### Abstract

This paper reports the first implementation of a new type of mass spectral library for the analysis of Chinese hamster ovary (CHO) cell metabolites that allows users to quickly identify most compounds in any complex metabolite sample. We also describe an annotation methodology developed to filter out artifacts and low-quality spectra from recurrent unidentified spectra of metabolites. CHO cells are commonly used to produce biological therapeutics. Metabolic profiles of CHO cells and media can be used to monitor process variability and look for markers that discriminate between batches of product. We have created a comprehensive library of both identified and unidentified metabolites derived from CHO cells that can be used in conjunction with tandem mass spectrometry to identify metabolites. In addition, we present a workflow that can be used for assigning confidence to a NIST MS/MS Library search match based on prior probability of general utility. The goal of our work is to annotate and identify (when possible), all liquid chromatography-mass spectrometry generated metabolite ions as well as create automatable library building and identification pipelines for use by others in the field.

### KEYWORDS

Chinese hamster ovary cells, global metabolite profiling, liquid chromatography-tandem mass spectrometry, nontargeted metabolomics, recurrent unidentified spectra

# 1 | INTRODUCTION

Chinese hamster ovary (CHO) cells are the predominant host cells for monoclonal antibody (mAb) production (Kunert & Reinhart, 2016). Metabolomics provides information on cellular phenotypes. Several metabolites have been demonstrated to be biomarkers of CHO cell status (Mohmad-Saberi et al., 2013). Metabolomic analysis of CHO cells has primarily been used in process or media/feed development and has predominantly focused on targeted metabolite analysis of major metabolites, although there are several studies that utilized global metabolite analysis (Stolfa et al., 2018). A comprehensive assessment of CHO cell metabolic profiles could lead to improvements in product yield and quality by providing further understanding of the CHO cell metabolome (Stolfa et al., 2018). Mass spectral libraries have been extremely popular

WILEY-BIOFICHNOLOGY

for more than 40 years for identifying volatile chemical compounds using gas chromatography-mass spectrometry (GC-MS). They are used to locate the most similar spectra in the reference library and present the compounds that generated them in a "hit list" sorted by their similarity to the acquired spectrum (S. Stein, 2012). Liquid chromatography-mass spectrometry (LC-MS) is a widely practiced method for identifying the chemical components in metabolomics (Gowda & Djukovic, 2014). For confident metabolite identifications. liquid chromatography-tandem mass spectrometry (LC-MS/MS) can be performed and the fragmentation pattern can be compared to a MS/MS spectral library. Commercial MS/MS libraries that contain curated spectra (the NIST Tandem [MS/MS] Mass Spectral Library and the Wiley MSforID Library) as well as free libraries that facilitate data sharing (MassBank, MassBank of North America [MoNA], LipidBlast, METLIN, mzCloud, GNPS, etc.) are available and have been reviewed recently (Kind et al., 2018). These libraries contain experimental spectra of known compounds and spectra of unidentified compounds are not documented there. Other libraries such as LipidBlast, Greazy/LipidLama, CFM-ID, and so forth are based on in silico prediction of the spectra of known or predicted metabolites (Kind et al., 2018).

A comprehensive library of both known and unidentified CHO cell metabolites will be beneficial to the field of CHO cell metabolite analysis. In addition to producing the NIST MS/MS Library, the NIST Mass Spectrometry Data Center (MSDC) has recently begun creating materialoriented libraries that are generated from the analysis of complex mixtures such as human plasma and urine (https://chemdata.nist.gov/ dokuwiki/doku.php?id = chemdata:arus) to address the issue of unknown metabolites (metabolites not identified by library searching), identify cross-platform metabolite signatures, and catalogue all spectra associated with a particular material of interest (Mallard et al., 2014; Remoroza et al., 2018; Simon-Manso et al., 2013; Simon-Manso et al., 2019; S. Stein, 2012; Telu et al., 2016). These material-oriented libraries contain recurrent spectra (spectra that occur repeatedly in the sample) for all detectable metabolites, both known and unknown that are processed to produce high-quality consensus spectra for the library. The MSDC has also created spectral libraries (Dong et al., 2018; Dong, Yan, Liang, & Stein, 2016) of the NISTmAb, a humanized IgG1<sup> K</sup> Monoclonal Antibody Reference Material (RM 8671; https://www.nist.gov/programsprojects/nist-monoclonal-antibody-reference-material-8671).

The use of tandem mass spectral libraries in biomedical and biomanufacturing applications has been very limited until recently with the development of omics technologies. To date, there are no reports of libraries being used for optimizing biomanufacturing processes and very little for discovering new metabolic pathways. Here, we implemented recurrent spectral libraries for use in CHO cell metabolite analysis that allows users to quickly identify most compounds in any complex metabolite sample. We also developed an annotation strategy for these libraries to filter out artifacts and low-quality spectra from recurrent unidentified spectra of metabolites. These libraries are focused on metabolite analysis, however, small peptides that extract along with the metabolites are also present. Furthermore, the limited coverage of tandem libraries is somewhat ameliorated by the use of the recently developed hybrid search (Burke et al., 2017; Cooper et al., 2019; Moorthy et al., 2017), which can identify compounds similar to, but not present in the library. The recurrent spectral library is unique in that it can be used to determine if an ion has been seen before in other analyses, assign the class identification for compounds not found in a library or commercially available, and enables library evolution based upon feedback from users. As more experiments are done, the library can continue to grow in coverage. The library and the associated metabolite identifications are freely available for download for use in the analysis of CHO cell metabolites by LC-MS/MS. Although this study was demonstrated in CHO cells, the developed methods for filtering spectra and assigning match confidence can be applied to not only other cell types, but also other metabolomics studies. In addition, work is currently underway at NIST to create a metabolite identification pipeline and graphical user interface (GUI) that those in the biomanufacturing community can use to implement their own libraries.

# 2 | EXPERIMENTAL METHODS

For the coverage of metabolites to be broad, CHO cells were extracted by four different methods available in the literature: (1) 50% acetonitrile in water (Dietmair et al., 2012), (2) Methanol (Dietmair, Timmins, Gray, Nielsen, & Kromer, 2010; Sellick et al., 2011), (3) methanol/methyl tertbutyl ether(MTBE)/water, and (4) methanol/dichloromethane(DCM)/ water (Matyash et al., 2008). Metabolites were separated with three different LC methods (reversed-phase [C<sub>18</sub>], hydrophilic interaction liquid chromatography [HILIC] and a reversed-phase method optimized for lipids [lipid C<sub>18</sub>]), and analyzed in positive and negative ionization mode with both higher-energy C-trap dissociation (HCD<sup>\*\*</sup>) over a range of collision energies and ion trap (IT) collision-induced dissociation. Media samples (fresh and spent) were resuspended in two different solvents (50% acetonitrile or pure methanol) after protein precipitation, separated with two different LC methods (C<sub>18</sub> and HILIC), and analyzed with the same breadth of methods as the CHO cell metabolites.

### 2.1 | Sample preparation

CHO-S cells (Thermo Fisher Scientific) were grown in ProCHO5 protein-free medium (Lonza) supplemented with 4 mmol/L L-glutamine (Thermo Fisher Scientific). CHO cells and spent media were harvested and metabolite extractions were performed. Protein precipitation was performed on the media with 80% (vol/vol) me-thanol. After drying and before analysis, media samples were resuspended in either pure methanol or 50% acetonitrile (vol/vol). Metabolites were extracted by four different methods: 50%

<sup>\*</sup>Certain commercial instruments are identified in this document. Such identification does not imply recommendation or endorsement by The National Institute of Standards and Technology, nor does it imply that the products identified are necessarily the best available for the purpose.

<sup>\*\*</sup>HCD is a term specific to the orbitrap mass spectrometer (Thermo Fisher Scientific). HCD and QTOF spectra are equivalent as they both result from beam-type collision-induced dissociation (versus ion trap collision-induced dissociation).

acetonitrile in water, methanol, methanol/methyl tert-butyl ether (MTBE)/water, and methanol/dichloromethane (DCM)/water. Additional details regarding sample preparation can be found in the supporting information.

### 2.2 | LC-MS/MS analysis

The metabolites were separated by three different liquid chromatography methods. Extracts containing polar metabolites (50% acetonitrile, methanol, lower phase for the methanol/MTBE/water extraction, and upper phase for the methanol/DCM/water extraction) were separated by both C<sub>18</sub> and HILIC. The organic phases of the two lipid extractions were separated by a lipid  $C_{18}$  method. Fresh and spent media samples were separated by C<sub>18</sub> and HILIC. These separations were coupled to either a Q Exactive or Orbitrap Fusion Lumos (Thermo Fisher Scientific). The data were collected in positive and negative ionization mode with data-dependent MS/MS acquisition. To provide as many spectra as possible for the library, HCD spectra were collected over a range of normalized collision energies from 10 to 50 using nitrogen as the collision gas. In addition, low-resolution IT and high-resolution IT spectra were acquired on the Lumos at a normalized collision energy of 35% using helium as the collision gas. The collision gases used were those recommended by the equipment manufacturer. Additional details regarding analysis can be found in the supporting information.

### 2.3 | Data analysis

Data were analyzed to produce recurrent spectral libraries as reported previously (Telu et al., 2016). Briefly, all data were processed with the NIST MSCQ pipeline (see below under "Annotation of Spectra" for a description of the pipeline). Recurrent spectra were exported from the output of the pipeline with a perfect score cutoff (1.0) to ensure all spectra (even identified ones) were included. Following this, consensus spectra were created from the experimental data using in-house developed software after grouping the data by polarity, fragmentation type (HCD or IT), and collision energy. The similarity of the spectra was based on precursor and the dot-product (Yang et al., 2014). Only similar spectra (a cluster) were used to create the consensus spectrum. Spectra dissimilar to the given cluster were placed in another cluster or, if unique, were ignored. After the libraries were created, the consensus spectra were searched against the NIST17 Library to obtain metabolite identifications. In addition, an annotation strategy was developed following manual evaluation of a representative data file. The data file analyzed was a 50% acetonitrile extraction that was separated on a C18 column and fragmented at HCD 20. The file was searched against the NIST17 Library with the NIST MSPepSearch software to provide tandem mass spectral library identifications as discussed below.

### 3 | RESULTS AND DISCUSSION

### 3.1 | Identification of metabolites

The first goal of this study was to collect, organize, and to the degree possible, identify all measurable tandem mass spectra in CHO cell metabolite and growth media extracts acquired using electrospray LC-MS/MS methods. To do this, we developed an HCD and IT fragmentation spectral library containing consensus spectra in both positive and negative ionization mode using a spectral clustering method developed in-house. The libraries contain data from both CHO cell metabolite analyses as well as media analyses and are annotated to show the origin of the spectra. In addition to metabolites, peptides that are co-extracted are also present in the libraries, although these are not the focus of the work. The resulting HCD recurrent spectral libraries contain 109,601 and 61,677 spectra for the positive and negative ionization mode libraries, respectively. The IT libraries contain 15,703 and 12,499 spectra for the positive and negative ionization mode libraries, respectively. IT spectra are similar to low energy HCD spectra, except for their low mass cut-off at about one-third of the precursor mass and their higher degree of fragmentation at these low energies; IT fragment ions are therefore more intense than low energy HCD spectra. Note that low energy spectra are generally easier to interpret than higher energy spectra due to their simpler mechanisms. Additional information about the libraries, including collision energies, precursor ion types, and source (CHO cell, media, or both) of the consensus spectra can be found in the supporting information. The results of CHO cell metabolite and media analyses are highly orthogonal as only 8%-13% of the consensus spectra in the libraries originate from both samples. The overlap would likely be higher if a chemically defined media was used.

To identify spectra, we searched the consensus spectra generated for the recurrent spectral libraries against the NIST17 MS/MS library (Yang et al., 2014; Yang et al., 2017). To compare our results with those previously published in the literature, the CHO cell metabolite identifications were summarized and compared to a literature review of CHO cell metabolite identifications. To summarize the identifications, we sorted the library match identifications by name and library match score. We kept only the top-scoring hit of each identification and then manually validated the library match result. Any poor matches were removed. In addition, we curated the data to remove identifications that are not previously observed as endogenous metabolites by searching for the identification in the Human Metabolome Database (HMDB) (Wishart et al., 2013, 2018), PubChem (Kim et al., 2019), or the LIPID MAPS structure database (Sud et al., 2007) as no comprehensive CHO cell metabolite library is available. If there was no information on if an identification was a metabolite, it was not removed. Spreadsheet 1 of supporting information contains all the library match identifications and can be mined for new or unexpected metabolites by experts in CHO cell metabolism. Our curated list resulted in 365 CHO cell metabolites WILEY-BIOTECHNOLOGY

(the majority identified by multiple ions or in multiple libraries) and an additional 304 di- or tri-peptides. We split out the peptides into a separate list because they are likely less interesting than other metabolites. Metabolites identified are reported in Table 1. A literature search resulted in a list of 232 metabolites. Identifications made by HPLC, GC-MS, MALDI-MS, and LC-MS were included. Of these 232 reported metabolites, we identified 43% in our data. For ones that were not identified, the majority (66%) were represented in the NIST17 library, but not identified in our experiments, possibly because they were below the detection limit. The remaining literature identifications not present in the NIST17 library that are compatible with analysis by LC-MS can be added to future versions of the NIST MS/MS library. Lists of identified metabolites summarized from our data as well as the literature review can be found in Spreadsheets 2 and 3 of the supporting information, respectively. These spreadsheets also contain information demonstrating the percentages reported herein.

# 3.2 | Improvement of accuracy of pipeline identifications

We developed a procedure to improve the accuracy of identifications obtained using the NIST MSQC pipeline by modifying the order of identifications in a hit list. The NIST pipeline, by default, sorts hits entirely by their score which reflects the quality of the spectral match between the experimental and library spectra. We identified four categories of errors in identification. For clarity, we labeled these as category A-D errors. Additional information on the errors, examples, and solutions for these errors can be found in the supporting information.

### 3.3 | Hybrid search

To discover the identity of compounds not represented in the library, a hybrid search was performed. The hybrid search match is a new search strategy available in the 2017 release of NIST MS Search software (version 2.3) (Burke et al., 2017; Cooper et al., 2019; Moorthy et al., 2017). This search finds compounds that differ by an inert chemical group, hence, can often match unidentified spectra with members of the same chemical classes that are present in the library. The term delta mass is used to represent the difference in mass between the query spectrum and library entry. An example of a hybrid match in the CHO cell metabolite data is for the match of a spectrum (ion m/z = 472.0011) to a sodiated Adenosine 5'diphosphate library spectrum with a delta mass of 21.9824 Da. This delta mass corresponds to a sodium, so the correct annotation of this ion is adenosine 5'-diphosphate [M-H+2Na]<sup>+</sup>. The hybrid search was also utilized to assist in the identification of two groups of related spectra. Information on these identifications can be found in the supporting information.

### 3.4 | Utility of recurrent spectral libraries

There are multiple metabolomics analysis software tools available. A recent review summarized those that are freely available (Spicer et al., 2017). In addition, there are a variety of freely available packages for processing MS/MS spectra (Kind et al., 2018). One such tool, RAM-ClustR (Broeckling et al., 2014) can group features extracted via XCMS (Smith et al., 2006) into spectra in an unsupervised manner and therefore identify features that originate from the same compound in an indiscriminant MS/MS (idMS/MS) data acquisition. Spectra can then be searched against a reference library such as the NIST MS/MS Library. The NIST MSOC pipeline (Rudnick et al., 2010; https:// chemdata.nist.gov/dokuwiki/doku.php?id=peptidew:msqcpipeline), a fully integrated software pipeline that was developed for the analysis of a tryptic protein digest to assist in the identification of variability caused by issues with analytical platforms, was used to process data files in this study. We have extended the application of the pipeline to identification of small molecule metabolites by modifying searching and scoring. The pipeline begins by reading a data file from a commercial instrument, extracting all spectral data, and searching the spectra against the NIST library using the NIST MS Search software. When multiple spectra are acquired for a single precursor ion, the most intense one is selected and its maximum MS1 abundance is recorded at its retention time. Figure 1 shows ion plots generated from the pipeline output after searching against the NIST17 MS/MS library or the Recurrent library and provides a visual representation of the data. Each object represents a clustered mass spectrum. More detailed plots of those shown in Figure 1 can be found in the supporting information. For these ion plots, the pipeline has found 5335 ion clusters in this data file. When searched against the NIST17 MS/ MS library, 80% of these clusters have no identification. When searched against the positive ion HCD recurrent spectral library, the number of clusters with no identification drops to 23%. Thirty-eight percent of the clusters have a recurrent label, which indicates they have matched spectra in the recurrent spectral library by either direct or hybrid MS/MS search. This increase in cluster identification demonstrates the utility of the recurrent spectral libraries. As we are cataloguing every observed ion in the libraries instead of just previously identified metabolites, we can identify these ions in future analyses of the same or similar materials.

### 3.5 | Annotation of spectra

The second goal of this study was to develop a comprehensive, automatable approach to annotate the spectra in the libraries of recurrent spectra for the purpose of filtering out artifacts and lowquality spectra from recurrent unidentified spectra of metabolites. This type of filtering is important because unknowns can be redundant signals, artifacts (man-made signals), and contaminants (real chemicals), instead of metabolites that are not present in the library used for spectral matching (Sindelar & Patti, 2020). Credentialing

### **TABLE 1** Compounds identified in the Recurrent Spectral Library created from CHO cell metabolite extracts

features (Mahieu et al., 2014) and isotopic ratio outlier analysis (IROA; de Jong & Beecher, 2012) are two isotopic-labeling techniques that have been developed to provide further confidence in metabolite identifications. Such techniques were not used in the creation of the mass spectral libraries. Therefore, an annotation strategy based on the comparison of the extracted ion chromatogram (EIC) between the sample and blank runs was developed to filter library spectra. Once spectra are filtered, efforts can be focused on identifying compounds that are likely to be unidentified recurrent spectra originating from CHO cells and/or media (vs. the environment or instrument) by searching the spectra against other available tandem mass spectral libraries and *in silico* prediction libraries. MassBank of North America (MoNA) in combination with the NIST MS/MS Library and *in silico* fragmentation tools CSI:FingerID and LipidBlast has been demonstrated to be effective in assigning structural annotation to MS/MS spectra (Blaženović et al., 2019).

To develop the annotation strategy, the search results of all the mass spectra contained in a representative data file were manually evaluated. Figure 2 is a graphical summary of the annotation strategy developed for filtering. First, spectra are removed if they do not have a sufficiently narrow chromatographic peak width (<30 s), unless they are identified. Second, spectra without sufficiently high spectral purity (>80%) are removed. Third, spectra without sufficient fragment ion abundances (summed product ion abundance/precursor ion

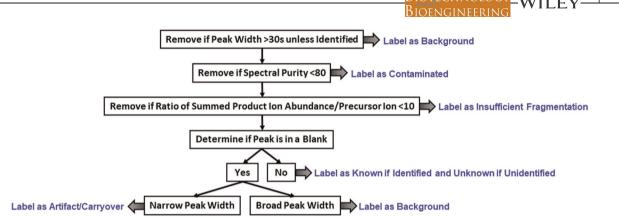

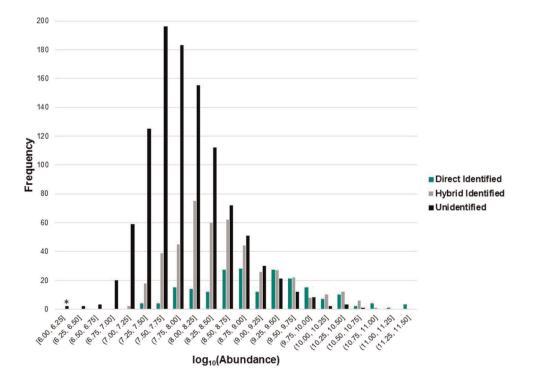

FIGURE 2 Workflow for annotation of spectra [Color figure can be viewed at wileyonlinelibrary.com]

abundance < 10) are removed. The data shown in Figure 1 was filtered using these parameters, which eliminated two-thirds of the 5335 spectra. The spreadsheet used for sorting and eliminating spectra can be found in Spreadsheet 4 of the supporting information. Of those eliminated, 9.5% of were background, 77.8% were possibly contaminated (due to the presence of another peak close in mass to the parent ion), and 12.8% contained insufficient fragmentation. Figure 3 shows the distribution of abundances of the 1752 identified (by direct and hybrid MS/MS match) and unidentified ion clusters. This figure shows that less abundant compounds are less likely to be identified. These unidentified ion clusters could be comprised of spectra of previously unidentified metabolites or metabolites that are not represented in the library as well as spectra of background and artifacts, which is why annotation is crucial.

1505

In the next step in spectral annotation after filtering, the EIC of the ion of the corresponding spectrum is compared to the EIC of the same ion in a blank run via visual inspection. If the peak is not present in the blank with intensity within 100x that of the sample, then this spectrum is labeled as either a known (if it is identified by MS/MS match) and annotated with the identification or as an unknown (metabolite not identified by library searching). If the peak is in the blank, then the spectrum can either be due to an artifact/carryover or background. During manual evaluation of EICs, we found that for the purposes of spectral classification, artifact/carryover ions can be

**FIGURE 3** Distribution of identified and unidentified ion clusters after filtering. \*0.2% of hybrid identified and 2.9% of unidentified spectra that were assigned abundance in this bin because the abundance could not be calculated were removed [Color figure can be viewed at wileyonlinelibrary.com]

### EY-BIOTNELINE

separated from background ions by examining the peak width. The background has a broad peak width (in regions where both hydrophilic and hydrophobic compounds elute) while an artifact/carryover has a narrow peak width. For most of the cases, differentiating between background and artifact/carryover was straightforward, however, for cases that were difficult to differentiate, we labeled ions as background if there was a substantial signal in both halves of the chromatogram (0-15 and 15-30 min). Separation using peak width is a quick method to classify spectra, but more accurate methods could be applied in an automated pipeline. Multiple algorithms (Cleary et al., 2019; Ho, Kuo, Wang, Chen, & Tseng, 2013; Zhang & Yang, 2008: Zhu et al., 2009) have been developed for the purpose of subtracting the background from LC-MS data. In addition, a hierarchical cluster analysis technique was developed to identify chemical interferants that are not removable by background subtraction (Caesar, Kvalheim, & Cech, 2018). Figure 4 shows examples of each of the above-mentioned classifications. For the unidentified recurrent spectra, these classifications are an effective way (that can be automated) to annotate the spectra for the library. These labels allow us to prioritize spectra needing identification first through library and literature searching. Unknowns represent compounds that originate from the CHO cells or cell culture media and are the highest priority to attempt to identify. Artifacts/carryover are the next priority because these may still be compounds that originate from the CHO cells or cell culture media. Background spectra are likely

not worth an analyst's time to try to identify as the background will be different in analyses from different labs. Table S4 shows the resultant annotation of the 20 most abundant unidentified ion clusters. Fifteen percent of the clusters are unknowns and would be the most useful to search the literature and online databases for the identities. Fifty percent of the clusters are artifacts/carryover and the remaining 35% are background.

### 3.6 Confidence in library match identifications

A framework for reporting confidence in metabolomics identifications was proposed in 2007 by the Chemical Analysis Working Group of the Metabolomics Standards Initiative (MSI) and is composed of four levels of metabolite confidence. These are identified compounds (Level 1), putatively annotated compounds (Level 2), putatively characterized compound classes (Level 3), and unknown compounds (Level 4) (Sumner et al., 2007). There has been discussion in the metabolomics community about providing more information about confidence by modifying/expanding the level system, introducing a quantitative system, or providing alphanumeric identification metrics, but no consensus has been reached (Creek et al., 2014; Schrimpe-Rutledge et al., 2016; Schymanski et al., 2014; Sumner et al., 2014; Viant et al., 2017). Schymanski et. al. (2014) proposed a framework for reporting confidence that was based on the MSI levels

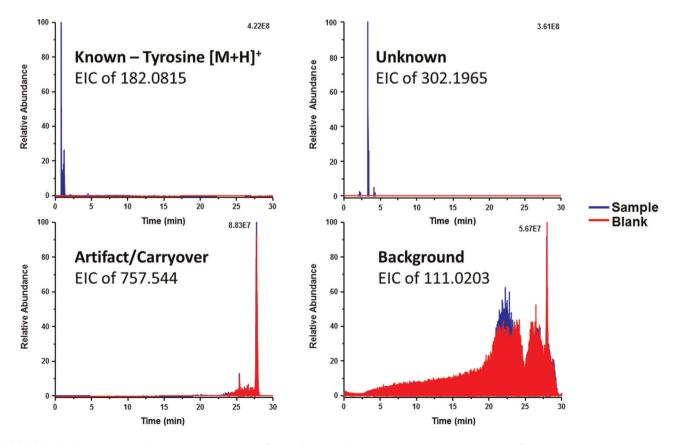

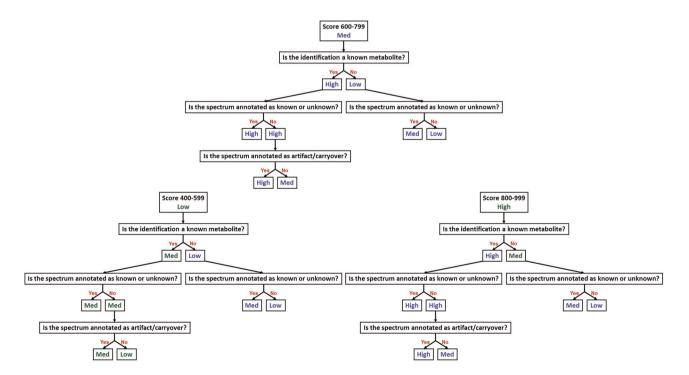

FIGURE 4 Examples of each type of annotated ion [Color figure can be viewed at wileyonlinelibrary.com]

and adapted for high-resolution mass spectrometry (HR-MS). These HR-MS specific confidence levels are most appropriate for our data and consist of five confidence levels. These are confirmed structure (Level 1), probable structure (Level 2), tentative candidate(s) (Level 3), unequivocal molecular formula (Level 4), and exact mass (Level 5). In this study, we have Level 2, 3, and 5 confidences. Level 1 is confirmed using two or more properties of reference standards using the same experimental conditions. Although the NIST17 MS/MS library is acquired using reference standards, the experimental data in this paper was not acquired on the same platform, so it is not a Level 1 confidence. This type of confirmation is unrealistic for our work where we are trying to catalogue all metabolites and identify as many as possible. The direct identifications reported in this study represent Level 2 confidence structure identifications as they are obtained with library matching. Hybrid match identifications are Level 3 because they are chemical class identifications made with library searching. To assign a Level 4 confidence, we would need to attempt to assign a chemical structure to the spectra in the libraries, which we have not done to date. All the spectra in the libraries are associated with accurate mass data, and spectra annotated as unknowns would have a Level 5 confidence. Some of the spectra annotated as artifact/ carryover could be originating from the sample and have a Level 5 confidence but finding these could be challenging and a method for doing this would require further development.

To provide additional detail about the confidence of both our direct and hybrid library MS/MS matches, we developed a workflow to assign a qualitative confidence level to each metabolite identification. The workflow starts with the match score and incorporates BIOTECHNOLOGY\_V

prior probability information about whether the identified compound has been previously observed as a metabolite. The workflow also incorporates the annotation as described above to ensure the identified spectrum originates from the sample. Match scoring performed by the pipeline is well documented in the literature for the NIST Tandem MS library and for the NIST MS Search program and is based upon the dot product of the spectra being compared (S. E. Stein, 1999). The match score has been validated by manual inspection of matches and correlates very well with the match quality as determined by visual inspection. A score cut-off of 400 removes essentially all poor matches and has been chosen as the default cutoff for metabolites. To assign confidence, an identification can initially be classified as high, medium, or low confidence, depending on the match score. Scores of 400-599, 600-799, and 800-999 correspond to low, medium, and high confidence, respectively. Of course, in cases of isomers with similar spectra, distinguishing them may not be possible without the use of reference standards. Prior probability as well the spectrum annotation can be used to raise or lower the qualitative level of confidence and can, to some degree, assist in isomer identification. Figure 5 depicts the workflow that was developed for assigning confidence. The workflow starting with a medium confidence is depicted at the top of the figure and is described below. The workflow starting with a low or high confidence is depicted at the bottom of the figure with the differences from the medium highlighted in green. The first step in the workflow is to determine if the identified compound is a known metabolite. For this study, performed a literature search for reported CHO cell we metabolites and searched the Human Metabolome Database

**FIGURE 5** Workflow for assigning confidence in MS/MS identifications. Initial confidence level is determined by the match score and initial medium confidence is shown at the top. MS, mass spectrometry [Color figure can be viewed at wileyonlinelibrary.com]

# WILEY-BIOIECHNOLOGY

(HMDB; Wishart et al., 2013, 2018) and/or PubChem (Kim et al., 2019) to see if the compound was a reported human metabolite (it was not considered a metabolite if it was on HMDB, but not endogenous). In addition, we searched for lipids using the LIPID MAPS structure database (Sud et al., 2007). If it was found in any of these places, the qualitative confidence level was increased and if not, it was decreased. For the initial confidence of medium, an identification was elevated to high confidence if it was a known metabolite and lowered to low confidence if it was not. The next step is determining if the spectrum is annotated as a known/unknown. For the right side of the workflow, if the spectrum is not a known/unknown, confidence remains low and if it is, confidence is elevated to medium. On the left side of the workflow, if the spectrum is a known/unknown, confidence remains high and if it is not, it is determined if the spectrum is annotated as an artifact/carryover. If the spectrum is an artifact/ carryover, then confidence remains high, and if it is not, confidence is lowered to medium. Confidence is only elevated once in the workflow to prevent a match with a low score from being elevated to high confidence. Table S5 shows the 20 most abundant identified ions from the data in Figure 1 and their associated confidence.

### 3.7 | Automation

One of the goals of this study was to develop tools that could be automated after initial development. The two workflows for annotation of spectra in the library and assignment of a qualitative confidence level for library identifications are amenable to automation via development of software tools. This will drastically increase the speed at which annotation and confidence assignment can occur. In addition, development of software tools for assessing prior probability and tools for automatic detection of spectra that are likely to be originating from the Pluronic F-68 in the cell culture media will be beneficial. However, expert evaluation of the output of any developed software tools will be required until the methods become routine.

# 4 | CONCLUSIONS

We have created the first recurrent spectral library for use in identifying CHO cell metabolites and outlined a procedure for future extensions. The library contains metabolites originating from a single CHO cell variety in a single cell culture media and represents the spectra of all compounds repeatedly observed in these samples and can be used as a tool by others in the field to quickly identify compounds in a CHO cell metabolite sample. During this analysis, we have developed a method capable of identifying all components commonly found in the LC-MS analysis of CHO cell metabolite extracts and media. An extension of this approach is expected to lead to both an automated way to extend this library and to develop similar libraries for other metabolite materials. Finally, we developed a strategy to assign qualitative confidence to NIST MS/MS library identifications. Although methods of representing the confidence of measurement have been developed for reporting individual metabolite identifications, this scheme could not adequately represent the confidence needed to properly annotate the identification made here—many of which cannot be regarded as definitive. The next step for this project will be automation of the workflows and release of the recurrent spectral libraries. The libraries can then be used in metabolomics studies of CHO cell metabolites using LC-MS/MS analyses.

### ACKNOWLEDGMENT

The authors thank Dr. Arun Moorthy of the NIST MSDC for aiding in writing the pseudocode for hit list sorting. The authors also thank Dr. Tytus Mak of the NIST MSDC as well as Dr. Michael J. Betenbaugh, Harnish Mukesh Naik, and Venkata Gayatri Dhara from Johns Hopkins University for discussions regarding the CHO cell metabolite analysis project.

### AUTHOR CONTRIBUTIONS

Kelly H. Telu and Stephen E. Stein contributed intellectually to project conceptualization and experiment design. Renae J. Preston and Lila Kashi grew the CHO cells used in the experiments. Zvi Kelman supervised CHO cell growth. Kelly H. Telu, Ramesh Marupaka, and Nirina R. Andriamaharavo performed the experiments. Kelly H. Telu, Yamil Simón-Manso, and Yuxue Liang contributed to LC-MS/MS method development. Yuri A. Mirokhin developed the algorithm Tallat H. Bukhari used to create the recurrent spectral libraries. The manuscript was drafted by Kelly H. Telu, revised by Stephen E. Stein, and then critiqued and approved by all co-authors. Stephen E. Stein supervised the project.

#### DATA AVAILABILITY STATEMENT

All programs and data are freely available at chemdata@nist.gov or via request to the corresponding author.
