Abstract

Bestrophin-1 modulates currents through voltage-dependent L-type Ca²⁺ channels by physically interacting with the β -subunits of Ca²⁺ channels. The main function of β -subunits is to regulate the number of pore-forming Ca_v-subunits in the cell membrane and modulate Ca²⁺ channel currents. To understand the influence of full-length bestrophin-1 on β -subunit function, we studied binding and localization of bestrophin-1 and Ca²⁺ channel subunits, together with modulation of Ca_v1.3 Ca²⁺ channels currents. In heterologous expression, bestrophin-1 showed co-immunoprecipitation with either, β 3-, or β 4-subunits. We identified a new highly conserved cluster of proline-rich motifs on the bestrophin-1 C-terminus between amino acid position 468 and 486, which enables possible binding to SH3-domains of β -subunits. A bestrophin-1 that lacks these proline-rich motifs (Δ CT-PxxP bestrophin-1) showed reduced efficiency to co-immunoprecipitate with β 3 and β 4-subunits. In the presence of Δ CT-PxxP bestrophin-1, β 4-subunits and Ca_v1.3 subunits partly lost membrane localization. Currents from Ca_v1.3 subunits were modified in the presence of β 4-subunit and wild-type bestrophin-1: accelerated time-dependent activation and reduced current density. With Δ CTPxxP bestrophin-1, currents showed the same time-dependent activation as with wild-type bestrophin-1, but the current density was further reduced due to decreased number of Ca²⁺ channels proteins in the cell membrane. In summary, we described new proline-rich motifs on bestrophin-1 C-terminus, which help to maintain the ability of β -subunits to regulate surface expression of pore-forming Ca_v Ca²⁺-channel subunits.

Introduction

Bestrophin-1 is an anion channel [1] which can also regulate voltage-dependent Ca²⁺ channels [2,3,4,5]. The regulatory effects include modulation of activation kinetics [2,3,5], voltage-dependent activation [3] and/or current amplitude [4,5].

Voltage-dependent Ca²⁺ channels are composed of pore-forming Ca_v-subunits (α 1-subunits) which determine the basic Ca²⁺ properties and of the auxiliary β , α 2 δ - and sometimes the γ -subunits [6,7]. The Ca²⁺ channel β -subunits have complex functions [8,9]: they modulate the electrophysiological properties of the pore-forming Ca_v-subunits, interact with kinases and are required for the transport of Ca_v-subunits to the cell membrane. It is most likely that described effects of bestrophin-1 on L-type channel activity are due to modulation of β -subunit function. Using heterologous co-expression of L-type Ca²⁺ channels and C-terminus fragments of bestrophin-1, proline-rich motifs between the amino acid positions 330 and 346 were identified to enable interaction with β -subunits of voltage-dependent Ca²⁺ channels via SH3 domains [4,5]. The physical interaction of full-length bestrophin-1 with Ca²⁺ channel β -subunits was confirmed by Reichhart et al. [5].

Mutations in the gene for bestrophin-1, BEST1, lead to different types of retinal or macular degenerations [1,10]. The most common phenotype is Best's vitelliform macular dystrophy [11,12,13]. Symptoms include macular degeneration, fast accumulation of lipofuscin and a reduction of the so called "light-peak" in the patient's electro-oculogram [14]. However, little is known about how mutations in BEST1 lead to disease. It is possible that BEST1's role as an anion channel and/or Ca²⁺ channel regulator could explain the typical changes seen in the electro-oculogram. Several lines of evidence show that the light-peak in the electro-oculogram is generated by activation of Cl⁻ conductance and is dependent on the presence of β 4- and Ca_v1.3 subunits [3,15,16,17] in the retinal pigment epithelium (RPE) which closely interacts with the photoreceptors in the retina [18]. Bestrophin-1 is known to be basolaterally located in the RPE and can function as both Cl⁻ channel and Ca²⁺ channel regulator. The combined function as a Ca²⁺-dependent anion channel and Ca²⁺ channel regulator would provide an efficient feedback loop to control Ca²⁺-dependent Cl⁻ transport, for example, by the RPE [1,18]. There are several studies which investigated eyes from Best patients [19,20,21,22,23,24]. So far, only one pathologic effect of a mutant bestrophin-1 has been found. This mutant form does not show

uniform basolateral localization [20]. Thus, the proper trafficking of bestrophin-1 and probably its interaction partners seem to be important for understanding bestrophin-1 function in disease. In this regard, determining the influence of bestrophin-1 on β -subunits derived regulation of pore-forming $\text{Ca}_v1.3$ -subunits in the plasma membrane would allow for better understanding of Best's disease.

The aim of our study is to first investigate the interaction of full-length bestrophin-1 with β -subunits and secondly, the influence of bestrophin-1 on the ability of β -subunits to regulate the surface expression of Ca_v -subunits. In order to test this hypothesis we performed immunoprecipitation experiments with heterologously expressed bestrophin-1, β -subunits and $\alpha 1$ -subunit $\text{Ca}_v1.3$ corresponding to the Ca^{2+} channel expressed in the RPE [3,25]. These interactions and the influence on membrane localization of $\text{Ca}_v1.3$ -subunits were verified by correlation with the subcellular localization using confocal microscopy. The functional effects were studied by patch-clamp analysis of Ca^{2+} channel currents from heterologously expressed $\text{Ca}_v1.3$ -subunits and $\beta 4$ -subunits.

Materials and Methods

Cell culture and transfection

CHO (ATCC, cat# CCL-61) cells were cultured in 100-mm culture dishes in Hams F12 medium (Invitrogen). HEK-293 (ATCC, cat# CRL-1573), and COS-7 cells (ATCC, cat# CRL-1651) were cultured in Dulbecco's modified Eagle's medium (DMEM) containing L-glutamine, 4500 mg/l glucose and 110 mg/l sodium pyruvate. ARPE-19 (ATCC, cat# CRL-2302) cells were cultured in DMEM/Ham's F-12 medium, 50:50 mixture supplemented with insulin/transferin, non essential amino acids, and 15 mM HEPES buffer (Invitrogen). All media were supplemented with 10% (v/v) fetal calf serum (Invitrogen), and 1% (v/v) penicillin-streptomycin (Invitrogen). Cells were cultured at 37°C, with relative humidity of 95% and 5% CO_2 concentration. Transfections were carried out using Lipofectamine 2000 transfection reagent (Invitrogen) following the manufacturer's instructions or by microinjections. Microinjections were performed using a FemtoJet Injector in conjunction with a InjectMan Manipulator (both Eppendorf, Hamburg, Germany). The detailed description is included in the chapter "Ca $_v1.3$ patch-clamp recordings".

Plasmid Constructs

1. Human bestrophin-1, BEST1 [Homo sapiens; NM_004183], hBest-pEGFP-N1 (N-terminal EGFP-tagged human bestrophin), hBest-pcDNA3.1 2. calcium channel, voltage-dependent, $\beta 1$ (Rattus norvegicus NM_017346), $\beta 3$ (Rattus norvegicus; NM_012828), and $\beta 4$ -subunit (Rattus norvegicus; Gene ID 25297 and 58942); depending on experimental conditions tagged either with His or c-Myc), $\beta 3$ -pCMV, and $\beta 4$ -pCDNA3; 3. Cacna1d, calcium channel, voltage-dependent, L-type, $\alpha 1D$ subunit $\text{Ca}_v1.3$ (Homo sapiens: NM_000720.2) $\alpha 1D$ subunit $\text{Ca}_v1.3$ -GFP; 4. $\alpha 2\delta 1$ -pcDNA3 (Gene ID 776), 5. eGFP pcDNA3 reporter plasmid was used as transduction control. Ca^{2+} channel constructs were provided by Prof. Striessnig (Innsbruck). Human bestrophin-1 constructs were provided by Prof. Weber (Regensburg). All described constructs were sequenced for integrity, and pure plasmid DNA was isolated by using a plasmid maxi kit (Qiagen).

DNA manipulations

Deletion of the C-terminal proline rich (CT-PxxP) region between 462-575aa (113 amino acids) was introduced into human

bestrophin-1 by PCR using the following primers: 5'- ATC-GCTCGAGCCACCATGACCATCACTTACACA and 5'- CG-ATGGATCCATGGCAGACTTGAAGGCGTC. Resulting PCR product was digested using XhoI and BamHI restriction enzymes, and subsequently inserted into pCDNA3-bestrophin-1 plasmid digested with XhoI/BamHI. All the constructs were verified by DNA sequencing.

Antibodies

Proteins were detected using the following antibodies: mouse monoclonal anti-human-bestrophin ab2182, mouse monoclonal anti His6 ab18184, rabbit polyclonal anti His6ab9108 (Abcam plc, Cambridge, UK), rabbit anti- $\beta 3$, rabbit Cav1.3 (Alomone Labs), goat anti Cav1.3 (Santa Cruz), mouse monoclonal anti beta-actin (clone JLA20, Hybridoma Bank Iowa), and mouse monoclonal anti-GFP (Roche). Rabbit polyclonal anti bestrophin-1 antibody was provided by Prof. Dr. Karl Kunzelmann (Regensburg). Proteins were visualized by Western blot using HRP-conjugated goat anti-rabbit or goat anti-mouse antibodies (New England Biolabs).

Immunoprecipitation

Subconfluent (70-80%) culture of CHO, HEK-293 or COS-7 cells were transiently transfected with combinations of plasmids encoding a human-bestrophin-1 (N-terminal EGFP-tagged or untagged), $\beta 3$ (untagged), $\beta 4$ -His $_6$ and $\text{Ca}_v1.3$ (N-terminal eGFP-tagged or untagged) subunits of voltage-dependent calcium channels using Lipofectamine 2000 transfection reagent (Invitrogen) according to the manufacturer's protocol. The pcDNA3.1 and pEGFP plasmids were used as negative control. After a 24-h incubation, cells were washed with 1xPBS and then lysed in culture dish with shaking for 15 min at 4°C with ice-cold lysis buffer (150 mM Tris-HCl, pH 7.5, 150 mM NaCl, 1% Nonidet-P40, 0.5% natrium deoxycholate, 1 tablet Complete Mini protein inhibitor mixture/10 ml (Roche Applied Science), and 0.7 $\mu\text{g}/\text{ml}$ pepstatin). Cell lysate was scraped and transferred to a new tube and lysed for additional 15 min at 4°C with rocking. The lysates were clarified by centrifugation at 13,000 $\times g$ for 10 min at 4°C.

Pre-clearing

Supernatants were applied to 50 μl of Protein G-Agarose (Sigma) and incubated 3 hours with rocking at 4°C. After pre-clearing and centrifugation at 13,000 $\times g$ for 1 min the lysates were applied to new tubes with 50 μl of Protein G-Agarose already incubated for 1 hour with 3 μg of suitable/relevant antibody. Subsequently, after overnight incubation on a rotating wheel at 4°C the beads were washed three times with washing buffer. All centrifugation steps were carried out at 1,200 $\times g$ for 1 min at 4°C. 1. Washing buffer (50 mM Tris-HCl, pH 7.5, 150 mM NaCl, 1% Nonidet-P40, 0.5% natrium deoxycholate, 1 tablet Complete Mini protein inhibitor mixture/10 ml (Roche Applied Science) and 0.7 $\mu\text{g}/\text{ml}$ pepstatin). 2. Washing buffer (50 mM Tris-HCl, pH 7.5, 250 mM NaCl, 0.1% Nonidet-P40, 0.05% natrium deoxycholate). 3. Washing buffer (50 mM Tris-HCl, pH 7.5, 50 mM NaCl, 0.1% Nonidet-P40, 0.05% natrium deoxycholate). Protein complexes were dissociated from beads by incubation at 37°C for 30 min in 4xSDS loading buffer. The immunoprecipitates were subjected together with total lysates to 7.5% or 10% SDS-PAGE and Western blot was carried out.

Western Blot Analysis

Western Blot analysis were performed as previously described in detail [3]. Lysates of membrane proteins were prepared by three

freezing and thawing steps (liquid N₂; 42°) and two centrifugation steps at 500 and 43,000 g, the pellet was suspended in lysis buffer and subjected to SDS-PAGE (7.5–10% gel). The proteins were blotted to nitrocellulose filter membranes (Polyscreen; NEN Life Science Products, Boston, MA). The blots were blocked in 5% non-fat dry milk and 5% bovine serum albumin. Primary antibodies were diluted as follow: anti-human-bestrophin, anti- β 3, and anti-GFP (1:5000), anti His6 (1:2500), anti Cav1.3, and anti beta-actin (1:1000). After incubation with primary antibodies, blots were visualized with a peroxidase-conjugated secondary antibody and a chemiluminescence kit according to manufacturer's instructions. Chemi-luminescence detection (*of bound secondary antibodies*) was carried out using Immobilon Western HRP substrate detection kit (Millipore). The images were digitalized using an image analyzer (Chemimager, Biozym).

Immunohistochemistry and confocal microscopy

For immunofluorescence experiments, transiently transfected CHO and ARPE-19 cells were grown on a sterile glass cover slip. 24 hours after the transfection cells were washed with 1× PBS, and fixed for 10 min at room temperature with 4% (w/v) para-formaldehyde. After three additional washing steps with 1× PBS, cells were permeabilized with blocking/permeabilization solution [10% (v/v) normal goat serum, 0.5% (v/v) Triton X-100 in 1× PBS] for 30 min. Cells were then labeled for 1 hour with anti-bestrophin-1 antibody, and anti- β 3 antibody diluted 1:500, and goat anti-Ca_v1.3 antibody diluted 1:100 in 2% normal goat serum, 0.1% Triton X-100 in 1× PBS. After three additional washing steps cells were incubated for 1 hour with appropriate secondary antibodies diluted 1:500 (conjugated with Alexa 488, Alexa 546, and Alexa 633, (Invitrogen). Cells were mounted in confocal matrix (Micro Tech Lab, Graz, Austria) and then examined using confocal microscope LSM510 (Carl Zeiss, Göttingen, Germany).

Quantitative c-localization analysis

For the quantitative co-localization analysis, ARPE-19 cells grown on glass cover slips were either double or triple transfected with various bestrophin constructs and labeled with corresponding primary antibody. After subsequent incubation with secondary antibodies conjugated with Alexa 488, 546, and 633 diluted 1:500 (Invitrogen, Germany), cover slips were examined using confocal microscope LSM 510 (Zeiss, Göttingen, Germany). Confocal microscopy has advantage over the standard fluorescence microscopy, because it generates thin optical sections and thus allows quantification of the co-localization of antigens. Triple fluorescence for green, red and infrared channels was obtained using excitation of an argon-helium-neon laser at wave lengths of 488, 546, and 633 nm. Emission of the different fluorophores was detected using appropriate filter sets and multi channel acquisition. Triple stained images were obtained by sequential scanning for each channel to eliminate the crosstalk of chromophores and to ensure reliable quantification of co-localization. Images were recorded at intensity levels below saturation, estimated by intensity analysis module. Confocal images were quantitatively analyzed using an ImageJ software package. Pearson's correlation coefficient (PCC) was employed to evaluate co-localization according to Abramoff [26]. PCC is one of the standard techniques applied in pattern recognition for matching one image to another in order to describe the correlation of the intensity distributions between channels. It takes into consideration only for the similarity of shapes between two images, and does not depend upon image pixel intensity values. Values of PCC are defined from -1 to 1 where -1 indicates no overlap and 1 is a complete co-localization. For surface expression analysis, confocal image files were loaded

into ImageJ (version.1.45b), and were submitted to edge detection process using built in edge detection algorithm (3×3 Sobel edge filter). In the next step, single cells were selected and cell surface was labelled using freehand tool. Intracellular regions were additionally selected, and all selected regions were saved as a region of the interest (ROI). Total number of pixels were counted using analyze particles command for each channel separately. The number of pixels from the whole cell was subtracted from the intracellular regions, thus giving the proportion of the pixel localized to the membrane. Furthermore, membrane pixel values were divided with intracellular pixel values, giving relative surface expression.

Patch-Clamp recordings of Ca_v1.3 channel currents - Microinjection

For patch-clamp experiments and confocal microscopy CHO cells were microinjected with plasmids coding Ca²⁺ channel subunits and different bestrophin-1 depending on the experiment as indicated in the results. Microinjections were performed under an inverted microscope (Carl Zeiss) equipped with a micromanipulator InjectMan NI2 (Eppendorf) by using an automated FemtoJet (Eppendorf) and Femtotip (Eppendorf) glass microcapillaries. CHO cells were plated on 12-mm glass plates and microinjected with plasmid DNA (50 ng/ μ l for each construct). Immediately after microinjection, cells were incubated overnight at 30°C, and next day cells were transferred into 37°C cell culture incubator. *Patch-clamp analysis*: Membrane currents were measured in the whole-cell configuration of the patch-clamp technique. While recording, transfected cells were superfused in a bath solution containing (mM): choline chloride 150, BaCl₂ 10, MgCl₂ 1, HEPES 10; pH 7.4 adjusted with CsOH; 333mOsm). To elicit voltage-dependent currents, cells were stimulated from a holding potential of -70 mV by stepwise depolarization. Gating currents were measured according to Fan et al. [27]. To measure gating currents, the Ca_v1.3 pore was blocked using 10 mM Co²⁺, which was used to replace Ba²⁺. Co²⁺ is known to block L-type channels as it is not able to permeate through the pore [27]. Before measuring the gating current amplitude the Ca_v1.3 currents were measured currents using Ba²⁺ as charge carrier. Only cells which showed a strong and robust Ba²⁺ current were used for gating current analysis. For proper measurement of gating currents, special care was taken to compensate for residual capacitive currents. The perfusion chamber was assessed by fluorescent microscope. Transfected cells were selected by their GFP fluorescence. For whole-cell recording, patch-pipettes of 3–5 M Ω were made from borosilicate tubes using a DMZ-Universal Puller (Zeitz, Augsburg Germany). Pipettes were filled with a pipette-solution containing (mM): CsCl 135, MgCl₂ 1, CsEGTA 10; pH 7.4 adjusted with CsOH; 283 mOsm). Membrane currents were recorded using an EPC-10 computer-controlled patch-clamp amplifier in conjunction with the TIDA software for data acquisition and analysis. The mean membrane capacitance was 22.04±1.3 pF (n = 25). The access resistance was compensated for to values lower than 10 M Ω . Analysis of voltage-dependent activation was done by plotting steady-state currents against membrane potentials of electrical stimulation. Individual cell plots were fitted using the Boltzmann equation. Gating current amplitudes were plotted against the voltages of the electrical stimulation. For comparison gating current density was calculated at +20 mV.

Calculations and statistical analysis

Experiments were repeated at least three times. The Western blots shown in the figures show a representative experiment. Mean

values were given as mean \pm SEM; n refers to the number of experiments. Statistical difference was tested by ANOVA; statistic significant difference was considered at p values smaller than 0.05.

Results

In order to determine the possible physical interaction between Ca^{2+} channel subunits and bestrophin-1, immunoprecipitation experiments were performed using heterologously expressed proteins. All proteins were determined to have no endogenous expression in CHO cells (Figure S1A). We first tested our experimental settings using known physiological interaction between pore-forming $\text{Ca}_v1.3$ subunits and accessory β -subunits [6,7] (Figure 1). CHO cells were co-transfected with $\text{Ca}_v1.3$ subunits and $\beta3$ -subunits. Immunoprecipitation of $\beta3$ -subunits showed the presence of $\text{Ca}_v1.3$ subunits (Figure 1A, left panel) and vice versa (Figure 1A, right panels). Using immunocytochemistry, we studied possible interaction of these proteins in intact cells (Figure 1B). ARPE-19 cells were chosen for co-localization experiments because bestrophin-1 is normally expressed in the RPE and protein trafficking differs in the RPE of other cell types [18]. ARPE-19 cells were transfected with $\text{Ca}_v1.3$ subunits and $\beta3$ -subunits and their subcellular localization was investigated by confocal microscopy. Both $\text{Ca}_v1.3$ and $\beta3$ -subunits were found in the cell membrane. To quantify the co-staining and co-localization of the two proteins in the cell membrane, Pearson's correlation coefficient was calculated. The resulting coefficient of $85.0 \pm 8\%$ ($n = 3$; Table 1) indicates a good co-localization. In order to further analyze membrane localization, we analyzed fluorescence profiles across the cells whilst avoiding the nuclear region. The confocal images were used to quantify the plasmalemmal localization by pixel analysis using edge detection (Figure S2A–C). This revealed a relative surface expression of 3.4 ± 0.13 for $\text{Ca}_v1.3$ and 2.9 ± 0.6 for $\beta3$ -subunits ($n = 3$; n.s.) (Figure 1C).

In order to detect the interaction of bestrophin-1 and β -subunits, co-localization studies were performed in intact cells (Figure 2) in the same way as described for interaction of $\text{Ca}_v1.3$ and β -subunits. ARPE-19 cells were co-transfected with $\beta3$ -subunits and bestrophin-1. In these cells, the majority of the two proteins showed a good co-localization (Table 1) and was diffuse across the cytosol (Figure 2A). Measurement of the relative surface expression by pixel analysis revealed values of 0.78 ± 0.06 for $\beta3$ -subunits and 0.877 ± 0.15 for bestrophin-1 (Figure 2E; $n = 3$; n.s.) indicating a cytoplasmic localization for $\beta3$ -subunits and bestrophin-1 when expressed together. When ARPE-19 cells were co-transfected with bestrophin-1, $\beta3$ -subunits and $\text{Ca}_v1.3$ subunits, all three proteins were located in the cell membrane (Figure 2B, Table 1). This differs significantly compared to the bestrophin-1 and $\beta3$ -subunit localization shown before. The localization of the three proteins is shown through pixel analysis which revealed a good surface expression with values of 3.80 ± 0.26 for $\text{Ca}_v1.3$, 3.06 ± 0.16 for $\beta3$ -subunits and 3.51 ± 0.25 for bestrophin-1 (all $n = 3$; Figure 2E). The same could be observed in cells co-transfected with $\text{Ca}_v1.3$, $\beta4$ -subunits and bestrophin-1 (Figure 2C). The relative surface expression were 3.65 ± 0.34 for $\text{Ca}_v1.3$, 2.99 ± 0.10 for $\beta4$ -subunits and 3.34 ± 0.25 for bestrophin-1 (all $n = 3$; Figure 2E). For comparison and validation of the fluorescence ratios, the ratio for the purinergic receptor P2Y₂-His₆, a typical membrane protein, was calculated (Figure 2D). This protein showed a relative surface expression of 5.19 ± 0.24 (Figure 2E).

To identify the mechanism of interaction between bestrophin-1 and β -subunits of Ca^{2+} channels, bestrophin-1 sequences were analyzed for interaction domains (Figure 3A). We searched for

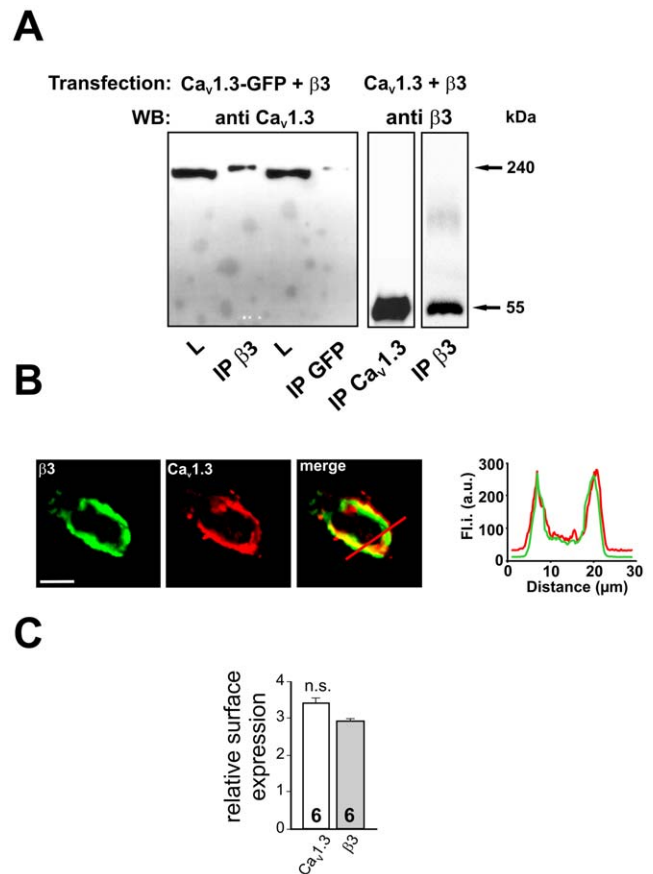

Figure 1. Interaction between pore-forming $\text{Ca}_v1.3$ and auxiliary β -subunits of voltage-dependent Ca^{2+} channels. 1A: Left panel: CHO cells were transfected with $\text{Ca}_v1.3$ -GFP fusion construct and $\beta3$ -subunits, precipitated with antibodies against $\beta3$ -subunits and blotted for $\text{Ca}_v1.3$ protein. Proteins precipitated using antibodies against GFP were positively stained with antibodies against $\text{Ca}_v1.3$ indicating identification of $\text{Ca}_v1.3$ subunits. **Right two panels:** CHO cells transfected with $\text{Ca}_v1.3$ and $\beta3$ -subunits; $\text{Ca}_v1.3$ was immunoprecipitated and blotted for $\beta3$ -subunits. Control experiment: precipitation using anti- $\beta3$ -antibody and blot stained against $\beta3$ -subunit. (L = lysate, 10% of total protein; IP = immunoprecipitation) **1B:** ARPE-19 cells transfected with $\beta3$ -subunit (green) and $\text{Ca}_v1.3$ (red). The merged picture shows co-localization of $\beta3$ -subunits and $\text{Ca}_v1.3$. On the right: fluorescence profile showing subcellular protein distribution. **1C:** To quantify plasma membrane localization, pixel analysis was performed for edge detection to calculate surface expression (data are mean \pm SEM; $n = 3$). Scale bar represents 10 μm . doi:10.1371/journal.pone.0019364.g001

proline-rich (PxxP) motifs which could bind to the SH3-domain of the β -subunits. Together with the already known cluster of PxxP motifs between amino acid position 330 and 346 on bestrophin-1 C-terminus [4] we detected a cluster of 4 proline-rich motifs, which are highly conserved among many species, between the amino acid positions 468 and 486. To explore the role of the newly detected cluster, we generated a deletion mutant of bestrophin-1 lacking the proline-rich motifs between amino acid positions 462 and 575 (named $\Delta\text{CT-PxxP}$). Using this mutant, immunoprecipitation experiments were performed to analyze binding between several β -subunits and mutant bestrophin-1. For this purpose, HEK-293 cells were transfected with wild-type or with mutant bestrophin-1 together with $\beta3$ - or $\beta4$ -subunits. Wild-type bestrophin-1 could be co-immunoprecipitated with either $\beta3$ - or $\beta4$ -subunits (Figures 3B and 3C). Similar results were obtained using

Table 1. Summary of Pearson's correlation coefficients to show co-localization of Ca^{2+} channel subunits and bestrophin-1 in confocal pictures.

Transfection	Pearson's co-localization coefficient*	Cells
Cav1.3 β 3	85 \pm 8	ARPE-19
β 3 +Best1	64 \pm 7	ARPE-19
Cav1.3+ β 3+Best1	63.5 \pm 5	ARPE-19
Cav1.3+ β 4-His+Best1	59 \pm 6	ARPE-19
Cav1.3+ β 4-His+Best1	57 \pm 4	CHO
Cav1.3+ β 4-His+ Δ CTPxxP-Best1	42 \pm 5	CHO
P2Y2-His+ Δ CTPxxP-Best1	14 \pm 4	CHO

doi:10.1371/journal.pone.0019364.t001

CHO or COS-7 (Figure S1B). Western blot analysis of the precipitates using antibodies directed against bestrophin-1 showed that Δ CT-PxxP could be precipitated with the same efficiency as the wild-type bestrophin-1 (Figure S3A). These precipitates were further analyzed for the presence of either β 3-subunits or β 4-subunits showing co-precipitation. The Δ CT-PxxP bestrophin-1 also showed co-precipitation with β 3-subunits or β 4-subunits. Based on the summarized amount of protein in the lysate, precipitation fraction and non-bound fraction, we calculated the relative co-precipitation efficiency of the Δ CT-PxxP mutant and β 3-subunits (Figures 3D and 3E). β 3-subunit showed a significant decrease in co-precipitation efficiency from 12 \pm 3% with wild-type bestrophin-1 to 4 \pm 1% (n = 5; p = 0.035 unpaired t-test) with the Δ CT-PxxP mutant of bestrophin-1. The β 4-subunits also showed a significant decrease in co-precipitation efficiency from 26.6 \pm 6% with wild-type bestrophin-1 to 4 \pm 0.1% with Δ CTPxxP bestrophin-1 (n = 3; p = 0.02 unpaired t-test, Figure S3B).

As shown by immunohistochemistry, $\text{Ca}_v1.3$, β -subunit and bestrophin-1 possibly form complexes. Thus, we analyzed this further by immunoprecipitation. HEK cells were double transfected by $\text{Ca}_v1.3$ together with bestrophin-1 or the Δ CTPxxP mutant form. $\text{Ca}_v1.3$ subunits were precipitated (Figure 4A) and analyzed by Western blot for the presence of either bestrophin-1 or Δ CTPxxP bestrophin-1 (Figure 4B/C). The Western blots revealed no co-precipitation with $\text{Ca}_v1.3$ subunits. In contrast, indirect co-precipitation of either bestrophin-1 or Δ CTPxxP bestrophin-1 with $\text{Ca}_v1.3$ subunits was observed in the presence of β 4-subunits. HEK cells were triple transfected with $\text{Ca}_v1.3$, β 4-subunits and with either bestrophin-1 or Δ CTPxxP bestrophin-1. $\text{Ca}_v1.3$ subunits were precipitated and analyzed by Western blot. In this case, Western blot analysis revealed co-precipitation of $\text{Ca}_v1.3$ subunits with β 4-subunits and bestrophin-1 (Figure 4 D/E). In addition, also co-precipitation of $\text{Ca}_v1.3$ subunits with β 4-subunits and Δ CTPxxP bestrophin-1 was observed (Figure 4 F/G).

To study the functional implications of the β -subunit and bestrophin-1 interaction, patch-clamp analysis of Ca^{2+} channel currents of heterologously expressed $\text{Ca}_v1.3/\beta$ 4 channels was performed (Figure 5). We chose β 4-subunits because they are known to be expressed in the RPE. To obtain stable membrane localization and reliable membrane current measurements, α 2 δ 1-subunits were additionally expressed. CHO cells were microinjected with all required plasmids. Cells which expressed $\text{Ca}_v1.3$, β 4-subunit and α 2 δ 1 subunits showed Ba^{2+} currents associated with L-type channels as previously reported (Figure 5A; see Table 2) [5,28,29,30]. To analyze whether the change in Ba^{2+} current density is due to modulation of the $\text{Ca}_v1.3$ pore or due to less $\text{Ca}_v1.3$ protein in the cell membrane, gating currents of

$\text{Ca}_v1.3$ channels were measured. When ionic currents were blocked after removal of Ba^{2+} and addition of Co^{2+} , depolarization led to voltage dependent outward currents which activated at membrane potentials more positive than -32.45 ± 2.0 mV (n = 5; Figure 5B/C). These currents represent the gating currents of the $\text{Ca}_v1.3$ subunit [27]. The maximal ionic Ba^{2+} current density was reduced from 15.63 ± 2.19 pApF $^{-1}$ (n = 10) to 8.95 ± 1.40 pApF $^{-1}$ (n = 11; p = 0.0169 unpaired t-test) by the additional presence of wild-type bestrophin-1 (Figure 5D). Without bestrophin-1 the gating current density of 1.33 ± 0.122 pApF $^{-1}$ (n = 5; Figure 5E) was not significantly different compared to the gating current density in the presence of bestrophin-1 (1.24 ± 0.26 pApF $^{-1}$; n = 4; p = 0.75 unpaired t-test). However, in the presence of the Δ CTPxxP bestrophin-1 mutant the current density was with values of 5.03 ± 0.44 pApF $^{-1}$ (n = 8) further decreased compared to that in the presence wild-type bestrophin-1 (Figure 5D; p = 0.034 unpaired t-test). In the presence of Δ CT-PxxP, the gating currents were reduced to a density of 0.13 ± 0.033 pApF $^{-1}$ (n = 4; p = 0.0001 unpaired t-test; Figure 5E) indicating less $\text{Ca}_v1.3$ protein in the cell membrane. The voltage-dependent activation of the currents was analyzed by fitting the normalized current/voltage relation by the Boltzmann function. Neither the voltage of half maximal activation nor the slope is significantly changed in the presence of bestrophin-1 (Figure 5F/G). In the presence of wild-type bestrophin-1, we found an acceleration of the time-dependent activation (Figure 5H) with an activation time constant at +20 mV of 1.26 ± 0.15 ms (n = 11) versus 2.30 ± 0.19 ms (n = 10; p = 0.0005 unpaired t-test) under control conditions without bestrophin-1 (Figure 5I). Using the Δ CT-PXXP form of the bestrophin-1 the $\text{Ca}_v1.3/\beta$ 4 currents showed acceleration of time-dependent activation (activation time constant of 1.18 ± 0.18 ms; n = 8) comparable to that in the presence of wild-type bestrophin-1 (Figure 5H/I). No differences of voltage-dependence of currents in the presence of the Δ CT-PxxP mutant compared to that in the presence of wild-type bestrophin-1 were observed (Figure 5F/G). CHO cells were analyzed by confocal microscopy after patch-clamp analysis (Figure 6). $\text{Ca}_v1.3$ and β 4-subunits were localized in the cell membrane which was not changed by the presence of wild-type bestrophin-1. Under these conditions all three proteins were found in the cell membrane (Figure 6A, Table 1) with relative surface expression values of 3.19 ± 0.13 for bestrophin-1, 3.02 ± 0.07 for β 4-subunits and 3.67 ± 0.122 for $\text{Ca}_v1.3$ (all n = 3; Figure 6D). However, in the presence of Δ CT-PxxP mutant, a larger proportion of bestrophin-1, $\text{Ca}_v1.3$ and β 4-subunit were found in the cytosol (Figure 6B) indicated by relative surface expression values of 1.2 ± 0.085 for Δ CTPxxP bestrophin-1, 2.1 ± 0.266 for β 4-subunits and

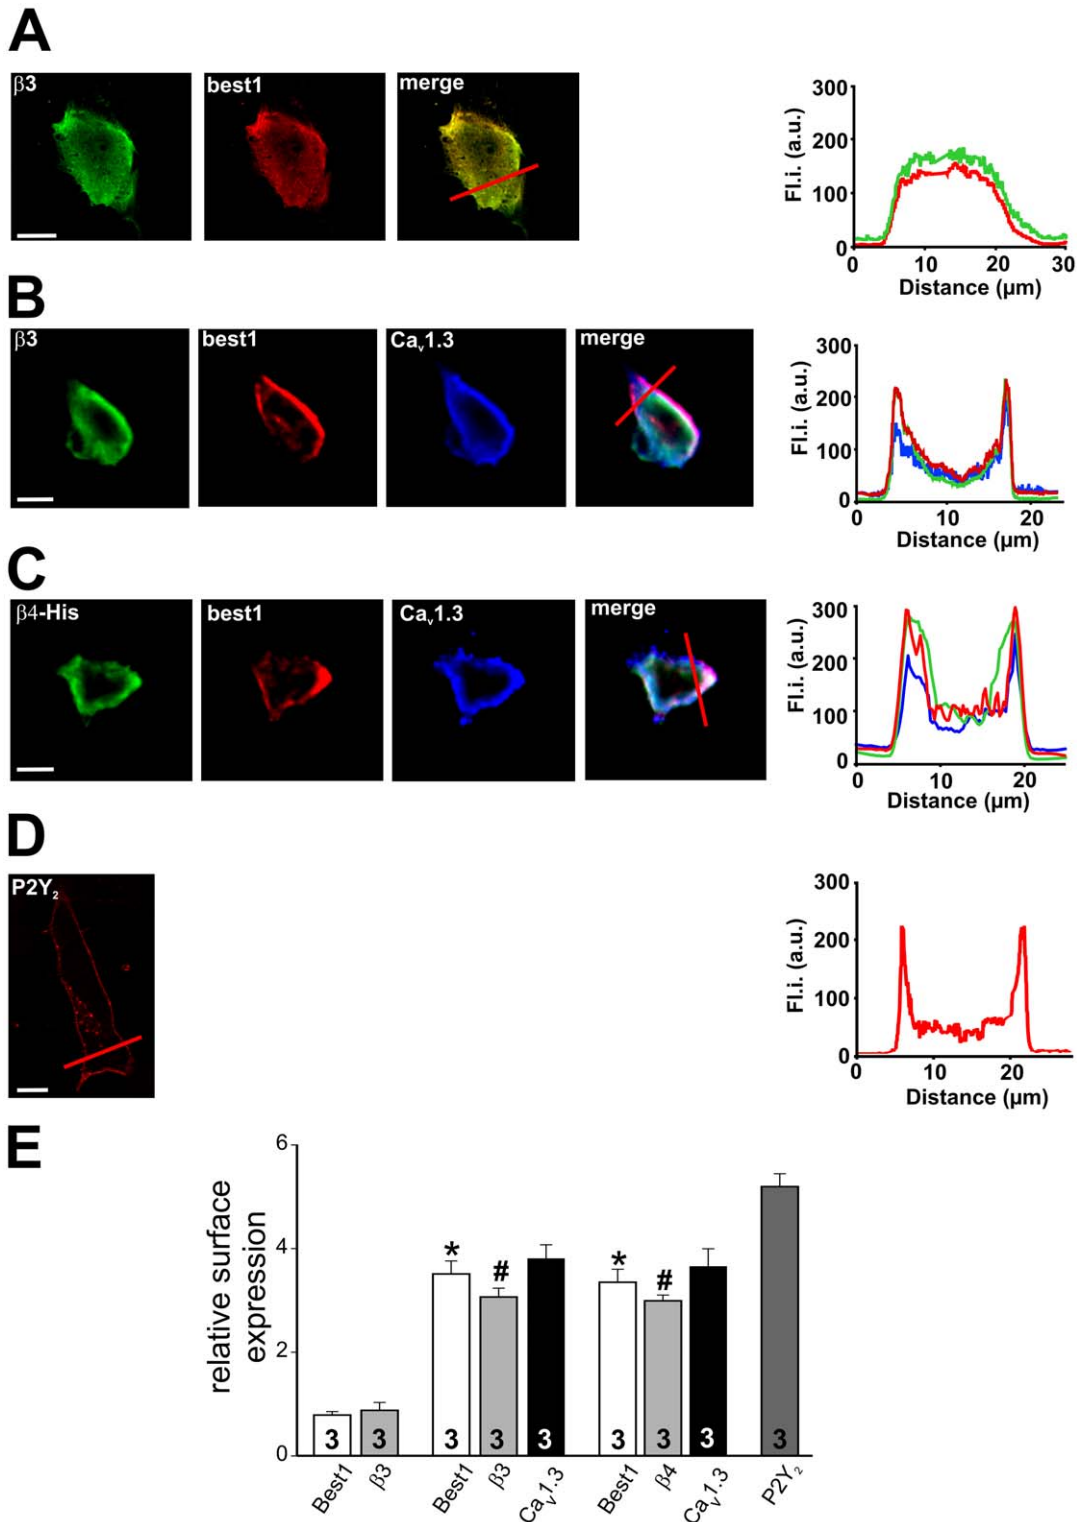

Figure 2. Subcellular localization of heterologously expressed $\text{Ca}_v1.3$, β -subunits of voltage-dependent Ca^{2+} channels and bestrophin-1: ARPE-19 cells were transfected with: β_3 -subunits and bestrophin-1, $\text{Ca}_v1.3$, β_3 or β_4 -subunits and bestrophin-1, and human P2Y_2 -His₆ receptor. **2A:** Cells transfected with β_3 -subunit (green) and bestrophin-1 (red). Yellow colour in the merged picture indicates interaction of both proteins. On the right: fluorescence profiles showing subcellular protein distribution. **2B:** Cells transfected with β_3 -subunit (green), bestrophin-1 (red), and $\text{Ca}_v1.3$ subunit (blue). White colour in the merged picture suggests co-localization of all three proteins. On the right: fluorescence profiles showing subcellular protein distribution. **2C:** Cells transfected with β_4 -subunit (green), bestrophin-1 (red), and $\text{Ca}_v1.3$ subunit (blue). White colour in the merged picture suggests co-localization of all three proteins. On the right: fluorescence profiles showing subcellular protein distribution. **2D:** Human P2Y_2 -His₆ receptor which shows plasma membrane localization as a control. Note: cells which express $\text{Ca}_v1.3$ and β -subunits always appear in a more spherical shape and do not remain flat due to the expression of the large L-type channel subunits. The smaller P2Y_2 -receptor did not change

the cell shape. **2E:** Relative surface expression quantified by edge detection analysis (data are mean \pm SEM; $n = 3$). (* = $p < 0.05$ for bestrophin-1; # = $p < 0.05$ for $\beta 3$ -subunits, unpaired t-test) Scale bar represents 10 μm . doi:10.1371/journal.pone.0019364.g002

2.8 ± 0.057 for $\text{Ca}_V1.3$ subunits (all $n = 3$; Figure 6D). The surface expression values measured in the presence of wild-type bestrophin-1 were significantly different to those measured in the presence of ΔCTPxxP bestrophin-1 ($p = 0.02\text{--}0.002$). As a control comparison, the effect of ΔCTPxxP mutant on non-interacting protein P2Y_2 receptor [31] was investigated by the same means (Figure 6C). Here the P2Y_2 receptor was found in the cell membrane (surface expression value 5.17 ± 0.42 ; $n = 3$) whereas the ΔCTPxxP bestrophin-1 was found in the cytoplasm (surface expression value 1.29 ± 0.03 ; $n = 3$) indicating an independent trafficking of the two proteins ($p = 0.0008$).

Discussion

In four independent studies bestrophin-1 appears to function as a regulator of voltage-dependent L-type Ca^{2+} channels [2,3,4,5]. We have newly discovered an additional cluster of highly conserved proline-rich motifs on the C-terminus of bestrophin-1 and show that this cluster is required for bestrophin-1 -dependent modulation of β -subunit function.

In order to study direct interaction of bestrophin-1 with Ca^{2+} channel subunits, co-immunoprecipitation and co-localization experiments of heterologously expressed bestrophin-1 and different Ca^{2+} channel subunits were performed. In our system, co-precipitation of $\text{Ca}_V1.3$ subunits with its physiological interaction partner $\beta 3$ -subunits could be observed [6,7]. Co-precipitation was independent of the expression system. Co-localization detection and co-precipitation were dependent on certain amino acid motifs on the C-terminus of bestrophin-1. Thus our experimental system allowed detecting physiological interaction between Ca^{2+} channel subunits and regulatory proteins.

Heterologously expressed bestrophin-1 showed co-precipitation with $\beta 3$ - or $\beta 4$ -subunits but not with $\text{Ca}_V1.3$ subunits. In the presence of β -subunits precipitation of $\text{Ca}_V1.3$ subunits resulted in indirect co-precipitation of bestrophin-1. Thus $\text{Ca}_V1.3/\beta$ -subunits can form complexes with bestrophin-1 via binding of bestrophin-1 with β -subunits. Confocal microscopy of cells transfected with bestrophin-1 and $\beta 3$ -subunits showed a co-localization of the two proteins which was however more uniformly distributed in the cytoplasm. When the cells were transfected with $\text{Ca}_V1.3$, $\beta 3$ -subunit and bestrophin-1 or $\text{Ca}_V1.3$, $\beta 4$ -subunit and bestrophin-1, all three proteins were found to be localized in the cell membrane. This indicates close and direct interaction of bestrophin-1 with Ca^{2+} channel β -subunits. However, the methods used here could only indicate direct interaction. A stronger proof of this interaction would require experiments showing detection of FRET (fluorescence resonance energy transfer) which is beyond the scope of this study. The presence of wild-type bestrophin-1 had two effects on the $\text{Ca}_V1.3/\beta 4$ currents: an acceleration of the time-dependent activation and a reduction of ionic current density. The acceleration of the time-dependent activation has also been previously reported for $\beta 2$ -subunit modulation of $\text{Ca}_V1.2$ currents in heterologous expression and endogenously expressed L-type channels in a RPE cell line [2,3]. The reduction in the maximal activity was reported for $\beta 1$ -, $\beta 2$ - and $\beta 4$ -subunit/bestrophin-1 interaction in the modulation of rat $\text{Ca}_V1.3$ currents [4] and for human $\text{Ca}_V1.3/\beta 4$ -subunit currents [5]. Since the gating currents were not different in the absence or presence of bestrophin-1, the reduction of the ionic current density was most likely not due to a

reduced number of $\text{Ca}_V1.3$ subunits in the cell membrane. Thus, wild-type bestrophin-1 influences the ability of β -subunits to modulate the pore-function of $\text{Ca}_V1.3$ subunits. This differs from observations made by Yu et al. [4] who used only the C-terminus of bestrophin-1 and not full length bestrophin-1 for gating current analysis.

The binding of β -subunits and bestrophin-1 could depend on the interaction between SH3 domains of β -subunits [6,7,32] with proline-rich motifs, PxxP, present on the C-terminus of bestrophin-1. One cluster with two PxxP motifs is between the amino acid positions 330 and 346 and has been reported to be responsible for bestrophin-1/ β -subunit interaction [4]. We found another cluster located between the amino acid positions 468–486 containing four PxxP motifs. To study its functional role, we made a deletion mutant lacking the PxxP motifs between amino acid positions 468–486 (named ΔCTPxxP). This mutant showed a reduced efficiency to co-precipitate with β -subunits by 70–80% depending on the isoform of β -subunit. However, the weak co-precipitation of ΔCTPxxP bestrophin-1 with β -subunits might result from the PxxP motifs between amino acid positions 330–346 which are still present. Furthermore, when studying indirect co-precipitation of $\text{Ca}_V1.3/\beta 4$ -subunit complex with bestrophin-1, we found no difference between wild-type bestrophin-1 and ΔCTPxxP mutant bestrophin-1. This can be explained by the occlusion of the SH3 domains in the free β -subunit crystal structure. [33,34,35]. It is hypothesized that the SH3 becomes accessible when the β -subunits bind to the Ca_V -subunits [36]. Thus, bestrophin-1 can probably bind to β -subunits with higher efficiency when β -subunits are part of the $\text{Ca}_V1.3/\beta$ -subunit complex.

The functional effect of PxxP motifs deletion between the amino acid positions 468–486 was studied by patch-clamp analysis of currents through human $\text{Ca}_V1.3$ subunit/ $\beta 4$ -subunits expressed together with ΔCTPxxP -bestrophin-1. The presence of the ΔCTPxxP mutant only further decreased the ionic current density. Analysis of the subcellular localization revealed that these cells have a larger proportion of ΔCTPxxP bestrophin-1 and $\text{Ca}_V1.3$ subunits in the cytoplasm. Furthermore, in the presence of ΔCTPxxP bestrophin-1, the gating current density was strongly reduced compared to that of wild-type bestrophin-1. Both observations indicate a reduced number of pore-forming $\text{Ca}_V1.3$ subunits in the cell membrane in the presence of ΔCTPxxP bestrophin-1. Since the ΔCTPxxP mutant bestrophin-1 still binds to the $\text{Ca}_V1.3/\beta 4$ -subunit complex, the reduced number of $\text{Ca}_V1.3$ subunits is due to an influence of the ΔCTPxxP bestrophin-1 on the ability of β -subunits to regulate Ca_V -subunit surface expression. Thus, when the PxxP motifs between amino acid positions 468–486 on the bestrophin-1 C-terminus are lacking β -subunits show reduced ability to enhance surface expression of $\text{Ca}_V1.3$ subunits. To show that the effect of the ΔCTPxxP bestrophin-1 specifically influences trafficking Ca^{2+} channel proteins, we expressed the ΔCTPxxP bestrophin-1 together with the P2Y_2 receptor which is known not to interact with bestrophin-1 [31]. Here, the P2Y receptor trafficked into the cell membrane whereas ΔCTPxxP bestrophin-1 stayed in the cytoplasm. Thus, the reduced amount of Ca^{2+} channel protein in the cell membrane by the presence by ΔCTPxxP bestrophin-1 is not due to unspecific protein aggregation in the cytosol. In addition, it should be noted that the ionic current density was reduced by 40% but the gating current density was reduced

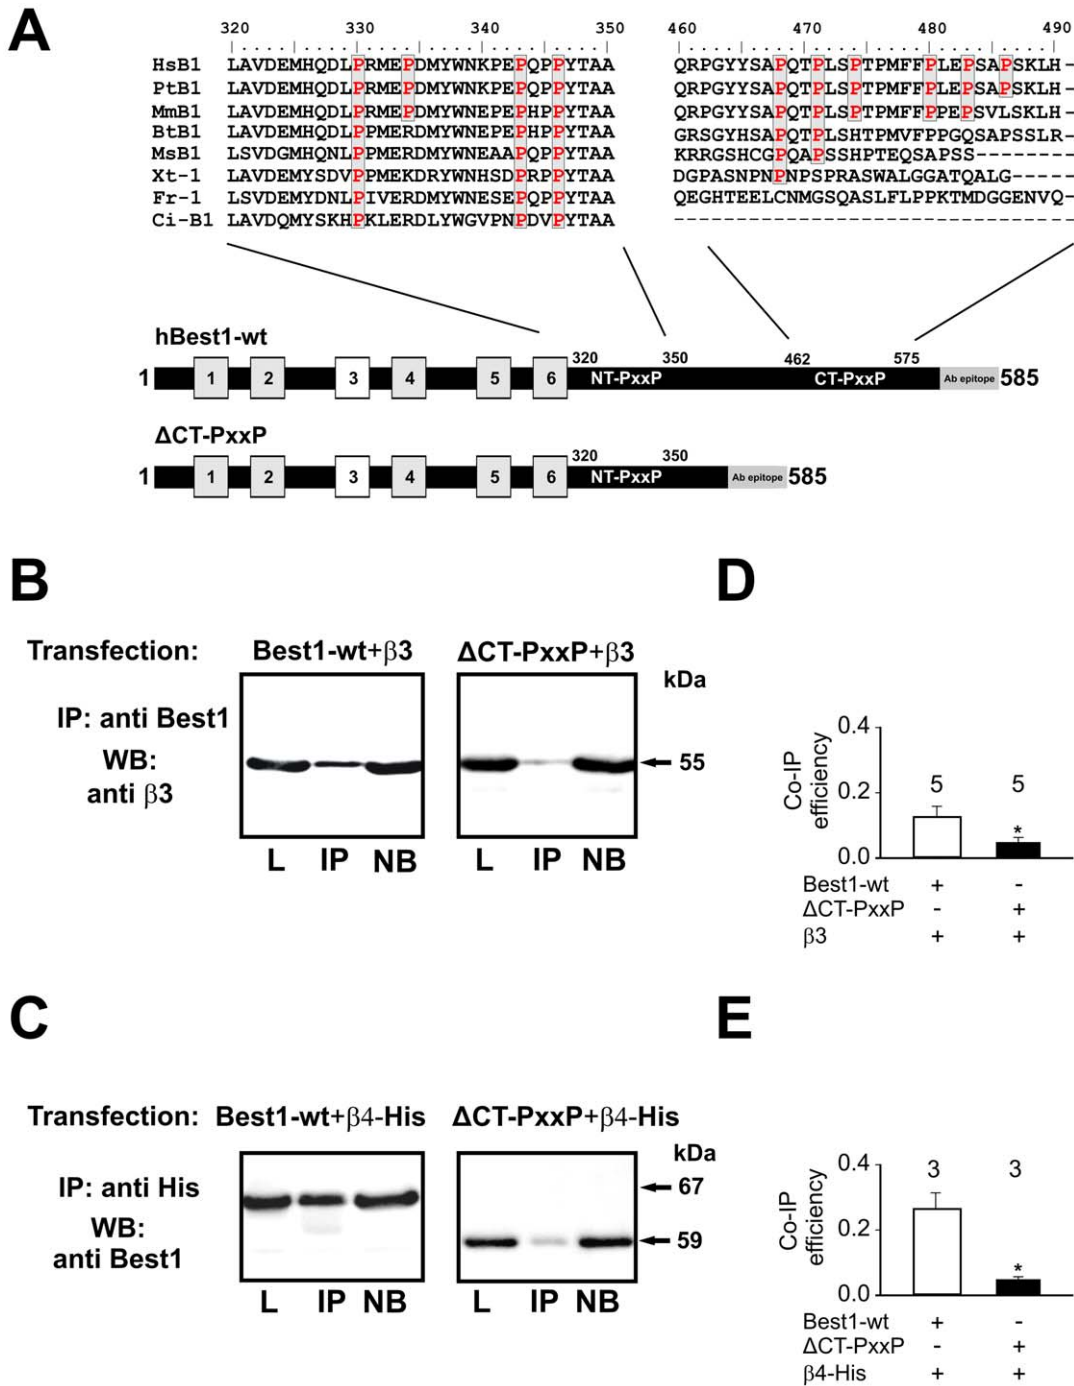

Figure 3. Detection of interaction sites between β -subunits and bestrophin-1. **3A:** Bestrophin-1 construct used in this study and alignment of amino acid sequences of the C-terminus of the bestrophin-1 from different species (Boxes: transmembrane domains). Two among vertebrate species highly conserved clusters of proline-rich motifs (PxxP) could be detected. In the Δ CTPxxP mutant form, PxxP motifs between amino acid 468 to 486 were removed with unchanged recognition sites for the anti bestrophin-1 antibody. **3B:** HEK-293 cells were transfected with β 3-subunits together with bestrophin-1 or Δ CTPxxP constructs. Proteins were precipitated using anti-bestrophin-1 antibody and blots were visualized for anti- β 3-subunit to show co-immunoprecipitation. **3C:** HEK-293 cells were transfected with His-tagged β 4-subunits together with bestrophin-1 wild type or Δ CTPxxP constructs. Proteins were precipitated using anti-His antibody and the blots were visualized with anti-bestrophin-1 antibody to show co-immunoprecipitation. **3D:** Relative co-immunoprecipitation of β 3-subunits with either wild-type or Δ CTPxxP bestrophin-1: efficiency was measured by densitometry (n=5). **3E:** Relative co-immunoprecipitation of β 4-subunits with either wild-type or Δ CTPxxP bestrophin-1: efficiency was measured by densitometry (n=3). (L = lysate; IP = immunoprecipitation; NB = not bound). The following species abbreviations were used: Hs, Homo sapiens, Mm, Macaca mulatta, Bt, Bos taurus, Ms, Mus musculus, Xt, Xenopus tropicalis, Fr, Fugu rubripes, and Ci, Ciona intestinalis. doi:10.1371/journal.pone.0019364.g003

Figure 4. Complex formation of Ca_v1.3, β 4-subunits and bestrophin-1. HEK cells were transfected with Ca_v1.3, His-tagged β 4-subunits, bestrophin-1 or Δ CTPxxP bestrophin-1. Immunoprecipitation was performed using anti-Ca_v1.3 antibodies, precipitates were analyzed by Western blot. **4A:** Transfection: Ca_v1.3 and bestrophin-1. Blot staining with anti-Ca_v1.3 antibody to show efficient precipitation of Ca_v1.3 subunits. **4B:** Transfection: Ca_v1.3 and bestrophin-1. Blot staining with anti-bestrophin-1 antibody showing no co-precipitation of Ca_v1.3 subunits with bestrophin-1. **4C:** Transfection: Ca_v1.3 and Δ CTPxxP bestrophin-1. Blot staining with anti-bestrophin-1 antibody showing no co-precipitation of Ca_v1.3 subunits with Δ CTPxxP bestrophin-1. **4D:** Transfection: Ca_v1.3, His-tagged β 4-subunits and bestrophin-1. Blot staining with anti-His antibody showing co-precipitation of Ca_v1.3 subunits with β 4-subunits. **4E:** Transfection: Ca_v1.3, His-tagged β 4-subunits and bestrophin-1. Blot staining with anti-bestrophin-1 antibody showing indirect co-precipitation of Ca_v1.3 subunits with bestrophin-1. **4F:** Transfection: Ca_v1.3, His-tagged β 4-subunits and Δ CTPxxP bestrophin-1. Blot staining with anti-His antibody showing co-precipitation of Ca_v1.3 subunits with β 4-subunits. **4G:** Transfection: Ca_v1.3, His-tagged β 4-subunits and Δ CTPxxP bestrophin-1. Blot staining with anti-bestrophin-1 showing indirect co-precipitation of Ca_v1.3 subunits with Δ CTPxxP bestrophin-1. (L = lysate; IP = immunoprecipitation; NB = not bound) doi:10.1371/journal.pone.0019364.g004

tenfold. Thus, the Δ CTPxxP mutant lost its ability to decrease the single channel conductance compared to wild-type bestrophin-1. In summary, the loss of the PxxP cluster between the amino acid positions 468–486 did not alter the binding of bestrophin-1 to the Ca_v1.3/ β -subunit complex but reduced the ability of β -subunits to guide pore-forming Ca_v-subunits to the cell membrane and possibly influences the gating behavior of the Ca_v1.3 subunit.

β -subunits modulate electrophysiological properties of the pore-forming Ca_v-subunits, help to transport Ca_v-subunits into the cell membrane and interact with protein kinases for further modulation of Ca²⁺ channel activity [8,9]. The absence of the PxxP motifs between amino acid positions 468–486 of bestrophin-1 impaired the ability of β -subunits to regulate the surface expression of pore-forming Ca_v-subunits and possibly modulate single channel properties of the Ca_v1.3 channel. The absence of the PxxP motifs between the amino acid positions 330–346 reduced binding to β -subunits but did not affect the trafficking of Ca_v1.3 subunits to the cell membrane [5]. Thus, the PxxP motifs

between amino acid positions 330–346 are more responsible for the binding of β -subunits and bestrophin-1 and the PxxP motifs between amino acid positions 468–486 help maintain the β -subunit regulatory properties over the surface expression of Ca_v-subunits.

We demonstrated that bestrophin-1 modulates human Ca_v1.3/ β 4-subunits which are expressed in the RPE. Morbus Best patients show reduced light-peak in the electro-oculogram [13,37,38]. Mouse models which show the same phenotype as Best patients are the Ca_v1.3 knock-out mouse [17] and the lethargic mice which are a natural knock-out of the β 4-subunit [16]. Thus Ca_v1.3/ β 4-subunits are of importance in the generation of the light-peak. The decreased light-peak in Best patients would probably result from altered modulation of L-type channels composed of Ca_v1.3/ β 4 subunits. Since L-type channels of the RPE regulate cell functions such as secretion or phagocytosis, the understanding of bestrophin-1 and Ca²⁺ channel interaction would then help to understand mechanisms of retinal degeneration [39,40].

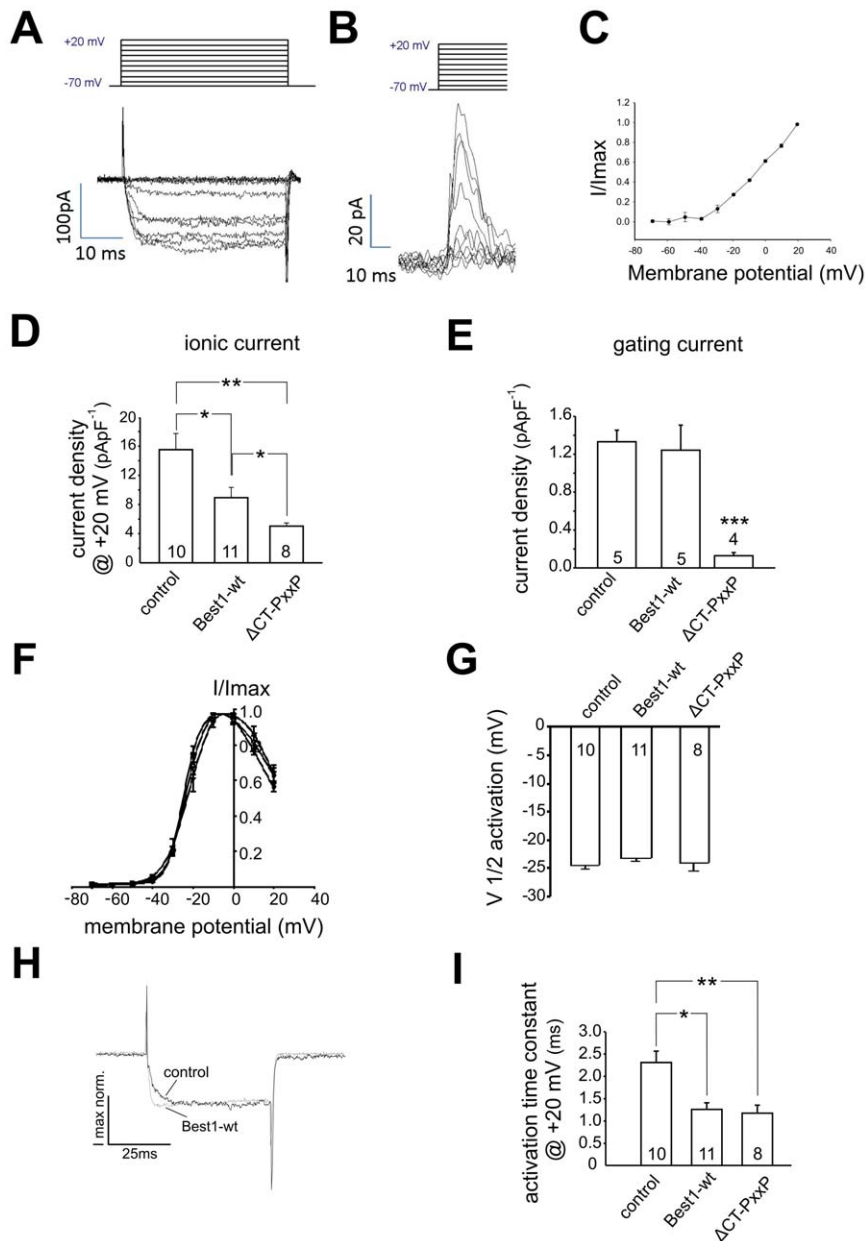

Figure 5. Patch-Clamp analysis of $\text{Ca}_v1.3/\beta_4$ currents under influence of bestrophin-1. **5A:** Whole cell Ba^{2+} -currents (lower panel) measured from CHO cells expressing $\text{Ca}_v1.3$, β_4 , $\alpha_2\delta_1$ -subunits. Currents were elicited by a series of 9 voltage-steps of 10 mV increasing amplitude and 50 ms duration from a holding potential of -70 mV (upper panel). **5B:** Gating currents: Currents elicited by the electrical stimulation as shown in 5A in the same cell after switching to Co^{2+} containing bath solution. **5C:** Plot of normalized gating currents to the membrane voltages of the electrical stimulation (mean \pm SEM, $n=3$). **5D:** Comparison of the ionic current density of L-type currents from heterologously expressed Ca^{2+} channel proteins and different bestrophins measured at +20 mV (note: the values are close to those we have published [5] but represent a different set of data). **5E:** Comparison of the gating current density in the presence of 10 mM Co^{2+} from heterologously expressed Ca^{2+} channel proteins and different bestrophins measured at +20 mV. **5F:** Normalized current/voltage plots of L-Type currents either in the absence, presence of bestrophin-1 or the $\Delta\text{CT-PxxP}$ mutant bestrophin-1, fit by Boltzmann equation. **5G:** Comparison of the voltages of half maximal activation obtained from Boltzmann fits of the curves in Fig. 5F. **5H:** Whole cell Ba^{2+} -currents measured from CHO cells expressing either $\text{Ca}_v1.3$, β_4 , $\alpha_2\delta_1$ subunits or $\text{Ca}_v1.3$, β_4 , $\alpha_2\delta_1$ subunits plus wt-bestrophin-1. Currents were elicited by a voltage-jump from -70 mV to +20 mV. The recording shows the currents normalized to their maximal amplitude for comparison. **5I:** Comparison of the time-dependent activation of L-type currents from different heterologously expressed Ca^{2+} channel proteins and bestrophins measured as time constant from single-exponential fit of the currents (note: the values are close to those we have published in [5] but represent a different set of data). (* = $p < 0.05$; ** = $p < 0.01$, unpaired t-test; n depicts the number of experiments)

doi:10.1371/journal.pone.0019364.g005

In summary, we were able to demonstrate the physical binding of full length bestrophin-1 with β_3 - and β_4 -subunits of Ca^{2+} channels. Additionally, we identified a new cluster of PxxP motifs

on the C-terminus of bestrophin-1 which is needed for the interaction of bestrophin-1 with Ca^{2+} channel β -subunits and probably other SH3 domain carrying proteins.

Figure 6. Subcellular localization of Ca^{2+} channel subunits and bestrophin-1 in cells used for patch-clamp analysis. **6A:** Confocal pictures of CHO cells expressing wt-bestrophin-1, $\beta 4$ -subunit, $\alpha 2\delta 1$ -subunit and $\text{Cav}1.3$. The merged picture and the fluorescence profiles measured along the red line (right panel) indicate the presence of $\beta 4$ -subunit, $\text{Cav}1.3$ and wt-bestrophin-1 in the cell membrane. **6B:** Confocal pictures of CHO cells expressing ΔCTPxxP bestrophin-1, $\beta 4$ -subunit, $\alpha 2\delta 1$ -subunit and $\text{Cav}1.3$. The merged picture and the fluorescence profiles measured along the red line (right panel) indicate the presence of $\beta 4$ -subunit, $\text{Cav}1.3$ and ΔCTPxxP bestrophin-1 in the cell plasma. **6C:** Confocal pictures of CHO cells expressing ΔCTPxxP bestrophin-1 and P2Y_2 receptor. The merged picture and the fluorescence profiles measured along the red line (right panel) indicate the presence of ΔCTPxxP bestrophin-1 in the cell plasma whereas the P2Y_2 receptor appears in the cell membrane. **6D:** Relative surface expression quantified by edge detection analysis (data are mean \pm SEM; $n=3$). Supporting Information

Figure S1 S1A: Control experiments: Proteins detected in transfected CHO cells are products of the plasmids used for transfection. Western blot of proteins isolated from CHO cells either transfected or not transfected by the corresponding plasmid. Only when the cells were transfected by plasmids carrying bestrophin-1, β 3-subunit, bestrophin-1-GFP or $\text{Ca}_v1.3$ subunits the Western blots revealed the presence of the corresponding proteins (bestrophin-1; 68kDa, β 3 subunit; 55kDa, bestrophin-1-GFP; 100kDa, and $\text{Cav}1.3$ subunit; 240 kDa). Anti β -actin antibody was used as a loading control. **S1B:** Physical interaction between bestrophin-1 and auxiliary β 3-subunits of voltage-dependent Ca^{2+} channels was independent from the cell line which was used as transfection system: CHO, COS-7, and HEK-293 cells were co-transfected with bestrophin-1-GFP and β 3-subunits, and β 3-subunits and GFP. Precipitates were obtained using anti GFP antibodies, and Western blots were stained using anti- β 3 and anti-GFP antibodies. β 3-subunits were detected only when cells were transfected with bestrophin-1-GFP fusion construct and β 3-subunits but not when cells were transfected with β 3-subunits and GFP vector. (TIF)
