DOI: 10.3892/ijmm.2021.5061

Abstract. Cartilage extracellular matrix (ECM) metabolism disorder caused by mechanical instability is a leading cause of osteoarthritis (OA), but the exact mechanisms have not been fully elucidated. Recent studies have suggested an important role of circular RNAs (circRNAs/circs) in OA. The present study aimed to investigate whether circRNAs might have a role in mechanical instability-regulated chondrocyte matrix metabolism in OA. The expression levels of circPhc3 in human and mouse OA cartilage samples were measured using reverse transcription-quantitative PCR and fluorescence in situ hybridization. The effects of circPhc3 on chondrocyte ECM metabolism were further investigated by overexpressing and knocking down circPhc3 in OA chondrocytes. The downstream target of circPhc3 was examined by performing a luciferase reporter assay. The results showed that the expression of circPhc3 was reduced in human and mouse OA cartilage. Moreover, circPhc3 was involved in mechanical loading-regulated production of ECM and cartilage-degrading enzymes. Further studies showed that circPhc3 regulated chondrocyte matrix metabolism primarily by binding to microRNA (miR)-93-3p, and mechanistic studies found that miR-93-3p targeting of FoxO1 was involved in chondrocyte matrix metabolism. Taken together, these results indicated that circPhc3 may serve an important role in the progression of OA and may be a good target for the treatment of OA.

Introduction

Osteoarthritis (OA) is a degenerative disease characterized by cartilage destruction and loss, subchondral bone thickening and hardening, and osteophyte formation accompanied by varying degrees of synovitis and joint capsule thickening (1). The occurrence of OA is associated with certain factors, including mechanical instability, age, inflammation, trauma and genetics (2). At present, no effective disease-modifying therapies exist for OA due to the limited understanding of its pathogenesis. Although studies have identified elements that are involved in the progression of OA, the precise mechanism of OA pathogenesis has not yet been elucidated.

Articular cartilage directly participates in maintaining normal joint motor functions and is primarily composed of cartilage extracellular matrix (ECM) and cartilage cells (3). Articular cartilage cells are the only type of cell found in articular cartilage (4), and maintain the metabolic balance of cartilage tissue by producing ECM molecules, including collagens and proteoglycans, as well as matrix-degrading enzymes, such as matrix metalloproteinases (MMPs) (5). The pathological destruction of joint tissues in OA is primarily due to the reduced ability of chondrocytes to generate articular cartilage ECM and the enhanced action of chondrocytes to generate catabolic matrix-degrading enzymes (6). Previous studies have demonstrated that the imbalance in chondrocyte matrix metabolism caused by mechanical instability is a critical factor in the development of OA (7,8). Therefore, exploring the molecular mechanisms by which mechanical instability causes the imbalance in chondrocyte matrix metabolism is important for prevention and treatment of OA.

Circular RNAs (circRNAs/circs) are a novel type of RNA that, unlike linear RNAs, form a covalently closed continuous loop and are highly represented in the eukaryotic transcriptome. A large number of circRNAs are derived from exon sequences and are located in the cytoplasm of eukaryotic cells (9). Numerous studies have demonstrated that some circRNAs are involved in the development of OA, such as circRNA.33186, circSERPINE2 and circCDK14 (10-13). Previous studies have confirmed that the most important regulation method of circRNAs involves competitive endogenous RNAs adsorbing microRNAs (miRNAs/miRs) to regulate the expression of downstream genes (14,15). Thus, exploring the roles of circRNAs and their potential miRNA regulators is critical for identifying the molecular mechanisms of OA. The present study aimed to investigate whether circRNAs might serve a role in mechanical instability-regulated chondrocyte matrix metabolism in OA. The expression levels of mechanics-related circPhc3 in human and mouse OA cartilage samples were measured using reverse transcription-quantitative PCR (RT-qPCR) and fluorescence *in situ* hybridization (FISH). The effects of circPhc3 on chondrocyte ECM metabolism were further investigated by overexpressing and knocking down circPhc3 in OA chondrocytes. The downstream target of circPhc3 was examined by performing a luciferase reporter assay. The results of present study revealed a fundamental role of circPhc3 in the progression of OA and provided a potential drug target for OA therapy.

Materials and methods

Primary OA and traumatic OA specimen selection. Healthy patients (n=10; 6 female patients and 4 male patients; age, 45±18 years) and 10 patients with knee OA (n=10; 6 female patients and 4 male patients; age, 54±17 years) were enrolled in Tongji Hospital affiliated to Tongji University (Shanghai, China) between October 2020 and December 2020. Healthy human knee cartilage samples were obtained from those patients undergoing arthroscopic partial meniscectomy with no evidence for OA. Patients presenting with cartilage chondrosis, bone-marrow lesions/edema and no ligamentous injury > grade I medial-collateral ligament strain were included as donors for healthy human knee cartilage samples. Human OA knee cartilage samples were obtained from patients with a diagnosis of advanced OA who underwent total knee arthroplasty. Knees were assessed by radiographs using the Kellgren-Lawrence (KL) scale (16) for OA. Any knees presenting imaging signs of previous bone fracture, previous knee surgery (including knee replacement procedures, ligamentoplasty and cartilage repair procedures) or poor image quality were excluded from the present study. All individuals provided written informed consent for the use of human specimens for experiments. The present study was approved by the Ethics Committee of Tongji Hospital of Tongji University (approval no. 2020TJYLL287).

Animal experiments. C57BL/6 mice (n=36; age, 8 weeks; weight, 20-30 g) were kept under standard animal room conditions at 25±3°C with 12-h light/dark cycles, 60% relative humidity and ad libitum access to food and water. Mice were divided randomly into the following two groups (n=18 per group): i) Sham operation; and ii) OA. The OA group underwent destabilized medial meniscus (DMM) surgery to trigger OA. Briefly, following induction of anaesthesia using an intraperitoneal injection of 1% sodium pentobarbital (50 mg/kg), the joint capsule was opened. The medial meniscotibial ligament was transected with microscissors, and the medial meniscus was displaced medially. After washing with saline to remove tissue debris, the skin incision was closed. In the Sham operation group, only the joint cavity was opened and then the skin incision was closed with suture. The health and behaviour of OA model mice and Sham mice were monitored once a day. No accidental death of animals was observed during the experiment. After 8 weeks, the mice were euthanized. Rapid weight loss (15-20% drop in one day) and some symptoms of the central nervous system (including head and neck skewing, deformity, epilepsy, turning circle and paralysis) were considered as humane endpoints of the animal experiment. All mice (n=36) were euthanised at the end of the study by cervical dislocation under deep anaesthesia. Subsequently, the joints were collected for mRNA quantification, histological assessments and cell culture. All animal care and experimental procedures were approved by the Institutional Animal Care and Use Committee of Tongji Hospital of Tongji University (approval no. IACUC20200422) and were carried out in accordance with the Guide for Laboratory Animal Use (https://life.tongji.edu.cn/05/e2/c12677a132578/page.htm).

Immunofluorescence staining. Mouse chondrocytes were fixed with 4% paraformaldehyde for 30 min at room temperature and then washed three times with PBS. Subsequently, cells were permeabilized with 0.4% Trion X-100, followed by blocking with 10% donkey serum (Abcam) for 1 h at room temperature. The samples and cells were then incubated with anti-collagen type II, α1 (Col2a1; 1:200; cat. no. sc-52658; Santa Cruz Biotechnology, Inc.), anti-Aggrecan (1:200; cat. no. MA3-16888; Invitrogen; Thermo Fisher Scientific, Inc.) and anti-MMP-3 (1:200; cat. no. ab39012; Abcam) primary antibodies in blocking solution at 4°C overnight. Next, the samples and cells were incubated with the corresponding mouse immunoglobulin G (H+L) (Alexa Fluor 488, 1:1,000; cat. no. A-11001; Invitrogen; Thermo Fisher Scientific, Inc.) and rabbit immunoglobulin G (H+L) secondary antibodies (Alexa Fluor 555; 1:1,000; cat. no. A-21428; Invitrogen; Thermo Fisher Scientific, Inc.) secondary antibodies (both Invitrogen; Thermo Fisher Scientific, Inc.) and DAPI for 1 h at room temperature. A fluorescence microscope (Carl Zeiss AG) was used to observe stained samples.

Histological analysis. Human and mice tissue samples were fixed in 4% paraformaldehyde for 30 min at room temperature and then decalcified with ethylenediaminetetraacetic acid-buffered saline solution (pH 7.4; 0.25 M). After conventional dehydration and paraffin embedding, specimens were sliced into $4-\mu$ m sections, and routinely dewaxed and washed with xylene. Hematoxylin and eosin (H&E) staining was performed, in which the slices were stained with hematoxylin for 5 min, followed by staining with 0.3% eosin solution for 3 min (Beyotime Institute of Biotechnology) at room temperature. For safranin-O/fast green staining, the slices were stained with solid green dye solution for 5 min, and then stained with Safranin O stain (Beijing Solarbio Science & Technology Co., Ltd.) for 2 min at room temperature. For toluidine blue staining, the slices were stained with 1% toluidine blue solution for 10 min at room temperature, then washed with distilled water for 5 min. After staining, specimens were dehydrated in an ascending alcohol and sealed with neutral resin. Histological changes from H&E and toluidine blue staining were observed. Proteoglycans/collagen contents were observed with safranin O-solid green staining. Staining was observed using a light microscope.

Chondrocyte culture and tensile strain loading. Cartilage was extracted from OA patients and healthy patients, followed by washing twice with PBS. The tissues were cut into

2 mm² pieces, and then digested with 1 mg/ml protease K (Sigma-Aldrich; Merck KGaA) for 30 min and 2 mg/ml collagenase overnight at 37°C. Human chondrocytes were collected by centrifugation (10,000 x g for 10 min) at room temperature. Mouse chondrocytes were isolated from articular cartilage in the knee joints of mice as previously described (17). Briefly, articular cartilage tissues were cut into small pieces (<1 mm³), followed by digestion with 0.25% trypsin and 0.2% type II collagenase (Roche Diagnostics GmbH). Following centrifugation (10,000 x g for 10 min) at room temperature, cells were cultured in DMEM/F12 media (Gibco; Thermo Fisher Scientific, Inc.) with 10% fetal bovine serum (FBS; Gibco; Thermo Fisher Scientific, Inc.) and 1% antibiotics at 37°C under 5% CO₂. Chondrocytes were identified by Alcian blue staining. Briefly, chondrocytes were fixed in 4% paraformaldehyde for 30 min at room temperature. Subsequently, 1% alcian blue solution was added to the cells for 12 h at room temperature. Cells were washed with distilled water for 5 min and then visualized using a light microscope.

At 70-80% confluence, cells were subjected to cyclic tensile strain with a 0.5 Hz sinusoidal curve at 5-20% elongation for 6-24 h using a Flexcell1 FX-5000 tension system (Flexcell International Corporation). The chondrocytes in the control group were cultured without intervention.

FISH. Mice articular cartilage tissue samples and chondrocytes were fixed in 4% paraformaldehyde for 30 min at room temperature. Mice tissue samples were decalcified with ethylenediaminetetraacetic acid-buffered saline solution (pH 7.4; 0.25 M). After conventional dehydration and paraffin embedding, specimens were sliced into $4-\mu m$ sections, and then routinely dewaxed and washed with xylene. An Alexa Fluor 488-labeled circPhc3 probe was designed and synthesized by Invitrogen (Thermo Fisher Scientific, Inc.). The probe signals were tested in articular cartilage tissue and chondrocytes with the Fluorescent in Situ Hybridization kit (Shanghai GenePharma Co., Ltd.) according to the manufacturer's protocol. FISH results were acquired using laser scanning confocal microscopy (LSM800; Carl Zeiss, AG). ImageJ software (National Institutes of Health) was used to analyse the immunofluorescence accumulation optical density of circPhc3 in cartilage samples.

Cell transfection. The overexpression plasmid vector of mouse circPhc3 was constructed by Shanghai GeneChem Co., Ltd. The circPhc3 sequence (1 kb upstream) was inserted into the pcDNA3.1 His c plasmid (Shanghai GeneChem Co., Ltd.). circPhc3 without the downstream reverse sequence was used as the Mock group. A short hairpin RNAs (shRNAs) directed against circPhc3 was constructed into the pGPU6/GFP/Neo vector (Shanghai GeneChem Co., Ltd.) to generate silencing plasmids. A non-specific scrambled shRNA was used as the negative control (NC). miR-93-3p mimic, miR-93-3p mimic-NC, anti-miRNA oligonucleotides (AMO)-93-3p and AMO-NC were purchased from Shanghai GeneChem Co., Ltd. Chondrocytes were seeded (1x10⁵ cells/cm²). At 70% confluence, cells were transfected with 1 μ g plasmid DNA or 100 nM miRNA mimic, AMO or corresponding NCs using Lipofectamine® 3000 reagent (Invitrogen; Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol

at 37°C. At 24 h post-transfection, transfection efficiency was determined via RT-qPCR. All functional experiments were performed at 48 h post-transfection. The sequences of the constructs used in the present study were as follows: miR-93-3p mimic, 5'-ACUGCUGAGCACUUCCCG-3'; AMO-93-3p, 5'-CGGGAAGUGCUCAGCAGU-3'; mimic NC, 5'-UUCUCCGAACGUGUCACGUTT-3'; AMO-NC, 5'-CAG UACUUUUGUGUAGUACAA-3'; circPhc3 shRNA, 5'-AGG TAATTCAGCAGGCCTTGC-3'; and shRNA-NC, 5'-TTC TCCGAACGTGTCACG-3'.

Western blotting. Chondrocytes were harvested and lysed with RIPA lysis buffer (Beyotime Institute of Biotechnology) as previously described (18). The total protein concentration was quantified using the bicinchoninic acid protein assay kit (Pierce; Thermo Fisher Scientific, Inc.). Proteins (50 µg) were separated via 7.5-10% SDS-PAGE and transferred to nitrocellulose membranes (Cytiva). After blocking with 5% dry milk in TBST (0.1% Tween-20) for 1 h, the membranes were incubated overnight at 4°C with primary antibodies targeted against recombinant MMP-3 (1:1,000; cat. no. ab52915, Abcam), Aggrecan (1:500; cat. no. MA3-16888; Invitrogen; Thermo Fisher Scientific, Inc.), Col2a1 (1:200; cat. no. sc-52658; Santa Cruz Biotechnology, Inc.), FoxO1 (1:1,000; cat. no. ab179450; Abcam), MMP-13 (1:1,000; cat. no. ab39012; Abcam), a disintegrin and metalloprotease with thrombospondin type 1 motif 5 (ADAMTS5; 1:1,000; cat. no. ab41037; Abcam) and β-actin (1:1,000; cat. no. ab8226; Abcam). Subsequently, the membranes were incubated with horseradish peroxidase-conjugated rabbit anti-mouse IgG H&L (1:1,000; cat. no. ab190475; Abcam) and goat anti-rabbit IgG H&L (1:1,000; cat. no. ab205718; Abcam) secondary antibodies for 1 h at room temperature. Target bands were visualized using Pierce[™] ECL Western Blotting Substrate (Thermo Fisher Scientific, Inc.). ImageJ software (version 1.8.0; National Institutes of Health) was used to semi-quantify protein expression with β -actin as the loading control.

RT-qPCR. Total RNA was isolated from chondrocytes and purified using the RNeasy Mini Kit (Qiagen GmbH) as previously described (19). Total RNA (1 μ g) was reverse transcribed into cDNA using Superscript II reverse-transcriptase (Thermo Fisher Scientific, Inc.). Subsequently, qPCR was performed using the SYBR Premix Ex Tag kit (Takara Bio, Inc.) and an ABI 7500 sequencing-detection system (Applied Biosystems; Thermo Fisher Scientific, Inc.). The following thermocycling conditions were used for qPCR: 95°C for 3 min; 40 cycles of 95°C for 10 sec and 60°C for 30 sec. A melt curve step from 65-95°C was performed in increments of 0.5°C per 5 sec. The sequences of the primers used in the present study are listed in Table I. The relative mRNA and miRNA expression levels were quantified using the 2- $\Delta\Delta$ Cq method (20) and normalized to the internal reference genes β-actin and U6, respectively.

Bioinformatics analysis. The bioinformatics database CircNet (http://circnet.mbc.nctu.edu.tw/) was used to predict the potential target miRNAs of circPhc3, which were further predicted by Shanghai Kangcheng Biotech. The miRDB (http://mirdb.org/) and TargetScanHuman (www.targetscan.

org) databases were used to predict the potential target genes of miR-93-3p.

Luciferase reporter assays. To reveal the interaction between circPhc3 and miR-93-3p, a circPhc3 sequence containing

the complementary sequences of miR-93-3p was chemically synthesized and cloned downstream of the firefly luciferase gene in the pMIR-REPORTTM reporter vector (Thermo Fisher Scientific, Inc.). After incubation in DMEM (Thermo Fisher Scientific, Inc.) supplemented with 0.5% FBS for 48 h, 293T cells (The Cell Bank of Type Culture Collection of The Chinese Academy of Sciences; 1x10⁵ cells/well) were co-transfected with 1 μ g pMIR-circPhc3, 50 ng pRL-TK vector (Promega Corporation) and 100 nM miR-93-3p mimic or miR-NC using Lipofectamine 3000 for 48 h at 37°C. At 48 h post-transfection, cells were collected and luciferase activities were measured using a dual luciferase reporter assay kit (Promega Corporation). Firefly luciferase activities were normalized to *Renilla* luciferase activities.

Statistical analysis. Data are presented as the mean \pm SD from three or more independent experiments. A two-sided unpaired Student's t-test was used to analyse the difference between two groups. Comparisons among multiple groups were analysed using one-way ANOVA followed by Tukey's post hoc test. Statistical analyses were performed using the NCSS statistical software (version 21.0.3; NCSS Statistical Software). P<0.05 was considered to indicate a statistically significant difference.

Results

circPhc3 expression is reduced in human and mouse OA cartilage. OA mouse models were established to determine the expression levels of mechanics-related circRNAs in OA cartilage. Alterations in articular cartilage in the DMM-induced mouse model of OA were observed by safranin O (Fig. 1A), H&E (Fig. 1B) and toluidine blue (Fig. 1C) staining. The results showed a greater loss of integrity and more severe destruction in OA mouse cartilage compared with that in Sham mouse cartilage. Subsequently, the expression levels of Col2a1, Aggrecan and MMP-3 in OA mouse cartilage were assessed by RT-qPCR (Fig. 1D). The mRNA expression levels of Col2a1 and Aggrecan were significantly decreased in OA mouse cartilage compared with those in Sham mouse cartilage, whereas MMP-3 mRNA expression was significantly increased in OA mouse cartilage, indicating that the mouse model of OA was successfully established. The expression levels of mechanics-related circRNAs were then measured in OA mouse cartilage, where circ_0011776, circ_0009580, circ_0004001, circ_0008444 and circ_0009975 were significantly upregulated, whereas circ_0006232, circ_0000436, circ_0000972, circ_0010621 (circPhc3) and circ_0008589 were significantly downregulated in OA mouse cartilage compared with that in Sham mouse cartilage (Fig. 1E). circPhc3 displayed the lowest expression levels among the differentially expressed circRNAs. Fluorescence in situ hybridization (FISH) staining showed that the expression of circPhc3 was decreased in OA mouse cartilage, which was evidenced by the significantly reduced green fluorescence of circPhc3 observed in OA mouse cartilage compared with that in Sham mouse cartilage (Fig. 1F and G). Furthermore, the expression of circPhc3 in knee articular cartilage from patients with OA was measured. Safranin-O staining of articular cartilage samples from patients with OA showed that the articular cartilage had suffered serious destruction (Fig. 1H), which was accompanied

Figure 1. circPhc3 expression is reduced in human and mouse OA cartilage. (A-C) Changes in articular cartilage in the destabilized medial meniscus-induced mouse model of OA were observed by (A) safranin O-fast green, (B) hematoxylin and eosin and (C) toluidine blue staining (n=6). (D) mRNA expression levels of Col2 α 1, Aggrecan and MMP-3 in mouse OA cartilage were analysed by RT-qPCR. **P<0.01 (n=4). (E) Expression levels of mechanics-related circRNAs in mouse OA cartilage were analysed by RT-qPCR. **P<0.01 (n=4). (E) Expression levels of mechanics-related circRNAs in mouse OA cartilage were analysed by RT-qPCR. **P<0.01 (n=4). (F) Expression of circPhc3 in mouse OA cartilage was (F) detected by fluorescence *in situ* hybridization staining and (G) quantified. **P<0.01 (n=4). (J) Expression levels of circPhc3 in cartilage tissues of patients with oA were analysed by RT-qPCR. **P<0.01 (n=4). (J) Expression levels of circPhc3 in cartilage tissues of patients with OA were analysed by RT-qPCR. **P<0.01 (n=4). (J) Expression levels of circPhc3 in cartilage tissues of patients with oA, osteoarthritis; Col2 α 1, collagen type II, α 1; MMP, matrix metalloproteinase; RT-qPCR, reverse transcription-quantitative PCR; mmu, Mus musculus.

by significantly increased expression levels of MMP-3 and decreased expression levels of Col2 α 1 and Aggrecan in the articular cartilage samples of patients with OA compared with those from healthy patients (Fig. 1I). The RT-qPCR results showed that the expression level of circPhc3 in the cartilage of patients with OA was significantly lower compared with that in the cartilage of healthy patients (Fig. 1J).

circPhc3 expression is reduced in chondrocytes in response to mechanical stimuli. Chondrocytes from OA model mice were isolated and identified by chondrocyte-specific Alcian blue staining (Fig. 2A). FISH staining showed that the expression of circPhc3 was markedly decreased in chondrocytes from OA model mice, as evidenced by a reduction in cytoplasmic green fluorescence compared with that in chondrocytes from Sham mice (Fig. 2B). The RT-qPCR results further confirmed that the expression of circPhc3 was significantly lower in chondrocytes from OA model mice compared with that in Sham mice (Fig. 2C). Next, chondrocytes were isolated from patients with OA and subjected to RT-qPCR. The results showed that the expression of circPhc3 was also significantly decreased in the chondrocytes isolated from patients with OA compared with that in chondrocytes isolated from healthy patients (Fig. 2D). In addition, the expression of circPhc3 in chondrocytes exposed to mechanical load of different strengths and for different time courses was assessed. The results demonstrated that mechanical stimuli reduced the expression of circPhc3 in a time- and strength-dependent manner (Fig. 2E and F).

circPhc3 is involved in the secretion of ECM and cartilage degrading enzymes. To investigate the role of circPhc3 in the secretion of ECM and cartilage degrading enzymes, circPhc3 expression was knocked down and overexpressed using shRNA-circPhc3 and circPhc3 overexpression vector, respectively (Fig. 3A and B). The western blotting results showed that silencing circPhc3 significantly increased the expression of MMP-3 and decreased the expression levels of Aggrecan and Col2 α 1 compared with that in the shRNA-NC group (Fig. 3C-F). By contrast, circPhc3 overexpression displayed the opposite effect on protein expression levels. Similar results observed using RT-qPCR (Fig. 3G-I). Compared with those in the shRNA-NC group,

Figure 2. circPhc3 expression is reduced in chondrocytes in response to mechanical stimuli. (A) Alcian blue staining was used to identify chondrocytes isolated from OA model mice (n=6). (B) fluorescence *in situ* hybridization staining demonstrated that circPhc3 expression was decreased in chondrocytes from OA model mice, as evidenced by decreases in cytoplasmic green fluorescence (n=6). (C) circPhc3 expression levels in chondrocytes isolated from OA model mice and Sham mice were analysed by RT-qPCR. **P<0.01 (n=4). (D) circPhc3 expression levels in chondrocytes isolated from patients with OA and healthy patients were analysed by RT-qPCR. **P<0.01 (n=4). (E) circPhc3 expression levels in chondrocytes treated with mechanical load of (E) different strengths or (F) for different time periods. *P<0.05 and **P<0.01 (n=4). circ, circular RNA; OA, osteoarthritis; RT-qPCR, reverse transcription-quantitative PCR.

circPhc3-silenced chondrocytes displayed significantly increased mRNA expression levels of MMP-3 and decreased mRNA expression levels of Aggrecan and Col2a1 (Fig. 3G-I). The immunofluorescence staining results revealed that the green fluorescence intensities of Col2a1 and Aggrecan were notably lower in the shRNA-circPhc3 group compared with those in the shRNA-NC group, whereas these fluorescence intensities were obviously stronger in the circPhc3 overexpression group compared with those in the Mock group (Fig. 3J). By contrast, the green fluorescence intensities of MMP-3 were markedly increased in the shRNA-circPhc3 group and lower in the circPhc3-overexpression group compared with those in the shRNA-NC and Mock groups, respectively. Moreover, the effect of circPhc3 on MMP-13 and ADAMTS5 expression levels in chondrocytes was assessed using western blotting. The results showed that no significant changes in MMP-13 and ADAMTS5 expression levels were observed in circPhc3-overexpression or -silenced chondrocytes (Fig. S1). Taken together, these results indicated that circPhc3 promoted the secretion of ECM and inhibited the production of cartilage degrading enzymes.

circPhc3 is involved in mechanical loading-regulated production of ECM and cartilage degrading enzymes. The western blotting results showed that the expression of MMP-3 was significantly increased and the expression levels of Aggrecan and Col2a1 were significantly decreased in chondrocytes treated with 10% tensile for 24 h compared with those in the Control group (Fig. 4A-D). These tensile-induced effects were significantly attenuated by circPhc3 overexpression in chondrocytes. Similar results were observed following immunofluorescence staining (Fig. 4E). The RT-qPCR results further confirmed that mechanical loading significantly promoted the expression of MMP-3 and inhibited the expression levels of both Aggrecan and $Col2\alpha 1$ in chondrocytes compared with those in the Control group (Fig. 4F-H). However, circPhc3 overexpression alleviated the effects of mechanical loading on MMP-3, Aggrecan and Col2a1 expression levels in chondrocytes. These results suggested that circPhc3 was involved in mechanical loading-regulated production of ECM and cartilage degrading enzymes.

miR-93-3p targeted by circPhc3 is involved in the secretion of ECM and cartilage degrading enzymes. To explore the molecular mechanisms by which circPhc3 participates in the secretion of ECM and cartilage degrading enzymes in chondrocytes, algorithms were used to predict the putative targeting miRNAs of circPhc3. According to bioinformatics analysis data provided by Shanghai Kangcheng Biotech, circPhc3 contained multiple binding sites for miR-93-3p (Fig. 5A). The dual luciferase

Figure 3. circPhc3 is involved in the secretion of extracellular matrix and cartilage-degrading enzymes. (A) circPhc3 expression levels in chondrocytes transfected with shRNA-NC or shRNA-circPhc3 were analysed by RT-qPCR. The results showed that circPhc3 silencing was effective. **P<0.01 (n=4). (B) circPhc3 expression levels in chondrocytes transfected with Mock and circPhc3 overexpression vector were analysed by RT-qPCR. The results showed that circPhc3 overexpression was effective. **P<0.01 (n=4). Protein expression levels were (C) determined by western blotting and semi-quantified for (D) MMP-3, (E) Aggrecan and (F) Col2α1 in chondrocytes transfected with shRNA-NC, shRNA-circPhc3, Mock or circPhc3 overexpression vector. **P<0.01 (n=4). mRNA expression levels of (G) MMP-3, (H) Aggrecan and (I) Col2α1 in chondrocytes transfected with shRNA-NC, shRNA-circPhc3, Mock or circPhc3, Mock and circPhc3, overexpression vector were detected by RT-qPCR. *P<0.05 and **P<0.01 (n=4). (J) Col2α1, Aggrecan and MMP-3 expression in chondrocytes transfected with shRNA-NC, shRNA-circPhc3, Mock and circPhc3 overexpression vector were detected by immunofluorescence staining (n=4). circ, circular RNA; shRNA, short hairpin RNA; NC, negative control; RT-qPCR, reverse transcription-quantitative PCR; MMP, matrix metalloproteinase; Col2α1, collagen type II, α1.

reporter assay results showed that firefly luciferase activity was significantly decreased following co-transfection with pMIR-circPhc3 and miR-93-3p mimics (Fig. 5B). Subsequently, the expression of miR-93-3p in chondrocytes overexpressing or silencing circPhc3 was assessed using RT-qPCR. The results showed that miR-93-3p expression was significantly increased in circPhc3-silenced chondrocytes compared with that in shRNA-NC-transfected chondrocytes, whereas miR-93-3p

Figure 4. circPhc3 is involved in mechanical loading-regulated production of extracellular matrix and cartilage-degrading enzymes. Protein expression levels were (A) determined by western blotting and semi-quantified for (B) MMP-3, (C) Aggrecan and (D) Col2 α l in chondrocytes transfected with Mock or circPhc3 overexpression vector, followed by treatment with 10% tensile for 48 h. **P<0.01 (n=4). (E) MMP-3, Aggrecan and Col2 α l expression and location in chondrocytes transfected with Mock or circPhc3 overexpression vector under 10% tensile were detected by immunofluorescence staining (n=4). mRNA expression levels of (F) MMP-3, (G) Aggrecan and (H) Col2 α l in chondrocytes transfected with Mock or circPhc3 overexpression vector under 10% tensile. **P<0.01 (n=4). circ, circular RNA; MMP, matrix metalloproteinase; Col2 α l, collagen type II, α l.

expression was significantly decreased in circPhc3-overexpression chondrocytes compared with those in the Mock group (Fig. 5C). These results indicated that miR-93-3p may be a high affinity target of circPhc3 in chondrocytes.

To investigate whether miR-93-3p was involved in the secretion of ECM and cartilage degrading enzymes, miR-93-3p was overexpressed or silenced in chondrocytes by transfection with miR-93-3p mimic or AMO-93-3p, respectively (Fig. 5D). The western blotting results showed that miR-93-3p mimic significantly decreased the expression levels of Aggrecan and Col2 α 1 and increased the expression levels of MMP-3 in chondrocytes compared with those in the miR-NC group (Fig. 5E and F). By contrast, AMO-93-3p displayed the opposite effect. Similar results were observed via RT-qPCR (Fig. 5G). To further

Figure 5. miR-93-3p targeted by circPhc3 is involved in the secretion of extracellular matrix and cartilage-degrading enzymes. (A) Bioinformatics analysis demonstrated the circPhc3 had multiple binding sites for miR-93-3p. (B) Dual luciferase reporter assay results showed that the firefly luciferase activity was significantly decreased when the cells were transfected with pMIR-circPhc3 and miR-93-3p mimics compared with those transfected with pMIR-circPh3 and miR-NC. **P<0.01 (n=4). (C) miR-93-3p expression levels in chondrocytes transfected with shRNA-NC, shRNA-circPhc3, Mock or circPhc3 overexpression vector were detected by RT-qPCR. **P<0.01 (n=4). (D) miR-93-3p expression levels in chondrocytes transfected with miR-NC, miR-93-3p mimic, AMO-NC or AMO-93-3p were detected by RT-qPCR. **P<0.01 (n=4). Protein expression levels were (E) determined by western blotting and (F) semi-quantified for Aggrecan, Col2a1 and MMP-3 in chondrocytes transfected with miR-NC, miR-93-3p mimics, AMO-NC or AMO-93-3p. **P<0.01 (n=4). (G) mRNA expression levels of Aggrecan, Col2a1 and MMP-3 in chondrocytes transfected with miR-NC, miR-93-3p mimics, AMO-NC or AMO-93-3p were detected by RT-qPCR. **P<0.01 (n=4). Protein expression levels were (H) detected by western blotting and (I) semi-quantified for Aggrecan, Col2α1 and MMP-3 expresssion in chondrocytes transfected with AMO-NC or AMO-93-3p under 10% tensile for 48 h. *P<0.05 and **P<0.01 (n=4). (J) mRNA expression levels of Aggrecan, Col2al and MMP-3 in chondrocytes transfected with AMO-NC or AMO-93-3p under 10% tensile for 48 h were detected by RT-qPCR. **P<0.01 (n=4). Protein expression levels were (K) determined by western blotting and (L) semi-quantified for Aggrecan, Col2a1 and MMP-3 in chondrocytes transfected with circPhc3 overexpression vector and AMO-NC or AMO-93-3p. *P<0.05 and **P<0.01 (n=4). (M) mRNA expression levels of Aggrecan, Col2a1 and MMP-3 in chondrocytes transfected with circPhc3 overexpression vector and AMO-NC or AMO-93-3p were detected by RT-qPCR. **P<0.01 (n=4). miR, microRNA; circ, circular RNA; NC, negative control; shRNA, short hairpin RNA; NC, negative control; RT-qPCR, reverse transcription-quantitative PCR; AMO, anti-miR oligonucleotides; Col 2α 1, collagen type II, α 1; MMP, matrix metalloproteinase.

Figure 6. miR-93-3p regulates chondrocyte matrix metabolism by targeting FoxO1. (A) Complimentary sequences between miR-93-3p and FoxO1. FoxO1 protein expression in the articular cartilage of OA model mice and Sham mice was (B) determined by western blotting and (C) semi-quantified. **P<0.01 (n=4). FoxO1 protein expression in chondrocytes treated with 10% tensile for 48 h was (D) determined by western blotting and (E) semi-quantified. **P<0.01 (n=4). FoxO1 protein expression in chondrocytes transfected with miR-NC, miR-93-3p mimics, AMO-NC or AMO-93-3p was (F) determined by western blotting and (G) semi-quantified. **P<0.01 (n=4). FoxO1 protein expression in chondrocytes transfected with miR-NC, miR-93-3p mimics or AMO-93-3p mimics or AMO-93-3p under 10% tensile for 48 h was (H) determined by western blotting and (I) semi-quantified. **P<0.01 (n=4). (L) Luciferase activity of the reporter containing the 3'-UTR of FoxO1 treated with miR-93-3p mimic was significantly decreased compared with that in the pMIR-FoxO1 group. **P<0.01 (n=6). miR, microRNA; OA, osteoarthritis; NC, negative control; AMO, anti-miR oligonucleotides; shRNA, short hairpin RNA; mmu, Mus musculus; UTR, untranslated region.

examine whether miR-93-3p was involved in the regulation of matrix synthesis and catabolism by mechanical loading in chondrocytes, the expression levels of Aggrecan, Col2α1 and MMP-3 were measured in chondrocytes transfected with AMO-93-3p, followed by 10% tensile treatment for 48 h. The western blotting and RT-qPCR results showed that miR-93-3p knock-down significantly alleviated mechanical loading-mediated upregulation of MMP-3 expression in chondrocytes (Fig. 5H-J). Mechanical loading-mediated downregulation of Aggrecan and Col2 α 1 expression levels were also attenuated by AMO-93-3p in chondrocytes. To further confirm whether circPhc3 could bind to miR-93-3p to regulate chondrocyte matrix metabolism, the expression level of miR-93-3p was altered in chondrocytes using miR-93-3p mimic and AMO-93-3p. The results showed that circPhc3 overexpression significantly increased the expression levels of Aggrecan and Col2 α 1 and decreased the expression

levels of MMP-3 in chondrocytes compared with those in the Control group (Fig. 5K-M). These changes were further enhanced by AMO-93-3p in chondrocyte (Fig. 5K-M). These results indicated that circPhc3 targeting of miR-93-3p was involved in the regulation of chondrocyte matrix metabolism by mechanical loading.

miR-93-3p regulates chondrocyte matrix metabolism by targeting FoxO1. Based on the aforementioned results, miR-93-3p was confirmed to be involved in chondrocyte matrix metabolism. Thus, miR-93-3p might target several regulatory factors related to chondrocyte matrix metabolism. To address this issue, computation and bioinformatics-based approaches were used to predict the putative targets of miR-93-3p using TargetScan (www.targetscan.org). These analyses identified FoxO1 as a candidate target of miR-93-3p (Fig. 6A). The western blotting results demonstrated that the expression of FoxO1 was significantly decreased in the articular cartilage from OA model mice compared with that from Sham mice (Fig. 6B and C). Furthermore, the expression of FoxO1 was also significantly downregulated in chondrocytes treated with 10% tensile for 48 h compared with that in Control chondrocytes (Fig. 6D and E). To observe the effect of miR-93-3p on FoxO1 expression in chondrocytes, chondrocytes were transfected with miR-93-3p or AMO-93-3p to overexpress or knock down the expression of miR-93-3p, respectively. The western blotting results showed that miR-93-3p overexpression significantly decreased the expression of FoxO1 in chondrocytes compared with that in the miR-NC group (Fig. 6F and G). However, FoxO1 expression was significantly increased in chondrocytes transfected with AMO-93-3p compared with that in AMO-NC chondrocytes. Further analysis revealed that miR-93-3p overexpression enhanced the inhibitory effect of mechanical loading on FoxO1 expression, whereas AMO-93-3p alleviated mechanical loading-mediated FoxOldownregulation (Fig. 6H and I). Subsequently, the effects of circPhc3 on FoxO1 expression in chondrocytes were assessed. Compared with the Mock and shRNA-NC groups, circPhc3 overexpression significantly increased the expression of FoxO1, whereas circPhc3 knockdown significantly downregulated FoxO1 expression in chondrocytes, respectively (Fig. 6J and K). A luciferase reporter assay was performed to investigate whether miR-93-3p bound to the 3'-UTR of FoxO1. The results showed that luciferase activity was significantly decreased in the reporter containing the 3'-UTR of FoxO1 treated with miR-93-3p compared with those treated with miR-NC, suggesting that FoxO1 was the target gene of miR-93-3p (Fig. 6L).

Discussion

Mechanical instability is a critical factor for the initiation and progression of OA (21). Previous studies have reported that mechanical instability could cause disorders of cartilage cell synthesis and matrix metabolism (7,8,22). The present study demonstrated that mechanical instability downregulated the expression of circPhc3 in articular cartilage tissue, and circPhc3 participated in the production of ECM and cartilagedegrading enzymes primarily via sponging miR-93-3p to regulate FoxO1 expression. Therefore, the present study provided a novel theoretical basis for understanding the pathogenesis of OA induced by mechanical instability.

Recent studies have confirmed that circRNAs serve an important role in the pathogenesis of OA (23-26). Zhou et al (10) found that interleukin-1 β increased the expression of circRNA_33186 in chondrocytes in a time- and dose-dependent manner. Silencing circRNA_33186 in chondrocytes could effectively alleviate interleukin-1\beta-induced apoptosis of chondrocytes, suggesting that circRNA_33186 is involved in the process of inflammatory factor-induced chondrocyte apoptosis in OA. Liu et al (27) reported that an increased expression of circCER was accompanied by increasing expression levels of interleukin-1 and tumour necrosis factor in chondrocytes. Silencing circCER with small interfering RNA suppressed MMP-13 expression and increased ECM formation. Furthermore, Li et al (28) confirmed that hsa_circ_0045714 could regulate ECM synthesis, as well as the proliferation and apoptosis of chondrocytes by promoting the expression of miR-193b. To the best of our knowledge, the present study demonstrated for the first time that circPhc3 was involved in mechanical instability-regulated chondrocyte matrix metabolism in OA.

The chondrocytes in damaged cartilage are particularly susceptible to mechanical stress, and the tensile properties of damaged cartilage are lost due to the disrupted collagen network (22). Previous studies have found that the regulation of circRNAs by mechanical stress is involved in the pathogenesis of numerous diseases, such as intervertebral disk degeneration, orthodontic tooth movement and endplate cartilage degeneration (29-31). Xiang et al (30) reported that circCOG8 expression was obviously downregulated by mechanical stress in disk nucleus pulposus cells. The circCOG8/miR-182-5p/FOXO3 pathway may also be considered an important underlying mechanism in the involvement of compression during the progression of intervertebral disc degeneration (30). Xiao et al (32) detected tension-sensitive circRNA_0058097 molecules in human endplate chondrocytes, which might lead to novel preventative and therapeutic strategies for endplate cartilage degeneration. The present study demonstrated that circPhc3 was susceptible to mechanical stress, which is a critical factor for the maintenance of the balance of ECM in OA. However, the exact mechanisms by which mechanical stress regulates circPhc3 expression in chondrocytes requires further investigation.

circRNAs serve a crucial role in regulating gene expression by acting as miRNA sponges (33). In the present study, miR-93-3p was confirmed to be a high-affinitive target of circPhc3 in chondrocytes, which was involved in the regulation of ECM metabolism by circPhc3 in OA. Numerous studies have shown that miR-93-3p participates in the pathogenesis of inflammatory-related diseases. miR-93-3p could alleviate lipopolysaccharide-induced inflammation and apoptosis in H9c2 cardiomyocytes by inhibiting toll-like receptor 4 (34). Butler et al (35) found that miR-93-3p was correlated with the level of C-reactive protein, a marker of inflammation. Furthermore, miR-93-3p was also confirmed to be involved in the regulation of bone metabolism. Peng et al (36) suggested that long non-coding RNA-NTF3-5/miR-93-3p/RUNX family transcription factor 2 could regulate the osteogenic differentiation of mesenchymal stem cells and might serve as a therapeutic target for bone regeneration in the posterior maxilla. Moreover, Mäkitie et al (37) confirmed that circulating levels of miR-93-3p were related to patients with osteoporosis susceptible to defective PLS3 function. However, to the best of our knowledge, no previous studies have demonstrated that miR-93-3p is an important regulator of OA; therefore, the present study was the first to investigate the role of miR-93-3p in OA.

The results of the present study showed that miR-93-3p regulated chondrocyte matrix metabolism by targeting FoxO1. Previous studies have indicated that FoxO1 is involved in maintaining the balance of anabolism and catabolism of cartilage matrix. Wang et al (38) found that FoxO1 was a crucial mediator of TGF-\u03b3/TAK1 signalling and protected against OA by maintaining articular cartilage homeostasis. Lee et al (39) reported that FoxO1 supported homeostasis and protected against meniscus damage in response to mechanical overuse and during aging and OA. FoxO1 is also a transcription factor as a regulator of chondrocyte oxidative stress resistance and tissue homeostasis (40). In the present study, the results confirmed that FoxO1 was a high-affinitive target of miR-93-3p in OA chondrocytes. Although the results demonstrated that FoxO1 was a target gene of miR-93-3p in OA chondrocytes, a number of previous studies have reported that miR-93-3p has multiple target genes (34,41,42). Therefore, whether other miR-93-3p-targeting genes are also involved in maintaining the balance of chondrocyte matrix metabolism should be explored in future studies.

In conclusion, the results of the present study suggested that the circPhc3/miR-93-3p/FoxO1 pathway might be involved in the regulation of chondrocyte matrix metabolism by mechanical loading in OA. The present study aimed to establish a molecular mechanism of mechanical instability-induced OA to provide novel insights into the development of pharmacological and physical therapies that can modify the course of OA.
