The asymmetric unit of the title 2:1 co-crystal,  $2C_8H_8O_2 \cdot C_{14}H_{14}N_4O_2$ , comprises an acid molecule in a general position and half a diamide molecule, the latter being located about a centre of inversion. In the acid, the carboxylic acid group is twisted out of the plane of the benzene ring to which it is attached [dihedral angle = 28.51 (8)°] and the carbonyl O atom and methyl group lie approximately to the same side of the molecule [hydroxy-O-C-C-C(H) torsion angle =  $-27.92 (17)^\circ$ ]. In the diamide, the central  $C_4N_2O_2$  core is almost planar (r.m.s. deviation = 0.031 Å), and the pyridyl rings are perpendicular, lying to either side of the central plane [central residue/pyridyl dihedral angle = 88.60 (5)°]. In the molecular packing, three-molecule aggregates are formed *via* hydroxy-O- $H \cdot \cdot \cdot N(pyridyl)$  hydrogen bonds. These are connected into a supramolecular layer parallel to ( $12\overline{2}$ ) *via* amide-N-H \cdot \cdot \cdot O(carbonyl) hydrogen bonds, as well as methylene-C-H \cdot \cdot \cdot O(amide) interactions. Significant  $\pi$ - $\pi$  interactions occur between benzene/benzene, pyridyl/benzene and pyridyl/pyridyl rings within and between layers to consolidate the three-dimensional packing.

#### 1. Chemical context

Multi-component crystals, incorporating co-crystals, salts and co-crystal salts, attract continuing interest for a wide variety of applications as this technology may be employed, for example, to provide additives to promote the growth of crystals, to stabilize unusual and unstable coformers, to generate new luminescent materials, to separate enantiomers, to facilitate absolute structure determination where the molecule of concern does not have a significant anomalous scatterer, etc. (Aakeröy, 2015; Tiekink, 2012). Arguably, the areas attracting most interest in this context are the applications of multicomponent crystals in the pharmaceutical industry (Duggirala et al., 2016). Controlled/designed crystallization of multicomponent crystals requires reliable synthon formation between the various components and that, of course, is the challenge of crystal engineering, let alone engineering small aggregates within crystals (Tiekink, 2014).

Systematic work on synthon propensities in multi-component crystals have revealed that carboxylic acids have a great likelihood of forming hydroxy-O-H···N hydrogen bonds when co-crystallized with molecules with pyridyl residues (Shattock *et al.*, 2008). A plausible explanation for this reliability is the formation of a supporting carbonyl-O···H interaction involving the hydrogen atom adjacent to the pyridyl-

nitrogen atom. Indeed, in the absence of competing hydrogenbonding functionality, the resulting seven-membered  $\{\cdots$ HOCO $\cdots$ HCN} heterosynthon is formed in more than 98% of relevant crystal structures (Shattock *et al.*, 2008). Recent systematic work in this phenomenon relates to molecules shown in Scheme 1, where isomeric molecules with two pyridyl rings separated by a diamide residue have been cocrystallized with various carboxylic acids (Arman, Miller *et al.*, 2012; Arman *et al.*, 2013, Syed *et al.*, 2016; Jotani *et al.*, 2016). As a continuation of these studies, the title 2:1 co-crystal was isolated and characterized crystallographically and by Hirshfeld surface analysis.

#### 2. Structural commentary

The title co-crystal, Fig. 1, was formed from the 1:1 co-crystallization of 2-methylbenzoic acid (hereafter, the acid) and N,N'-bis(pyridin-4-ylmethyl)ethanediamide (hereafter, the diamide) conducted in ethanol solution. The asymmetric unit comprises a full acid molecule in a general position and half a diamide molecule, located about a centre of inversion, so the co-crystal is formulated as a 2:1 acid:diamide co-crystal.

In the acid, the carboxylic acid group is twisted out of the plane of the benzene ring to which it is attached with the O3– C8–C9–C10 torsion angle being 150.23 (14)°, and, to a first approximation, with the carbonyl-O3 atom and methyl group lying to the same side of the molecule as indicated in the O2–C8–C9–C10 torsion angle of -27.92 (17)°. The structure of the parent acid and several co-crystals featuring coformers shown in Scheme 2 are available for comparison; data are collected in Table 1. The common feature of all structures is the relative orientation of the carbonyl-O and methyl groups. Twists in the acid molecules vary from almost co-planar to the situation found in the title co-crystal structures.

In the centrosymmetric diamide, the central  $C_4N_2O_2$  core is essentially planar with an r.m.s. deviation (O1, N2, C6, C7 and symmetry equivalents) = 0.031 Å. This arrangement facilitates

The molecular structures of the molecules comprising the title co-crystal showing the atom-labelling scheme and displacement ellipsoids at the 50% probability level: (a) 2-methylbenzoic acid and (b) N,N'-bis(pyridin-4-ylmethyl)ethanediamide; unlabelled atoms in the diamide are generated by the symmetry operation (-1 - x, 2 - y, 1 - z).

Figure 2

to this with the central residue/pyridyl dihedral angle being 88.60 (5)°. The aforementioned structural features match literature precedents, *i.e.* the two polymorphic forms of the parent diamide and the diamide in co-crystals with carboxylic acids and in a salt with a carboxylate, Table 3. Finally, the central C–C bond length, considered long for a  $Csp^2-Csp^2$  bond (Spek, 2009), matches the structural data included in Table 3; see Scheme 3 for chemical diagrams of coformers.

#### 3. Supramolecular features

Molecular packing in the title co-crystal: (*a*) three-molecule aggregate sustained by hydroxy-O-H···N(pyridyl) hydrogen bonds, (*b*) supra-molecular layers whereby the aggregates in (*a*) are connected by amide-N-H···O(carbonyl) and methylene-C-H···O(amide) interactions, and (*c*) a view of the unit-cell contents shown in projection down the *a* axis, highlighting the intra- and inter-layer  $\pi$ - $\pi$  interactions to consolidate a three-dimensional architecture. The O-H···N, N-H···O, C-H···O and  $\pi$ - $\pi$  interactions are shown as orange, blue, green and purple dashed lines, respectively.

The molecular packing of the title co-crystal is dominated by hydrogen bonding, detailed in Table 2. The acid is connected to the diamide *via* hydroxy-O-H···N(pyridyl) hydrogen bonds to form a three-molecule aggregate, Fig. 2*a*. The interacting residues are not co-planar with the dihedral angle between the pyridyl and three CO<sub>2</sub> groups being 25.67 (8)° so

Table	4		
$\pi - \pi$ In	teractions	(Å,	°).

Ring 1	Ring 2	Inter-centroid distance	Dihedral angle	Symmetry
N1,C1-C5	N1,C1-C5	3.5980 (8)	0	-x, 1-y, 1-z
N1,C1-C5	C9-C14	3.7833 (9)	4.63 (7)	1 - x, 1 - y, -z
C9-C14	C9-C14	3.8473 (8)	0	-1-x, -y, -z

that the carbonyl-O3···H3 distance is 2.60 Å. This suggests only a minor role for the putative seven-membered heterosynthon {···OCOH···NCH} mentioned in the *Chemical context* and is consistent with the significant hydrogen-bonding interaction involving the carbonyl-O3 atom to another residue. Indeed, the three-molecule aggregates are connected into a supramolecular layer parallel to  $(12\overline{2})$  *via* amide-N-H···O(carbonyl) hydrogen bonds as well as methylene-C-H···O(amide) interactions, Fig. 2b. Within layers,  $\pi$ - $\pi$  interactions occur between pyridyl rings, and between layers additional  $\pi$ - $\pi$  interactions occur between pyridyl/benzene and benzene/benzene rings to consolidate the three-dimensional packing, Table 4 and Fig. 2c. Globally, the packing may be described as comprising alternating layers of aromatic rings and non-aromatic residues.

#### 4. Analysis of the Hirshfeld surfaces

Crystal Explorer 3.1 (Wolff et al., 2012) was used to generate Hirshfeld surfaces mapped over  $d_{norm}$ ,  $d_e$ , electrostatic potential, shape-index and curvedness for the title 2:1 cocrystal. The electrostatic potentials were calculated using *TONTO* (Spackman et al., 2008; Jayatilaka et al., 2005) integrated with Crystal Explorer, using the experimentally determined geometry as the input. Further, the electrostatic potentials were mapped on Hirshfeld surfaces using the STO-3G basis set at Hartree–Fock theory over a range ±0.15 au. The contact distances  $d_i$  and  $d_e$  from the Hirshfeld surface to the nearest atom inside and outside, respectively, enabled the analysis of the intermolecular interactions through the mapping of  $d_{norm}$ . The combination of  $d_i$  and  $d_e$  in the form of a two-dimensional fingerprint plot (Rohl et al., 2008) provides a summary of the intermolecular contacts.

Views of the Hirshfeld surfaces mapped over  $d_{\text{norm}}$ : (a) acid and (b) diamide in the title 2:1 co-crystal. The contact points (red) are labelled to indicate the atoms participating in the intermolecular interactions.

Table	5						
Major	percentage	contribution	of	the	different	intermolecular	inter
actions	s to the Hirsl	hfeld surfaces	for t	the	acid, diam	ide and 2:1 co-c	rystal

Contact	Acid	Diamide	Co-crystal
н. н	18 7	45.2	40.0
O···H/H···O	20.6	25.6	21.3
$C{\cdot}{\cdot}{\cdot}H/H{\cdot}{\cdot}{\cdot}C$	16.7	12.0	15.9
$N{\cdots} \cdot H/H{\cdots} \cdot N$	3.8	8.9	2.7
$C{\cdots}C$	5.9	6.4	6.6

The strong hydroxy-O-H···N(pyridyl) and amide-N-H···O(carbonyl) interactions between the acid and diamide molecules are visualized as bright-red spots at the respective donor and acceptor atoms on the Hirshfeld surfaces mapped over  $d_{norm}$ , and labelled as 1 and 2 in Fig. 3. The intermolecular methylene-C-H···O(amide) interactions appears as faintred spots in Fig. 3b, marked with a '3'. The immediate environment about each molecule highlighting close contacts to the Hirshfeld surface by neighbouring molecules is shown in Fig. 4. The full fingerprint (FP) plots showing various crystal packing interactions in the acid, diamide and 2:1 co-crystal are shown in Fig. 5; the contributions from various contacts are listed in Table 5.

The prominent long spike at  $d_e + d_i \sim 1.8$  Å in the upper left (donor) region for the FP plot of the acid corresponds to H···N contacts and the spike at the same distance in the lower right (acceptor) region of the FP plot for the diamide are the result of hydroxy-O-H···N(pyridyl) interactions, Fig. 5a and b, respectively. However, these spikes are not apparent in the

Figure 4

Hirshfeld surfaces mapped over  $d_{\text{norm}}$  showing hydrogen bonds with neighbouring molecules with the reference molecule being the (a) acid and (b) diamide.

overall FP for the 2:1 co-crystal as they no longer contribute to the surface of the resultant aggregate, Fig. 5c. Pairs of somewhat blunted spikes corresponding to  $N \cdots H/H \cdots N$  contacts at  $d_e + d_i \sim 2.9$  Å result from amide- $N-H \cdots O$ (carbonyl) interactions between the acid and diamide molecules are evident in the overall FP, Fig. 5c.

The O···H/H···O contacts, which make a significant contribution to the molecular packing, show different characteristic features in the respective delineated FP plots of the acid and diamide. For the acid, Fig. 5*a*, a long prominent spike at  $d_e + d_i \sim 2.5$  Å in the acceptor region corresponds to a 6.6% contribution from H···O contacts to the Hirshfeld surface, and a short spike at  $d_e + d_i \sim 2.15$  Å in the donor region with a 14.0% contribution. The reverse situation is observed for the diamide molecule wherein the FP plot, Fig. 5*b*, contains a long

## research communications

Table 6	
Enrichment ratios (ER) for the acid, diamide an	nd co-crystal

Interaction	Acid	Diamide	Co-crystal
$H \cdots H$	1.02	0.97	1.02
$O{\cdots} \cdot H/H{\cdots} \cdot O$	1.22	1.46	1.30
$\mathbf{C} \cdots \mathbf{C}$	2.30	3.60	2.55
$C \cdot \cdot \cdot H/H \cdot \cdot \cdot C$	0.75	0.66	0.71
$N{\cdots} \cdot H/H{\cdots} \cdot N$	1.06	1.20	0.84

prominent spike in the donor region and the short spike in the acceptor at the same  $d_e + d_i$  distance, and with 10.7 and 14.9% contributions from O···H and H···O contacts, respectively.

FP plots for the co-crystal delineated into  $H \cdots H$ ,  $O \cdots H/H \cdots O$ ,  $C \cdots H/H \cdots C$ ,  $N \cdots H/H \cdots N$  and  $C \cdots C$  are shown in Fig. 6a-e, respectively. The  $H \cdots H$  contacts appear as asymmetrically scattered points covering a large region of the FP plot with a single broad peak at  $d_e = d_i \sim 1.2$  Å for each of the co-crystal constituents, with percentage contributions of 48.7 and 45.7% for the acid and diamide molecules, respectively.

Figure 6

The two-dimensional fingerprint plot for the title 2:1 co-crystal showing contributions from different contacts: (a)  $H \cdots H$ , (b)  $O \cdots H/H \cdots O$ , (c)  $C \cdots H/H \cdots C$ , (d)  $N \cdots H/H \cdots N$ , and (e)  $C \cdots C$ .

Figure 7

Hirshfeld surfaces mapped over the shape index for (a) the acid and (b) the diamide, highlighting the regions involved in  $\pi$ - $\pi$  stacking interactions.

The overall 49.9% contribution to Hirshfeld surface of the cocrystal results in nearly symmetric through the superimposition of individual fingerprint plots, Fig. 6a.

The FP plot for  $O \cdots H/H \cdots O$  contacts, Fig. 6b, has two pairs of spikes superimposed in the  $(d_{\rm e}, d_{\rm i})$  region with minimum  $d_e + d_i$  distances ~ 2.2 and 2.5 Å. These correspond to a 21.3% contribution to the Hirshfeld surface, and reflect the presence of intermolecular  $N-H\cdots O$  and  $C-H\cdots O$ interactions, identified with labels 1 and 2 in Fig. 6b. The 15.9% contribution from the  $C \cdots H/H \cdots C$  contacts to the Hirshfeld surface results in a symmetric pair of wings, Fig. 6c. The FP plot corresponding to  $C \cdot \cdot \cdot C$  contacts, Fig. 6e, in the  $(d_e, d_i)$  region between 1.7 to 2.2 Å appears as the two distinct, overlapping triangles identified with red and yellow boundaries in Fig. 6e, and shows two types of  $\pi$ - $\pi$  stacking interactions: one between dissimilar rings (pyridyl and benzene) and the other between symmetry-related rings (benzene and benzene, and pyridyl and pyridyl). The presence of these  $\pi$ - $\pi$ stacking interactions is also indicated by the appearance of red and blue triangles on the shape-indexed surfaces identified with arrows in the images of Fig. 7, and in the flat regions on the Hirshfeld surfaces mapped with curvedness in Fig. 8.

The intermolecular interactions were further assessed by using the enrichment ratio, ER (Jelsch *et al.*, 2014). This is a relatively new descriptor and is based on Hirshfeld surface analysis. The ER for the co-crystal together with those for the acid and diamide molecules are listed in Table 6. The largest

Figure 8

contribution to the Hirshfeld surfaces are from  $H \cdots H$ contacts, Table 5, and their respective ER values are close to unity. This shows that the contribution from dispersive forces are significant in the molecule packing of the title 2:1 cocrystal, in contrast to that observed in a related, recently published structure, namely, the salt [2-({[(pyridin-1-ium-2ylmethyl)carbamoyl]formamido}methyl)-pyridin-1-ium][3,5dicarboxybenzoate], i.e. containing the diprotonated form of the isomeric 2-pyridyl-containing diamide (Syed et al., 2016). In the latter,  $O \cdots H/H \cdots O$  contacts make the greatest contribution to the crystal packing. It is the presence of different substituents in the benzene ring in the acid molecule in the co-crystal, i.e. methyl, as opposed to carboxylic acid/ carboxylate groups in the salt, that provides an explanation for this difference. The ER value for  $O \cdots H/H \cdots O$  contacts, *i.e.* 1.30, shows the propensity to form hydroxy-O- $H \cdot \cdot \cdot N(pyridyl)$  and amide- $N - H \cdot \cdot \cdot O(carbonyl)$  hydrogen bonds as well as methylene- $C-H \cdots O(amide)$  interactions. The formation of extensive  $\pi$ - $\pi$  interactions is reflected in the relatively high ER values corresponding/related to C···C contacts, Table 6. The absence of  $C-H\cdots\pi$  and related interactions is reflected in low ER values, *i.e.* < 0.8. Conversely, the  $N \cdots H/H \cdots N$  contacts in a crystal having ER values equal to greater than or equal to unity for the acid/ diamide molecules reduces to 0.84 in the 2:1 co-crystal, indicating a reduced likelihood of formation once the co-crystal is stabilized by other interactions. The enrichment ratios for other contacts are of low significance as they are derived from

less important interactions which have small contributions to Hirshfeld surfaces.

#### 5. Database survey

As mentioned in the *Chemical context*, the diamide in the title 2:1 co-crystal and isomeric forms have attracted considerable interest in the crystal engineering community no doubt owing to the variable functional groups and conformational flex-ibility. Indeed, the diamide in the title co-crystal featured in early studies of halogen  $I \cdots N$  halogen bonding (Goroff *et al.*, 2005). Over and above these investigations, the role of the diamide in coordination chemistry has also been studied. Bidentate bridging is the prominent coordination mode observed in both neutral, *e.g.*  $[HgI_2(diamide)]_n$  (Zeng *et al.*, 2008) and charged, *e.g.* polymeric  $[Ag(diamide)NO_3]_n$  (Schauer *et al.*, 1998) and oligiomeric { $[Ph_2PCH_2PPh_2Au_2(diamide)]_2(CIO_4)_4(EtOEt)_4$ } (Tzeng *et al.*, 2006), species.

#### 6. Synthesis and crystallization

The diamide (0.2 g), prepared in accord with the literature procedure (Schauer *et al.*, 1997), in ethanol (10 ml) was added to a ethanol solution (10 ml) of 2-methylbenzoic acid (Merck, 0.1 g). The mixture was stirred for 1 h at room temperature after which a white precipitate was deposited. The solution was filtered by vacuum suction, and the filtrate was then left to

stand under ambient conditions, yielding colourless prisms after 2 weeks.

#### 7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 7. The carbon-bound H-atoms were placed in calculated positions (C-H = 0.95-0.99 Å) and were included in the refinement in the riding-model approximation, with  $U_{iso}(H)$  set to  $1.2U_{eq}(C)$ . The oxygen- and nitrogenbound H-atoms were located in a difference Fourier map but were refined with distance restraints of  $O-H = 0.84 \pm 0.01$  Å and N-H =  $0.88\pm0.01$  Å, and with  $U_{iso}(H)$  set to  $1.5U_{ea}(O)$ and  $1.2U_{eq}(N)$ .

## A 2:1 co-crystal of 2-methylbenzoic acid and *N*,*N*'-bis(pyridin-4-ylmethyl)ethanediamide: crystal structure and Hirshfeld surface analysis

### Sabrina Syed, Mukesh M. Jotani, Siti Nadiah Abdul Halim and Edward R. T. Tiekink

**Computing details** 

Data collection: *CrysAlis PRO* (Agilent, 2014); cell refinement: *CrysAlis PRO* (Agilent, 2014); data reduction: *CrysAlis PRO* (Agilent, 2014); program(s) used to solve structure: *SHELXS97* (Sheldrick, 2008); program(s) used to refine structure: *SHELXL2014* (Sheldrick, 2015); molecular graphics: *ORTEP-3 for Windows* (Farrugia, 2012) and *DIAMOND* (Brandenburg, 2006); software used to prepare material for publication: *publCIF* (Westrip, 2010).

2-Methylbenzoic acid-\ N,N'-bis(pyridin-4-ylmethyl)ethanediamide (2/1)

Crystal data

 $C_{14}H_{14}N_4O_2 \cdot 2C_8H_8O_2$   $M_r = 542.58$ Triclinic, *P*1 a = 6.8948 (5) Å b = 9.7219 (5) Å c = 9.9621 (7) Å  $a = 82.971 (5)^{\circ}$   $\beta = 81.638 (6)^{\circ}$   $\gamma = 85.686 (5)^{\circ}$  $V = 654.58 (8) Å^{3}$ 

#### Data collection

Agilent Technologies SuperNova Dual diffractometer with an Atlas detector Radiation source: SuperNova (Mo) X-ray Source Mirror monochromator Detector resolution: 10.4041 pixels mm<sup>-1</sup> ω scan Absorption correction: multi-scan (*CrysAlis PRO*; Agilent, 2014)

#### Refinement

Refinement on  $F^2$ Least-squares matrix: full  $R[F^2 > 2\sigma(F^2)] = 0.041$  $wR(F^2) = 0.106$ S = 1.062993 reflections 188 parameters Z = 1 F(000) = 286  $D_x = 1.376 \text{ Mg m}^{-3}$ Mo K $\alpha$  radiation,  $\lambda = 0.71073 \text{ Å}$ Cell parameters from 3840 reflections  $\theta = 3.5-30.0^{\circ}$   $\mu = 0.10 \text{ mm}^{-1}$ T = 100 K Prism, colourless  $0.21 \times 0.15 \times 0.10 \text{ mm}$ 

 $T_{\min} = 0.580, T_{\max} = 1.000$ 15067 measured reflections 2993 independent reflections 2358 reflections with  $I > 2\sigma(I)$   $R_{\text{int}} = 0.044$   $\theta_{\max} = 27.5^{\circ}, \theta_{\min} = 3.0^{\circ}$   $h = -8 \rightarrow 8$   $k = -12 \rightarrow 12$  $l = -12 \rightarrow 12$ 

2 restraints Hydrogen site location: mixed  $w = 1/[\sigma^2(F_o^2) + (0.0434P)^2 + 0.2225P]$ where  $P = (F_o^2 + 2F_c^2)/3$   $(\Delta/\sigma)_{\text{max}} < 0.001$   $\Delta\rho_{\text{max}} = 0.34 \text{ e } \text{Å}^{-3}$  $\Delta\rho_{\text{min}} = -0.23 \text{ e } \text{Å}^{-3}$ 

#### Special details

**Geometry**. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
