Abstract: Chronic kidney disease (CKD) is a risk factor for end-stage renal failure and cardiovascular events. In patients with CKD, anemia is often caused by decreased erythropoietin production relative to hemoglobin levels. As correction of anemia is associated with improved cardiac and renal function and quality of life, erythropoiesis-stimulating agents (ESAs) are standard therapy for anemia in CKD patients. However, traditional ESAs such as epoetin or darbepoetin have short half-lives and require frequent administration, dose changes, and close monitoring of hemoglobin concentration to maintain target hemoglobin levels. Methoxy polyethylene glycol-epoetin beta (MPG-EPO) is the only ESA that is generated by chemical modification of glycosylated erythropoietin through the integration of one specific, long, linear chain of polyethylene glycol. This ESA induces continuous erythropoietin receptor activation and has a long half-life (approximately 130 hours). Subcutaneous or intravenous administration of MPG-EPO once every 2 weeks or monthly achieved a high hemoglobin response rate in patients with anemia associated with CKD, regardless of whether the patient was undergoing dialysis. According to data from an observational time and motion study, MPG-EPO maintains hemoglobin levels when the same dose is administered, however infrequently. This suggests that compared with the use of traditional ESAs, administration of MPG-EPO reduces the overall time and cost associated with the management of anemia in CKD patients undergoing dialysis. MPG-EPO is generally well tolerated and most adverse events are of mild to moderate severity. The most commonly reported adverse effects are hypertension, nasopharyngitis, and diarrhea. Subcutaneous injection of MPG-EPO is significantly less painful than subcutaneous injection of darbepoetin. In conclusion, MPG-EPO is as effective and safe as traditional ESAs in managing renal anemia, irrespective of whether the patient is undergoing dialysis.

Keywords: methoxy polyethylene glycol-epoetin beta, renal anemia, end-stage renal failure, hemoglobin, erythropoiesis-stimulating agent

Introduction

Chronic kidney disease (CKD) is a known risk factor for end-stage renal failure and cardiovascular events.¹ Anemia is a common complication in patients with CKD. The most probable reason for a decline in hemoglobin levels in CKD patients is decreased erythropoietin production relative to hemoglobin levels.² Correction of anemia is associated with improved cardiac and renal function and quality of life.³ Therefore, erythropoiesis-stimulating agents (ESAs) are standard therapy for renal anemia in CKD patients.

ESAs are glycosylated proteins with a peptide core of 165 amino acids. A major limitation of epoetin, the first ESA to be marketed, is that it is usually administered by

injection two or three times per week.⁴ To develop a longer-acting erythropoietic agent, additional *N*-linked glycosylation sites were introduced into erythropoietin by site-directed mutagenesis.⁵ This modification resulted in a 37.1-kDa glycoprotein, darbepoetin alfa (DA), the half-life of which is three times that of epoetin, thus only needs to be administered by injection once weekly, or once every 2 weeks in most patients.^{6,7} However, conventional treatment with ESAs to manage anemia in CKD patients requires frequent administration, dose changes, and close monitoring of hemoglobin concentration to maintain target hemoglobin levels.

Methoxy polyethylene glycol-epoetin beta (MPG-EPO; Mircera[®], Roche, Basel, Switzerland) is a novel agent that has a different interaction with the erythropoietin receptor than previous agents and has a long elimination half-life (approximately 130 hours).⁸ MPG-EPO is the only ESA generated by chemical modification of glycosylated erythropoietin, by the integration of one specific, long, linear chain of polyethylene glycol. The resultant molecule has a molecular weight of approximately 60 kDa, which is twice that of epoetin. The methoxy polyethylene glycol polymer chain is integrated through amide bonds between the *N*-terminal amino group or the ϵ -amino group (predominantly lysine-52 or lysine-45) with a single butanoic acid linker.⁹

The interaction between MPG-EPO and the erythropoietin receptor differs from that of epoetin beta.¹⁰ The comparative erythropoietin receptor-binding properties of MPG-EPO and epoetin beta were assessed by surface plasmon resonance using soluble recombinant EPO receptors and by competition binding on cultured UT-7 cells. Calculated equilibrium dissociation constants (surface plasmon resonance assay) for MPG-EPO and epoetin beta were 140 and 2.9 nmol/L, respectively. Respective IC₅₀ values (competition binding assay) were 200 and 1.5 nmol/L. Compared with epoetin beta, MPG-EPO has an approximately 50- to 100-fold lower affinity for erythropoietin receptor-binding sites. Analysis of the equilibrium binding curves indicates that the difference in affinity is mainly due to slower association. The different

receptor-binding properties of MPG-EPO may enable continuous stimulation of erythropoiesis combined with a long half-life and slow systemic clearance.¹⁰ As a result, MPG-EPO stimulates erythropoiesis when administered intravenously or subcutaneously at a prolonged dosing interval (Table 1).

This review focuses on the therapeutic efficacy and tolerability of MPG-EPO in CKD patients with renal anemia who are or are not undergoing dialysis.

Therapeutic efficacy

Several Phase I, four Phase II, and seven Phase III randomized open-label, parallel-group, multicenter studies have investigated the therapeutic efficacy of MPG-EPO in CKD patients with renal anemia (Table 2).^{8,11–22} These studies have included patients who were or were not undergoing dialysis. In addition, the open-label, non-comparative (MIRACEL) study assessed the efficacy of MPG-EPO in a real-life situation.²³

In a Phase I trial using healthy volunteers ($n = 42$), subcutaneous administration of MPG-EPO in the arm, thigh, or abdomen (3.0 $\mu\text{g}/\text{kg}$) increased mean reticulocyte counts relative to baseline by 258%, 273%, and 269%, respectively. These results suggest that the pharmacokinetic and pharmacodynamic properties of MPG-EPO effectively increase reticulocyte counts, irrespective of the skin site of subcutaneous administration.¹¹ Similarly, in a Phase I trial in patients receiving peritoneal dialysis ($n = 16$), a single subcutaneous (0.8 $\mu\text{g}/\text{kg}$) or intravenous (0.4 $\mu\text{g}/\text{kg}$) dose of MPG-EPO induced a reticulocyte response that peaked at a median of 8 days after administration and returned to baseline values by day 20. The time course for reticulocyte counts was not different between the two routes of administration. These results suggest that extended administration intervals of MPG-EPO are feasible in patients with CKD.⁸

In the Phase II trials, four studies determined the administration intervals and optimal starting dose in patients with CKD, some of whom were undergoing dialysis, while others

Table 1 Half-lives of erythropoiesis-stimulating agents (ESAs)

ESA	Population	Mean half-life (h)	
		Intravenous administration	Subcutaneous administration
Epoetin alfa	Healthy volunteers ⁴	6.8	19.4
Epoetin beta	Healthy volunteers ⁴	8.8	24.2
Darbepoetin alfa	CKD patients not on dialysis ⁶		69.6
	CKD patients on dialysis ⁷	25.3	48.8
Methoxy polyethylene glycol-epoetin beta	CKD patients on dialysis ⁸	134	139

Table 2 Therapeutic efficiency of methoxy polyethylene glycol-epoetin beta

Method, dose, and frequency of administration	Population	Numbers	Results
A single SC dose (0.8 µg/kg) or IV dose (0.4 µg/kg) ⁸	Patients on PD	16	MPG-EPO has a prolonged half-life after IV (134 h) and SC (139 h) administration
A single SC dose (3.0 µg/kg) ¹¹	Healthy volunteers	42	MPG-EPO increases reticulocyte counts, irrespective of the skin site of SC administration
SC doses (0.15, 0.30, and 0.45 µg/kg) once every 1, 2, or 3 weeks ¹²	ESA-naïve patients on dialysis	61	SC dose (0.60 µg/kg) once every 2 weeks is optimal in CKD patients on dialysis
IV doses (0.25, 0.4, or 0.6 µg/kg/week) ¹³	Patients on dialysis converted from EPO	91	Administration can be switched from EPO 3 times/week to MPG-EPO once every 1 or 2 weeks
SC doses (0.4, 0.8, or 1.2 µg/kg) once every 1, 3, or 4 weeks ¹⁴	Patients on dialysis converted from SC EPO	137	SC MPG-EPO at up to once-monthly intervals provides stable Hgb levels in dialysis patients converting from EPO 1–3 times/week
SC doses (0.15, 0.3, or 0.6 µg/kg) once every 1, 2, or 4 weeks ¹⁵	ESA-naïve patients not on dialysis	91	SC (0.6 µg/kg) dose once every 2 weeks is optimal in CKD patients not on dialysis
IV dose (0.4 µg/kg) once every 2 weeks ¹⁶ (AMICUS study)	Patients on dialysis	181	IV MPG-EPO once every 2 weeks is safe and effective as 3 times weekly EPO for correcting anemia
SC dose (0.6 µg/kg) once every 2 weeks ¹⁷ (ARCTOS study)	ESA-naïve patients not on dialysis	324	SC MPG-EPO once every 2 weeks is as safe as DA once every 1 week
IV doses (60, 100, 180 µg) once every 2 weeks and IV doses (120, 200, 360 µg) once every 4 weeks ¹⁸ (MAXIMA study)	Patients on HD converted from IV EPO	673	IV MPG-EPO is as safe as conventional EPO treatment and can maintain anemia management from IV EPO
SC doses (60, 100, 180 µg) once every 2 weeks and SC doses (120, 200, 360 µg) once every 4 weeks ¹⁹ (PROTOS study)	Patients on HD converted from SC EPO	572	SC MPG-EPO once every 2 or 4 weeks maintains tight and stable Hgb levels from SC EPO
IV doses (60, 100, 180 µg) once every 2 weeks ²⁰ (STRIATA study)	Patients on HD converted from IV DA	313	Stable Hgb levels are maintained in patients on HD converted IV MPG-EPO every 2 weeks from DA
SC/IV doses (60, 100, 180 µg) once every 2 weeks ²¹ (RUBRA study)	Patients on dialysis converted from SC/IV EPO	336	MPG-EPO once every 2 weeks maintains stable Hgb control in patients on dialysis converted from EPO
IV doses (120, 200, or 360 µg) once every 4 weeks ²² (PATRONUS)	Patients on HD converted from IV DA	490	MPG-EPO maintains target Hgb more successfully than DA

Abbreviations: SC, subcutaneous; IV, intravenous; PD, peritoneal dialysis; MPG-EPO, methoxy polyethylene glycol-epoetin beta; ESA, erythropoiesis-stimulating agent; CKD, chronic kidney disease; EPO, epoetin; Hgb, hemoglobin; DA, darbepoetin alfa; HD, hemodialysis.

were not.^{12–15} de Francisco et al investigated 61 ESA-naïve patients with CKD who were undergoing dialysis and were randomized to MPG-EPO treatment at doses of 0.15, 0.30, and 0.45 µg/kg once per week.¹² Within these dose groups, patients were further randomized into once weekly, once every 2 weeks, or once every 3 weeks groups. In total, 90% of patients in the 0.30 µg/kg once per week group and 79% of patients in the 0.45 µg/kg once per week group responded to treatment (hemoglobin increase, ≥ 1.0 g/dL), compared with 72% in the 0.15 µg/kg once per week group and the response was unrelated to administration frequency. Provenzano et al studied administration intervals (once every 1, 2, or 4 weeks) and optimal starting doses (0.15, 0.30, or 0.60 µg/kg once per

week) of MPG-EPO subcutaneously administered in ESA-naïve patients with CKD who were not receiving dialysis.¹⁵ The hemoglobin response rate increased with escalating doses, with 67%, 72%, and 90% of patients responding in the groups treated with MPG-EPO at 0.15, 0.30, and 0.60 µg/kg once per week, respectively, and the response was unrelated to administration frequency. Overall, these results suggest that 0.60 µg/kg of MPG-EPO administered subcutaneously or intravenously once every 2 weeks is an optimal starting dose and a suitable time interval for the initiation of anemia correction in patients with CKD, regardless of dialysis dependency.

Two Phase III studies investigated the efficacy of intravenous or subcutaneous MPG-EPO administered once every

2 weeks in ESA-naïve patients with renal anemia who were either receiving dialysis (CERA [continuous erythropoietin receptor activator (methoxy polyethylene glycol-epoetin beta)] administered intravenously for anemia correction and sustained maintenance in dialysis [AMICUS]) or not (Administration of CERA in CKD patients to treat anemia with a Twice-monthly Schedule [ARCTOS]).^{16,17} In the AMICUS study, patients with CKD stage 5D who were receiving hemodialysis or peritoneal dialysis (n = 181) were recruited. After a 2-week run in, patients were randomly assigned to receive MPG-EPO or epoetin (epoetin alfa or beta). The MPG-EPO dose was started at 0.4 µg/kg, which was adjusted to achieve a defined hemoglobin response (≥ 11 g/dL), and an increase of ≥ 1.0 g/dL from the patients' baseline hemoglobin levels during a 24-week correction period. Hemoglobin response rates (intent-to-treat population) were 93.3% with MPG-EPO and 91.3% with epoetin. The mean changes in hemoglobin levels from baseline to the end of the correction period were 2.70 ± 1.45 g/dL with MPG-EPO and 2.56 ± 1.31 g/dL with epoetin. These results show the utility of intravenous MPG-EPO administered once every 2 weeks in ESA-naïve dialysis patients.¹⁶

In the ARCTOS study, patients who had CKD and were not receiving dialysis (n = 324) were recruited. Patients were randomly assigned to receive MPG-EPO once every 2 weeks or DA once weekly during an 18-week correction period and a 10-week evaluation period. The MPG-EPO dose was started at 0.6 µg/kg and was adjusted to achieve a defined hemoglobin response (≥ 11 g/dL) and an increase of ≥ 1.0 g/dL from the patients' baseline hemoglobin levels during a 28-week period after the first dose. Hemoglobin response rates were 97.5% for MPG-EPO and 96.3% for DA. The mean changes in hemoglobin levels from baseline to evaluation were 2.15 g/dL for MPG-EPO and 2.00 g/dL for DA. These results show that subcutaneous administration of MPG-EPO once every 2 weeks corrects anemia in ESA-naïve patients who are not receiving dialysis.¹⁷

Five Phase III maintenance studies (Maintenance of haemoglobin eXcels with IV administration of CERA [MAXIMA],¹⁸ Patients Receiving CERA Once a month for the mainTenance Of Stable hemoglobin [PROTOS],¹⁹ Stabilizing haemoglobin Targets in dialysis following IV CERA Treatment of Anaemia [STRIATA], Targeting sUstained hemogloBin in dialysis with IV and SC CERA Administration [RUBRA], and comPARator sTudy of CERA and darbepOetin alfa in patieNts Undergoing dialySis [PATRONUS]) investigated the efficacy of

intravenous or subcutaneous MPG-EPO in maintaining stable hemoglobin levels in CKD patients with renal anemia on dialysis who had been converted from another ESA (epoetin alfa or beta or DA).^{18–22}

In the MAXIMA, PROTOS, STRIATA, and RUBRA studies, patients were randomized to groups in which MPG-EPO was administered once every 2 or 4 weeks, or in which their current ESA (epoetin alfa or beta, or DA) dose was continued.^{18–22} Patients in these trials had been receiving hemodialysis or peritoneal dialysis and had stable baseline hemoglobin levels of 10.5–13.0 g/dL with adequate iron status. The doses were adjusted during a 28-week titration period followed by an 8-week evaluation period to maintain the hemoglobin levels within 10–13.5 g/dL and within ± 1 g/dL of the baseline hemoglobin value. During the evaluation period, 66%–76% of MPG-EPO recipients, 67%–72% of epoetin alfa or beta recipients, and 72% of DA recipients maintained an average hemoglobin level within ± 1 g/dL of baseline values.^{18–21} During the titration and evaluation periods, blood transfusions were required by 6%–12% of patients treated with MPG-EPO and 8%–10% of patients treated with traditional ESAs.^{18–21} The results of these Phase III maintenance studies demonstrate that MPG-EPO administered once every 2 or 4 weeks is comparable to epoetin alfa, epoetin beta (MAXIMA, PROTOS, RUBRA), or DA (STRIATA) in maintaining stable hemoglobin levels over the evaluation period.

Erythropoietin resistance is one of the main causes for anemia in patients with CKD. Up to 10% of patients receiving erythropoietin are hyporesponsive to the therapy and require large doses of the agent.²⁴ All of the ESA (MPG-EPO, epoetin alfa or beta, and DA) recipients maintained stable hemoglobin levels and there were no differences in percentages of blood transfusions in the above studies.^{18–21} These data suggest that frequency of erythropoietin resistance is similar among MPG-EPO, epoetin alfa or beta, and DA. It has been reported that the hemoglobin cycling described by Fishbane and Berns is associated with adverse outcomes such as increases in morbidity and mortality.²⁵ Selby et al described a trend toward fewer patients on MPG-EPO (68.4%) experiencing hemoglobin excursions than on epoetin beta (87.8%, $P = 0.054$), and that the MPG-EPO group also required fewer dose changes.²⁶ These data demonstrate that the longer half-life of MPG-EPO may offer a small advantage in reducing the degree of hemoglobin variability, possibly because of fewer dose changes per patient.

The PATRONUS study was a multinational, randomized, prospective trial that compared hemoglobin maintenance

achieved with once per month administration of MPG-EPO and DA. After the 26-week titration period using MPG-EPO once monthly or DA every 2 weeks, patients entered a second 26-week period of once per month MPG-EPO and DA. Doses of MPG-EPO increased by 6.8% and those of DA increased by 58.8% during once-monthly treatment, indicating that MPG-EPO maintained target hemoglobin more efficiently than DA at once per month dosing intervals.²²

The MIRACEL study was a prospective, open-label, multicenter study performed at 90 nephrology centers in Germany, which was undertaken to examine whether monthly administration of MPG-EPO maintains stable hemoglobin levels when administered according to local clinical judgment.²³ Of the 661 screened hemodialysis patients, 424 receiving epoetin or DA were converted to monthly intravenous MPG-EPO, with a 5-month titration phase followed by a 2-month evaluation phase. A mean of two MPG-EPO dose changes were required during the 7-month treatment period. During the screening, titration, and evaluation phases, mean hemoglobin was 11.7 ± 0.7 g/dL, 11.6 ± 0.9 g/dL, and 11.4 ± 1.0 g/dL, respectively. Patients exhibiting a change of ≤ 1 g/dL from phase-specific individual means was 90.6%, 70.4%, and 82.9%, respectively. These results indicate that the conversion of hemodialysis patients from epoetin or DA to monthly MPG-EPO is practical, convenient, and provides adequate control of hemoglobin levels.

Tolerability

In the MAXIMA study,¹⁸ of 673 randomized patients, 666 receiving MPG-EPO every 2 weeks ($n = 221$), MPG-EPO every 4 weeks ($n = 220$), or epoetin 1–3 times per week ($n = 225$) received at least one treatment. At least one adverse event was reported in 619 (93%) of patients (MPG-EPO every 2 weeks [$n = 203$], MPG-EPO every 4 weeks [$n = 202$], or epoetin 1–3 times per week [$n = 214$]); most adverse events were mild to moderate. The incidence of adverse events did not differ between groups ($P = 0.12$).

The most commonly reported adverse effects were hypertension, nasopharyngitis, headache, and diarrhea. In addition, 287 patients had serious adverse events in the three groups (MPG-EPO every 2 weeks [$n = 101$], MPG-EPO every 4 weeks [$n = 87$], or epoetin 1–3 times per week [$n = 99$]). The most common serious adverse events were sepsis, pneumonia, and arteriovenous graft thrombosis. Only six patients had serious adverse events that were judged to be treatment related and the occurrence of serious adverse events did not differ between groups (MPG-EPO every 2 weeks [$n = 3$], MPG-EPO every 4 weeks [$n = 2$], or

epoetin 1–3 times per week [$n = 1$]; $P = 0.40$) (Table 3A). The results of the PROTOS study were similar to those of the MAXIMA study. In total, 90% of patients across all treatment groups (twice per month MPG-EPO [90.0%], once per month MPG-EPO [93.2%], or epoetin 1–3 times weekly [87.4%]) experienced at least one adverse event.

The most commonly reported adverse effects were hypertension, procedural hypotension (hypotension during dialysis), nasopharyngitis, headache, and diarrhea. Most events were mild or moderate in intensity and were evenly distributed across the different treatment groups. The incidence of treatment-related adverse events was low (twice-monthly MPG-EPO, 4%; once-monthly MPG-EPO, 6%; and epoetin 1–3 times weekly, 2%). Only one death was considered to be related to study treatment (once-monthly MPG-EPO; gastrointestinal necrosis followed by sepsis) (Table 3B).¹⁹ In addition, the occurrences of cerebral hemorrhage (0.2%), myocardial infarction (0.2%), and hypertensive encephalopathy (0.2%) were limited, according to the patient package insert from the pharmaceutical company.²⁷ These results indicate that MPG-EPO is as well tolerated and safe as conventional ESA treatments. However, the long-term adverse effects of MPG-EPO need to be ascertained.

Pain following subcutaneous administration of MPG-EPO or DA was compared among healthy volunteers ($n = 84$). Pain was assessed on a 100 mm visual analog scale immediately after drug administration. Visual analog scale was 21.5 mm for MPG-EPO and 33.4 mm for DA ($P < 0.0001$), showing that subcutaneous injection of MPG-EPO is significantly less painful than subcutaneous injection of DA.²⁸

Pharmacoeconomics

An observational time and motion study was carried out in twelve dialysis centers in the UK and Germany (six centers per country).²⁹ Time measurements for observed tasks were obtained by trained observers using a stopwatch. Cost results in 2006 were expressed as average observed costs, including staff costs for observation periods and costs of supplies. ESA drug acquisition costs were not considered in the analysis. According to this study, the estimated average total annual costs for traditional ESA treatment for a hypothetical center of 100 dialysis patients were €17,031 and GBP£18,739 for German and UK centers, respectively. Assuming 100% conversion from traditional ESAs to once-monthly MPG-EPO in a hypothetical center of 100 dialysis patients, the estimated time savings were 36.9 days per year in an average UK center, and 43.4 days per year in an average German center. This leads to an estimated reduction in annual costs of €9,798

Table 3 Adverse events of methoxy polyethylene glycol-epoetin beta

Adverse events	Methoxy polyethylene glycol-epoetin beta every 2 weeks (n = 221)	Methoxy polyethylene glycol-epoetin beta every 4 weeks (n = 220)	Epoetin 1–3 times per week (n = 225)

Abbreviation: CERA, continuous erythropoietin receptor activator (methoxy polyethylene glycol-epoetin beta).

(−58%) for the German center and GBP£6,615 (−35%) for the UK center. These data suggest that once-monthly MPG-EPO reduces the overall time and cost associated with anemia management in CKD patients on dialysis compared with the use of traditional ESAs.

Dosage and administration

In ESA-naïve patients, the recommended starting dose is 0.6 µg/kg administered once every 2 weeks as a subcutaneous or intravenous injection, in order to reach a hemoglobin level of >11 g/dL. The dose may be increased by approximately 25% if hemoglobin levels increase by <1.0 g/dL over a month. Further increases of approximately 25% may be made once per month until the individual target hemoglobin level is reached. If a hemoglobin level of >11 g/dL is reached for an individual patient, MPG-EPO may be continued once per month using a dose equal to twice the previous dose once every 2 weeks.

Patients currently being treated with ESA can be directly converted to MPG-EPO administered once per month as a single intravenous or subcutaneous injection. The starting dose of this agent is based on the calculated weekly equivalent dose of DA or epoetin at the time of conversion (Table 4). The first injection of MPG-EPO should start at the next scheduled dose of the previously administered DA or epoetin dose.

In patients receiving treatment with ESA and in those naïve to ESA, the MPG-EPO dose should be reduced by approximately 25% if the hemoglobin level increases by more than 2 g/dL in 1 month or if the hemoglobin level approaches 12 g/dL. If hemoglobin levels continue to increase, MPG-EPO administration should be interrupted until these levels begin to decrease (a decrease of approximately 0.35 g/dL per week is expected). Therapy should then be resumed at a dose approximately 25% less than the

Table 4 Recommended starting dose of methoxy polyethylene glycol-epoetin beta in patients with anemia associated with chronic kidney disease previously treated with erythropoiesis-stimulating agents

Previous weekly IV or SC darbepoetin alfa dose ($\mu\text{g}/\text{week}$)	Previous weekly IV or SC epoetin dose (IU/week)	Monthly IV or SC methoxy polyethylene glycol-epoetin beta dose ($\mu\text{g}/\text{month}$)
<40	<8000	120

previously administered dose. Dose adjustments should not be made more frequently than once per month.

Since treatment experience is limited in patients receiving peritoneal dialysis, regular hemoglobin monitoring and strict adherence to dose adjustment guidance is recommended in this population.^{30,31}

Conclusion

Among patients with anemia associated with CKD, regardless of whether the patient is receiving dialysis, subcutaneous or intravenous administration of MPG-EPO achieves a high hemoglobin response rate in ESA-naïve patients when administered once every 2 weeks and maintains stable hemoglobin levels in patients previously treated with ESAs when administered once per month. MPG-EPO is as well tolerated and safe as traditional ESA treatments. In addition, compared with the use of traditional ESAs, administration of MPG-EPO may reduce the overall time and cost associated with anemia management in CKD patients.

International Journal of Nephrology and Renovascular Disease

Dovepress

Publish your work in this journal

The International Journal of Nephrology and Renovascular Disease is an international, peer-reviewed open-access journal focusing on the pathophysiology of the kidney and vascular supply. Epidemiology, screening, diagnosis, and treatment interventions are covered as well as basic science, biochemical and immunological studies. The journal welcomes

original research, clinical studies, reviews & evaluations, expert opinion and commentary, case reports and extended reports. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
