Abstract

Purpose This systematic review and meta-analysis aimed to determine the effectiveness of psychologically informed practice (PIP) with behavioural graded activity (BGA) compared to (1) waitlist controls (WLC), (2) other interventions (OI), (3) PIP alone or (4) BGA alone in cancer patients and survivors (CPaS).

Methods PubMed, Web of Science and Embase were screened for randomised controlled trials encompassing BGA + PIP in CPaS. Effect sizes were inventoried for outcomes regarding physical activity (PA), quality of life (QoL) and debilitating symptoms (DS), which were assessed at four time points: post-intervention (PI), follow-up F1 (1 to 3 months), F2 (4 to 6 months) and F3 (> 6 months). The quality of the evidence was classified by the GRADE approach.

Results Thirty-three studies were found eligible, comprising 4330 participants. Significant effects with low heterogeneity of PIP + BGA comparing to WLC were found for anxiety (SMD − 1.29 [− 1.71; − 0.86]), depression (SMD − 0.79 [− 1.10; − 0.48]), functional impairment (SMD − 0.72 [− 0.95; − 0.50]), PA (self-reported: (SMD − 0.58 [− 0.84; − 0.32]) and objectively measured: (SMD − 0.51 [− 0.90; − 0.13])) and social impairment (SMD − 0.33 [− 0.58; − 0.08]). When comparing PIP + BGA to OI, fatigue (SMD − 0.35 [− 0.51; − 0.20]) and PA (SMD − 0.26 [− 0.41; − 0.11]) at PI, and fatigue (SMD − 0.34 [− 0.58; − 0.10]) at F1 were found significant with low heterogeneity. No significant effects were observed in the meta-analyses of studies comparing PIP + BGA to BGA or PIP alone.

Conclusions PIP with BGA has a favourable effect on DS, PA and QoL in CPaS when compared to non-behavioural interventions such as WLC, usual care and education. However, further research is needed on ‘how’ and ‘when’ PIP + BGA should be provided in cancer rehabilitation.

Implications for Cancer Survivors PIP + BGA has the potential to facilitate CPaS to reach the recommended amount of PA and reduce DS.

Keywords Adverse effects · Behaviour therapy · Exercise · Meta-analysis · Neoplasms · Quality of life

Introduction

Cancer is one of the most prevalent diseases in the world, with a burden estimated to have risen to 19.3 million new cases and 9.9 million deaths in 2020 [1]. For the most frequent occurring cancers, the 5-year survival has increased to 70% in most developed countries [2]. However, many cancer patients will experience a range of side effects and treatment-related problems that arise during and after treatment. During the

treatment phase, most cancer patients will face adverse effects [3]. After completion of cancer treatments, sequelae can be long term or latent [4], with pain, fatigue, anxiety, depression and sleep disturbances being the most commonly occurring [3]. The highly debilitating nature of these not only result in significant limitations in cognitive functioning, psychosocial functioning and physical activity levels, but also in a reduced health-related quality of life (HRQoL) [3, 5, 6].

The past decades have demonstrated that physical exercise programmes during and after cancer treatment have favourable effects on cancer recurrence, survival rate, pain, daily functioning and global health [7, 8]. A recently published Cochrane review reported that exercise programmes, including

Extended author information available on the last page of the article

goal setting, graded activity and guidance of how to perform behaviour, facilitates patients with and beyond cancer to reach and maintain the recommended amount of daily activity [9]. Behavioural graded activity (BGA) is a treatment based on operant conditioning, targeting patient's reported difficulties and chief complaints during participation in meaningful activities of daily living. This patient-tailored programme is based on an operant behavioural paradigm and teaches patients, after establishing a baseline tolerance level, how to gradually increase their meaningful activities in their daily life on a safe and time-contingent manner [10]. Considering this, BGA could enhance patients' willingness to maintain a healthy behaviour compared to other provided interventions [9].

Up until now, BGA has been investigated mainly in non-malignant chronic pain populations and demonstrated, for instance, positive effects on pain, debilitating symptoms and physical functioning [10–12]. However, BGA often occurs in a variety of behavioural therapies such as cognitive behavioural therapy (CBT), acceptance and commitment therapy (ACT) and other psychological programmes [13], which all fall under the denominator of psychologically informed practice (PIP) [14]. Graded activity appears foremost in CBT, which has demonstrated its positive effects on psychosocial functioning such as fatigue, depression, anxiety and HRQoL in cancer patients and survivors (CPaS) [15–18]. Other studies also demonstrated the benefit of the combination of CBT with physical exercise (PE) [17, 19].

The importance of determining the added value of PIP with BGA in cancer rehabilitation has been shown, as clinical guidelines recommend behavioural therapy or CBT and exercise [20, 21] with an individual approach based on functional needs, however without specific instructions for different symptoms. For this void, PIP and BGA can provide an evidence-based approach for different biopsychosocial symptoms within the cancer population.

However, so far, no systematic review has been published about the effect of PIP and BGA on different psychosocial symptoms, HRQoL and physical activity within cancer populations.

Therefore, the aim of this meta-analysis was to determine if PIP with BGA is more effective than (1) waitlist controls (WLC) or (2) other interventions in CPaS, on debilitating sequelae, HRQoL and physical activity level, and to evaluate the added value of BGA by comparing PIP with BGA to (3) PIP or (4) BGA alone.

Methods

Design

This systematic review and meta-analysis was completed following the PRISMA guidelines [22]. It was registered in Prospero under following number of classification: CRD42020190333.

Eligibility criteria

To be included, studies had to meet the following criteria: (1) Subjects of the experimental and control group needed to be identified as CPaS (cancer patients are individuals, who are diagnosed with cancer and currently receiving treatment with curative intent, and cancer survivors are individuals who have completed their primary cancer treatment (with the exception of maintenance therapy) and have no evidence of active disease [23]), and needed to be adults (18 years or older); (2) The intervention comprised of, or included BGA, in which goal-setting, time-contingent increase, patient and self-monitoring were indispensable components; (3) All types of control interventions were allowed; (4) Our main outcomes were debilitating (cancer-related) symptoms (such as anxiety, depression, fatigue, pain, insomnia/sleep, psychological distress and social impairment), HRQoL and physical activity level; (5) The design of the studies had to be randomised controlled trials (RCTs); (6) Studies needed to be written in English; and (7) Studies needed to be published past January 2000.

The next criteria were applied for exclusion: (1) Studies using healthy controls or patients with other diseases; (2) Studies with interventions that did not include BGA (e.g. interventions solely based on psychological aspects or without any active component, or studies with active components but without any behavioural aspects); (3) Studies with the following study design: literature reviews, cross-sectional studies, cohort studies, case reports, pilot studies, protocols, congress abstracts and letters.

Information sources

Articles regarding BGA in the cancer population were retrieved in PubMed, Web of Science and Embase based on the PICO acronym (population: CPaS; intervention: BGA (graded activity, graded exercise, operant conditioning, etc.) and PIP (ACT, behaviour strategies, cognition therapy, CBT, etc.)) with a filter on publication date (2000/01/01 to 2021/05/01). An overview of the applied search terms and their combinations can be found in Appendix Table 5.

Study selection

After removing duplicates, two reviewers (A.L. and I.R.) independently (i.e. blinded from each other) screened all the titles and abstracts for eligibility in a blinded standardised manner using the Rayyan software [24]. All divergences between the two reviewers were resolved by a third researcher (L.L.). Subsequently, two reviewers (A.L. and I.R.) screened the included abstracts on full-text, and any divergences were again resolved by a third researcher (L.L.). Additional studies were searched

independently by two researchers (A.L. and I.R.) via reverse citation and screening reference lists of included studies.

Data collection process

The data extraction file was created and based on the template of the data collection form provided by the Cochrane Collaboration [25], found in Appendix Table 7. For each study, sample size (N), age, intervention and control intervention (content and format), outcomes and outcome measurement, and effect size (95% CI) were put in the extraction file. When data were missing (i.e. standard deviation, mean or effect size), the author of the paper in question was contacted for more information. Two researchers (A.L. and I.R.) performed the data extraction independently, which was double-checked by a third researcher (L.L.) in case of divergences.

Quality assessment

The methodological quality was assessed by two researchers (A.L. and I.R.) independently using RoB 2: A revised Cochrane risk-of-bias tool for randomised trials. Judgement can be 'Low' or 'High' risk of bias or can express 'Some concerns' [26].

Besides that, a checklist was developed to assess the therapeutic validity of the studies, i.e. the requirements for BGA, which was subsequently checked and approved by an expert in the field (P.v.W). When the BGA-intervention of the included studies did not address a certain item, it was scored 0. A study was categorised as good if the following four criteria were present: the goal of the intervention is to improve function, the intervention uses goal-setting, the physical exercise is preceded by an educational session and the intervention is patient-tailored and time-contingent. Appendix Table 8 presents an overview of the BGA checklist.

For assessments of the overall quality of evidence for each outcome that included pooled data from RCTs only, the evidence was downgraded from 'high quality' by one level for serious: risk of bias, indirectness of evidence, inconsistency, imprecision of effect estimates or potential publication bias, as presented in the GRADE approach [27].

Summary measures

The primary outcome measure was the standardised mean difference (SMD) with 95% confidence intervals (CIs) for all outcomes of interest. If the SMD with 95% CIs was not reported, the mean difference, the mean change or the mean with their standard deviations or standard error were extracted in order to calculate the SMD for each outcome separately by using the Revman software (Review Manager 5.3.) and other calculators described in the Cochrane handbook [28].

Planned methods of analysis

Based on the intervention given to the control group, included studies were divided in four different categories: PIP with BGA versus WLC, PIP with BGA versus PIP, PIP with BGA versus BGA and PIP with BGA versus others. PIP incorporated interventions such as CBT, ACT and other psychological programmes. BGA was defined as a behavioural intervention with goal-setting, a gradual increase of activities and self-monitoring. WLC represented the no-intervention groups. Other intervention was defined as either usual care, physical activity as seen in a booklet, standard recommendation or education by itself. Comparing PIP with BGA to homogenous comparable interventions makes it easier to evaluate the added value of PIP with BGA, PIP alone and BGA alone.

A meta-analysis was performed for outcomes described in 2 or more studies. When different studies with identical participants had multiple outcomes, the most common and validated outcome was preferred. The method proposed by Higgins et al. was used for the assessment of the heterogeneity (I^2), in which the I^2 value represents the percentage of variability in effect estimates that can be attributed to heterogeneity rather than sampling error [28]. If I^2 was higher than 50%, subgroup analyses were performed based on the methodological quality of studies, evaluated by the ROB 2, and the quality of the given BGA intervention, which had to meet the four most valuable BGA items of the checklist. Both subgroup analyses were performed to possibly clarify the underlying systematic differences and avoid under- or overestimation of the effects. Sensitivity analyses were performed based on the population to evaluate the robustness of the effect. Results were described using SMD, for which a negative SMD indicated the degree to which the intervention (PIP with BGA) was more efficacious than the comparator [29].

In order to perform meta-analyses based on time of assessment, four different groups were formed: one post-intervention group and three follow-up groups. Follow-up F1 encompassed values from 1 to 3 months post-intervention, F2 from 4 to 6 months and F3 from more than 6 months after intervention.

Results

Study selection

The systematic search resulted in a total of 6733 articles, of which 33 articles (4330 participants) were included in this systematic review (Fig. 1) [30–62].

Study characteristics

All included studies were RCTs, with sample sizes ranging from 37 to 422 participants. All studies, except for one

[62], were conducted in high-income countries. Twenty-one of our studies investigated cancer survivors [30, 34, 36–39, 41, 43, 45–51, 53–57, 59] and the other twelve focused on cancer patients [31–33, 35, 40, 42, 44, 52, 53, 58, 61, 62]. Breast cancer was the most explored cancer, with nine studies on this condition [34, 36, 37, 43, 44, 50, 51, 56, 62], two studies referred to ovarian cancer [58, 61] and two to prostate cancer [33, 49]. The remaining 20 studies included all cancer types [30–32, 35, 38–42, 45–48, 52–55, 57, 59, 60].

Twelve studies were categorised in PIP with BGA versus WLC [30, 34, 36, 38, 39, 41, 43, 45, 53, 57, 59, 60], seven in PIP with BGA versus BGA [36, 40, 45–48, 57], six in PIP with BGA versus PIP [35, 36, 41, 44, 55, 59] and 18 in PIP with BGA in comparison to other interventions (e.g. usual care [31–33, 35, 37, 40, 50, 52, 58, 61], education [33, 42, 51, 54, 62] or physical activity [49, 52, 56]).

The length of the provided intervention varied from 1 [37, 49, 61] to 6 months [30–33, 38–40, 60]. The length of the follow-up assessments ranged from 10 weeks [60] to 2 years [32].

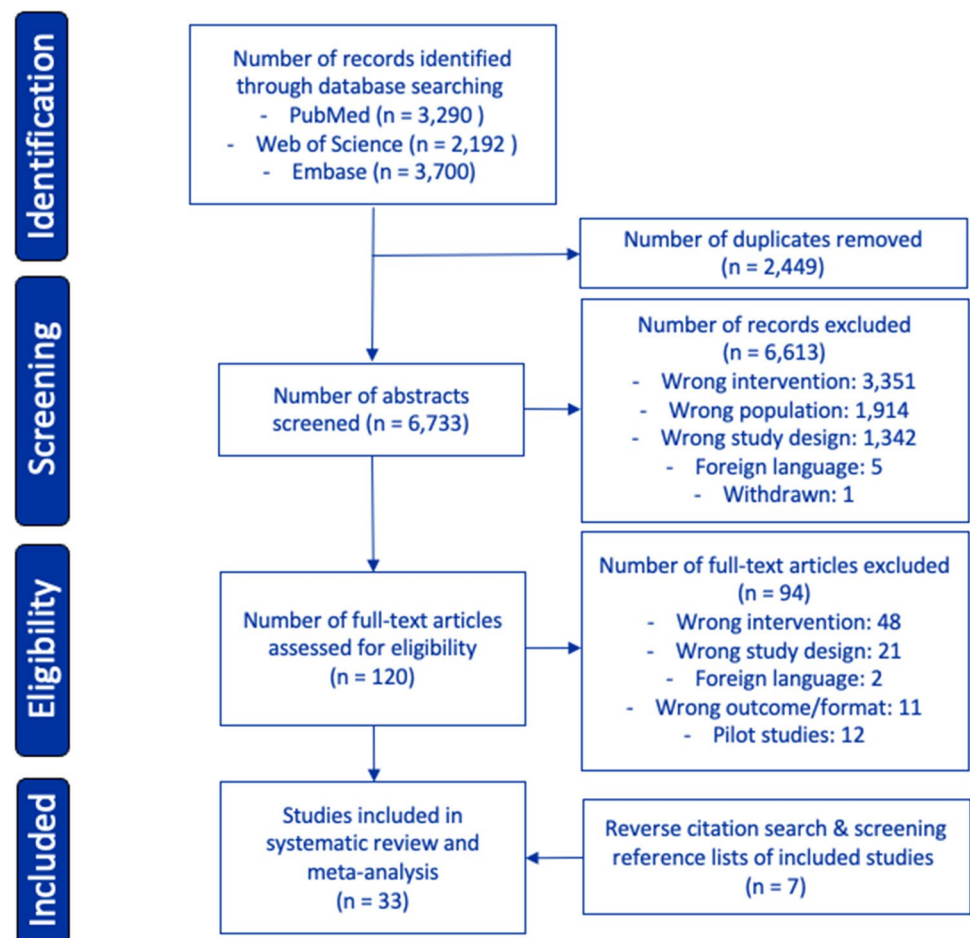

Twenty studies described self-reported physical activity [31, 33–37, 40, 43–45, 47–52, 54–57], 18 reported on fatigue [30, 31, 34, 37, 38, 40, 47, 49–58, 61], 17 on psychological distress [30, 32–38, 44, 45, 47, 49, 50, 54, 55, 57, 59], 14 on

HRQoL [30, 33, 34, 36, 37, 42, 44, 45, 47, 52, 55, 56, 60, 61], 13 on depression [32–34, 37, 41, 42, 44, 46, 58–62], eleven on anxiety [32, 33, 37, 41, 42, 44, 46, 59–62], eleven on functioning [30, 33, 34, 36, 38, 42, 44, 45, 47, 52, 53, 55, 61], nine on objectively measured physical activity [33, 34, 37, 40, 48, 50, 53, 55, 56], eight on social impairments [33, 34, 41, 44–47, 54, 55, 59], five on pain [33, 35, 36, 44, 45], five on sleep/insomnia [35, 54, 55, 58, 61] and three on cognitive functioning [39, 47, 55]. In several articles, the absence of effect sizes and mean changes entailed contacting the authors [30–38, 40–46, 48, 49, 51–58]. Some authors did not reply and therefore were excluded [35] from the meta-analysis when SMD could not be calculated by formula provided by Cochrane handbook [28].

Quality assessment within studies

The risk of bias within studies can be found in Appendix Table 6. When studies had multiple arms, all the control groups were scored on risk of bias for each extracted outcome. All studies had a high risk of bias except for two [40, 48]. One study had a low risk of bias [48], and the other one had some concerns [40], both for the outcome of physical activity measured objectively.

Fig. 1 Flowchart of the study selection process

A mean score of 6 out of 9 was found for the BGA checklist amongst studies, with 14 studies [31, 33, 37, 52–58] having the four most valuable BGA items present in the intervention given. An overview can be found in Table 1.

Synthesis of the results

This synthesis will discuss the significant meta-analyses of the different control interventions concerning the following outcome categories: debilitating symptoms, HRQoL and physical activity. The results of all meta-analyses are summarised in Table 2 and the effect size of single studies in Appendix Tables 9, 10, 11 and 12. An overview of the subgroup and sensitivity analyses can be found in Tables 3 and 4. For each control group, a summarizing GRADE table can be found in Appendix Table 13.

Debilitating (cancer-related) symptoms

Pain Pain demonstrated nonsignificant effect sizes (Table 2). No subgroup analysis could be performed and sensitivity analysis remained nonsignificant.

Fatigue

PIP + BGA versus WLC

PIP with BGA showed a significant decrease of fatigue (SMD = -0.86 [-1.18 ; -0.54]), with substantial heterogeneity in cancer survivors ($I^2 = 61\%$) [30, 34, 38, 53, 57]. Subgroup analysis did not reduce the heterogeneity and sensitivity analysis could not be performed.

PIP with BGA versus others

The pooled analysis demonstrated that PIP with BGA significantly decreases fatigue (SMD = -0.35 [-0.51 ; -0.20]) with moderate heterogeneity ($I^2 = 48\%$) [31, 37, 40, 49–52, 54, 56, 58, 61]. For follow-up F1, similar outcomes were found (SMD = -0.34 [-0.58 ; -0.10], $I^2 = 47\%$) [31, 37, 51, 52, 54, 58]. For follow-up F2, the significant effect could not be preserved (Table 2) [31, 52]. No subgroup analysis could be performed. Sensitivity analysis based on populations remained robust (Table 4).

Anxiety

PIP + BGA versus WLC

PIP with BGA demonstrated a significant decrease in anxiety (SMD = -1.29 [-1.71 ; -0.86]; $I^2 = 0\%$) [41, 60].

PIP with BGA versus others

Similar results were observed for post-intervention and follow-up F1, with considerable heterogeneity, respectively in cancer patients (SMD = -0.47 [-0.88 ; -0.06]; $I^2 = 83\%$) [32, 33, 42, 62, 63] and (SMD = -1.54 [-2.88 ; -0.21]; $I^2 = 87\%$) [61, 62]. For follow-up F2, an insignificant and homogeneous effect was found (Table 2) [32, 33]. Subgroup analysis could not reduce the high heterogeneity and sensitivity analyses based on population were not possible.

Depression

PIP + BGA versus WLC

Pooled analysis demonstrated that depression significantly decreased post-intervention (SMD = -0.79 [-1.10 ; -0.48]; $I^2 = 0\%$) [34, 41, 60]. Sensitivity analysis remained robust (Table 4).

PIP + BGA versus others

The pooled post-intervention effect was in favour of PIP with BGA (SMD = -0.46 [-0.84 ; -0.09]), with considerable heterogeneity ($I^2 = 82\%$) [32, 33, 42, 58, 61, 62]. In the follow-up F1, a larger effect was found (SMD = -1.43 [-2.46 ; -0.39]; $I^2 = 89\%$) [58, 61, 62]. For follow-up F2, an insignificant and homogeneous effect was found [32, 33]. Subgroup analysis did not reduce the heterogeneity (Table 3) and sensitivity analysis based on population was not possible (Table 4).

Insomnia/sleep

PIP + BGA versus others

The post-intervention pooled effect was not significant and heterogeneous (Table 2) [54, 58, 61]. Subgroup analysis reduced the heterogeneity and the effect remained insignificant (Table 3) [54, 58]. Sensitivity analysis remained non-significant (Table 4).

Psychological distress

PIP + BGA versus WLC

The pooled analysis demonstrated that PIP including BGA decreases psychological distress (SMD = -0.58 [-0.82 ; -0.34]), with substantial heterogeneity ($I^2 = 51\%$) [30, 34, 36, 38, 41, 45]. In the follow-up F1, a similar result was found (SMD = -0.89 [-1.76 ; -0.02]), with high heterogeneity ($I^2 = 82\%$) [36, 59]. The high heterogeneity could be reduced for the low quality of given BGA (SMD = -0.67 [-0.90 ; -0.44], $I^2 = 27\%$), and sensitivity analysis was not possible.

Abbreviations: *Study did not report the item; in bold: most valuable BGA items; 0: article did not include the item; 1: article did include the item

Social impairment

PIP + BGA versus WLC

Social impairment was significantly reduced in the PIP including BGA group (SMD = -0.33 [-0.58 ; -0.08]; $I^2=0\%$), in the post-intervention pooled analysis [34, 41, 45]. No sensitivity analysis could be performed.

Health-related quality of life

Quality of life

PIP + BGA versus WLC

The QoL was significantly higher (SMD = -0.38 [-0.68 ; -0.09]) for PIP including BGA, with moderate heterogeneity ($I^2=51\%$) [30, 34, 45, 60]. Subgroup analysis did not reduce the heterogeneity, and sensitivity analysis remained robust for cancer survivors (Table 4).

Functional impairment

PIP + BGA versus WLC

Patients receiving PIP with BGA had less functional impairment (SMD = -0.72 [-0.95 ; -0.50]; $I^2=0\%$) [30, 34, 38, 53].

Emotional functioning Emotional functioning did not demonstrate significant effect sizes (Table 2). Subgroup or sensitivity analysis could not be performed.

Role functioning Role functioning did not show significant effect sizes (Table 2). No subgroup or sensitivity analysis could be performed.

Physical activity level

Self-reported physical activity

PIP + BGA versus WLC

Physical activity significantly increased (SMD = -0.58 [-0.84 ; -0.32]), with moderate heterogeneity ($I^2=47\%$) [34, 36, 43, 45].

PIP + BGA versus others

Similar results were observed post-intervention (SMD = -0.26 [-0.41 ; -0.11]; $I^2=44\%$) [31, 33, 37, 40, 49–52, 54, 56]. In the follow-up F1, 6 studies [31, 37, 49, 51, 52, 54] also showed a significant effect (SMD = -0.26 [-0.51 ;

0.00]) in a heterogenic environment ($I^2=65\%$). In the follow-up F2, 3 studies [31, 33, 52] demonstrated insignificant effects (Table 2). Subgroup analysis made the heterogeneity of the follow-up F1 drop, and the effect size remained significant (SMD = -0.39 [-0.70 ; -0.08]; $I^2=44\%$). Sensitivity analysis increased the effect of the cancer patients during follow-up F1 (SMD = -0.64 [-0.95 ; -0.34], $I^2=0\%$).

PIP + BGA versus PIP

Post-intervention did not demonstrate a better effect, with high heterogeneity (Table 2) [36, 44, 55]. The same trend was observed after F1, with no heterogeneity [36, 44]. After sensitivity analysis, two studies remained in the cancer survivor group and the post-intervention effect size became larger and significant for PIP with BGA (SMD = -0.50 [-1.58 ; -0.58]; $I^2=88\%$) (Table 4).

Objectively measured physical activity

PIP + BGA versus WLC

Two homogenic studies [34, 53] took an objective measure of physical activity with pooled analysis showing significantly better results (SMD = -0.51 [-0.90 to -0.13]; $I^2=0\%$) post-intervention.

Discussion

The aims of this paper were first to examine the effectiveness of PIP with BGA in a cancer population on sequelae, HRQoL and physical activity. Secondly, PIP with BGA was compared to BGA alone and to PIP alone to identify the added value of BGA.

A total of 33 studies were included which together provided 14 outcomes divided over 4 control groups post-intervention and extended over 3 follow-up categories.

This meta-analysis revealed that PIP with BGA has a favourable effect on fatigue, anxiety, depression, psychological distress, social impairment, QoL, functional impairment and physical activity in comparison to WLC. The same result was found for psychological measures after 1 to 3 months. When PIP with BGA was compared to other interventions, significant effects were found for self-reported physical activity, fatigue, anxiety and depression. After 1 to 3 months, the significant reduction remained for fatigue, anxiety and depression. This positive and significant effect could not be preserved in analyses of studies comparing PIP with BGA to BGA alone or PIP alone.

The results obtained from these meta-analyses were consistent with previous literature. In 2011, a meta-analysis was performed to quantify the effects of behavioural and exercise

interventions in breast cancer patients and survivors [16]. The results indicated that behavioural techniques improved fatigue, depression, anxiety and stress.

For the effect of physical exercise interventions, statistically significant results were found on fatigue, depression, body-image and HRQoL [16].

Fatigue is one of the primarily studied sequelae in cancer. A meta-analysis published in 2017 indicated that behavioural techniques had statistically significant moderate effects on cancer-related fatigue, even compared to pharmaceutical interventions [65]. However, two other systematic reviews could not significantly support the effect of PIP and education on fatigue in cancer patients [18, 66]. The added value of graded activity on fatigue was investigated in a crossover trial, which demonstrated a significant reduction of cancer-related fatigue compared to the other CBT components (such as regulation of the sleep–wake rhythm and reformulation of fatigue-related cognitions) [67]. This meta-analysis could not analyse the added value of BGA for fatigue due to a lack of studies.

For the outcomes psychological distress, pain, QoL and physical activity, significant positive effects were found, which are in concordance with previous studies. A systematic review of 2015 investigated interventions including behavioural changes in breast cancer survivors and demonstrated significant changes in patients' physical activity [68]. Another review evaluated pain intensity, sensation, suffering or perceived control with a significant effect of all PIP interventions in women with metastatic breast cancer [66]. In the same review, RCTs could not support the effect of PIP on QoL [66]. On the other hand, Ye et al. [15] performed a meta-analysis that reinforced a significant positive effect of PIP on QoL, depression and anxiety in breast CPaS. An older meta-analysis with poor quality found that, overall, breast cancer patients who were administered CBT techniques had significantly less distress and pain than WLC or UC [69].

Implications for clinicians

This meta-analysis found evidence from RCTs that PIP with BGA appears to be effective in improving sequela, QoL and physical activity compared to non-behavioural interventions in CPaS. These results can be used to better inform patients about the benefits of including PIP with BGA in the rehabilitation programme [70]. In addition, recent findings of another meta-analysis demonstrated that exercise and psychological interventions are more effective in reducing fatigue, depression, anxiety and stress during and after cancer treatment, and they are significantly better than the available pharmaceutical options [65]. These findings could help physicians, nurses and patients make informed choices about the importance of including PIP with BGA in the standard care practice to reduce patient's medication use. Furthermore, PIP with BGA should be patient-tailored which makes it appropriate for every cancer stage. However, currently few studies report the

adverse events of the intervention. So, it is not clear if there were any or if they were not reported. For future implementation, the adverse events of PIP with BGA should be first investigated and reported. Moreover, to avoid unforeseen situations, it might be interesting to request medical clearance before the intervention.

This review revealed that up to now BGA is not (well) defined in included studies; however, a big proportion of researchers apply BGA as part of their intervention. In this meta-analysis, clinicians can find a checklist, co-written by experts in the field of chronic pain, with an overview of the most important criteria. Nevertheless, it is not only important to put the emphasis on 'what' is BGA but also on 'how' it should be provided, in order to give clinicians, the best possible treatment plan [71]. For training purposes, a multidisciplinary collaboration can be recommended, so psychologists could focus on the behavioural and psychological aspects and physiotherapists on the behavioural and graded exercise aspects in their approach. Forthcoming protocols have been developed to implement a standardised programme of BGA in chronic pain populations, e.g. osteoarthritis, breast cancer survivors and low back pain patients [72–76].

Strengths and limitations

This meta-analysis included RCTs up to May 2021, has a large sample size ($n = 4330$) and is more comprehensive, than any previously published meta-analyses on psychotherapeutic and physical interventions in CPaS [15, 16]. In a cancer population, no meta-analysis was ever performed yet to compare PIP with BGA to other interventions in terms of various outcome measures.

However, several limitations of the current study should also be noted. First, high heterogeneity was observed in the pooling of various outcome measures in the intervention compared to WLC, PIP alone, BGA alone and other interventions. For this heterogeneity, several explanations can be found, such as a difference in subtype of patients (e.g. predominated fatigue, low activity level, anxiety, depression) or the inclusion of cancer patients as well as cancer survivors. In addition, despite our strict inclusion criteria, the differences in the approach to delivering the behavioural treatment might impute the observed heterogeneity, which can downgrade the strength of the results [15]. As a consequence, random effect analyses were used, resulting in wider confidence intervals and relatively more weight being given to smaller studies [77].

Second, in most studies, blinding of the therapists and/or patients is not possible for these behavioural interventions. This had a large impact on the risk of bias (ROB 2), which clearly decreased the quality of studies [78].

Finally, publication bias was detected for the outcomes of fatigue and functional impairment in the WLC, self-reported physical activity in the PIP group and anxiety and depression in the other interventions. As a result, studies with minor or negative results could have been missed.

Future recommendations

Further studies are encouraged to address the remaining gaps highlighted by this review. First, more RCTs should provide a solid description of their graded activity programme to specify BGA. In this meta-analysis, a lot of studies with behavioural interventions were included for BGA and a checklist was used to score and verify the quality of the provided BGA. However, studies with a low score on the BGA checklist had several criteria that were not reported which can lead to an under- or over-estimation of the results. This checklist could help future researchers with better reporting of details on their provided intervention. Second, future work should examine whether clinical and demographic characteristics influence outcomes following PIP with BGA because in this systematic review, no additional subgroup analyses could be added since too many subgroup analyses can potentially lead to misleading results [79]. Besides, more studies of each cancer stage are needed to be able to make a clear distinction at what time point PIP with BGA or BGA alone should be incorporated in the cancer treatment. For instance, a meta-analysis about fatigue in cancer patients concluded that it would be more favourable to give patients physical exercise during their primary treatment, whereas psychological and physical exercise combined with psychological intervention might be most effective for survivors who have completed primary treatment [65]. Similar results were not clearly observed in our meta-analysis after sensitivity analysis, this due to a lack of studies. Third, to optimise patient treatments, future studies are needed to find the optimal sequence and dosage of BGA for cancer patients, including virtual versus face-to-face sessions, provided in-group versus individually. Additionally, to engage patients to their care, studies should incorporate qualitative assessments which can provide greater insight into their experiences on the provided intervention [80].

Lastly, as a result of the COVID-19 situation, assurance had an increasing interest in eHealth modalities in routine care over the past few years. Thus, more research about the acceptability and feasibility of implementing telehealth BGA in cancer populations will be warranted [81].

Conclusions

PIP with BGA had a favourable effect on several debilitating symptoms, physical activity level and HRQoL in CPaS when compared to non-behavioural interventions such as WLC, education, physical activity and usual care. However, these significant positive results could not be preserved when the intervention was compared to other PIP and BGA alone. Future studies should focus on providing a clear framework for the administration of BGA and further research is needed on 'how' and 'when' PIP and BGA should be provided in the cancer rehabilitation.

Appendix 4

Table 8 BGA checklist

Intervention characteristics	Elaboration	Yes/no/NR
Was the primary goal of treatment improvement of functioning in daily living?	<ul style="list-style-type: none"> - Yes: Improvement of functioning is clearly stated as the primary goal - No: Pain relief or other goals were set up front 	
The therapist was required to have a healthcare degree and to have a minimal training in BGA?	<ul style="list-style-type: none"> - Yes: The therapist was a healthcare provider trained in an operant BGA - No: The therapist was not a healthcare provider or was not trained in BGA 	
Pacing: did the therapist starts with assessing the patient's activity patterns and corrects him/her if necessary?	<ul style="list-style-type: none"> - Yes: The therapist assessed the patient's routine (an activity diary may aid). Afterwards, he/she used pacing or shaping as a strategy when coming upon patients with inadequate activity patterns (e.g. avoiding or persisting in activities) - No: Patterns were not assessed and/or pacing was not used as a tool before starting behavioural graded activity 	
Goal setting: did the patient self-select activities of daily living, followed by a process of shared decision-making with the therapist?	<ul style="list-style-type: none"> - Yes: Patient's self-selected activities of daily living were determined by what he/she wanted to achieve (e.g. he/she wants to be able to garden twice a week for 4 consecutive hours) - No: Activities were selected by therapist and/or activities were equal to everyone 	
Were baseline values individually determined and used for tailored treatment?	<ul style="list-style-type: none"> - Yes: Baseline values were individually determined and used for tailored treatment - No: Baseline values were not determined or used in the treatment 	
Was the BGA preceded by an educational intervention?	<ul style="list-style-type: none"> - Yes: BGA was preceded by an educational intervention which removed barriers for self-efficacy (e.g. CBT, PNE...) - No: BGA was not preceded by any educational intervention 	
Was there an individually based scheme made on a time-contingent basis for each goal?	<ul style="list-style-type: none"> - Yes: Weekly increase (fixed) of the level (duration) of activities. The exact increase and duration are based on the baseline values and agreement in the tailored programme - No: Increase or decrease of the activity level is based for example on the amount of pain 	
During the intervention, support and reinforcement were provided by the therapist?	<ul style="list-style-type: none"> - Yes: The therapist provided support (e.g. telephone, next appointment...) and verbal and/or non-verbal reinforcement, during the intervention - No: The therapist did not provide any support. The patient could not contact the therapist with problems, and he/she did not receive any reinforcement or feedback, during the intervention 	
Was the patient able to integrate the gradually increased activities in his/her daily life (generalization phase)?	<ul style="list-style-type: none"> - Yes: The goal was reached, and the patient could integrate new activities in his/her daily life by themselves - No: The goal was not reached, and the patient could not integrate new activities in his/her daily life by themselves 	

Abbreviations: *BGA*, behavioural graded activity; *CBT*, cognitive behavioural therapy; *PNE*, pain neuroscience education, Bold: **primary content**
