**Objective:** To compare the analgesic efficacy and safety of acupuncture and lornoxicam in acute renal colic (ARC).

**Design, Setting, Participant:** A randomized, double-blind, parallel-controlled, single-centered trial was conducted at Susong County People's Hospital from October 2019 to November 2020. Eighty-four patients with ARC were randomly divided into lornoxicam group (Group L) and acupuncture group (Group A). Group A was treated with acupuncture at Sanyinjiao (SP6), Yinlingquan (SP9) and normal saline, and Group L was treated with sham acupuncture at SP6, SP9 and lornoxicam.

**Main Outcome Measures:** Visual analogue scale (VAS) scores and adverse reactions such as nausea and dizziness were recorded within 5, 10, 15, 20 and 40 minutes after treatment. The main outcome of this study was the short-term effective (STE) rate, the secondary outcome was the onset time, and the safety index was incidence of adverse reactions.

**Results:** A total of 80 patients completed this study, including 41 patients (21 males and 20 females) in Group L and 39 patients (21 males and 18 females) in Group A. Group A exhibited lower scores versus group L after treatment ( $P < 0.05$ ). The overall STE of group L was 61.00% (25/41), significantly lower than group A [84.62% (33/39)] ( $P < 0.001$ ). There was no difference in the incidence of adverse reactions between group A [2.6% (1/39)] and group L [7.3% (3/41)] ( $P = 0.616$ ). The ordered logistic regression analysis showed patients receiving acupuncture therapy are more likely to be cured [OR = 2.887, 95% CI: (1.190, 7.000),  $P = 0.019$ ].

**Conclusion:** Acupuncture at SP6, SP9 and intramuscular injection of lornoxicam can effectively and safely relieve ARC, but the former has faster and better analgesic effect. Moreover, the incidence of adverse reactions was similar between the two treatments. This acupuncture therapy is recommended as a complementary therapy for ARC.

**Keywords:** acupuncture, lornoxicam, renal colic, analgesia

## Introduction

The worldwide incidence of kidney stones is 114 to 720 per 100,000, with a prevalence of 1.7% to 14.8%, and this prevalence is increasing year by year.<sup>1</sup> The ongoing challenge of growing members of kidney stone disease (KSD) has been proven to link to global warming, with a major component, rising temperature, contributing to a 24–84% increase in stone presentation as well as an increase of 1.6 to 2.2 million urolithiasis cases over a lifetime in the United States by 2050.<sup>2</sup> KSD results in huge medical bills—for example, a total cost of £190–324 million in an acute or surgical treatment caused by upper tract stones in the UK, equivalent to the cost of prostate and

bladder cancer combined in 2018.<sup>3</sup> Acute renal colic (ARC) is a common complication of renal-ureteral calculi,<sup>4</sup> causing 7–9% of all emergency department visits, excluding trauma patients.<sup>5</sup> Pain relief is the primary goal with non-steroidal anti-inflammatory drugs (NSAIDs) recommended as first-line treatment for patients with an acute stone episode.<sup>4</sup> Beyond that, adverse events of NSAIDs such as nausea, vomiting, and even allergic reactions, kidney failure, or gastrointestinal bleeding may offset the benefit—an utmost concern raised by health-care officials.<sup>6</sup> In addition, opioids, alpha blockers, spasmolytic drugs, and surgery are also recommended to treat ARC,<sup>4,7</sup> but opioids drugs may have some adverse reactions and abuse problems,<sup>6,8,9</sup> and surgery is very expensive.<sup>10</sup>

Previous studies have ascertained that acupuncture is effective in chronic pain relief, superior to placebos,<sup>11,12</sup> with improved patient satisfaction, lower costs, and fewer adverse reactions.<sup>13</sup> However, insufficient evidence from sparse data of acupuncture's effect on ARC lead to a growing demand for relevant RCTs. Therefore, we conducted a rigorous RCT that compared the efficacy and safety of acupuncture versus lornoxicam, an NSAID with analgesic property, in ARC.<sup>14,15</sup>

## Materials and Methods

### Trails Design

A randomized, double-blind, parallel-controlled, single-centered trial was designed and conducted to assess the efficacy and safety of acupuncture versus lornoxicam in ARC treatment. Patients diagnosed as ARC at our hospital from October 2019 to November 2020 were recruited. The study protocol was consistent with the Declaration of Helsinki and has been approved by the Ethics Committee of Susong County People's Hospital (Ethics Number: 2019-001A) and registered at Chinese Clinical Trial Registry (<http://www.chictr.org.cn>), the registration ID is ChiCTR1900026517. We have the patient's written consent that any information should be kept as anonymous as possible.

### Drugs and Acupuncture Needle Involved in the Trail

1. Lornoxicam for injection, drug specifications: 8mg/ampoule, Yangtze River Pharmaceutical Group Co., LTD. National Medicine Permission Number (NMPN): H20080329; 2. 0.9% Normal saline for injection, drug specification: 100mL/bottle, CR Double-Crane Pharmaceutical

Co., LTD. National Medicine Permission Number (NMPN): H61020015; 3. Aseptic acupuncture needle, specification 0.16mm\*100mm, Taixing Tianhe Medical Instrument Co., LTD. Producing Certificate of Jiangsu Province Food & Drug Administration: No. 2013-0073.

## Participants

### Inclusion Criteria

Patients were included in our study if they (i) were male or female of ureteral calculi confirmed by ultrasonography, KUB (kidney-ureter-bladder), or CT (computed tomography), (ii) aged 18 to 75 years, (iii) had no prior or ongoing history of analgesics use before the visit, (iv) had a visual analog scale (VAS) score of  $\geq 3$  at baseline; (v) wounds, ulcers, varicose veins, and other factors affecting the efficacy evaluation were undetectable at the acupoints. Patients signed the informed consent form before entering the study.

### Exclusion Criteria

Patients were excluded if they fulfilled the following criteria: (i) ureteral stricture or deformity; (ii) renal colic caused by a steinstrasse after extracorporeal shock wave lithotripsy; (iii) unstable vital signs, for example, septic shock; (iv) unable to cooperate with treatment due to mental illness or cognitive impairment; (v) pregnant and menstruating women; (vi) allergic to NSAIDs; (vii) active gastrointestinal ulcer/bleeding; (viii) needle sickness, coagulation and fibrinolysis disorder, long-term anticoagulant, sedative, analgesic, or antidepressant therapy; (ix) other conditions unsuitable for an entry into the study, as defined by the researcher.

## Interventions

### Acupoint Selection and Operation Specification

The name and location of acupoints in this study were referenced to the Nomenclature and Location of Acupuncture Points described in the national GB/T12346-2006 acupoint standard. Acupuncture procedures were implemented per GB/T21709.20-2009 Standardized Manipulations of Acupuncture and Moxibustion - Part 20: Basic Techniques of Filiform Needle. Two acupoints, Sanyinjiao (three yin intersection, SP6) and Yinlingquan (yin mound spring, SP9) were selected for acute pain relief in patients with ARC. SP6 is located on the medial side of the lower leg, 3 cun (cun means "body cun" or "finger-breadth cun" or "proportional unit of body"). Patients put the index finger, middle finger, ring finger and little finger together, take the striation of the second knuckle of the

middle finger as the reference line, and the width of the four fingers as 3 cun.) superior to the prominence of the medial malleolus in a depression close to the medial crest of the tibia. SP9 is located on the medial side of the lower leg, at an angle formed by the medial condyle of the tibia and the posterior border of the tibia.

### Treatments

Participants in the control (lornoxycam group, group L) and the treatment groups (acupuncture group, group A) received lornoxycam (8 mg) and isovolume normal saline injections into the gluteus maximus, respectively. Acupoints were covered by self-adhesive skin electrodes after disinfection for blinding. The converted electrodes not only play a role in shielding, but also play a role in fixing acupuncture needles for sham acupuncture, which appears to be real acupuncture. For the patients in group A, needles were vertically inserted into bilateral SP6 and SP9 acupoints, up to 1 cun under the skin, and the acupuncturist manipulated the needles until patients had intensive deqi feeling (sour, numb, swelling up, or

painful). For group L, the acupuncturist only needed to touch skin with the tip of the needle to make patients feel acupuncture sensation without penetrating their skin (Figure 1). After 20 min of needle retention, a standard bandage was applied to each acupoint for all patients in both groups.

### Outcomes

The primary outcome of this trial included short-term outcomes (STE). The secondary outcomes were onset time and the frequency of adverse events.

### STE

The VAS scores were assessed at the outset of acupuncture therapy and 40 min after the treatment. Patients self-reported the pain intensity score on a 10-cm scale from 0 (painless) to 10 (unbearable pain). The pain relief rate (PRR) was calculated as follows:  $PRR = \left( \frac{VAS_{0min} - VAS_{40min}}{VAS_{0min}} \right) \times 100\%$ .

Based on PRR values, therapeutic efficacy was graded into four levels: grades A (cure), B (markedly effective), C (effective), and D (ineffective). Grade A (PRR = 100%)

**Figure 1** Schematic diagram of acupuncture and sham acupuncture. (A) sham acupuncture model; (B) conceptual diagram of acupuncture and sham acupuncture, 1: needle; 2: self-adhesive medical electrode; 3: skin; (C) Model case.

was defined as the complete disappearance of pain in the kidney or ureter after 40 min of acupuncture therapy. Grades B ( $75\% \leq \text{PRR} < 100\%$ ) referred to significant pain relief after the treatment. Grade C ( $50\% \leq \text{PRR} < 75\%$ ) was rated in a case of pain improvement following acupuncture treatment. Patients reporting a nonsignificant amelioration were classified into grade D ( $\text{PRR} < 50\%$ ). STE was evaluated by the ratio of patients with satisfactory results (grades A, B, and C) to the total participants.

### Onset Time

The time to onset was indirectly reflected by counting the number of patients with satisfactory results (grades A, B, or C) at 0–5, 6–10, 11–15, 16–20, 21–40 min intervals and the number of cases without efficacy response after more than 40 min of treatment.

### Safety Evaluation

All adverse reactions reported during the trial were recorded by a specially trained nurse. The safety of acupuncture was assessed by the frequency of adverse events.

### Sample Size

The response rate of lornoxicam for ARC was 75%,<sup>15</sup> and the response rate of acupuncture was estimated to be 90%. Our significance level was  $\alpha = 0.05$ , and the power of the trial was 0.1 ( $\beta$ ),  $\delta$  was defined as a difference in the response rate between groups A and L.

The sample size was calculated using the following formula:

$$N = \pi_0(1 - \pi_0) \left[ \frac{u_\alpha + \mu_\beta}{\delta} \right]^2$$

$\pi_0 = 75\%$ ,  $\pi_1 = 90\%$   $\delta = \pi_1 - \pi_0 = 0.15\%$ ,  $\mu_{0.1} = 1.282$ ,  $\mu_{0.05} = 1.645$ ,  $N = 71.3 \approx 72$

Concerning a drop-out rate of no more than 20%, only 84 patients (42 in each group) were ultimately included in our study.

### Randomization, Allocation Concealment and Blinding

All participants were stratified by sex and randomly assigned to either group by a blind, independent statistician. Random numbers were generated with RV.UNIFORM generator in SPSS 25.0 and mapped to pre-defined number ranges (1–42 for female patients and 43–84 for male patients). All random numbers were allocated to group A and L by using Visual Binning instruction

according to the number size, with 21 male and 21 female patients in each group. Then the statistician made a random number table with three lines. The first line is the sequence number of enrolled patients, the second line is the generated random number that corresponded to the sequence number, and the third line is the grouping identification, with “A” represents the acupuncture group and “L” represents the lornoxicam group. Then the statistician made enrollment cards with random numbers and treatment methods and sequentially concealed in opaque envelopes marked 1–84, to an out-patient physician for patient recruitment. Female or male patients who meet the inclusion criteria were randomly selected from envelopes numbered 1–42 or numbered 43–84, respectively. Eligible participants were asked to send their envelopes to the acupuncturist who determined the treatment based on the number in the envelope.

Patients were blinded to the treatment plan. The performing acupuncturist was neither blinded to the treatment nor allowed to participate in the follow-up and statistical analysis. The nurse who recorded VAS scores was also blinded to the treatment. Acupuncture procedures were manipulated by the same acupuncturist, followed by the assessment by an independent nurse to avoid bias.

### Statistical Methods

Continuous variables following normal distribution were expressed as mean  $\pm$  standard deviation (SD), while those with a non-normal distribution as median (IQR). Independent-sample *T*-test or Mann–Whitney *U*-test was employed to compare the differences between two groups, and the rank-sum test was used to compare data before and after the treatment in each group. Categorical variables were described as frequencies (or percentages), and differences between groups were analyzed using the chi-square test or Wilcoxon test. All data were processed using SPSS version 25.0 (SPSS Inc., Chicago, IL, USA).

### Results

Initially, 143 ARC patients were recruited in this study, and 59 were excluded according to the eligibility criteria, of whom 34 declined participation, 17 did not fulfill the inclusion criteria, and 8 had a history of analgesic use before the visit. There were 84 participants eligible for analysis. During the study, two females in group A and one in group L dropped out as they discontinued VAS assessments. Another female with an intense fear of

acupuncture manipulation was ruled out from group A. Finally, 39 patients (21 males and 18 females) in group A and 41 (21 males and 20 females) in group L were included (Figure 2).

## Comparison of Clinical Characteristics Between the Acupuncture versus Lornoxicam Groups

There were no statistically significant differences in gender, age, body temperature, pulse rate, systolic blood pressure (SBP), stone size and location, and the degree of hydronephrosis between groups A and L ( $P > 0.05$ ) (Table 1A). However, diastolic blood pressure (DBP) in group L was markedly higher than that in group A ( $P = 0.041$ ). This might be attributed to the limited statistical power caused by the small sample size, without impacts on final results.

Thirty-seven cases (46.25%) presented with calculi in the left ureter and 43 (53.75%) had right ureter stones. Cases of lower ureteric stones occupied 58.75% (47/80) of all participants, followed by the upper ureteric stone (23/80, 28.75%) and the middle ureteric stone (10/80,

12.50%). Despite five cases (6.25%) with no hydronephrosis, different degrees of hydronephrosis were detectable in most participants at admission. Among them, 85% (68/80) exhibited mild hydronephrosis, 8.75% (7/80) moderate hydronephrosis, and severe hydronephrosis was undetectable (Table 1B and C).

Details of underlying conditions of 9 cases (23.08%) in group A and 7 (17.07%) in group L incorporated hypertension, diabetes, coronary heart disease, and others. Ureteric and renal stones confirmed by either CT scan or ultrasonography were found in 16 patients (41.03%) in group A and 11 (26.83%) in group L. There were 3 patients combined with renal cysts and one with bladder stones in group L, 2 with renal cysts and 3 with teratoma, pleural effusion, and hepatic cysts, respectively, in group A (Supplementary Table 1).

## Correlation Analysis of VAS Score on Admission

Multiple linear regression was used to analyze the correlation between admission VAS score and gender, stone location, stone size and degree of hydronephrosis. The results showed that taking lower ureteral calculi, no hydronephrosis

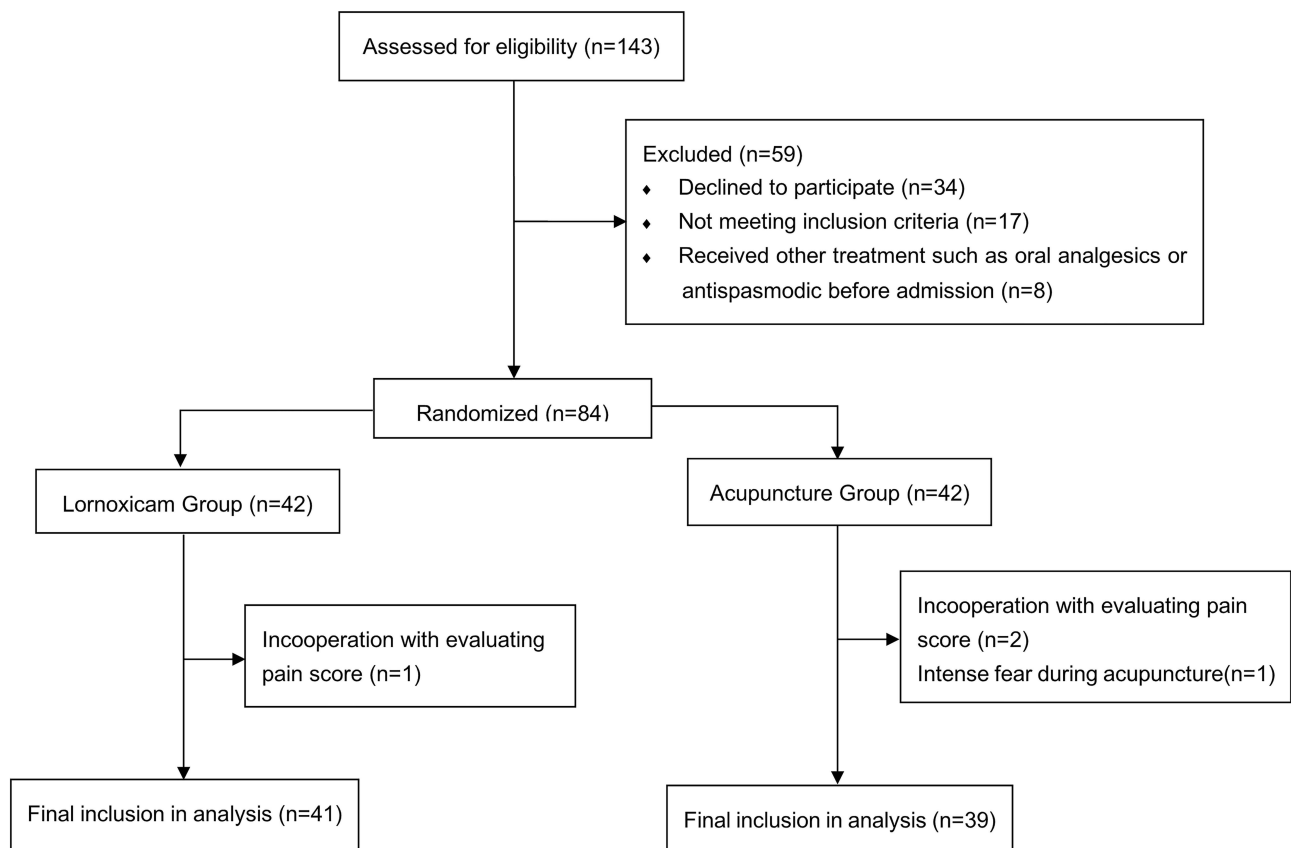

Figure 2 Patient enrolment flow chart.

<b>B Stone Position Between Two Groups</b>									
Group	Stone Position						Total	Z	P
	Left			Right					
	Upper	Middle	Lower	Upper	Middle	Lower			
Acupuncture	10 (25.64%)	3 (7.69%)	8 (20.51%)	5 (12.82%)	1 (2.56%)	12 (30.77%)	39 (100%)	-1.087	0.277
Lornoxicam	2 (4.88%)	3 (7.32%)	11 (26.83%)	6 (14.63%)	3 (7.32%)	16 (39.02%)	41 (100%)		
Total	12 (15.00%)	6 (7.50%)	19 (23.75%)	11 (13.75%)	4 (5.00%)	28 (35.00%)	80 (100%)		
<b>C Hydronephrosis Degree Between Two Groups</b>									
Group	Hydronephrosis Degree			Total	Z	P			
	No Hydronephrosis	Mild Hydronephrosis	Moderate Hydronephrosis						
Acupuncture	3 (7.69%)	33 (84.62%)	3 (7.69%)	39 (100%)	-0.679	0.497			
Lornoxicam	2 (4.88%)	35 (85.37%)	4 (9.76%)	41 (100%)					
Total	5 (6.25%)	68 (85.00%)	7 (8.75%)	80 (100%)					

and female patients as reference, upper or middle ureteral calculi, mild or moderate hydronephrosis, male patients had no effect on admission VAS score ( $P > 0.05$ ), and stone size had no effect on admission VAS score ( $P > 0.05$ ) (Table 2).

### Lower VAS Scores After Acupuncture Therapy

The baseline VAS scores were the same between the two groups ( $P = 0.957$ ). Participants in groups A and L reported significantly lower VAS scores at 5, 10, 15, 20, and 40 min post-treatment versus baseline scores ( $P < 0.001$ ). Group A exhibited lower scores versus group L at 5, 10, 15, 20, and 40 min post-treatment ( $P < 0.05$ ) (Table 3 and Figure 3).

### STE is Improved After Acupuncture Therapy

According to the 4-grade outcome assessment, 7 cases (17.95%) were rated as grade A, 21 (53.85%) were

grade B, 5 (12.82%) were grade C, and 6 (15.38%) were grade D in the group A. Therefore, the overall STE of acupuncture was 84.62% (33/39). However, only 2 cases (4.88%) were graded as “cure”, 19 (46.34%) as “markedly effective”, 4 (9.76%) as “effective”, and 16 (39.02%) as “ineffective” in group L. The overall STE of lornoxicam was 61.00% (25/41), significantly lower than group A ( $P = 0.000$ ). The grading of each group was summarized in Table 4.

### Faster Onset of Pain Relief Provided by Acupuncture

As a result, 89.70% (35/39) and 92.30% (36/39) of patients in group A responded within 15 and 40 min, respectively, versus 21.95% (9/41) and 60.98% (25/41) in group L. There were statistically significant differences between the two groups ( $P = 0.000$ ), indicating a faster onset of pain relief delivered by acupuncture (Table 5).

**Table 2** Correlation Analysis of VAS Score on Admission with Gender, Stone Size and Hydronephrosis Degree

Parameter	Standardized Coefficients	t	P	95.0% CI for B		Collinearity Statistics	
	B					Tolerance	VIF
(Constant)		18.697	0.000	7.179	8.893

Female	0.035	0.290	0.772	-0.267	0.358	0.913	1.095

**Table 3** VAS Score Difference Between the Two Groups After Treatment

Group	VAS <sub>0min</sub>	VAS <sub>5min</sub>	VAS <sub>10min</sub>	VAS <sub>15min</sub>	VAS <sub>20min</sub>	VAS <sub>40min</sub>
Acupuncture	8.00 (1.2)	3.00 (3) <sup>a</sup>	3.00 (2) <sup>a</sup>	2.00 (2) <sup>a</sup>	2.00 (2) <sup>a</sup>	2.00 (2) <sup>a</sup>
Lornoxicam	8.10 (0.9)	7.00 (1) <sup>a</sup>	7.00 (2.3) <sup>a</sup>	6.00 (2) <sup>a</sup>	5.00 (4) <sup>a</sup>	2.00 (5) <sup>a</sup>
Z	-0.054	-5.714	-5.899	-5.486	-4.411	-2.232
P	0.957	<0.001	<0.001	<0.001	<0.001	0.026

Note: <sup>a</sup>P < 0.05 (Compare VAS at different time points in the same group, Z is not given).

## Related Factors on the Efficacy of Acupuncture

The effect grade was taken as dependent variable, and the treatment method, stone size and stone location were taken as independent variables for ordered Logistic regression analysis. The Omnibus test result shows the model was meaningful ( $P = 0.048$ ). The results indicated the size of the stone [OR = 0.529, 95% CI: (0.191, 1.463),  $P = 0.529$ ] and the location of the stone [comparison between upper and lower ureter: OR = 1.918, 95% CI: (0.707, 5.206),  $P = 0.201$ , comparison between middle and lower ureter: OR = 2.219, 95% CI: (0.556, 8.858),  $P = 0.259$ ] were no significant correlation between acupuncture efficacy. The treatment method is the only factor affecting the short-term effective rate of patients. Patients receiving acupuncture therapy had a greater chance of being cured [OR = 2.887, 95% CI: (1.190, 7.000),  $P = 0.019$ ] ([Supplementary Table 2](#)).

## Safety Comparison Between Acupuncture versus Lornoxicam

Adverse reactions in group L consisted of nausea (2 cases) and dizziness (1 case) post-treatment, which

completely disappeared after bed rest. One patient in group A reported frequent urination after acupuncture, whose condition was spontaneously relieved 2 hours later. The frequency of adverse reactions was 2.6% in group A and 7.3% in group L. There was a nonsignificant difference between the two groups ( $P = 0.616$ ).

## Outcomes of Patients in Group A and Group L

In group A, 6 patients (15.38%) had spontaneous stone expulsion, 10 patients (25.64%) were discharged after conservative treatment, and 23 patients (58.97%) received extracorporeal shock wave lithotripsy, ureteral stents, or transurethral ureteroscopic lithotripsy. In the group L, there were 1 (2.44%), 8 (19.51%) and 32 (78.05%) patients with these three outcomes, respectively. There was no statistically significant difference between the two groups ( $P = 0.074$ ) ([Supplementary Table 3](#)).

## Discussion

### Research Design Innovation

Acupuncture is a unique form of traditional Chinese medicine that has been ubiquitously used as a well-tolerated and effective source for pain relief, and numerous acupuncture studies have been published since the 1970s.<sup>16</sup> However, the efficacy of acupuncture in the treatment of ARC is currently lacking in evidence-based medical evidence, mainly due to the lack of high-quality randomized controlled clinical trials. First, there is a lack of exact description of random method, allocation concealment and blinding method in study design. Secondly, the types and methods of use of the control drugs are not recommended in the guidelines. For example, intravenous infusion of morphine was used as the control group in the recent study of Beltaief et al,<sup>17</sup> while Chen and Li<sup>18</sup> chose intramuscular injection of Fortanodyn as the control group.

Third, there were few trials with placebo acupuncture, which will lead to different psychological expectations of patients due to different treatment, and may also lead to bias in VAS score during follow-up. Finally, the selection of complex acupoints and the manipulation of acupuncture at specific points require a long period of training, which limits the promotion of acupuncture therapy.<sup>17–19</sup> In our study, acupuncture offered a rapid, robust analgesic effect in ARC, superior to lornoxicam. Manipulations at SP6 and SP9 in the lower legs were an easy job without pronounced adverse reactions. All these unfold the feasibility of acupuncture for acute pain. In addition, intramuscular administration of lornoxicam was used as a positive control in this study for the following three reasons: (1) EAU (European Association Of Urology) Guidelines recommend NSAIDs as the first choice for ARC;<sup>4</sup> (2) There is no difference in the efficacy of intramuscular

**Table 4** Comparison of Short-Term Efficacy Between the Two Groups

Group	Grade				Total	Z	P
	A (Cured)	B (Markedly Effective)	C (Effective)	D (Ineffective)			
Acupuncture	7 (17.95%)	21 (53.85%)	5 (12.82%)	6 (15.38%)	39 (100%)	-3.903	<0.001

administration of lornoxicam and intravenous administration of lornoxicam for ARC.<sup>14</sup> Third, intramuscular injection of NSAIDs in the treatment of ARC can have more lasting analgesic effect and fewer adverse reactions.<sup>20</sup> Finally, the ideal sham acupuncture must meet two main criteria: on the one hand, there is no or only a small specific effect, on the other hand, there is no difference or high similarity between other aspects, allowing the successful implementation of blind method.<sup>21</sup> A meta-analysis has shown that non-penetrating acupuncture at non-acupoints or acupoints are more suitable for sham acupuncture.<sup>11</sup> In order to avoid different mental expectations of patients for different therapies, we chose non-penetrating acupuncture at acupoints as sham acupuncture therapy.

## Efficacy and Safety of Treatment

Acute renal colic is one of the most severe pain. Sasmaz and Kirpat found that the pain level was independent of stone size.<sup>22</sup> In addition, 11% of patients had no hydronephrosis at the time of acute presentation, and 71% presented with mild hydronephrosis,<sup>23</sup> only severe hydronephrosis was significantly related to stone size.<sup>24</sup> In our study, 6.25% of patients had no hydronephrosis, 85% had mild hydronephrosis, and no patients with severe hydronephrosis. Our multiple linear regression analysis indicated that the VAS score at admission was independent of stone size, hydronephrosis degree and gender, which was generally consistent with the conclusion of previous studies.

In this study, the VAS score of patients receiving acupuncture at all time points was lower than that of the control group, and the final short-term effective rate was also higher than that of the control group. Orderly logistics analysis indicated that the treatment method was the only factor affecting the efficacy, and the probability of patients receiving acupuncture being cured was about 2.9 times higher than that receiving lornoxicam. In addition, the acupuncture effect was significantly faster than that of

lornoxicam and could be rapidly activated within 10 minutes. This may be due to the following reasons: on the one hand, acupuncture analgesia may exert analgesic effect through opioid system and non-opioid system, which is a complex and rapid neurohumoral immune reaction.<sup>25</sup> On the other hand, lornoxicam reduces prostaglandin synthesis via inhibiting cyclo-oxygenase 2 (COX-2) to exert an analgesic effect, and increases in plasma dynorphin and  $\beta$ -endorphin levels to inhibit spinal pain sensation will only be possible through at least 5 days of lornoxicam administration.<sup>26</sup> Therefore, acupuncture is superior to lornoxicam in relieving pain. All these indicate that acupuncture of SP6 and SP9 is a rapid and effective treatment for ARC.

The time of spontaneous expulsion of ureteral calculi was about 17 days,<sup>27</sup> and the probability of spontaneous expulsion of calculi of different sizes and positions was different. The spontaneous expulsion rates of calculi <5mm, 5–7mm and >7mm were 89%, 49% and 29%, respectively. The spontaneous removal rates of calculi in upper, middle and lower ureteral segments were 52%, 70% and 83%, respectively.<sup>28</sup> In this study, six patients in group A had spontaneous stone expulsion after treatment, while only one in group L. Although there was no statistical difference ( $P=0.074$ ), it seems that acupuncture at SP6 and SP9 can promote the expulsion of ureteral stones, which requires further study.

It has been reported that about 1% of patients experience adverse reactions due to receiving analgesics when treating acute renal colic.<sup>27</sup> However, adverse reactions caused by acupuncture are extremely rare, and the estimated probability of serious adverse reactions (such as nausea, syncope, and strong emotional reactions) is only 1.3%.<sup>29</sup> In this study, both lornoxicam and acupuncture showed good safety. Although three patients in the group L had adverse reactions of nausea and dizziness, these adverse reactions were very mild and resolved spontaneously without any intervention. Moreover, one patient in group A reported frequent urination after acupuncture, and this symptom

was relieved 2 hours later. We speculate that this condition is related to enhanced ureteral and bladder contraction or stone removal by acupuncture stimulation. Although there are no direct reports that acupuncture at SP6 and SP9 can promote ureteral contraction, Yi et al reported that acupuncture at SP6, Shuidao (ST28), Epangxian III (MS4) and Zusanli (ST36) can improve the maximal cystometric capacity, maximal flow rate, and bladder compliance of patients after total hysterectomy.<sup>30</sup> Animal experiment has also shown that acupuncture at Weizhong (BL40), SP6 and SP9 can increase the intravesical pressure and bladder adenosine triphosphate (ATP) content in rabbits with acute urinary retention.<sup>31</sup> Finally, it should be noted that acupuncture of SP6 is prohibited for pregnant women, because it is important to note that acupuncture is contraindicated for pregnant women because SP6 stimulation may also lead to miscarriage.<sup>32</sup>

## Potential Mechanisms of Treatment Effectiveness

Despite dilatation, extension, and spastic activity of ureter in acute ureteric calculus obstruction, molecular research has revealed enhanced local release of inflammatory mediators, such as prostaglandin F<sub>2α</sub> (PGF<sub>2α</sub>) and 5-hydroxytryptamine (5-HT), and bradykinin synthesis, subsequently increasing renal intrapelvic pressure, resulting in severe and unbearable renal colic.<sup>33–35</sup> Although myogenic factors are essential in the control of ureteral peristalsis, sympathetic and parasympathetic nerves also play a role in this process. Ureteral contraction can be enhanced by via activating α<sub>1</sub>-adrenergic, muscarinic, purinergic, histamine H1 receptors on ureteric smooth muscle cells as well as increased substance P, 5-HT levels cohesively, and the ureter is dilated through activating β<sub>2/3</sub>-receptors and histamine H<sub>2</sub> receptors and upregulating endothelial oxide and prostaglandin E<sub>1</sub>, E<sub>2</sub> expressions.<sup>35</sup> These mechanisms may be both the cause of renal colic and the effect of acupuncture.

The acupuncture analgesia mechanism is associated with nerve activity, body-fluid exchange, and endocrine regulation.<sup>25</sup> Preexisting evidence shows that acupuncture manipulation can mitigate pain via promoting mast cell (MC) degranulation and ATP/adenosine, IL-10, and opioid peptide release, stimulating P2XRs (purinergic ligand-gated cationic channels) and A1R (adenosine A1 receptor), and mechanical sensitive membrane channels such as ASIC3 (acid-sensing ion channel 3) and TRPV (transient

receptor potential vanilloid 1), and downregulating pronociceptive receptor expression in peripheral neurons.<sup>25,36</sup> Glial cell activation, resulting from signaling activation in the spinal cord by acupuncture manipulations, can be inhibited by downregulating the chemokine CX3CL1 (XC chemokine ligand) expression and upregulating the expression of anti-inflammatory IL-10. Glial cell inhibition may further reduce the release of tumor necrosis factor (TNF)-α, IL-1β, IL-6, prostaglandins E<sub>2</sub>, and other pain-related substances.<sup>37</sup> In terms of the roles of the central nervous system, acupuncture provides analgesic relief via activating the periaqueductal gray (PAG), anterior cingulate cortex (ACC), rostral ventromedial medulla (RVM), and hippocampus to release β-endorphins and other central analgesic substances.<sup>25,37,38</sup> Studies have shown that acupuncture of Sanyinjiao and Zusanli can reduce the expression of cyclooxygenase-2 (COX-2) and the synthesis of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) in spinal cord in animal models of nerve pain, and its analgesic effect is significantly better than celecoxib.<sup>39</sup> Acupuncture at Hegu point and Sanyinjiao can relieve labor pain by increasing the expression of κ-opioid receptor and Prodynorphin protein in spinal cord, and thereby increasing the concentration of serum Dynorphin.<sup>40</sup>

Intersegmental neuronal connectivity is a determinant of specific acupoint-organ correlation.<sup>41</sup> SP9 and SP6 are paired-acupoints for pain relief in urinary obstruction, including ARC, through dredging the meridians.<sup>42,43</sup> Anatomically, ureter receives branches from T<sub>11</sub>-L<sub>2</sub> and S<sub>2-4</sub> nerve fibers,<sup>44</sup> and branches from L<sub>4</sub>-S<sub>1</sub> nerves are located in SP6 acupoint.<sup>45</sup> Branches around SP9 are innervated by the tibial nerve. Therefore, it is speculated that SP6 and SP9 stimulation exert a potent analgesic effect via signal transduction from the tibial nerve to the corresponding spinal cord segments and brain regions.

## Limitations of This Study

Our study has the following limitations. It was a single-center study with small sample size and insufficient objective measurements like serum or urinary substance P levels, due to limited funds. The 40-min observation is not long enough to examine the maintenance of efficacy of acupuncture and may underestimate the therapeutic effect of lornoxicam. Moreover, it is well known that there is no optimal type of sham acupuncture design.<sup>21</sup> Therefore, although we had made some efforts in the blind method, it is not a recognized method and needs to be verified by more samples. Our sham acupuncture runs the risk of

being identified by patients because it does not penetrate the skin. Furthermore, administration of normal saline to gluteus maximus as a control for lornoxicam remains to be improved as we found some patients to feel pain in injection area, although it was bearable. Finally, whether acupuncture can reduce hospitalization rates, costs and hospitalization days remains to be further assessed.

## Conclusion

We found that acupuncture at SP6 and SP9 delivers a better therapeutic effect on ARC versus lornoxicam, which is worthy of recommendation in emergencies as such, particularly when analgesics do not work or patients are allergic to these drugs. The underlying stone passage and pro-peristaltic function of acupuncture at SP6 and SP9 need further validations.

## Acknowledgments

We would like to thank all the members for their contributions to the success of this trial.

## Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

## Journal of Pain Research

### Publish your work in this journal

The Journal of Pain Research is an international, peer reviewed, open access, online journal that welcomes laboratory and clinical findings in the fields of pain research and the prevention and management of pain. Original research, reviews, symposium reports, hypothesis formation and commentaries are all considered for publication. The manuscript

management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/journal-of-pain-research-journal>
