(Received 11 November, 2020; Accepted 11 February, 2021; Published online 7 May, 2021)

Cellular senescence is an intricate and multifactorial phenomenon, which is characterized by an irreversible cellular growth arrest, it is caused in response to irretrievably DNA damage, telomere shortening, activation of oncogene, and oxidative stress. Human diploid fibroblasts are a well-established experimental model for premature senescence-related studies, and exposure of fibroblasts to H₂O₂ is widely used as a SIPS model. Recently, it has been reported many studies of CoQ₁₀ as to anti-aging effects, however the effect of CoQ₁₀ on H₂O₂-induced SIPS model of human skin fibroblasts has not been understood. So that, we investigated that human skin fibroblasts were used to investigate the prevention effect of CoQ₁₀ against H₂O₂-induced SIPS model. We created SIPS model fibroblasts with treatment of 100 μM H₂O₂ for 2 h. In this study, CoQ₁₀ also increased cell viability and mRNA levels of type I, IV collagen and protein level of type I collagen. Moreover, it is shown that CoQ₁₀ suppressed oxidative stress, degradation of collagen by increasing MMP expression, and decreasing senescence-associated phenotypes (e.g. SA-βgal positive staining and SASP) for preventing skin aging via H₂O₂-induced SIPS model. These results suggested that CoQ₁₀ has possibility to be contributory for extension of healthy life expectancy in Japan.

Key Words: coenzyme Q₁₀ (CoQ₁₀), anti-aging, SIPS, oxidative-stress

Senescence of cells is an intricate and multifactorial phenomenon that is characterized by an irreversible cellular growth arrest, and it is brought about by in response to irretrievably DNA damage, telomere shortening, activation of oncogene, protein aggregation, telomere attrition, mitochondrial dysfunction, inflammation, and oxidative stress. In addition, senescent cells exhibit specific morphological alterations, a flat and enlarged cell shape, senescence-associated β-galactosidase (SA-β-gal) positive cells and decrease of synthesis of extracellular matrix (ECM).⁽¹⁾ Oxidative stress is especially play an important role in aging process, and progression of that is postulated in the free radical theory.⁽²⁾ It is well known that it is a very strong relationship between oxidative stress and aging. Moreover, reactive oxygen species (ROS) induces DNA damage response (DDR) causing for continuous accumulation of cellular damage, so that DDR is trigger for principle pathway that accumulation of senescent cells can contribute to the aging phenotype.⁽³⁾ Besides, sublethal doses of various compounds such as superoxide anions (O₂⁻), hydroxyl radicals (OH[•]), and hydrogen peroxide (H₂O₂) also induce phenomena similar to replicative senescence in normal cells, a phenomenon termed premature senescence. For instance, human diploid fibroblasts are a well-utilized experimental model for premature senescence-related studies, and

exposure of normal fibroblasts to H₂O₂ is widely used as a stress-induced premature senescence (SIPS) model.⁽⁴⁻⁷⁾ Furthermore, it has reported that exposure to ultraviolet and H₂O₂ increase intracellular ROS levels and induces premature senescence in fibroblasts.^(8,9) Meanwhile, Coppé *et al.*⁽¹⁰⁾ have reported that in human cells exposed to genotoxic stress, it secretes myriad factors associated with inflammation and malignancy. The phenomenon is called senescence-associated secretory phenotype (SASP). SASP comprises complex factors including cytokines, growth factors, chemokines, and matrix metalloproteinase (MMP), so that it is reported SASP facilitate the tumorigenesis of normal cells.⁽¹¹⁾ Additionally, it has also been reported that DDR plays an important role for induction of SASP *in vitro*.⁽¹²⁾ While, SASP observed in both SIPS model and replicative senescence.⁽¹³⁾ Therefore, it has been thought that inhibition of SASP is important for prevention to several diseases, anti-aging, suppression of tumorigenesis, and inflammation.

Coenzyme Q₁₀ (CoQ₁₀) is an essential electron carrier for the mitochondrial electron transport system and an important for energy production. In addition, CoQ₁₀ also serves as a free radical scavenger, and prevents oxidative damage in the human body. Furthermore, it is known that CoQ₁₀ participate in inflammation process,^(14,15) apoptosis,^(16,17) and gene expression.^(18,19) In addition, several studies have demonstrated that CoQ₁₀ has broad therapeutic effects including diabetes,⁽²⁰⁾ cardiovascular disease,⁽²¹⁾ and neurological disorder.⁽²²⁾ On the other hand, it also has been known that the intracellular CoQ₁₀ level decreases after the age of 20 years.⁽²³⁾ As an evidence, the antioxidant effect of reduced form CoQ₁₀ has been demonstrated *in vivo* and *in vitro* in various biological system. Interestingly, CoQ₁₀ decreased aging speed in SAMP1 mice.^(24,25) Moreover, in rats with a polyunsaturated fatty acid (PUFA)-rich diet, CoQ₁₀ treatment protects from age-related DNA double-strand breaks, and prolongs lifespan of the rat.⁽²⁶⁾ These reports suggest that CoQ₁₀ may involve in aging. Many researchers had been reported in aging skin cells for observation of physiological, biochemical, and molecular characteristics. In particularly, ECM level in aging skin cells is one of the most change, which affect the wrinkle formation, elasticity, and morphology change. MMP plays an important role in regulating the collagen levels, and the elevated level of that induce collagen degradation in aged skin.⁽²⁷⁾ It has shown that the SIPS model of human diploid fibroblasts disassemble collagen via MMPs regulating.⁽²⁸⁾ Furthermore, because MMPs are key SASP factors contribute to degradation of the ECM, it is suggested that MMPs participate the aging process, which are regulated by the intracellular ROS levels.⁽²⁹⁾ These reports support the notion that CoQ₁₀

with potent antioxidant effect raises the possibility of have the anti-aging effect via inhibition of intracellular MMP and ROS levels. However, the effect of CoQ₁₀ on SIPS model of human skin fibroblasts has not been understood. Therefore, in this study, we investigated for anti-aging effect of CoQ₁₀ on H₂O₂-induced SIPS model of human skin fibroblasts.

Materials and Methods

Materials. CoQ₁₀ powder, PureSorb-Q™40 (P40), which is containing 40 w/v% CoQ₁₀, was kindly donated by Nisshin Pharma Inc. (Tokyo, Japan).⁽³⁰⁾ Antibody against type I collagen was obtained from COSMO BIO Co., Ltd. (Tokyo, Japan). All other chemicals used were of analytical grade available from commercial suppliers.

Cell culture. Normal human dermal fibroblast (NHDF) was purchased from Lonza Co. Ltd. (Tokyo, Japan). Fibroblasts were grown in Dulbecco's modified Eagle's medium (DMEM, Nacalai Tesque, Kyoto, Japan) supplemented with 2% fetal bovine serum (FBS; MP Biomedicals, Illkirch, France), 2 mM glutamine, 100 units/ml penicillin and 100 mg/ml streptomycin (Nacalai Tesque). The cells were incubated under 37°C in a humidified atmosphere of 5% CO₂ and 95% air in a CO₂ incubator. After 24 h, culture medium was replaced by the DMEM containing 2% FBS and P40, and the cells were subsequently pre-cultured for 1 week in the CO₂ incubator until the experiments.

Cell viability. After treatment, cell viability was quantified using Cell Counting Kit-8 (Dojindo Laboratories, Kumamoto, Japan).⁽³¹⁾ The assay was carried out in accordance with the instruction manual. On the other hand, cell viability was also visualized by DAPI-staining. The assay was carried out in accordance with the instruction manual. After the fibroblasts on each well of 24-well plate were washed with PBS twice, the cells were incubated with DAPI staining solution (Dojindo Laboratories) for 30 min in CO₂ incubator, fluorescence of DAPI-DNA complex meaning cell death was observed by using fluorescence microscopy (IX-71, Olympus). For detection of dead cells, the fibroblasts were imaged by using fluorescence microscopy.

Intracellular ROS production. The fibroblasts were incubated with PBS containing 2.5 μM CM-H₂DCFDA (Invitrogen) at 37°C for 30 min in CO₂ incubator. Fluorescence of 2',7'-dichlorodihydrofluorescein, which was oxidation product of CH-H₂DCFDA by ROS produced in cells, was observed by using fluorescence microscopy. The assay was carried out in accordance with the instruction manual.

Cell senescence. We examined SA-βgal staining, a biomarker of senescence. Senescence of fibroblasts were measured using Senescence Detection Kit (BioVision, Mountain View, CA) based on SA-βgal staining. The assay was carried out in accordance with the instruction manual.

Real-time PCR. Whole RNA of cultured skin fibroblasts was extracted using RNeasy Mini Kit (Qiagen, Chatsworth, CA) in accordance with the instruction manual. The mRNA expression was quantified by methods of TaqMan with real-time reverse transcriptase (RT)-PCR. PCR primers were purchased from SIGMA-ALDRICH custom oligonucleotide synthesis service (Sigma Aldrich, St. Louis, MO). Primer sequences are COL1 (forward, 5'-GGGATTCCCTGGACCTAAAG-3' and reverse, 5'-GGAACACCTCGCTCTCCA-3'), COL4 (forward, 5'-AGGAGAGAAGGGCGCTGT-3' and reverse, 5'-TCCAGGTAA GCCGTCACA-3'), MMP2 (forward, 5'-CCCCAAAACGGA CAAAGAG-3' and reverse, 5'-TGTCCTTCAGCACAAACA GG-3'), MMP8 (forward, 5'-TGACAGAGACCTCATTTT CCTATTTA-3' and reverse, 5'-CTGCGTCAATTGCTTGGA-3'), GLB1 (forward, 5'-GCTCCTCCGACCCAGATT-3' and reverse, 5'-CTGGCCCTCCATTCTGATAG-3'), IL-6 (forward, 5'-CAG GAGCCCAGCTATGAACT-3' and reverse, 5'-GAAGGCAGC AGGCAACAC-3'), IL-8 (forward, 5'-AGACAGCAGAGC

ACACAAGC-3' and reverse, 5'-AGGAAGGCTGCCAAGAG AG-3'), and p21 (forward, 5'-CCGAGGCACTCAGAGGAG-3' and reverse, 5'-AGCTGCTCGCTGTCCACT-3'). The PCR was carried out using Applied Biosystems Veriti Thermal Cycler and the reaction conditions were followed; 95°C for 10 min, 40 cycles of amplification at 95°C for 15 s, 60°C for 1 min, followed by 95°C for 15 s, 60°C for 30 s and 95°C for 15 s. Target gene expression level was normalized to the housekeeping gene, 18sRNA, expression level.

Immunostaining. After fibroblast was fixed with 4% paraformaldehyde for 20 min, the cells were washed with PBS three times, and then permeabilized and blocked with 0.2% Triton-X and 1% normal goat serum (NGS) containing phosphate-buffered saline (PBS) for 20 min at room temperature. The permeabilized cells were treated with type I collagen antibody (1:300). After overnight incubation at 4°C, the fibroblasts were washed with PBS three times, the fibroblasts were treated with Alexa Fluor 488 probe (1:500, Invitrogen, Carlsbad, CA) for 1 h at room temperature in dark. The fibroblasts were mounted with DAPI and imaged by using fluorescence microscopy.

Protein quantity. Proteins were quantified using Protein Quantification Kit-Rapid (Dojindo Laboratories) based on the method of Bradford,⁽³²⁾ and standard BSA solution was used to generate a standard curve for this assay.

Statistical analysis. Data are expressed as mean ± SD. The significance of differences between individual data was determined by using Student's unpaired *t* test. The *p* values less than 0.05 were considered significant.

Results

CoQ₁₀ protects H₂O₂-induced cell death of fibroblasts. SIPS model of fibroblasts are prepared by H₂O₂ treatment, high concentration of H₂O₂ may induce cell death. Therefore, we investigated whether CoQ₁₀ can prevent 100 μM H₂O₂-induced cell death by MTT and DAPI assay. When SIPS-induced fibroblasts were treated with 100 μM H₂O₂, the cell viability significantly decreased to 17% (Fig. 1A). 1 μM and 10 μM CoQ₁₀ significantly increased the cell viability to 24.2% and 30.6%, respectively. The same protective effect of CoQ₁₀ was also detected by DAPI staining (Fig. 1B). These results suggest that CoQ₁₀ can prevent H₂O₂-induced cell death of fibroblast because of its antioxidative activity.

CoQ₁₀ suppresses senescent phenotypes in the fibroblasts. GLB1 genes which encodes lysosomal enzyme, SA-βgal is an important markers of replicative senescence and induced senescence.⁽³³⁾ SA-βgal is using a biomarker of cell aging. When SIPS-induced fibroblasts were treated with H₂O₂ for 2 h, intracellular SA-βgal and GLB1 mRNA level were increased (Fig. 2A and B), whereas SA-βgal positive cell number and GLB1 mRNA level were diminished by addition of 1 or 10 μM CoQ₁₀. These results indicated that CoQ₁₀ suppresses the senescent phenotype induced by H₂O₂-treatment in fibroblasts.

Effect of CoQ₁₀ on the H₂O₂-induced changes of Collagen and MMP levels of fibroblasts. Although, Collagen is the most abundant protein in human body, its expression decreased in aging. While, MMP have been known as catabolic enzyme of ECM, such as collagen, elastin, and laminin, and plays notably an important role in degradation of collagen. Therefore, we examined the effect of H₂O₂ on collagen and MMP expression levels of human skin fibroblasts. As the results, H₂O₂ decreased the mRNA levels of type I and IV collagens, but increased the levels of type II and VIII MMPs. On the other hands, CoQ₁₀ returned the H₂O₂-induced changes of collagen mRNA and MMP levels to control levels dose-dependently (Fig. 3A). In addition, H₂O₂ also decreased the protein level of type I collagen of the fibroblasts (Fig. 3B). These results suggest that CoQ₁₀ suppresses

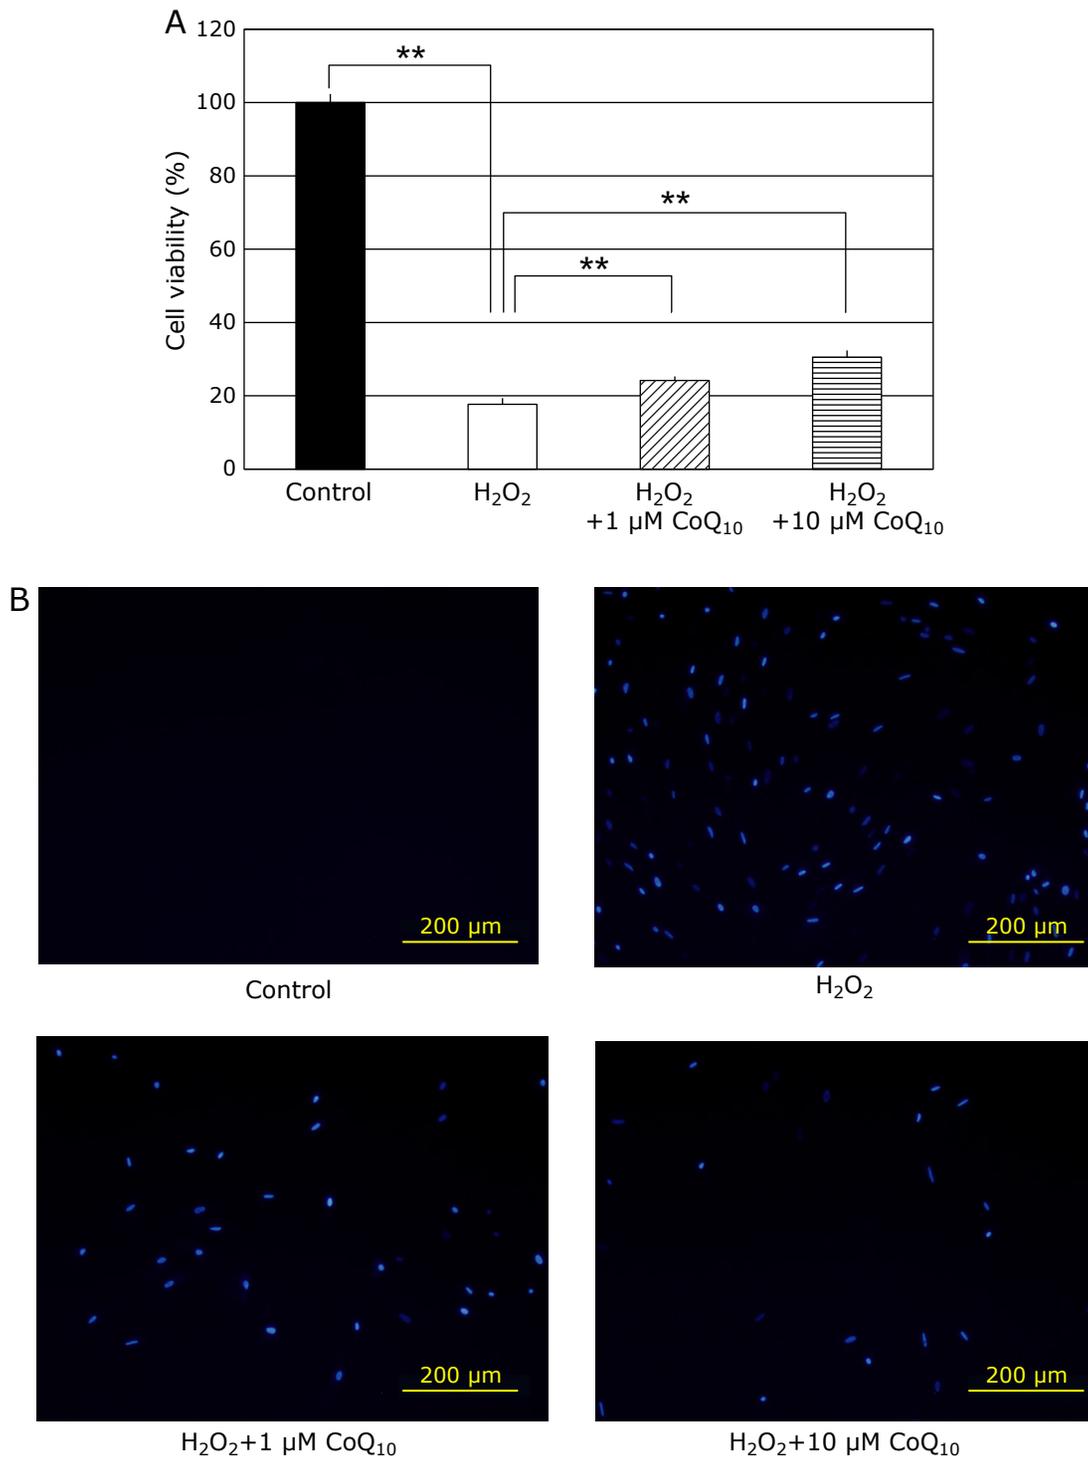

Fig. 1. Cell viability in fibroblasts were detected with MTT assay and DAPI staining methods. (A) The cell viability was 100% (closed bar), 17.7% (open bar), 24.2% (hatched bar), and 30.6% (horizontal striped bar), respectively. (B) The image of cell death was obtained using DAPI staining in fibroblasts under the fluorescence microscopy. Results are means \pm SD. $n = 3-5$, $**p < 0.01$.

cell senescence via maintenance of intracellular collagen level induced by H₂O₂-treatment in fibroblasts.

Effect of CoQ₁₀ on the H₂O₂-induced change of SASP levels of skin fibroblasts. SASP, which is released from senescent cells, stimulates tumorigenesis promotion, evokes of chronic inflammation, and promotes development of age-related

diseases.⁽³⁴⁾ Therefore, we examined the effect of H₂O₂ on mRNA levels of p21, IL-6, and IL-8 of fibroblasts. As the results, the mRNA levels of p21, IL-6, and IL-8 increased of fibroblasts. On the other hands, 10 μM CoQ₁₀ suppressed the H₂O₂-induced up-regulations of p21, IL-6, and IL-8 mRNA levels (Fig. 4). These results suggest that CoQ₁₀ suppresses cell senescence via

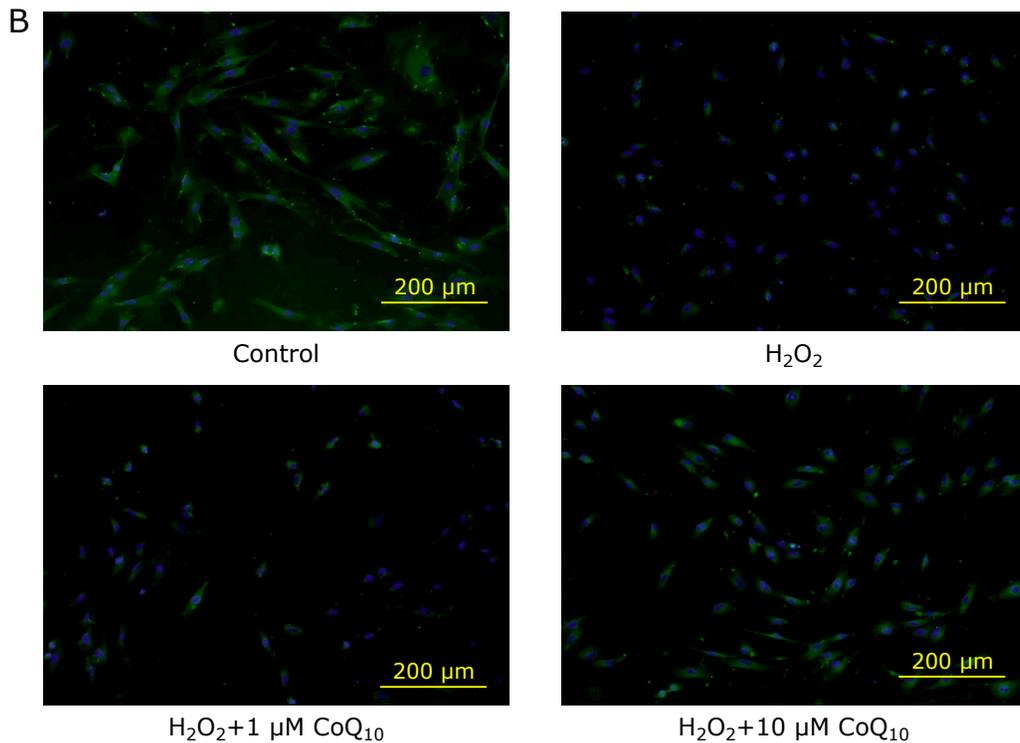

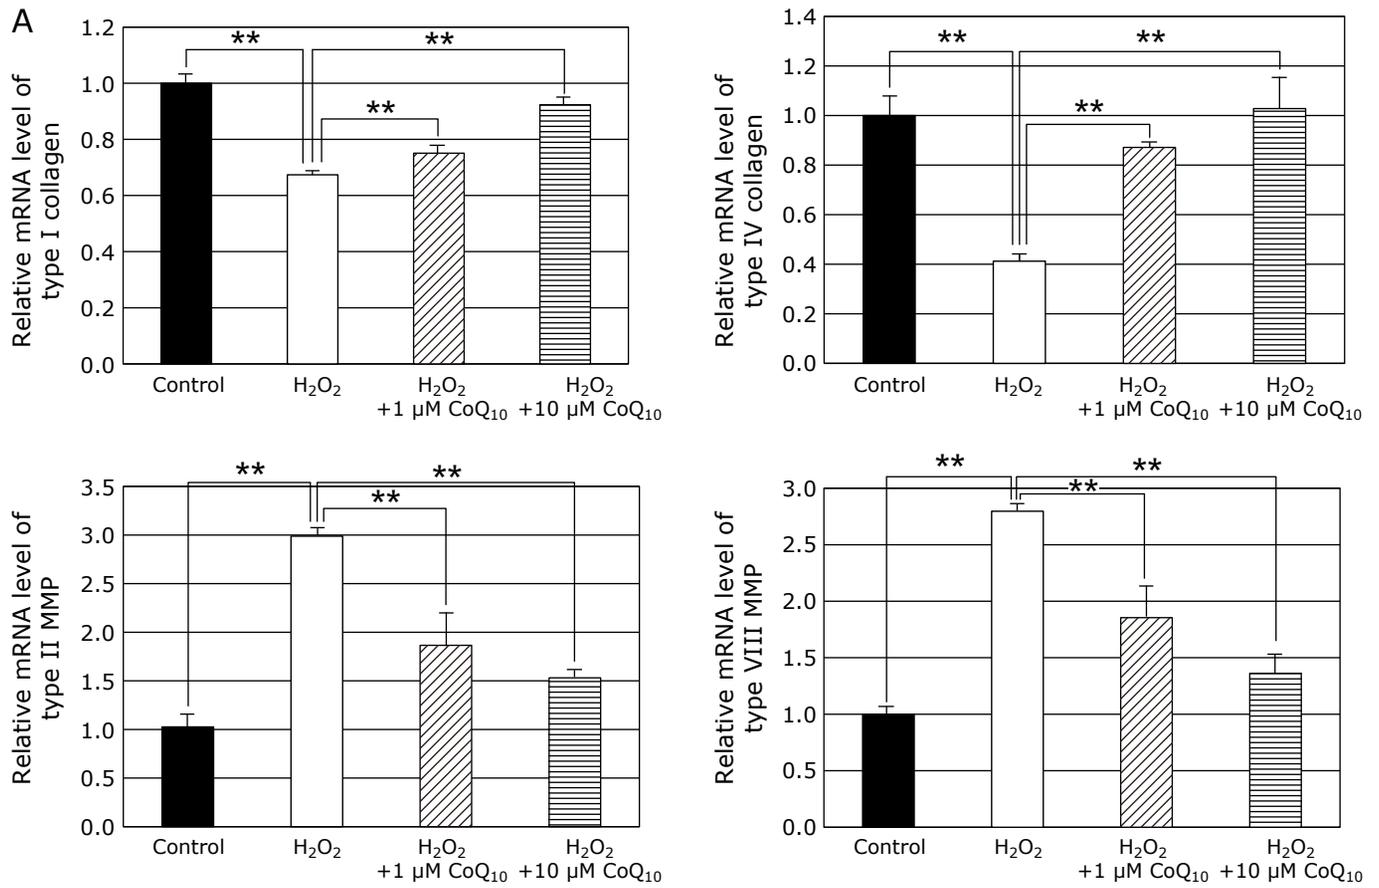

Fig. 3. Relative mRNA expression of type I, IV collagens and type II, VIII MMP were determined by RT-PCR method and the target gene levels were normalized to the housekeeping gene 18sRNA. (A) The mRNA level of type I, IV collagen was increased by treatment of CoQ₁₀, and it also dose-dependently enhanced in fibroblasts. Conversely, CoQ₁₀ treatment decreased the mRNA levels of type type II, VIII MMP. Results are means ± SD. *n* = 3–7, ***p*<0.01. (B) Type I collagen protein expression in fibroblasts of SIPS model was determined by immunofluorescence, cell nuclei are stained blue with DAPI, and type I collagen protein is stained green with Alexa Fluor 488 probe.

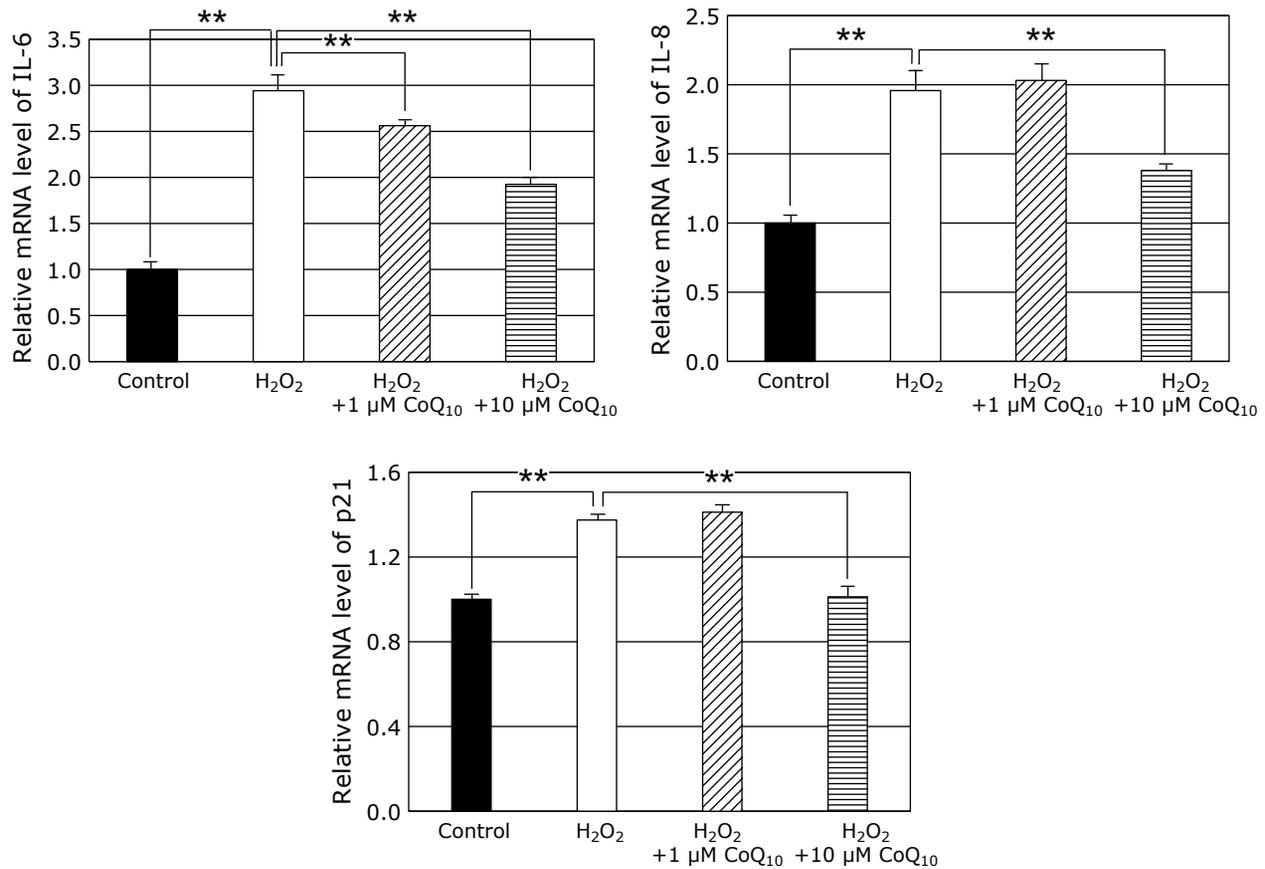

Fig. 4. We confirmed effects of CoQ₁₀ on IL-6, IL-8, and p21 gene expression in fibroblasts of SIPS model. The SASP (such as IL-6, IL-8, and p21) related to aging was increased by the addition of H₂O₂, while it decreased the mRNA levels of IL-6, IL-8, and p21 with CoQ₁₀ treatment. Results are means ± SD. *n* = 3–6, ***p* < 0.01.

Discussion

Cellular senescence is complexly and represent multiple dysfunction such as growth arrest and secretory of SASP factors, so that it has been recognized as an important feature during tumorigenesis suppression and contribution of aging.⁽³⁶⁾ Among them, oxidative stress is particularly important role for cellular senescence process.⁽²⁾ Therefore, SIPS model cells induced by oxidative stress (especially H₂O₂) are widely used in senescence-related studies in recently.^(4,5) However, the fundamental effectiveness or mechanism of CoQ₁₀ on H₂O₂-induced SIPS model of human skin fibroblasts have not been reported. Consequently, this study evaluated mainly the effects of CoQ₁₀ as to collagen synthesis and degradation, it is purpose to elucidate their underlying mechanism in preventing skin aging of SIPS model.

Oxidative stress especially plays a major role in the aging process, which is postulated in the free radical theory of aging.⁽²⁾ In addition, DNA damage induced by oxidative stress have been known to cause cell death, so that aging process evoked by DDR.⁽³⁾ Therefore, it has been thought that inhibition of oxidative stress with antioxidant reagent leads to the suppression of DDR, which eventually prevent cellular senescence. In this study, CoQ₁₀ protected cell death induced by H₂O₂, then it is likely involved in the potent antioxidant effects of CoQ₁₀ (Fig. 1). Moreover, it is reported that CoQ₁₀ has broad therapeutic effects, including diabetes,⁽²⁰⁾ cardiovascular disease,⁽²¹⁾ and neurological disorder,⁽²²⁾ besides these are likely to be involved in potent antioxidative effects of CoQ₁₀. Furthermore, CoQ₁₀ significantly decreased the number of SA-βgal senescence positive cells on

SIPS model in this study (Fig. 2). These results suggested that CoQ₁₀ attenuated the cellular senescence, thereby CoQ₁₀ have the possibility of adaptation to age-related diseases.

Senescent cells also secreted SASP factors, such as IL-6, IL-8, and MMP, which promote even more the cellular senescence and tumor progression, further it also induced the cycle inhibitors p16 and p21.^(11,13) In contrast, chronic inflammation is associated with aging and play an important role in several age-related diseases, and this phenomenon has been termed as inflammaging,⁽³⁷⁾ which mainly activate NF-κB as a master regulator of the SASP.⁽³⁸⁾ Besides, it is reported senescent cells often downregulate ECM protein and upregulate ECM degrading enzymes in replicative senescence.⁽³⁹⁾ Among them, MMP has attracted a lot of attention for skin aging. MMP belonging to the family of zinc-binding, have been known as chemokine which degrade components of the ECM such as collagen. It has been reported that collagen expression and protein levels decrease in aged skin, because the event caused by downregulation of collagen expression and upregulation of MMP expression. In addition, dermal fibroblasts express increased levels of collagen-degrading MMP-1 in aged compared with young human skin *in vivo*.⁽⁴⁰⁾ Moreover, Inui *et al.*⁽⁴¹⁾ have reported that collagen is degraded via increasing MMP expression by UVB. Oxidative stress, inflammation, and aging are intimately related to each other, it is possible that skin aging can be improved by suppressing these factors. Therefore, assessing the loss of collagen, either decreased synthesis or increased degradation, is important in analyzing the factors that may contribute to skin aging.⁽⁴²⁾ In this study, we examined as to collagen and MMP expression levels in

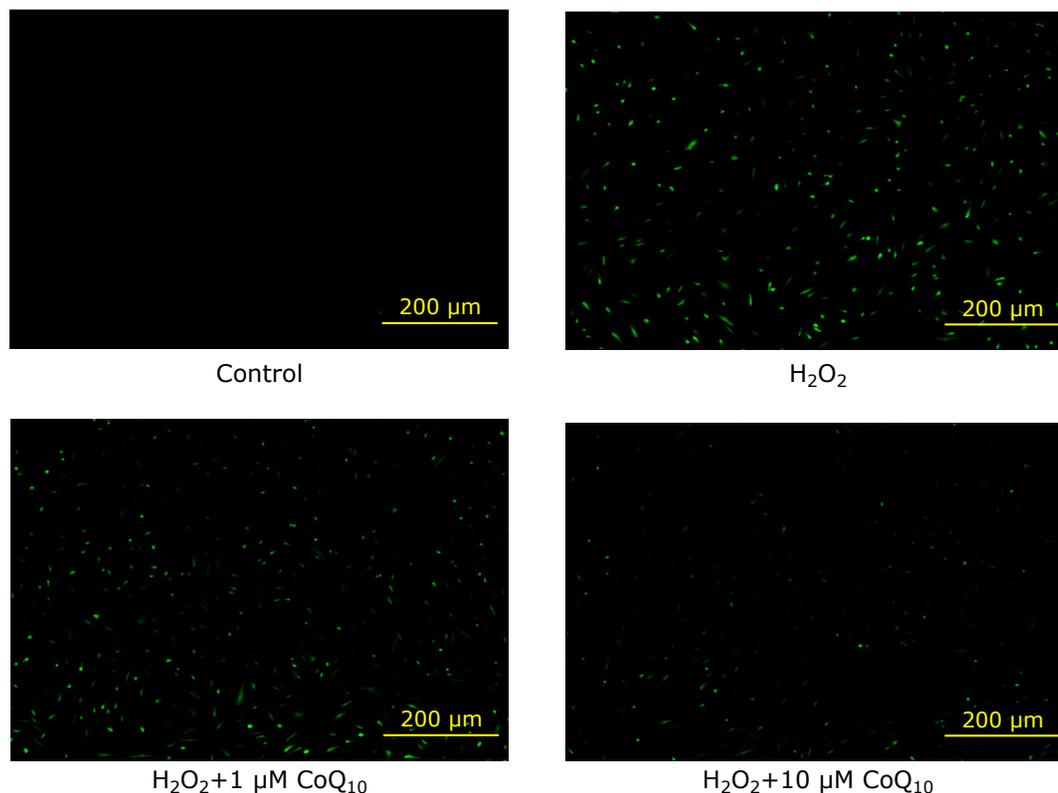

Fig. 5. We observed intracellular ROS levels with CM-H₂DCFDA in fibroblast of SIPS model, and the green fluorescence intensity was monitored by fluorescence microscopy.

H₂O₂-induced SIPS model of human skin fibroblasts. It is showed that CoQ₁₀ effectively enhanced collagen synthesis and inhibited collagen degradation indicated by upregulation of collagen genes, type I, IV collagen synthesis and downregulation of type II, VIII MMP genes on SIPS model of fibroblasts (Fig. 3A). Furthermore, CoQ₁₀ increased protein levels of type I collagen in this result (Fig. 3B). Meanwhile, the mRNA of p21, IL-6, and IL-8, it is better elevated in SIPS model, whereas CoQ₁₀ treatment suppressed upregulation of p21, IL-6, and IL-8 mRNA levels (Fig. 4). These results suggested that CoQ₁₀ treatment ameliorate the skin aging, and inhibited synthesis of SASP factors in SIPS model.

Intracellular excessive oxidative stress has harmful effects on biomolecules such as lipids, proteins, and DNA and eventually leads to cellular senescence. In addition, Sublethal doses of various compounds such as O²⁻, OH[•], as well as H₂O₂ also induce phenomena similar to replicative senescence in normal cells, a phenomenon termed premature senescence. For instance, the exposure of human skin fibroblasts to a sublethal concentration of H₂O₂ induces phenotypic changes that mimic those seen in replicative senescence.^(8,9) Therefore, a senescence model of H₂O₂-induced SIPS was used to investigate the protective effects of CoQ₁₀ against the oxidative stress induced by H₂O₂. In this study, H₂O₂ increased green fluorescence indicating intracellular ROS levels, whereas suppression of ROS was observed by CoQ₁₀ treatment in SIPS model (Fig. 5). This effect is thought to be a potent antioxidant effect possessed by CoQ₁₀. Mellors and Tapple⁽⁴³⁾ reported that the antioxidant effects of CoQ₁₀ is comparable to α -tocopherol in antioxidant potential. In recent study, it is known that senescent cells increase chromosomal DNA fragments on cytoplasm, which is one cause, and it provoke the SASP factors secretion induced by ROS-dependent DDR.⁽⁴⁴⁾ In general, CoQ₁₀ is lipid-soluble, which have a low absorption rate on the human body, although P40 exhibited higher uptake

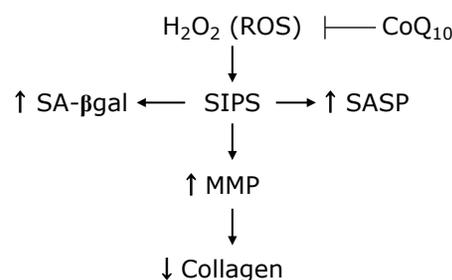

Fig. 6. Proposed scheme for anti-aging effects of CoQ₁₀ in SIPS model. H₂O₂ has been used in various studies as the senescence induction agent, that modeled of SIPS in this study. In this study, SA-βgal activity and SASP synthesis increased in SIPS model of fibroblasts. In addition, increasing of MMP expression levels induced the collagen degradation and decrease of intracellular collagen levels. Furthermore, intracellular ROS levels increased in SIPS model. This change is similar to a well-known phenomenon of replicative senescence in human skin fibroblasts. So, the scheme suggested that CoQ₁₀ could show that anti-aging effects to inhibit ROS that induce SIPS model of fibroblasts.

compared with CoQ₁₀.⁽³²⁾ In this study, it is shown that CoQ₁₀ suppress oxidative stress, degradation of collagen by increasing MMP expression, and decreasing senescence-associated phenotypes (e.g., SA-βgal positive staining and SASP) for preventing skin aging via H₂O₂-induced SIPS model (Fig. 6). Therefore, it is considered CoQ₁₀ had an anti-aging action in SIPS model of human skin fibroblasts. These results suggested that CoQ₁₀ has possibility to be contributory for extension of healthy life expectancy in Japan. We hope that this study will help further clarify the mechanism of aging and development of aging control method.
