARS-CoV-2 and, to a less extent, $\Delta 6$ SARS-CoV-2 were attenuated
239 in the K18 human ACE2 transgenic mice³⁰. Mechanistically, we found that ORF3a protein
240 antagonized the innate immune response by blocking STAT1 phosphorylation during type-I
241 interferon signaling. Thus, the deletion of ORF3a conferred SARS-CoV-2 more susceptible to
242 type-I interferon suppression. These findings have uncovered a previously uncharacterized role
243 of ORF3a in the context of SARS-CoV-2 infection. The ORF3a protein was recently shown to
244 form a dimer in cell membrane with an ion channel activity³¹, which may account for its role in
245 cell membrane rearrangement, inflammasome activation, and apoptosis³²⁻³⁴. Whether the ion
246 channel activity of ORF3a is required for the inhibition of STAT1 phosphorylation remains to be
247 determined.

248 The attenuated $\Delta 3678$ virus may be pivoted for a veterinarian vaccine. SARS-CoV-2 can
249 infect a variety of animal species, among which cats, ferrets, fruit bats, hamsters, minks,

250 raccoon dogs, and white-tailed deer were reported to spread the infection to other animals of
251 the same species³⁵⁻³⁹, and potentially spillback to humans. A live-attenuated $\Delta 3678$ vaccine may
252 be useful for the prevention and control of SARS-CoV-2 on mink farms⁴⁰. Since zoonotic
253 coronaviruses may recombine with the live-attenuated vaccine in immunized animals, we
254 engineered the $\Delta 3678$ viruses with mutated TRS to eliminate the possibility of recombination-
255 mediated emergence of WT or replicative chimeric coronaviruses (**Fig. 1a**). This mutated TRS
256 approach was previously shown to attenuate SARS-CoV and to prevent reversion of the WT
257 virus^{21,22}. Given the continuous emergence of SARS-CoV-2 variants, we could update the
258 vaccine antigen by swapping the variant spike glycoproteins into the current $\Delta 3678$ virus
259 backbone.

260 The attenuated $\Delta 3678$ virus could serve as a research tool that might be used at BSL-2.
261 Using mNG as an example, we developed an mNG $\Delta 3678$ virus for high throughput testing of
262 antibody neutralization and antiviral inhibitors (**Fig. 6**). Depending on research needs, other
263 reporter genes, such as luciferase or other fluorescent genes, could be engineered into the
264 system. This high-throughput assay can be modified for testing neutralization against different
265 variants by swapping the variant spike genes into the $\Delta 3678$ backbone. The approach has been
266 successfully used to study vaccine-elicited neutralization against variants in the context of
267 complete SARS-CoV-2⁴¹⁻⁴³. Finally, our *in vitro* and *in vivo* attenuation results support the
268 possible use of the $\Delta 3678$ virus at BSL-2. If further attenuation is needed, more mutations, such
269 as inactivating the NSP16 2'-O methyltransferase activity⁴⁴, can be rationally engineered into
270 the $\Delta 3678$ virus.

271 One limitation of the current study is that we have not defined the attenuation mechanisms
272 of the ORF 3b, 6, 7b, or 8 deletion, even though they reduced the lung viral loads in the K18-
273 hACE2 mice (**Fig. 5b**). SARS-CoV-2 ORF8 protein was recently reported to contain a histone
274 mimic that could disrupt chromatin regulation and enhance viral replication⁴⁵. Truncations or

275 deletions of ORF7b and ORF8 were reported in SARS-CoV-2 clinical isolates^{46,47}. Future
276 studies are needed to understand the molecular functions of OFR 3b, 6, and 7b proteins.
277 Nevertheless, our results indicate that Δ 3678 virus could serve as a live-attenuated vaccine
278 candidate and as an experimental system that can likely be performed at BSL-2 for COVID-19
279 research and countermeasure development.

280

281 **Method**

282 **Ethics statement**

283 Hamster and mouse studies were performed in accordance with the guidance for the
284 Care and Use of Laboratory Animals of the University of Texas Medical Branch (UTMB).
285 The protocol was approved by the Institutional Animal Care and Use Committee
286 (IACUC) at UTMB. All the animal operations were performed under anesthesia by
287 isoflurane to minimize animal suffering. The use of human COVID-19 sera was
288 reviewed and approved by the UTMB Institutional Review Board (IRB#: 20-0070). The
289 convalescent sera from COVID-19 patients (confirmed by the molecular tests with
290 FDA's Emergency Use Authorization) were leftover specimens and completely de-
291 identified from patient information. The serum specimens were heat-inactivated at 56°C
292 for 30 min before testing.

293 **Animals and Cells**

294 The Syrian golden hamsters (HsdHan:AURA strain) were purchased from Envigo
295 (Indianapolis, IN). K18-hACE2 mice were purchased from the Jackson Laboratory (Bar
296 Harbor, ME). BALB/c mice were purchased from Charles River Laboratories
297 (Wilmington, MA). African green monkey kidney epithelial Vero-E6 cells (laboratory-

298 passaged derivatives from ATCC CRL-1586) were grown in Dulbecco's modified
299 Eagle's medium (DMEM; Gibco/Thermo Fisher, Waltham, MA, USA) with 10% fetal
300 bovine serum (FBS; HyClone Laboratories, South Logan, UT) and 1%
301 antibiotic/streptomycin (P/S, Gibco). Vero-E6-TMPRSS2 cells were purchased from
302 SEKISUI XenoTech, LLC (Kansas City, KS) and maintained in 10% fetal bovine serum
303 (FBS; HyClone Laboratories, South Logan, UT) and 1% P/S and 1 mg/ml G418 (Gibco).
304 The A549-hACE2 cells that stably express hACE2 were grown in the DMEM
305 supplemented with 10% fetal bovine serum, 1% P/S and 1% 4-(2-hydroxyethyl)-1-
306 piperazineethanesulfonic acid (HEPES); ThermoFisher Scientific) and 10 μ g/mL
307 Blastidicin S. Human lung adenocarcinoma epithelial Calu-3 cells (ATCC, Manassas,
308 VA, USA) were maintained in a high-glucose DMEM containing sodium pyruvate and
309 GlutaMAX (Gibco) with 10% FBS and 1% penicillin/streptomycin at 37°C with 5% CO₂.
310 The EpiAirway system is a primary human airway 3D tissue model purchased from
311 MatTek Life Science (Ashland, MA, USA). All cells were maintained at 37°C with 5%
312 CO₂. All cell lines were verified and tested negative for mycoplasma.

313 **Generation of SARS-CoV-2 mutant viruses**

314 (1) Generate mutant viruses with accessory ORF deletions. The ORF 6, 7, and 8
315 deletions (Δ 678) and ORF 3, 6, 7, and 8 deletions (Δ 3678) were constructed by overlap
316 PCR using an infection clone of USA-WA1/2020 SARS-CoV-2⁸. The Δ 3a, Δ 3b, Δ 6, Δ 7a,
317 Δ 7b, Δ 8 mutants were engineered into an infection clone of a mouse-adapted SARS-CoV-2
318 (MA-SARS-CoV-2)²⁹ using a standard molecular cloning protocol. For generating Δ ORF6 and
319 Δ ORF8 mutants, an overlapping PCR strategy was used to delete the ORF and the upstream
320 transcriptional regulatory sequence (TRS). For generating Δ ORF3a and Δ ORF7a mutants, the

321 complete ORF3 and ORF7 were replaced with the ORF3b- and ORF7b-coding sequence,
322 respectively. For generating Δ ORF3b mutant, several nonsense mutations were introduced into
323 MA-SARS-CoV-2 to disrupt the initiation codon of ORF3b without affecting the translation of
324 ORF3a (*i.e.*, the change of sequence from wild-type TATGATG to mutant TACGACG; ORF3b-
325 coding sequence is underlined). For producing Δ ORF7b mutant, the initiation codon of ORF7b
326 was disrupted, and the ORF7b gene was deleted from the fifth nucleotide position onward. (2)
327 Generate reporter viruses with accessory ORF deletions. The mNG WT and mNG
328 Δ 3678 SARS-CoV-2s were generated by engineering the mNeonGreen (mNG) gene
329 into the ORF7 position of the WT and Δ 3678 viruses. The mutant infectious clones were
330 assembled by *in vitro* ligation of contiguous DNA fragments following the protocol
331 previously described⁴⁸. *In vitro* transcription was then performed to synthesize genomic
332 RNA. For recovering the viruses, the RNA transcripts were electroporated into Vero-E6
333 cells. The viruses from electroporated cells were harvested at 40 h post-electroporation
334 and served as P0 stocks. All viruses were passaged once on Vero-E6 cells for
335 subsequent experiments and sequenced after RNA extraction to confirm no undesired
336 mutations. Viral titers were determined by plaque assay on Vero-E6 cells. All virus
337 preparation and experiments were performed in a BSL-3 facility. Viruses and plasmids
338 are available from the World Reference Center for Emerging Viruses and Arboviruses
339 (WRCEVA) at the University of Texas Medical Branch.

340 **RNA extraction, RT-PCR, and cDNA sequencing**

341 Cell culture supernatants or clarified tissue homogenates were mixed with a five-fold
342 excess of TRIzol™ LS Reagent (Thermo Fisher Scientific, Waltham, MA). Viral RNAs
343 were extracted according to the manufacturer's instructions. The extracted RNAs were

344 dissolved in 20 μ l nuclease-free water. For sequence validation of mutant viruses, 2 μ l
345 of RNA samples were used for reverse transcription by using the SuperScript™ IV First-
346 Strand Synthesis System (Thermo Fisher Scientific) with random hexamer primers.
347 Nine DNA fragments flanking the entire viral genome were amplified by PCR. The
348 resulting DNAs were cleaned up by the QIAquick PCR Purification Kit, and the genome
349 sequences were determined by Sanger sequencing at GENEWIZ (South Plainfield, NJ).

350 **Viral infection of cell lines**

351 Approximately 3×10^5 Vero-E6 or Calu-3 cells were seeded onto each well of 12-well
352 plates and cultured at 37°C, 5% CO₂ for 16 h. SARS-CoV-2 WT or mutant viruses were
353 inoculated onto Vero-E6 and Calu-3 cells at an MOI of 0.01 and 0.1, respectively. After
354 2 h infection at 37°C with 5% CO₂, the cells were washed with DPBS 3 times to remove
355 any detached virus. One milliliter of culture medium was added to each well for the
356 maintenance of the cells. At each time point, 100 μ l of culture supernatants were
357 collected for detection of virus titer, and 100 μ l of fresh medium was added into each
358 well to replenish the culture volume. The cells were infected in triplicate for each group
359 of viruses. All samples were stored at -80°C until analysis.

360 **Viral infection in a primary human airway cell culture model**

361 The EpiAirway system is a primary human airway 3D mucociliary tissue model
362 consisting of normal, human-derived tracheal/bronchial epithelial cells. For viral
363 replication kinetics, WT or mutant viruses were inoculated onto the culture at an
364 indicated MOI in DPBS. After 2 h infection at 37°C with 5% CO₂, the inoculum was
365 removed, and the culture was washed three times with DPBS. The infected epithelial
366 cells were maintained without any medium in the apical well, and the medium was

367 provided to the culture through the basal well. The infected cells were incubated at
368 37°C, 5% CO₂. From 1-7 days, 300 µl of DPBS were added onto the apical side of the
369 airway culture and incubated at 37°C for 30 min to elute the released viruses. All virus
370 samples in DPBS were stored at –80°C.

371 **Quantitative real-time RT-PCR assay**

372 RNA copies of SARS-CoV-2 samples were detected by quantitative real-time RT-PCR
373 (RT-qPCR) assays were performed using the iTaq SYBR Green One-Step Kit (Bio-Rad)
374 on the LightCycler 480 system (Roche, Indianapolis, IN) following the manufacturer's
375 protocols. The absolute quantification of viral RNA was determined by a standard curve
376 method using an RNA standard (*in vitro* transcribed 3,480 bp containing genomic
377 nucleotide positions 26,044 to 29,883 of SARS-CoV-2 genome).

378 **Hamster immunization and challenge assay**

379 Four- to six-week-old male golden Syrian hamsters, strain HsdHan:AURA (Envigo,
380 Indianapolis, IN), were immunized intranasally with 100 µl WT virus (10⁶ PFU, n=20) or
381 Δ3678 mutant virus (10⁶ PFU, n=20). Animals received DMEM media (supplemented
382 with 2% FBS and 1% penicillin/streptomycin) served as Mock group (n=20). On day 28,
383 the animals were challenged with 10⁵ PFU of WT SARS-CoV-2. The animals were
384 weighed and monitored for signs of illness daily. Nasal washes and oral swabs were
385 collected in 400 µl sterile DPBS and 1 ml DMEM media at indicated time points. For
386 organ collection, animals were humanely euthanized on days 2, 30, and 32, tracheae
387 and lungs were harvested and placed in a 2-ml homogenizer tube containing 1 ml of
388 DMEM media. On day 49, animals were humanely euthanized for blood collection,

389 serum were then isolated for neutralization titer (NT₅₀) detection. The NT₅₀ values were
390 determined using an mNG USA-WA1/2020 SARS-CoV-2 as previously reported²³.

391 To test if lower dose immunization could achieve protection, hamsters were
392 immunized with 10², 10³, 10⁴, or 10⁵ PFU of Δ3678 virus. Nasal washes, oral swabs and
393 organs were collected at indicated time points. The animals were weighed and
394 monitored for signs of illness daily.

395 **Hamster transmission assay**

396 Hamster transmission assay was performed per our previous protocol²⁴. Briefly,
397 hamsters were immunized intranasally with 10⁶ PFU Δ3678 mutant virus (n=5). Animals
398 who received DMEM media served as a mock group (n=5). On day 28 post-
399 immunization, the animals were challenged with 10⁵ PFU of WT SARS-CoV-2. One day
400 later, one infected donor animal was co-housed with one naïve animal for 8 h (5 pairs
401 for mock group, 5 pairs for Δ3678 group). After the 8-h contact, the donor and recipient
402 animals were separated and maintained in individual cages. Nasal washes were
403 collected at indicated time points. On day 42, animals were humanely euthanized for
404 blood collection.

405 **Mouse infection of Δ3678 virus**

406 Eight- to 10-week-old K18-hACE2 female mice were intranasally infected with 50 μl
407 different doses of WT or Δ3678 virus (4, 40, 400, 4,000, 40,000 PFU, n=10 per dose).
408 Animals received DMEM media served as a mock group. Lungs were collected on days
409 2, 4, and 7 post-infection. Animals were weighed and monitored for signs of illness daily
410 and were sacrificed on day 14.

411 To define the role of each ORF in attenuating $\Delta 3678$ virus, 8- to 10-week-old
412 BALB/c female mice were intranasally infected with 50 μ l WT mouse-adapted-SARS-
413 CoV-2 (10^4 PFU, n=10) or $\Delta 3a$, $\Delta 3b$, $\Delta 6$, $\Delta 7a$, $\Delta 7b$, $\Delta 8$ virus (10^4 PFU, n=10 per virus).
414 On day 2 post-infection, animals were humanely euthanized for lung collection.

415 **Histopathology**

416 Hamsters were euthanized with ketamine/xylazine injection and necropsy was
417 performed. The lungs were inspected for gross lesions and representative portions of
418 the lungs were collected in 10% buffered formalin for histology. Formalin-fixed tissues
419 were processed per a standard protocol, 4 μ m-thick sections were cut and stained with
420 hematoxylin and eosin (HE). The slides were imaged in a digital scanner (Leica Aperio
421 LV1). Lung sections were examined under light microscopy using an Olympus CX43
422 microscope for the extent of inflammation, size of inflammatory foci, and changes in
423 alveoli, alveolar septa, airways, and blood vessels. The blinded tissue sections were
424 semi-quantitatively scored for pathological lesions.

425 **Plaque assay**

426 Approximately 1.2×10^6 Vero-E6 cells were seeded to each well of 6-well plates and
427 cultured at 37°C, 5% CO₂ for 16 h. Virus was serially diluted in DMEM with 2% FBS and
428 200 μ l diluted viruses were transferred onto the monolayers. The viruses were
429 incubated with the cells at 37°C with 5% CO₂ for 1 h. After the incubation, overlay
430 medium was added to the infected cells per well. The overlay medium contained DMEM
431 with 2% FBS, 1% penicillin/streptomycin, and 1% sea-plaque agarose (Lonza,
432 Walkersville, MD). After a 2-day incubation, the plates were stained with neutral red

433 (Sigma-Aldrich, St. Louis, MO) and plaques were counted on a lightbox. The detection
434 limit of the plaque assay was 10 PFU/ml.

435 **Genetic stability of Δ 3678 SARS-CoV-2**

436 The P0 Δ 3678 SARS-CoV-2 was continuously cultured for five rounds on Vero-E6 cells.
437 Three independent passaging experiments were performed to assess the consistency
438 of adaptive mutations. The P5 viral RNAs from three independent replicates were
439 extracted and subjected to RT-PCR. Whole-genome sequencing was performed on RT-
440 PCR products. The mutations that occurred in the P5 Δ 3678 viruses were analyzed.

441 **ORF3a-mediated suppression of type-I interferon signaling**

442 A549-hACE2 cells were infected with WT or Δ ORF3a SARS-CoV-2 at an MOI of 1 for 1
443 h, after which the cells were washed twice with PBS and cultured in a fresh medium.
444 Intracellular RNAs were harvested at 24 h post-infection. Viral RNA copies and mRNA
445 levels of IFN- α , IFITM1, ISG56, OAS1, PKR, and GAPDH were determined by
446 quantitative RT-PCR. The housekeeping gene GAPDH was used to normalize mRNA
447 levels and the mRNA levels are presented as fold induction over mock samples. As a
448 positive control, uninfected cells were treated with 1,000 units/ml IFN- α for 24 h.

449 **Suppression of STAT1 phosphorylation by ORF3a protein**

450 A549-hACE2 cells were pre-treated with 1,000 units/ml IFN- α for 6 h. Mock-treated cells
451 were used as a control. Cells were infected with WT or Δ ORF3 SARS-CoV-2 at an MOI
452 1 for 1 h. Inoculums were removed; cells were washed twice with PBS; fresh media with
453 or without 1,000 units/ml IFN- α were added. Samples were collected at 24 h post-
454 infection by using 2 x Laemmli buffer (BioRad, #1610737) and analyzed by Western

455 blot. Recombinant human α -interferon (IF007) was purchased from Millipore
456 (Darmstadt, Germany). Anti-STAT1 (14994S, 1:1,000), anti-pSTAT1 (Y701) (7649S,
457 1:1,000), anti-STAT2 (72604S, 1:1,000), anti-pSTAT2 (Y690) (88410S, 1:1,000)
458 antibodies were from Cell Signaling Technology (Danvers, MA); anti-GAPDH (G9545,
459 1:1,000) antibodies were from Sigma-Aldrich; SARS-CoV-2 (COVID-19) nucleocapsid
460 antibody (NB100-56576, 1:1000) were from Novus Biologicals (CO, USA).

461 **Fluorescent focus reduction neutralization test (FFRNT)**

462 Neutralization titers of COVID-19 convalescent sera were measured by a fluorescent
463 focus reduction neutralization test (FFRNT) using mNG Δ 3678 SARS-CoV-2. Briefly,
464 Vero-E6 cells (2.5×10^4) were seeded in each well of black μ CLEAR flat-bottom 96-well
465 plate (Greiner Bio-one™). The cells were incubated overnight at 37°C with 5% CO₂. On
466 the following day, each serum was 2-fold serially diluted in the culture medium with the
467 first dilution of 1:20. Each serum was tested in duplicates. The diluted serum was
468 incubated with 100-150 fluorescent focus units (FFU) of mNG SARS-CoV-2 at 37°C for
469 1 h (final dilution range of 1:20 to 1:20,480), after which the serum-virus mixtures were
470 inoculated onto the pre-seeded Vero-E6 cell monolayer in 96-well plates. After 1 h
471 infection, the inoculum was removed and 100 μ l of overlay medium (DMEM
472 supplemented with 0.8% methylcellulose, 2% FBS, and 1% P/S) was added to each
473 well. After incubating the plates at 37°C for 16 h, raw images of mNG fluorescent foci
474 were acquired using Cytation™ 7 (BioTek) armed with 2.5 \times FL Zeiss objective with
475 widefield of view and processed using the software settings (GFP [469,525] threshold
476 4000, object selection size 50-1000 μ m). The foci in each well were counted and
477 normalized to the non-serum-treated controls to calculate the relative infectivities. The

478 curves of the relative infectivity versus the serum dilutions (log₁₀ values) were plotted
479 using Prism 9 (GraphPad). A nonlinear regression method with log (inhibitor) vs.
480 response-variable slope (four parameters) model (bottom and top parameters were
481 constrained to 0 and 100, respectively) was used to determine the dilution fold that
482 neutralized 50% of mNG SARS-CoV-2 (defined as FFRNT₅₀) in GraphPad Prism 9.
483 Each serum was tested in duplicates.

484 **Antiviral testing**

485 A549-hACE2 cells were used to evaluate the efficacy of a monoclonal antibody IgG14
486 and antiviral drug remdesivir. The sources of IgG14 and remdesivir were previously
487 reported^{9,49}. Briefly, A549-hACE2 cells (1.2×10^4) were seeded in each well of black
488 μ CLEAR flat-bottom 96-well plate (Greiner Bio-one™). The cells were incubated
489 overnight at 37°C with 5% CO₂. For antibody testing, on the following day, IgG14 was 3-
490 fold serially diluted and incubated with mNG Δ 3678 at 37°C for 1 h, after which the
491 antibody-virus mixtures were inoculated into the 96-well plates that were pre-seeded
492 A549-hACE2 cells. For antiviral testing, remdesivir was 3-fold serially diluted in DMSO
493 and further diluted as 100 folds in the culture medium containing mNG Δ 3678 virus.
494 Fifty μ l of the compound-virus mixture were immediately added to the cells at a final
495 MOI of 1.0. At 24 h post-infection, 25 μ l of Hoechst 33342 Solution (400-fold diluted in
496 Hank's Balanced Salt Solution; Gibco) were added to each well to stain the cell nucleus.
497 The plate was sealed with Breath-Easy sealing membrane (Diversified Biotech),
498 incubated at 37°C for 20 min, and quantified for mNG fluorescence on CX5 imager
499 (ThermoFisher Scientific). The raw images (2 \times 2 montage) were acquired using 4x
500 objective. The total cells (indicated by nucleus staining) and mNG-positive cells were

501 quantified for each well. Infection rates were determined by dividing the mNG-positive
502 cell number by total cell number. Relative infection rates were obtained by normalizing
503 the infection rates of treated groups to those of no-treated controls. The curves of the
504 relative infection rates versus the concentration were plotted using Prism 9 (GraphPad).
505 A nonlinear regression method was used to determine the concentration of antiviral that
506 suppress 50% of mNG fluorescence (EC_{50}). Experiment was tested in quadruplicates.

507 **Statistics**

508 Hamsters and mice were randomly allocated into different groups. The investigators
509 were not blinded to allocation during the experiments or to the outcome assessment. No
510 statistical methods were used to predetermine sample size. Descriptive statistics have
511 been provided in the figure legends. For *in vitro* replication kinetics, Kruskal–Wallis
512 analysis of variance was conducted to detect any significant variation among replicates.
513 If no significant variation was detected, the results were pooled for further comparison.
514 Differences between continuous variables were assessed with a non-parametric Mann–
515 Whitney test. The PFU and genomic copies were analyzed using an unpaired two-tailed
516 *t* test. The weight loss data were shown as mean \pm standard deviation and statistically
517 analyzed using two-factor analysis of variance (ANOVA) with Tukey's post hoc test. The
518 animal survival rates were analyzed using a mixed-model ANOVA using Dunnett's test
519 for multiple comparisons. Analyses were performed in Prism version 9.0 (GraphPad,
520 San Diego, CA).

521

522 **Acknowledgements**

523 We thank the colleagues at University of Texas Medical Branch (UTMB) for helpful discussions
524 during the course of this work. P.-Y.S. was supported by NIH grants HHSN272201600013C,
525 AI134907, AI145617, and UL1TR001439, and awards from the Sealy & Smith Foundation, the
526 Kleberg Foundation, the John S. Dunn Foundation, the Amon G. Carter Foundation, the Gilson
527 Longenbaugh Foundation, and the Summerfield Robert Foundation. V.D.M. was supported by

533 UTMB.

534

535 **Author contributions**

536 V.D.M., X.X., and P.-Y.S. conceived the study. Y.L., X.Z., J.L., H.X., J.Z., A.E.M., S.P.,
537 J.A.P., N.E.B., C.K., K.S.P., and X.X. performed the experiments. Y.L., X.Z., J.L., H.X., S.P.
538 N.E.P., A.B., P.R., V.D.M., K.S.P., X.X., S.C.W., and P.-Y.S. analyzed the results. V.D.M. and
539 P.R. provided critical reagents. Y.L., X.Z., J.L., H.X., V.D.M., K.S.P., X.X., S.C.W., and P.-Y.S.
540 wrote the manuscript.

541

542 **Competing interests**

543 The Shi laboratory has received funding support in sponsored research agreements from
544 Pfizer, Gilead, Novartis, GSK, Merck, IGM Biosciences, and Atea Pharmaceuticals. P.Y.S. is a
545 member of the Pfizer COVID Antiviral Medical Board, a member of the Scientific Advisory Board
546 of AbImmune, and a founder of FlaviTech.

547

548 **Data Availability**

549 The results presented in the study are available upon request from the corresponding
550 authors. The mNG reporter Δ 3678 SARS-CoV-2 will be deposited to the World Reference
551 Center for Emerging Viruses and Arboviruses (<https://www.utmb.edu/wrceva>) at UTMB for
552 distribution.

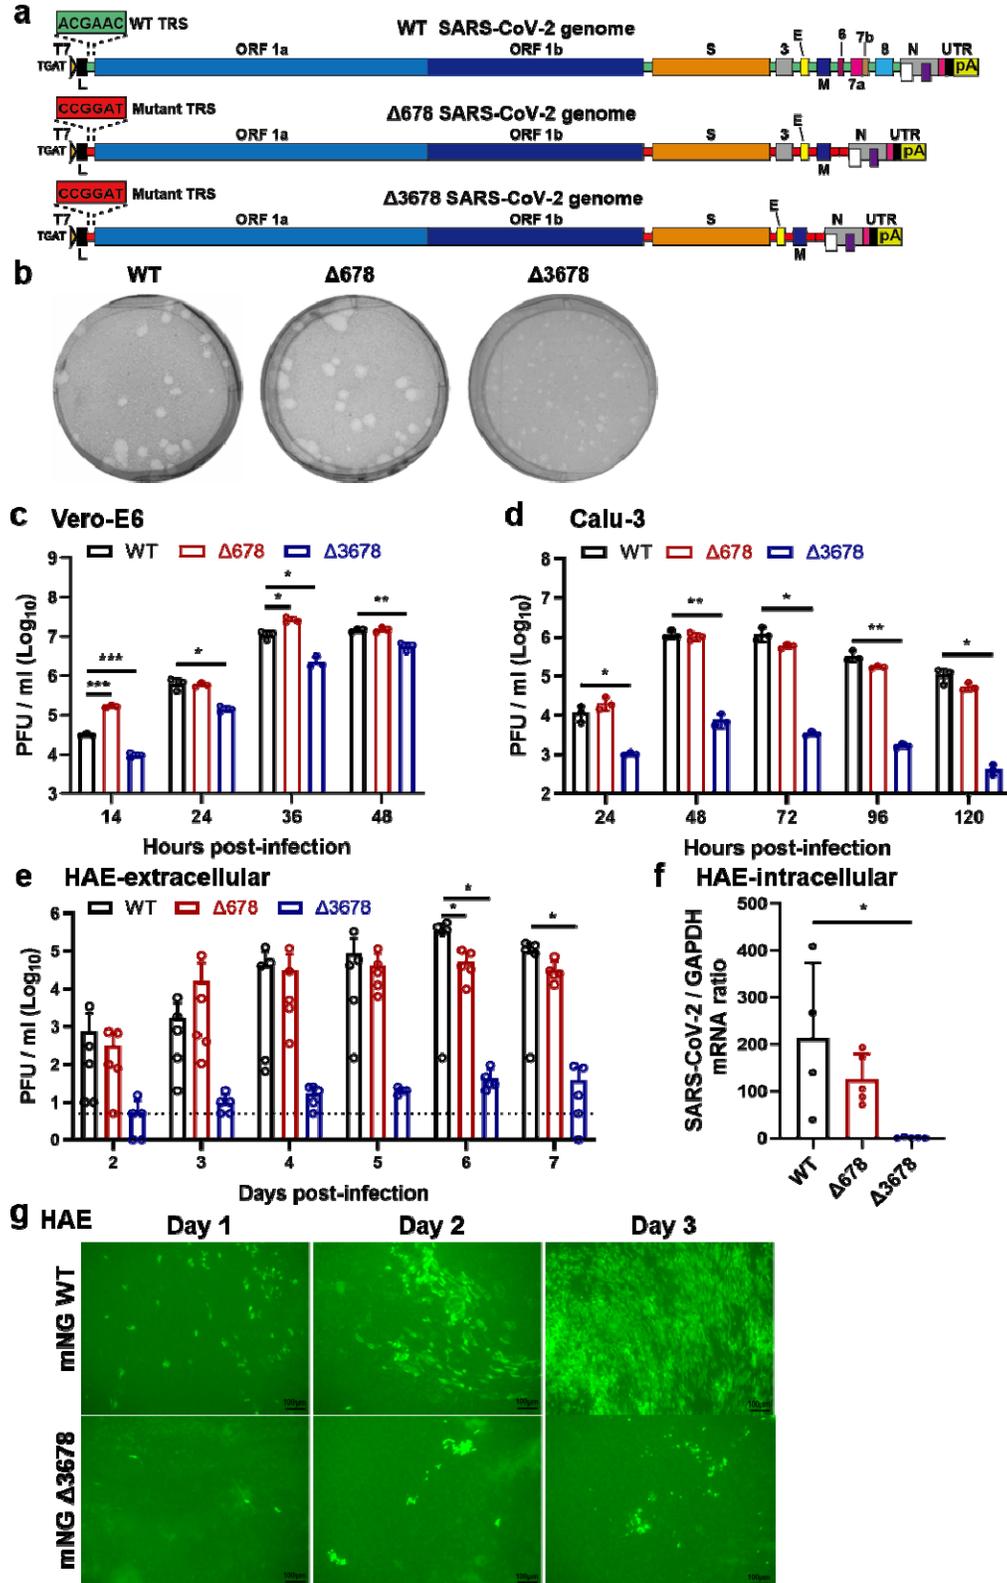

Figure 1. Attenuation of Δ3678 SARS-CoV-2 in cell culture.

a, Scheme diagram for the construction of Δ678 and Δ3678 SARS-CoV-2. The deletions

were introduced to the backbone of USA-WA1/2020 strain. T7, T7 promoter; L, leader sequence; TRS, transcription regulatory sequences; ORF, open reading frame; E, envelope glycoprotein gene; M, membrane glycoprotein gene; N, nucleocapsid gene; UTR, untranslated region; pA, poly A tails. **b**, Plaque morphologies of recombinant WT, $\Delta 678$, and $\Delta 3678$ viruses. Plaque assays were performed on Vero-E6 cells and stained on day 2.5 post-infection. **c-e**, Replication kinetics of WT, $\Delta 678$, and $\Delta 3678$ SARS-CoV-2s on Vero-E6 (**c**), Calu-3 (**d**), and HAE (**e**) cells. WT, $\Delta 678$, and $\Delta 3678$ viruses were inoculated onto Vero-E6, Calu-3, and HAE cells at MOIs of 0.01, 0.1, and 2, respectively. After a 2-h incubation, the cells were washed three times with DPBS and continuously cultured under fresh 2% FBS DMEM. Culture supernatants were measured for infectious virus titers using plaque assays on Vero-E6 cells. **f**, Intracellular levels of WT, $\Delta 678$, and $\Delta 3678$ RNA in HAE cells on day 7 post-infection. The HAE cells were washed with DPBS for three times, lysed by Trizol for RNA isolation, quantified for viral RNAs using RT-qPCR. Dots represent individual biological replicates (n=3 for Vero-E6 and Calu-3; n=5 for HAE). The values in the graph represent the mean \pm standard deviation. An unpaired two-tailed *t* test was used to determine significant differences between WT and $\Delta 678/\Delta 3678$ groups. *P* values were adjusted using the Bonferroni correction to account for multiple comparisons. Differences were considered significant if $p < 0.025$; $P < 0.025$, *; $P < 0.005$, **; and $P < 0.0005$, ***. **g**, mNG-positive HAE cells after infection with mNG WT or mNG $\Delta 3678$ virus at an MOI of 0.5. Scale bar, 100 μm .

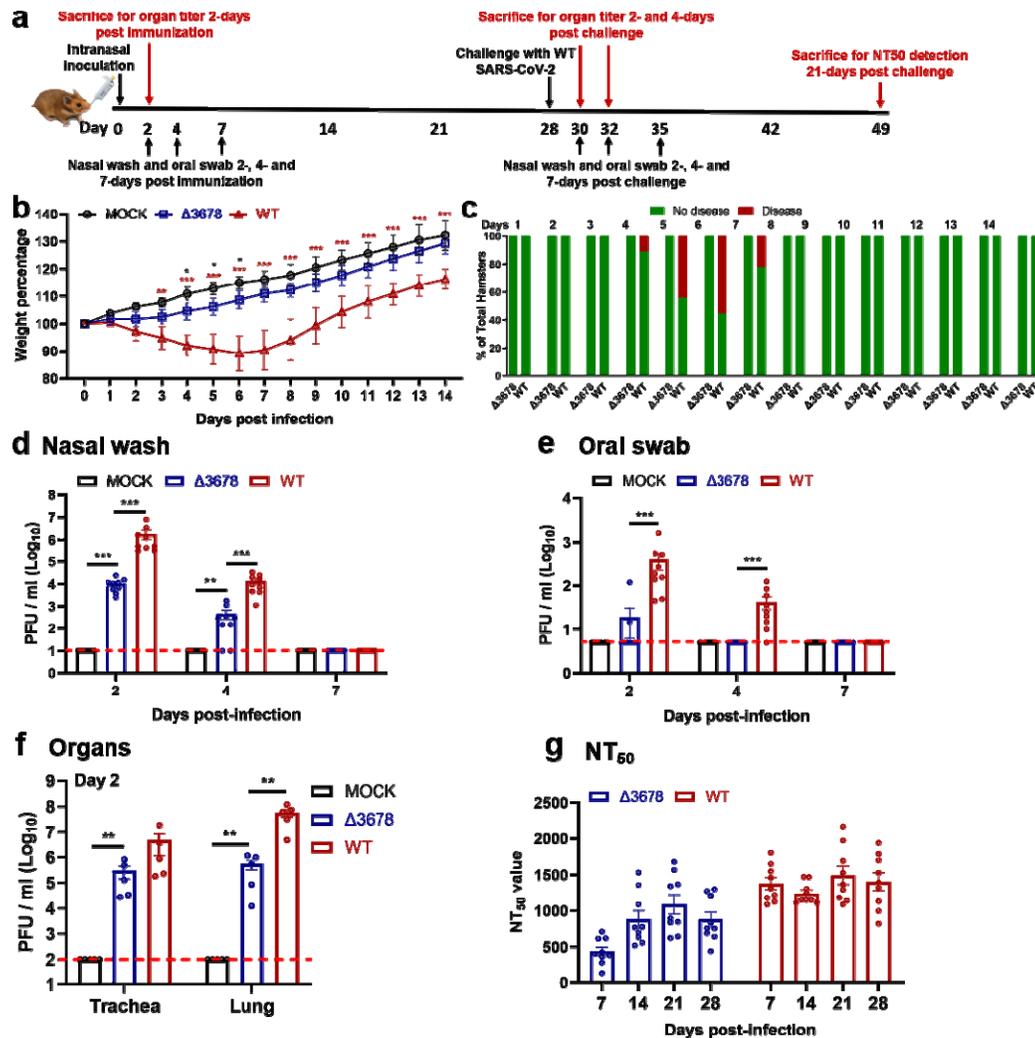

Figure 2. Attenuation of $\Delta 3678$ SARS-CoV-2 in hamsters.

a, Experimental scheme of $\Delta 3678$ virus immunization and WT virus challenge. Hamsters were intranasally (I.N.) inoculated with 10^6 PFU of WT or $\Delta 3678$ virus. On day 2 post-inoculation, organ viral loads ($n=5$) were measured by plaque assays on Vero-E6 cells. Nasal washes and oral swabs ($n=10$) were collected on days 2, 4, and 7 post-inoculation. On day 28 post-immunization, the hamsters were challenged by 10^5 PFU of WT SARS-CoV-2. On days 2 and 4 post-challenge, plaque assays were performed to measure organ viral loads ($n=5$). On day 21 post-challenge, the animals were terminated to measure neutralization titer (NT_{50}).

b, Weight changes of hamsters after intranasal infection with WT ($n=9$) or $\Delta 3678$ ($n=9$) SARS-CoV-2. Uninfected mock group ($n=9$) was included as a negative control. Body weights were measured daily for 14 days. The data are shown as mean \pm standard deviation. The weight changes between $\Delta 3678$ and mock or WT groups were analyzed using two-factor analysis of variance (ANOVA) with Tukey's post hoc test. The black and red asterisks stand for the statistic difference between $\Delta 3678$ and mock or WT, respectively. *, $P<0.05$; **, $P<0.01$; ***, $P<0.001$.

c, Disease of $\Delta 678$ and $\Delta 3678$ virus-infected animals. The diseases include ruffled fur, lethargic, hunched posture, and orbital tightening. The percentages of animals

with or without diseases are presented. **d-f**, Viral loads in nasal wash (**d**), oral swab (**e**), trachea, and lung (**f**) after infection with $\Delta 3678$ or WT virus. Dots represent individual animals ($n=5$). The mean \pm standard error is presented. A non-parametric two-tailed Mann-Whitney test was used to determine the differences between mock, $\Delta 3678$, or WT groups. P values were adjusted using the Bonferroni correction to account for multiple comparisons. Differences were considered significant if $p < 0.025$. *, $P < 0.025$; **, $P < 0.005$; ***, $P < 0.0005$. **g**, Neutralization titers of sera from WT- and $\Delta 3678$ virus-inoculated hamsters on days 7, 14, 21, and 28 post-inoculation. The neutralization titers were measured against WT SARS-CoV-2.

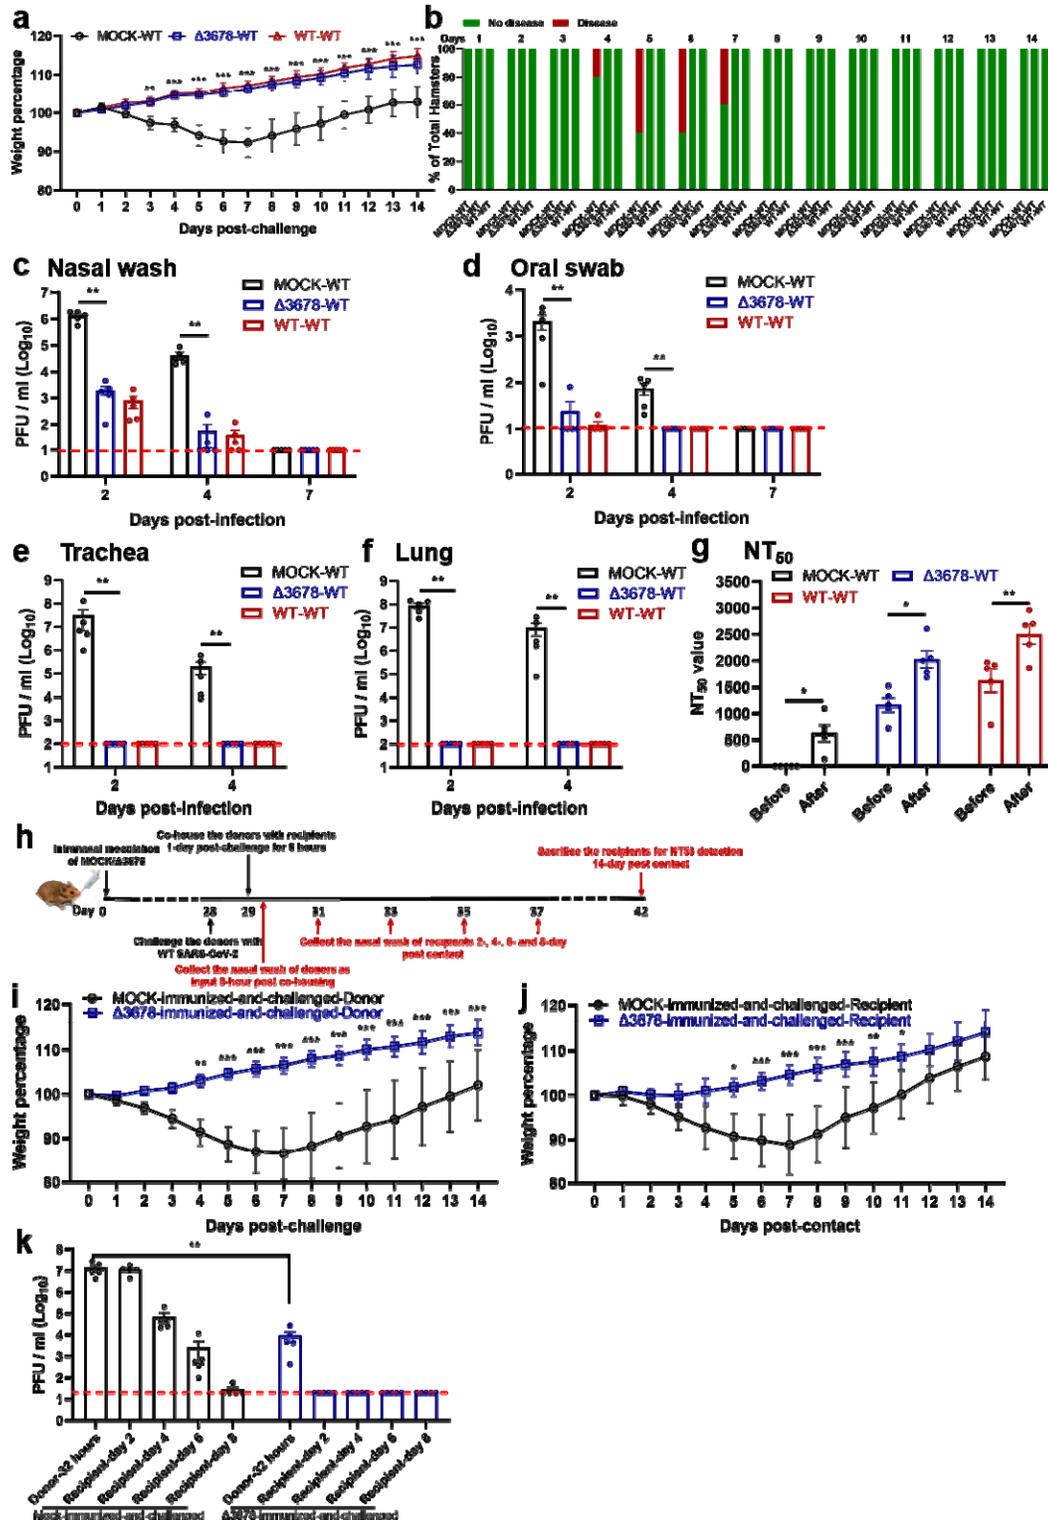

Figure 3. Protection of Δ3678 virus-immunized hamsters from WT SARS-CoV-2 challenge and transmission.

a, b, Weight loss (**a**) and diseases (**b**) of immunized and challenged hamsters. **a,**

Mock-immunized (n=5), Δ 3678 virus-immunized (n=5), and WT virus-inoculated (n=5) hamsters were challenged with 10^5 PFU of WT SARS-CoV-2. The body weights were measured daily for 14 days post-challenge. The data are shown as mean \pm standard deviation. The weight changes between Δ 3678- and mock- or WT-inoculated groups were statistically analyzed using two-factor analysis of variance (ANOVA) with Tukey's post hoc test. No statistical difference was observed between the Δ 3678- and WT-inoculated groups. The statistical difference between the Δ 3678- and mock-immunized groups are indicated. **, $P < 0.01$; ***, $P < 0.001$. **b**, After the challenge, animals developed diseases, including ruffled fur, lethargic, hunched posture, and orbital tightening. The percentages of animals with or without diseases were presented. **c-f**, Viral loads in the nasal wash (**c**), oral swab (**d**), trachea (**e**), and lung (**f**) after challenge. Dots represent individual animals (n=5). The values of mean \pm standard error of the mean are presented. A non-parametric two-tailed Mann-Whitney test was used to determine the statistical differences between Δ 3678-immunized and mock-immunized or WT-inoculated groups. *P* values were adjusted using the Bonferroni correction to account for multiple comparisons. Differences were considered significant if $p < 0.025$. *, $P < 0.025$; **, $P < 0.005$. **g**, Neutralization titers of immunized hamsters before and after challenge. The "before challenge" sera were collected on day 28 post-immunization. The "after challenge" sera were collected on day 21 post-challenge. **h**, Experimental design of transmission blockage in hamsters. Hamsters were immunized with 10^5 PFU of Δ 3678 virus (n=5) or medium mock (n=5). In day 28 post-immunization, the hamsters were challenged with 10^4 PFU of WT SARS-CoV-2; these animals served as transmission donors. On day 1 post-challenge, the donor hamsters were co-housed with clean recipient hamsters for 8 h. The nasal washes of donor hamsters were collected immediately after contact (*i.e.*, 32 h post-challenge). The nasal washes of recipient hamsters were collected on days 2, 4, 6, and 8 post-contact. **i-j**, Weight loss of donors post-challenge (**i**) and recipients post-contact (**j**). The data are shown as mean \pm standard deviation. The weight changes were statistically analyzed using two-factor analysis of variance (ANOVA) with Tukey's post hoc test. *, $P < 0.05$; **, $P < 0.01$; ***, $P < 0.001$. **k**, Viral loads in nasal wash of donors post-challenge and recipients post-contact. Dots represent individual animals (n=5). The values in the graph represent the mean \pm standard error of mean. A non-parametric two-tailed Mann-Whitney test was used to analyze the difference between the mock-immunized-and-challenged and Δ 3678-immunized-and-challenged hamsters. **, $P < 0.01$.

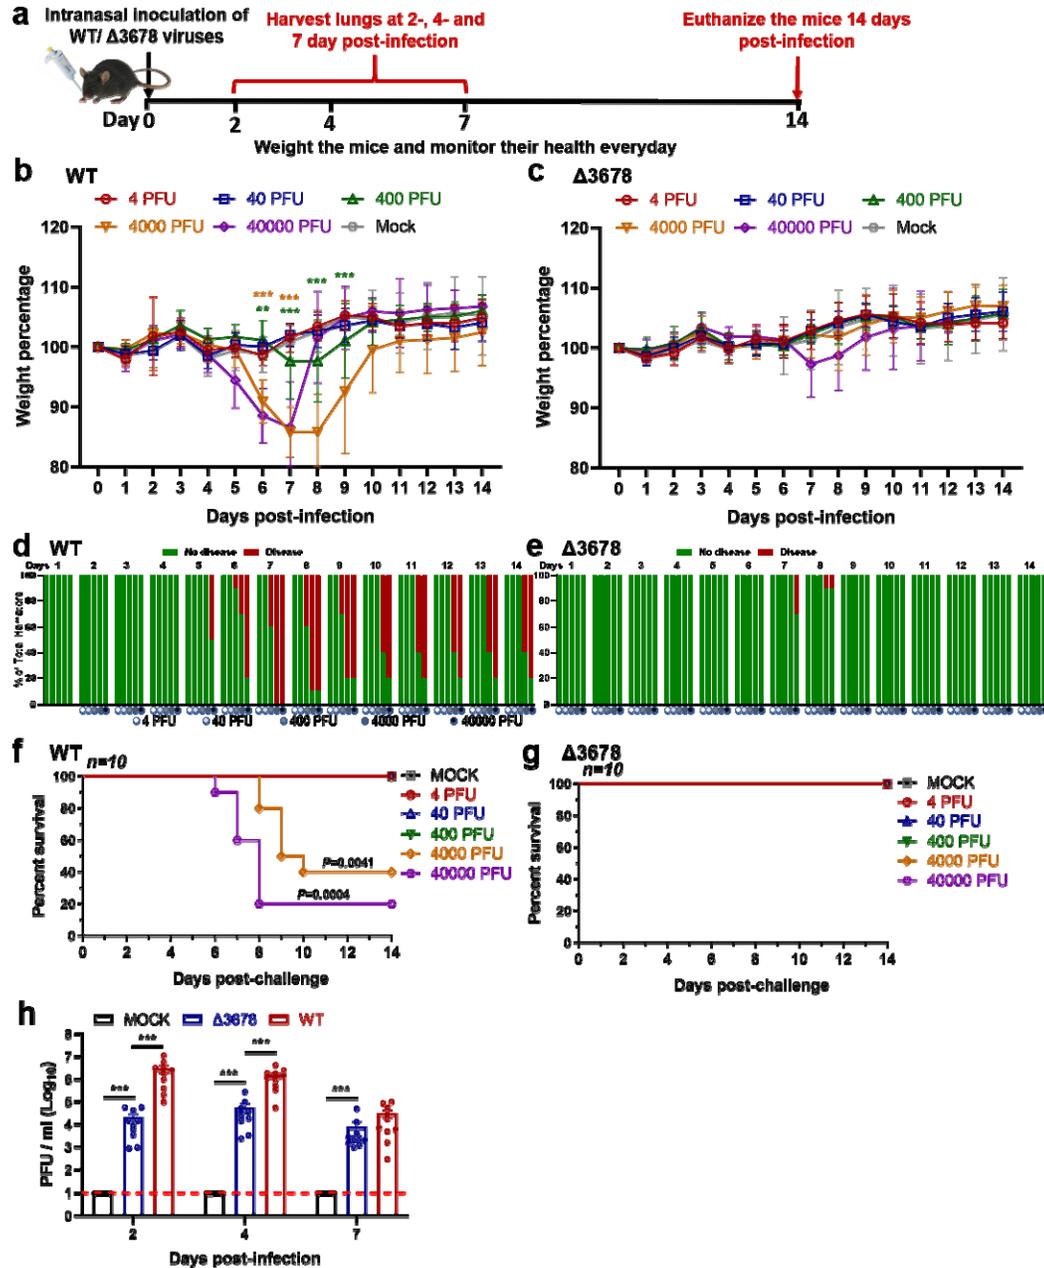

Figure 4. Attenuation of $\Delta 3678$ SARS-CoV-2 in K18-hACE2 mice.

a, Experimental scheme. K-18-hACE2 mice were intranasally inoculated with 4, 40, 400, 4,000, or 40,000 PFU of WT ($n=10$) or $\Delta 3678$ virus ($n=10$). Lung viral loads were measured on days 2, 4, and 7 post-infection. The infected mice were monitored for body weight (**b,c**), disease (**d,e**), and survivals (**f,g**) for 14 days. The data are shown as mean \pm standard deviation. **b,c**, Bodyweight changes. Different viral infection doses are indicated by different colors. The weight changes between mock- and virus-infected groups were statistically analyzed using two-factor analysis of variance (ANOVA) with Tukey's post hoc test. The green and brown asterisks indicate the statistical difference between mock and 4,000- or 40,000-PFU infection groups. **, $P<0.01$; ***, $P<0.001$. **d,e**, Disease. The diseases include

ruffled fur, lethargic, hunched posture, or orbital tightening. The percentages of hamsters with or without diseases were presented. **f,g**, Survival. A mixed-model ANOVA using Dunnett's test for multiple comparisons was used to evaluate the statistical significance. **h**, Lung viral loads from WT- and Δ 3678K-infected K18-hACE2 mice. Dots represent individual animals ($n = 10$). The mean \pm standard error of mean is presented. A non-parametric two-tailed Mann-Whitney test was used to determine statistical significance. *P* values were adjusted using the Bonferroni correction to account for multiple comparisons. Differences were considered significant if $p < 0.025$. ***, $P < 0.0005$.

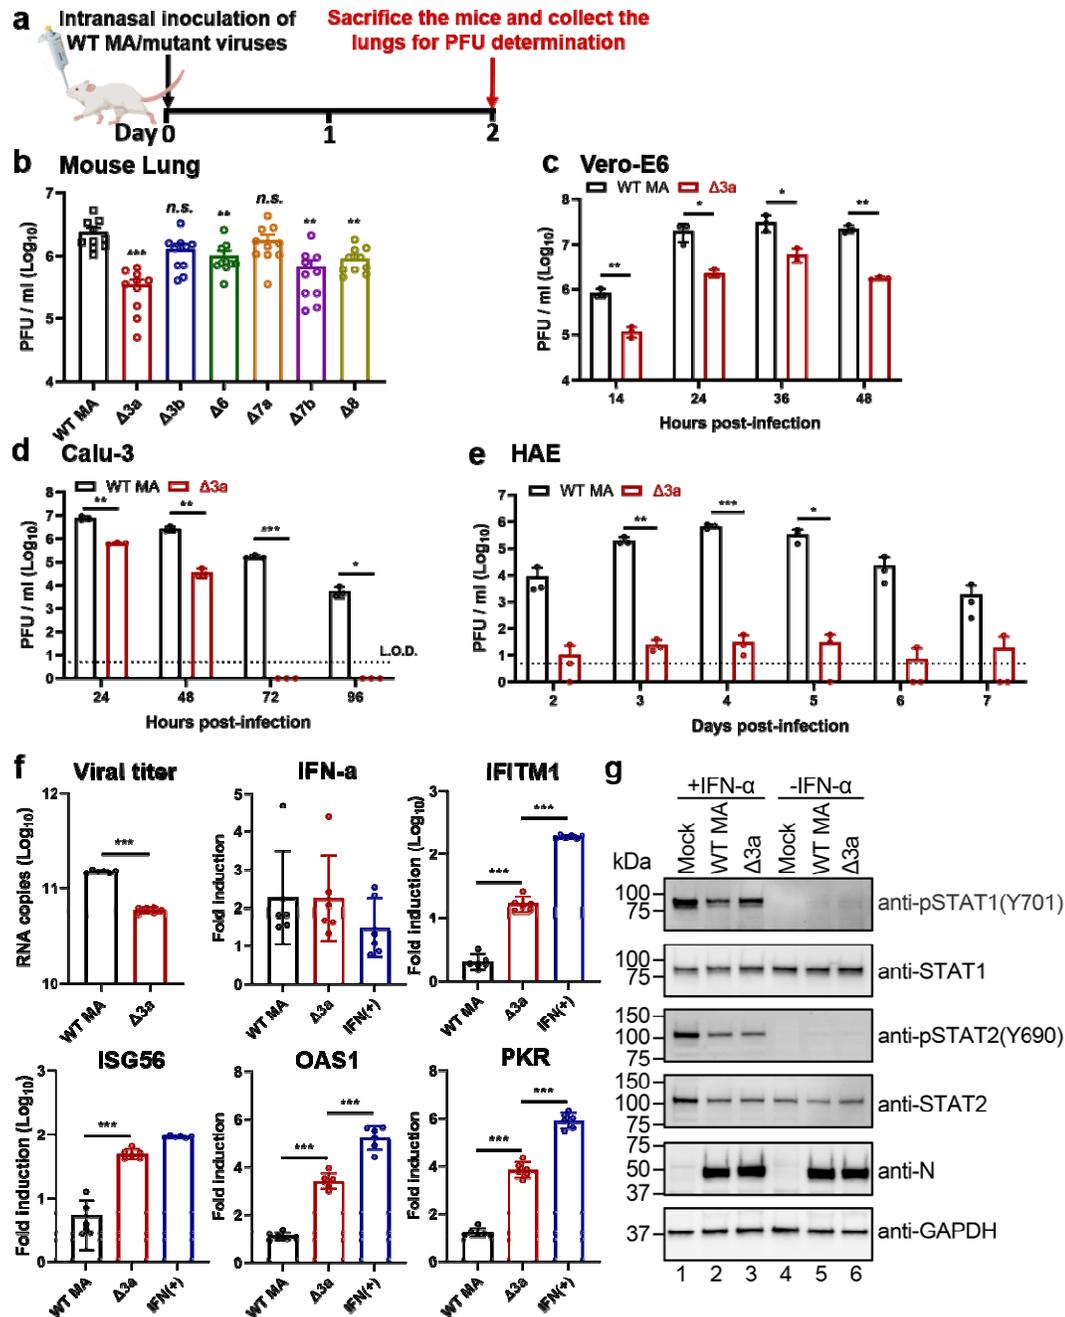

Figure 5. ORF3a deletion is mainly responsible for the attenuation of $\Delta 3678$ virus through interfering with STAT1 phosphorylation during type-I interferon signaling. **a,b**, Analysis of individual ORFs in BALB/c mice. **a**, Experimental design. A mouse-adapted SARS-CoV-2 (MA) was used to construct individual ORF-deletion viruses. BALB/c mice were intranasally infected with 10^4 PFU of WT and individual ORF deletion viruses ($n=10$ per virus) and quantified for lung viral loads on day 2 post-infection. **b**, Lung viral loads from mice infected with different ORF deletion viruses. Dots represent individual animals ($n=10$). The mean \pm standard error of mean is presented. A non-parametric two-tailed Mann-Whitney test was used to determine the statistical

difference between the WT and ORF deletion groups. *P* values were adjusted using the Bonferroni correction to account for multiple comparisons. Differences were considered significant if $p < 0.0083$. *, $P < 0.0083$; **, $P < 0.0017$; ***, $P < 0.00017$. **c-e**, Replication kinetics of $\Delta 3a$ virus in Vero-E6 (**c**), Calu-3 (**d**), and HAE (**e**) cells. The WT-MA and $\Delta 3a$ were inoculated onto Vero-E6, Calu-3 and HAE cells at an MOI of 0.01, 0.1, and 2, respectively. After 2 h of incubation, the cells were washed three times with DPBS, continuously cultured with fresh 2% FBS DMEM, and quantified for infectious viruses in culture fluids at indicated time points. Dots represent individual biological replicates ($n=3$). The values represent the mean \pm standard deviation. An unpaired two-tailed *t* test was used to determine significant differences *, $P < 0.05$; **, $P < 0.01$; ***, $P < 0.001$. **f**, ORF3a deletion increases ISG expression in $\Delta 3a$ -infected A549-hACE2 cells. A549-hACE2 cells were infected with WT or $\Delta 3a$ virus at an MOI of 1 for 1 h, after which the cells were washed twice with DPBS and continuously cultured in fresh medium. Intracellular RNAs were harvested at 24 h post-infection. Viral RNA copies and mRNA levels of IFN- α , IFITM1, ISG56, OAS1, PKR, and GAPDH were measured by RT-qPCR. The housekeeping gene GAPDH was used to normalize the ISG mRNA levels. The mRNA levels are presented as fold induction over mock samples. As a positive control, uninfected cells were treated with 1,000 units/ml IFN- α for 24 h. Dots represent individual biological replicates ($n=6$). The data represent the mean \pm standard deviation. An unpaired two-tailed *t* test was used to determine significant differences between $\Delta 3a$ and WT-MA or IFN(+) groups. *P* values were adjusted using the Bonferroni correction to account for multiple comparisons. *, $P < 0.025$; **, $P < 0.005$; ***, $P < 0.0005$. **g**, ORF3a suppresses type-I interferon by reducing STAT1 phosphorylation. A549-hACE2 cells were pre-treated with or without 1,000 units/ml IFN- α for 6 h. The cells were then infected with WT-MA or $\Delta 3a$ virus at an MOI of 1 for 1 h. The infected cells were washed twice with DPBS, continuously cultured in fresh media with or without 1,000 units/ml IFN- α , and analyzed by Western blot at 24 h post-infection.

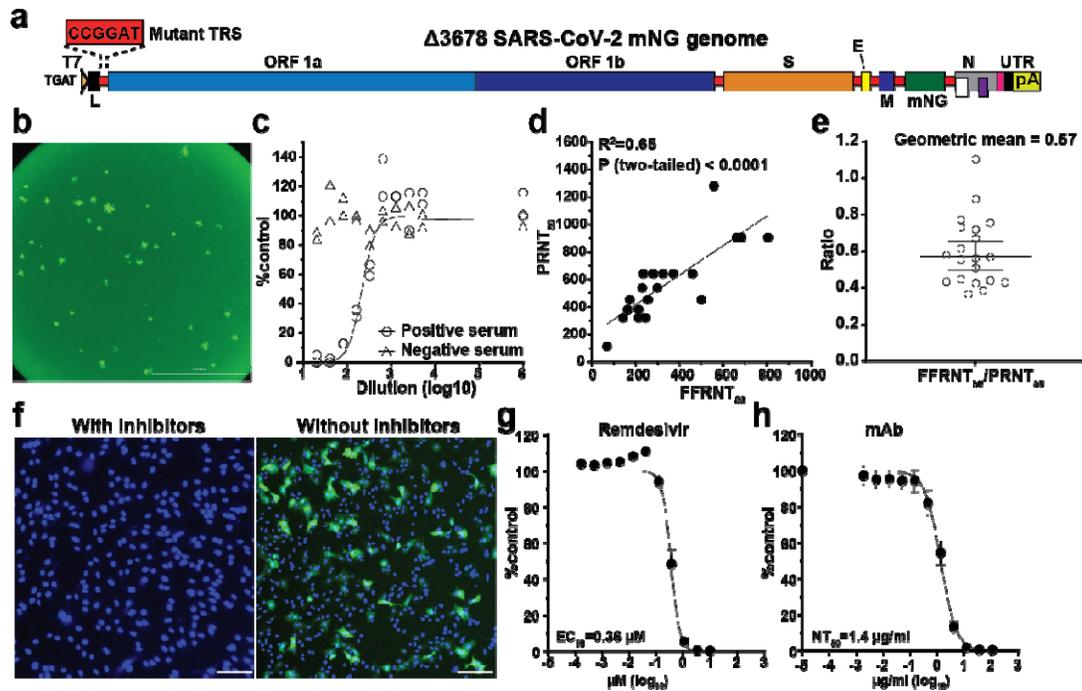

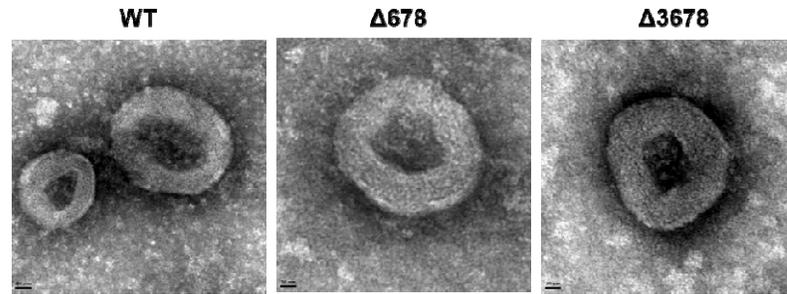

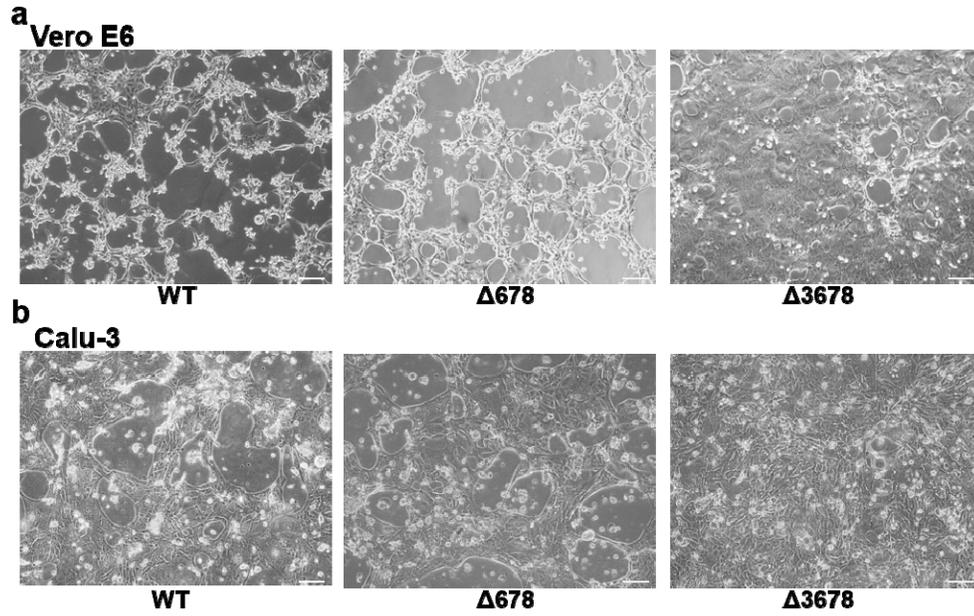

Figure 6. Development of mNG Δ 3678 virus for high-throughput neutralization and antiviral testing.

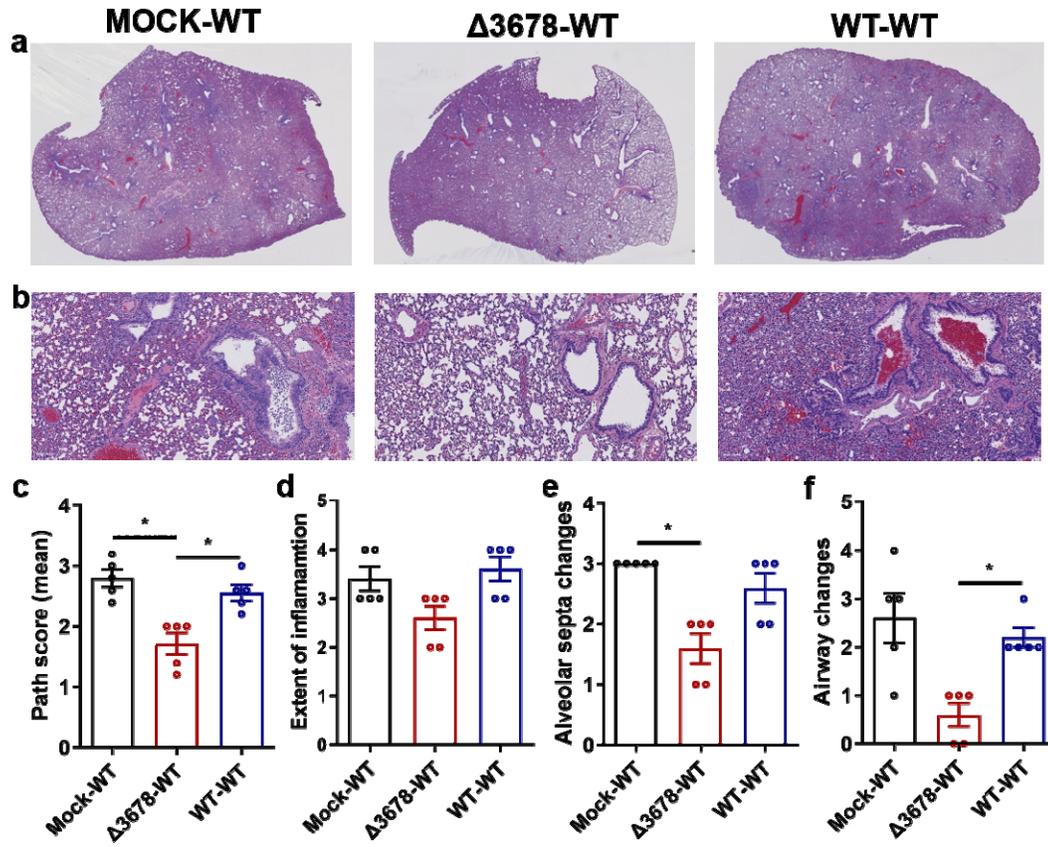

a, Genome structure of mNG Δ 3678 SARS-CoV-2. The mNG gene was inserted between M and N genes. **b**, mNG foci of Vero-E6-TMPRSS2 cells that were infected with mNG Δ 3678 SARS-CoV-2 for 16 h. **c**, Representative FFRNT neutralization curves for a COVID-19 antibody-positive and -negative serum. **d**, Correlation between FFRNT₅₀ with PRNT₅₀ values of 20 COVID-19 convalescent sera. The Pearson correlation efficiency and *P* value are shown. **e**, Scatter-plot of FFRNT₅₀/PRNT₅₀ ratios. The geometric mean is shown. Error bar indicates the 95% confidence interval of the geometric mean. **f**, Inhibition of mNG-positive cells by remdesivir. A549-hACE2 cells were infected with mNG Δ 3678 SARS-CoV-2 in the presence and absence of 10 μ M remdesivir. The antiviral activity was measured at 24 h post-infection. **g**, Antiviral response curve of remdesivir against mNG Δ 3678 SARS-CoV-2. The calculated 50% effective concentration (EC₅₀) is indicated. Error bars indicate the standard deviations from four technical replicates. **h**, The Dose response curve of a monoclonal antibody IgG14. A549-hACE2 cells were infected with Δ 3a virus in the presence of different concentrations of IgG14. The mNG signals at 24 h post-infection were used to calculate the NT₅₀.

Extended Data Figure 1. Negative-staining electron microscopic images of WT, $\Delta 678$, and $\Delta 3678$ SARS-CoV-2s. Scale bar, 20 nm.

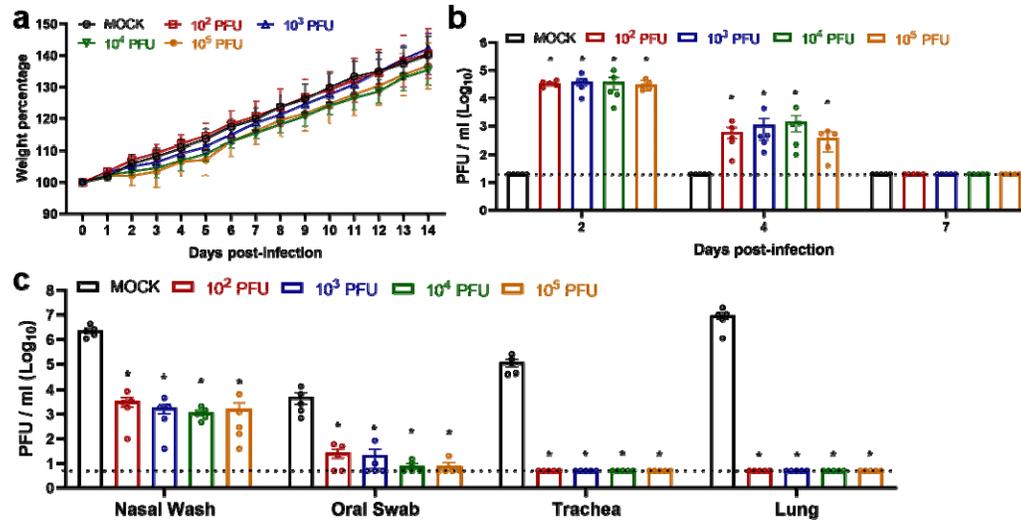

Extended Figure 2. Brightfield images of the cytopathic effects of WT, $\Delta 678$, and $\Delta 3678$ SARS-CoV-2-infected Vero-E6 and Calu-3 cells. The Vero-E6 and Calu-3 cells were infected with WT, $\Delta 678$, or $\Delta 3678$ virus at an MOI of 0.1 and 1.0, respectively. The images of infected Vero-E6 (**a**) and Calu-3 cells (**b**) were taken at 24 and 48 h post-infection, respectively. Scale bar, 100 μm .

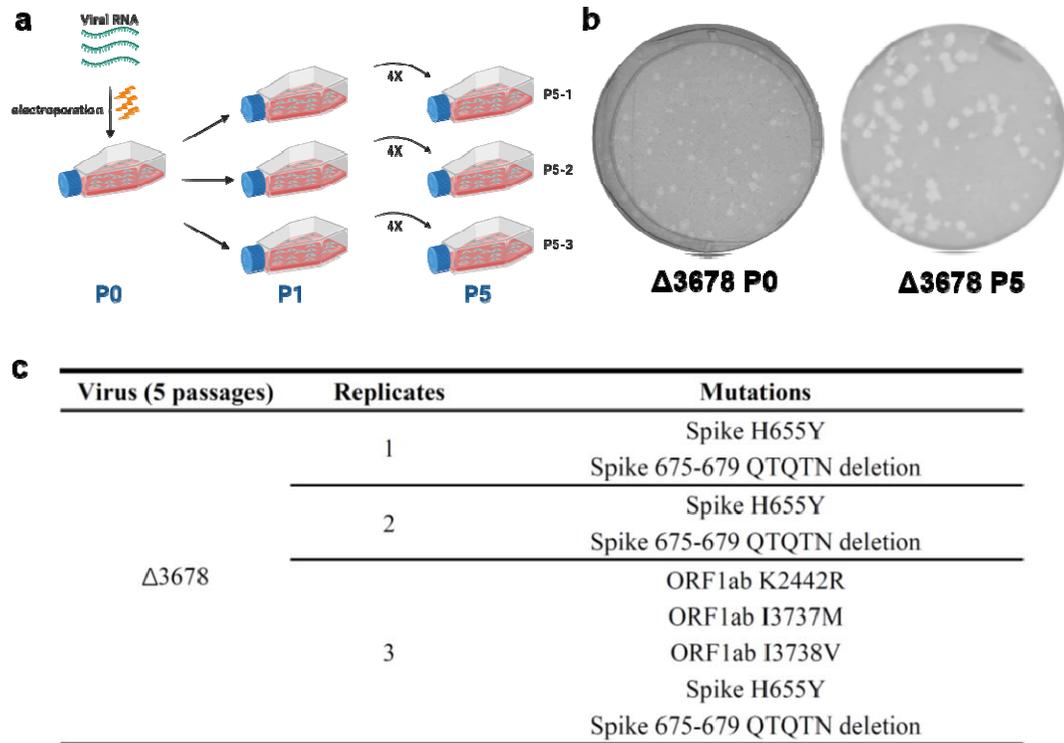

Extended Data Figure 3. Lung pathology of $\Delta 3678$ virus-immunized and WT SARS-CoV-2-challenged hamsters.

a, Lung sections show typical interstitial pneumonia with moderate to severe inflammatory changes in mock-immunized and WT virus-challenged animals (mock-WT) or in WT virus-inoculated and WT virus-challenged animals (WT-WT). Reduced inflammatory changes are observed in $\Delta 3678$ virus-immunized and WT virus-challenged animals ($\Delta 3678$ -WT). **b**, Higher magnification images show large inflammatory cells in the airways and prominent septal thickening in the mock-WT and WT-WT groups. Such changes are minimal or absent in the $\Delta 3678$ -WT group. **c-f**, Comparative pathology scores calculated based on the criteria described in Table S1. The $\Delta 3678$ -WT group shows a significant reduction in total pathology score (**c**), extent of inflammation (**d**), alveolar septa changes (**e**), and airway changes (**f**). Dots represent individual animals ($n=5$). The values of mean \pm standard error of mean are presented. A non-parametric two-tailed Mann-Whitney test was used to determine the statistical differences between $\Delta 3678$ -WT and mock-WT or WT-WT groups. P values were adjusted using the Bonferroni correction to account for multiple comparisons. *, $P < 0.025$.

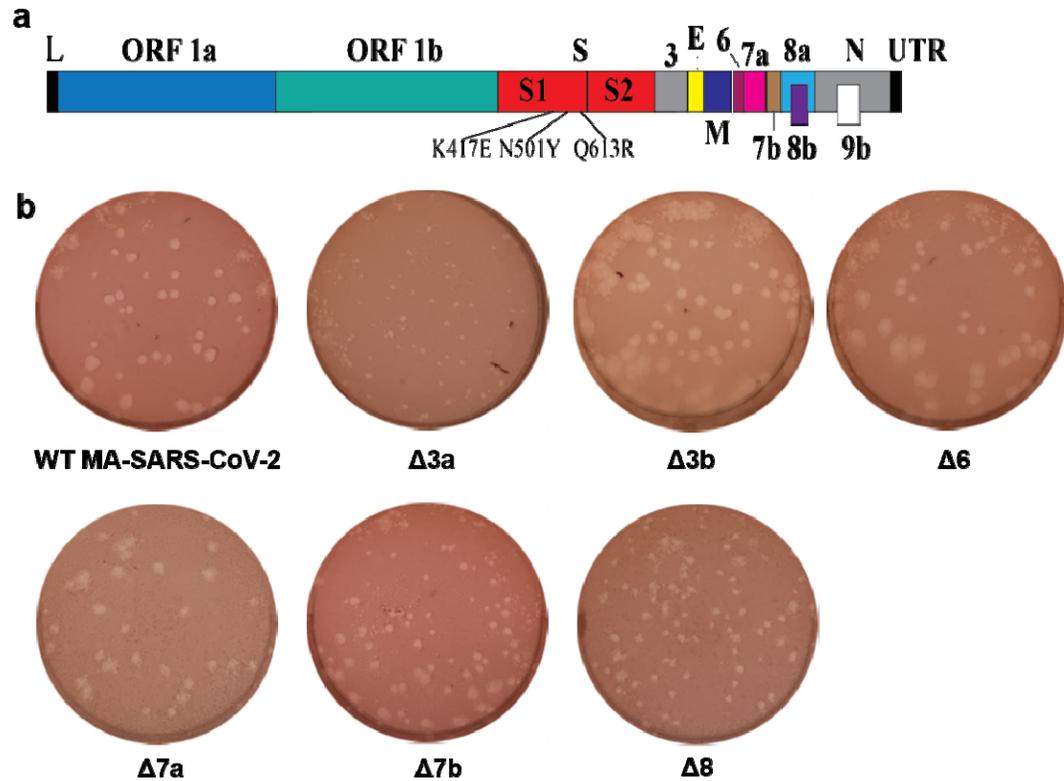

Extended Data Figure 4. Dose range immunization of $\Delta 3678$ virus to protect hamsters from WT SARS-CoV-2 challenge.

a, Weight loss of hamsters immunized with four different doses of $\Delta 3678$ virus. Hamsters were intranasally inoculated with 10^2 , 10^3 , 10^4 , or 10^5 PFU of $\Delta 3678$ virus ($n=5$ per dose). Body weights were measured for 14 days post-inoculation. The data are shown as mean \pm standard deviation. The weight changes were statistically analyzed using two-factor analysis of variance (ANOVA) with Tukey's post hoc test. No statistic differences were observed among mock and all $\Delta 3678$ dose groups. **b**, Nasal viral loads in $\Delta 3678$ virus-immunized hamsters on days 2, 4, and 7 post-immunization. **c**, Viral loads in nasal wash, oral swab, trachea, and lung from $\Delta 3678$ -immunized and WT virus-challenged hamsters. The $\Delta 3678$ -immunized hamsters were challenged with WT SARS-CoV-2 on day 28 post-immunization. The viral loads were measured on day 2 post-challenge. **b,c**, Dots represent individual animals ($n=5$). The values in the graph represent the mean \pm standard error of mean. Dash lines indicate assay detection limitations. A non-parametric two-tailed Mann-Whitney test was used to determine the statistical differences between mock- and $\Delta 3678$ -immunized hamsters. P values were adjusted using the Bonferroni correction to account for multiple comparisons. Differences were considered significant if $p < 0.0125$. *, $P < 0.0125$.

Extended Data Figure 5. Genetic stability analysis of Δ3678 SARS-CoV-2.

a, Experimental scheme. Passage 0 (P0) Δ3678 virus was divided into three T25 flasks for five rounds of independent passaging on Vero-E6 cells. **b**, Plaque morphologies of P0 and P5 Δ3678 virus. **c**, Mutations recovered from three independently cultured P5 Δ3678 viruses. The P5 Δ3678 viral RNAs were extracted and amplified by RT-PCR. Whole-genome sequencing was performed on the RT-PCR products. Mutations from the P5 viruses were annotated with amino acid changes and specific genes.

Extended Data Figure 6. Construction of mouse-adapted SARS-CoV-2s with individual ORF deletions.

a, Mouse-adapted SARS-CoV-2 genome. Mouse-adapted SARS-CoV-2 (MA-SARS-CoV-2) contains three mutations in spike glycoprotein: K417E, N501Y, and Q613R. These mutations confer SARS-CoV-2 to replicate in BALB/c mice. Open reading frames, ORFs; E, envelope glycoprotein gene; L, leader sequence; M, membrane glycoprotein gene; N, nucleocapsid gene; UTR, untranslated region. **b**, Plaque morphologies of MA-SARS-CoV-2s with individual ORF deletions. All these ORF deletion viruses were constructed in the backbone of MA-SARS-CoV-2. Plaque assays were performed on Vero-E6 cells and stained on day 2.5 post-infection.

Extended Data Table 1. Criteria for histopathology scoring

		Scores				
		0	1	2	3	4
A	Extent of inflammation (% tissue involved)	0	<10	10-30	30-60	>60
B	Inflammatory foci type	No inflammation	Patchy inflammatory foci, few (<2)	Patchy inflammatory foci, many (>2)	Large inflammatory foci, few (<2)	Large inflammatory foci, many (>2)
C	Alveolar septa	Thin and delicate	Thickened in <10% HPF	Thickened in <30% HPF	Thickened in <60% HPF	Thickened in >60% HPF
D	Airways	Clear; no cells	Few cells in airway	Moderate cells in airway	More cells in air way; Epithelial hyperplasia	Occlusion of air way/epithelial hyperplasia or desquamation
E	Alveoli/ perivascular cuff/blood vessels/ pleuritis/cell types	Clear; no inflammatory cells	Few cells. Few PMN or MNC	Moderate cells/ PVC/mild congestion/ mild pleuritis/mostly MNC	More cells/PVC/ more congestion and pleuritis/more MNC and PMN	Abundant cells/large PVC/severe congestion or pleuritis/mixed cells

HPF – high power field (>10x); PMN – polymorphonuclear cells/heterophils; MNC – mononuclear cells including lymphocytes and macrophages; PVC – perivascular cuff.
