## ABSTRACT

The efficacy of *Vernonia amygdalina* against chemical toxicity has attracted attention. The aim of this study was to evaluate the protective potentials of *Vernonia amygdalina* methanol extract (BLME) against petroleum toxicity. Thirty six male albino rats (*Rattus norvegicus*) were redistributed randomly into six groups of six rats each and fed with growers feed for a period of 30 days according to the following description: Group A = Feed; Group B = Feed + 100 mg kg<sup>-1</sup> body weight of BLME; Group C = Feed + 200 mg kg<sup>-1</sup> body weight of BLME; Group D = Feed (100 g Feed + 4 mL crude petroleum); Group E = Feed (100 g Feed + 4 mL crude petroleum) + 100 mg kg<sup>-1</sup> body weight of BLME; Group F = Feed (100 g Feed + 4 mL crude petroleum) + 200 mg kg<sup>-1</sup> body weight of BLME. Animals were sacrificed at the end of the experimental period and the serum and kidney were harvested for biochemical and histological analysis following standard procedures. The data generated were subjected to analysis of variance (ANOVA). The study revealed that crude petroleum stimulated alterations in kidney dysfunction makers: urea, creatinine and serum electrolytes which were significantly ( $P < 0.05$ ) ameliorated by BLME administration relative to control. Oxidative stress markers, lipid peroxidation and enzymatic and non-enzymatic antioxidant profiles (MDA levels, GSH, Vitamin C, FRAP, CAT, SOD, GPx, GSTs) as well as oxidase enzymes (AO, SO, MO and XO) induced changes by crude petroleum were positively modulated by BLME administration. The study concluded that crude petroleum contaminated diets are injurious to animal health and BLME is able to prevent the renal dysfunction induced by crude petroleum contaminated diets.

## 1. Introduction

Crude petroleum is an unrefined petroleum hydrocarbon mixture which has from simple to complex structures such as resins, asphaltenes and others. Chemically, it is composed of hydrogen, carbon, sulphur, nitrogen, oxygen and metals [1]. Polar compounds contained in crude petroleum contain heteroatoms of oxygen, nitrogen or sulphur and are ascertained by so many names, including heterocyclics, resins and NSO<sub>3</sub> [2]. Heterocyclic compounds of crude petroleum may be composed of metals in salts of carboxylic acids form or distinctively as porphyrin chelates or organo-metal complexes [2,3]. When it is refined, its contents entail different fractions which are majorly used as fuels. The nearly unavoidable importance of these fractions is what makes them in constant and daily contact with human such as petrol, diesel and lubricating oils for powering automobiles, kerosene for cooking, and heavy gas oils for tarring roads [1]. Over the years, the increased trend in the domestic and industrial utilization of crude petroleum and its products has necessitated its concomitant exposure of humans and

other animals to its high level risk [4]. In certain cases, these products such as kerosene, diesel, and gasoline find itself into the food chain and gradually build up its negative effects in the tissues especially as it relates to nephrotoxicity [5–8].

In recent times, plants and plants-based materials are being tested as possible antidotes for crude petroleum toxicity in animals [9,10]. One important plant commonly grown in the tropical regions of the world with nutritional and health giving properties is bitter leaf (*Vernonia amygdalina*) [11]. The medicinal properties of *Vernonia amygdalina* are highly documented by Ijeh and Ejike [11]. It possesses anti-diabetic property, anthelmintic activities; antioxidant properties; hypolipidemic and anticancer activity [11]. Also, the cathartic effect; abortifacient; antifertility; antimicrobial; antiplatelet and anticoagulant; antimalarial; hepatoprotective; analgesic activity; anti-inflammatory; anti-pyretic activity; antimutagenicity and effect on CD4+ cell count (HIV/AIDS) were also reported [11]. Moreover, the safety of bitter leaf had been established through sole administration as well as administration in the presence of toxicants [12–14].

It is well established that crude petroleum and its fractions exposure has been severally implicated in their ability to alter the functionality of the kidney via the mechanistic increase in the concentrations of serum electrolytes, urea and creatinine and alteration in oxidative stress status [1,15,16]. At the time of this investigation however, there was no documented evidence on the use of bitter leaf to prevent the renal damage induced by crude petroleum contaminated diets. The aim of this study was to evaluate the role of bitter leaf (*Vernonia amygdalina*) methanolic extract in prevention of renal toxicity induced by crude petroleum contaminated diet.

## 2. Materials and methods

### 2.1. Materials

Matured bitter leaf (*Vernonia amygdalina Del*) was harvested from a farm at Abraka, Nigeria and was identified by Dr. Erhenhi A.H of Department of Botany, Delta state University, Abraka, Nigeria. The credentials of the leaf were corroborated at the Forestry Research Institute of Nigeria, Jericho Hill, Ibadan, Nigeria, where a specimen with the voucher number, F101863 was deposited at the herbarium. Thirty six male albino rats (*Rattus norvegicus*) were obtained from the animal house of the Faculty of Basic Medical Sciences; Delta State University, Nigeria. The rats were housed in a wooden cage and left to acclimatize for one week and were fed with grower's mash throughout the acclimatization period. The grower's mash used is a product of Rainbow Feed Limited and the composition as declared by the manufacturer is depicted in Table 1. All other reagents used for biochemical assay were of analytical grades.

### 2.2. Experimental design and treatment

After the period of acclimatization the rats were weighed and an average weight of 150 g–182 g was obtained. This followed the distribution of the animals randomly into six groups of six rats each and fed with growers feed for a period of 30 days according to the following description.

Group A = Feed  
 Group B = Feed + 100 mg kg<sup>-1</sup> body weight of BLME  
 Group C = Feed + 200 mg kg<sup>-1</sup> body weight of BLME  
 Group D = Feed (100 g Feed + 4 mL crude petroleum)  
 Group E = Feed (100 g Feed + 4 mL crude petroleum) + 100 mg kg<sup>-1</sup> body weight of BLME  
 Group F = Feed (100 g Feed + 4 mL crude petroleum) + 200 mg kg<sup>-1</sup> body weight of BLME

### 2.3. Preparation of bitter leaves extract

The bitter leaves were washed and air dried at an open space within the laboratory confinement of the Department of Biochemistry, Delta State University, Abraka at room temperature for one week. At the end

of the drying period, the bitter leaf was chopped off and macerated using a warren blender to a smooth dry powder and the extract of the bitter leaf obtained using methanol extraction technique as previously described by Okpoghono et al. [10]. One hundred (100 g) of the powdered leaf was dissolved in 400 mL of methanol through sonication for 10 min, then filtered with Whatman No.1 using vacuum pump. The extract was then concentrated using rotary evaporator at 40–50 °C under reduced pressure to obtain the bitter leaf methanol extract (BLME). The extract was stored at –8 °C until required.

### 2.4. Administration of bitter leaves extract

The bitter leaf extract used for administration was freshly prepared at the point of administration by dissolving 20 g of the extract in 100 mL of distilled water to obtain 200 mg mL<sup>-1</sup> out of which aliquots of the freshly dissolved extract was administered by gavage according to the rats body weight once daily. Rats in group A had no bitter leaf extract treatment. Rats in group B and C were fed with normal diet as those in group A, but were simultaneously treated with 100 mg kg<sup>-1</sup> body weight of BLME and 200 mg kg<sup>-1</sup> body weight of BLME; respectively. While rats in group D had crude petroleum contaminated diet without any treatment, whereas rats in groups E and F were fed with crude petroleum contaminated diet along with 100 mg kg<sup>-1</sup> body weight of BLME and 200 mg kg<sup>-1</sup> body weight of BLME mg of bitter leaf extract. All the treatments lasted for 30 days to allow for chronic exposure. These doses had been established to be clinically tolerable by experimental rats [12]. The rats in groups A and D were not administered the extracts while all animals were allowed free access to water. National research council guide for the care and use of laboratory animals was adhered to during the experiment [17].

### 2.5. Sample collection

At the end of the treatment period of 30 days, the animals were sacrificed by cervical decapitation on the 31st day after an overnight fast. Blood samples were collected immediately by cardiac puncture into sterile plain tubes and labeled. The blood samples collected were spun using centrifuge at 3200g for 15 min and the serum collected for various biochemical assays. The kidneys also were harvested into labeled containers under cold conditions. Kidney wet tissue measuring 0.5g was homogenized in 9.0 mL of normal saline using pre-chilled mortar and pestle and the supernatant obtained was stored in the refrigerator and used for biochemical analysis following standard procedures within 48 h.

### 2.6. Biochemical analysis

Determination of serum kidney function profiles were done using commercial Teco diagnostic kits for potassium ion, sodium ion, calcium ion, chloride ion, bicarbonate ion and creatinine (Cr) while Randox diagnostic kit was used for the determination of urea. The following standard methods were employed for the assay of biochemical indices. Lipid peroxidation (MDA) was determined according to the method of Gutteridge and Wilkins [18], in a reaction based on the reaction of malondialdehyde (MDA) with thiobabituric acid (TBA) to form a MDA – TBA adduct that absorbs light strongly at 532 nm. Aldehyde oxidase activity was determined by the method of Johns [19] in a reaction based on the oxidation of benzaldehyde to benzoate using 2,6-dichloroindolephenol (DCIP) as the electron acceptor. The activity of the enzyme is given in units per gramme tissue and one unit is the amount of enzyme that produces one micromole of benzoate per minute. Sulphite oxidase activity was determined by the method of Macleod et al. [20] based on the oxidation of sulphite to sulphate by the enzyme using ferricyanide as electron acceptor. The activity of the enzyme was expressed in units per gramme tissue and one unit represents the amount of the enzyme that reduces one micromole of ferricyanide per minute.

**Table 1**  
Nutritional composition of growers mash used.

Crude protein	18.00%
Fats/oil	6.00%
Crude fibre	5.00%
Calcium	1.00%
Available phosphorus	0.04%
Lysine	1.85%
Methione	0.35%
Salt (min)	0.30%
M. Energy (min)	3000 kcal/kg
Net Weight	25 kg

Monoamine oxidase activity was determined by the method of McEwen [21] based on the oxidative deamination of benzylamine to benzaldehyde. The activity of the enzyme is expressed in units per gramme tissue and one unit of the enzyme is defined as the amount of enzyme that is required for the production of one micromole of benzaldehyde per minute. The activity of xanthine oxidase was determined by the method of Stirpe and Della Corte [22] using xanthine as the substrate and oxygen as electron acceptor. The enzyme activity was expressed as units per gramme tissue where each unit is the amount of the enzyme that produces one micromole of uric acid. Ferric-reducing antioxidant power (FRAP) assay was based on the formation of an intense blue colour complex formed when ferric tripyridyltriazine complex is reduced to the ferrous form giving a chromophore that absorbs maximally at 540 nm [23]. The method of Ellman [24] was used for the assay of reduced glutathione while assay for vitamin C employed the method reported by Achuba [25] based on the use of 2,6-dichlorophenol-indophenol (DCIP) and iodine as a titrant. Superoxide dismutase (SOD) activity was determined based on its ability to inhibit the oxidation of epinephrine by superoxide anion. One unit of superoxide dismutase activity is calculated as the amount of enzyme required for 50% inhibition of the oxidation of epinephrine to adrenochrome at 480 nm per min [26]. Catalase activity was determined by the method of Rani et al. [27] based on the fact that catalase breaks down hydrogen peroxide to give oxygen that oxidizes potassium dichromate and the activity was expressed in terms of moles of  $H_2O_2$  consumed/min. The oxidation of chromate gives a chromophore that absorbs maximally at 610 nm. Glutathione-S-transferase activity was assayed spectrophotometrically at 340 nm by measuring the rate of 1-chloro-2, 4-dinitrobenzene conjugation with reduced glutathione as a function of time according to the established method of Habig [28]. The activity of glutathione peroxidase was determined based on the reduction of hydrogen peroxide to the corresponding stable alcohol and water using glutathione as the reducing reagent. The activity was expressed in terms of  $\mu\text{mol}$  of glutathione utilized/minute/mg protein [29].

### 2.7. Histological examination

A known portion of the kidney, of each rat was harvested and fixed in 10% formal saline for 48 h and processed for paraffin wax embedding with an automatic tissue processor by dehydrating through 70%, 90%, 95% and two changes of absolute ethanol for 90 min each. Clearing was achieved through two changes of xylene for 2 h each; and infiltrating with two changes of paraffin wax for 2 h. Sections were cut at  $5\mu\text{m}$  with a rotary microtome. The sections were stained by haematoxylin and eosin (H and E) using the method of Al-Attar et al. [30], examined and photographed using a light microscope.

### 2.8. Statistical analysis

Analysis of data was carried out using the single Factor analysis of Variance (ANOVA) with the aid of the Statistical Package for the Social Sciences version 17 (SPSS 17). Post hoc analysis (comparisons across Groups) was done using Bonferroni at  $P < 0.05$  level of significance.

## 3. Results

As shown in (Table 2), results showed that treatment of rats with  $100\text{ mg kg}^{-1}$  and  $200\text{ mg kg}^{-1}$  body weight of BLME caused a significant ( $P < 0.05$ ) reduction in serum creatinine and compared to normal control rats in group A and rats fed crude petroleum contaminated diets without treatment (group D). Rats fed with crude petroleum contaminated diets and treated with  $100\text{ mg kg}^{-1}$  and  $200\text{ mg kg}^{-1}$  body weight of BLME in groups E and F showed significant decrease in creatinine concentration compared to rats maintained on crude petroleum contaminated diet without any treatment (group D). However, administration of BLME did not significantly

( $P < 0.05$ ) alter urea, sodium ion, potassium ion, calcium ion. chloride ion and bicarbonate ion levels in rats fed with crude petroleum contaminated diet without BLME treatment (group D).

The administration of BLME to rats fed with crude petroleum contaminated diet did not reduce lipid peroxidation in the kidney of rats (Table 3). However, BLME administration enhanced the activities of the oxidase enzymes (AO, SO MO and XO) significantly ( $P < 0.05$ ) across all groups compared to rats in control group (group A) and rats fed with crude petroleum treated diet only (group D).

Treatment of rats with various doses of BLME did not alter the level of glutathione but significantly improved the levels of the other non-enzymatic antioxidants in the kidney of rats fed crude petroleum contaminated diet (Table 4). The ferric reducing antioxidant power (FRAP) and vitamin C in rats fed contaminated diets and treated with  $100\text{ mg kg}^{-1}$  and  $200\text{ mg kg}^{-1}$  (groups E and F) were significantly ( $P < 0.05$ ) higher compared to the untreated rats (group D). The increase in the levels of these antioxidants was more pronounced at  $200\text{ mg kg}^{-1}$  body weight treatment.

Results presented in Table 5 shows the consequence of BLME treatment on the activities of the enzymatic antioxidants: SOD, CAT, GSTs and GPx in rats fed with crude petroleum adulterated diet. The inclusion of crude petroleum in diet caused significant ( $P < 0.05$ ) reductions in the activities of the enzymes in rats fed with adulterated diet without BLME treatment (group D) compared to the activity in control rats (group A) that were given untainted diets. However, treatment with  $100\text{ mg kg}^{-1}$  and  $200\text{ mg kg}^{-1}$  body weight of BLME (groups E and F) improved the activities of the enzymes compared to the activities in normal control (group A). Moreover, administration of  $200\text{ mg kg}^{-1}$  body weight of BLME enhanced the enzyme activities more than  $100\text{ mg kg}^{-1}$  body weight of BLME

The preventive attributes of BLME on the histopathological impact of crude petroleum contaminated diets in the kidney of rats are presented in Fig. 1. There were very clear and visible glomeruli renal tubules and renal arteries in all groups. However, there were observed significantly visible distortions of kidney architecture signaled by early stage of tissue necrosis and inflammation in the kidney of rats in group C which were fed uncontaminated diets but treated with  $200\text{ mg kg}^{-1}$  body weight of BLME. Also rats fed contaminated diets without treatment showed more visible stages of tissue necrosis and blood coagulations while rats in group E had slight visible signs of necrosis, the rats in group F were observed to have a normal kidney without necrosis indicating possible prevention of the necrosis observed in other groups.

## 4. Discussion

The deleterious effects of crude petroleum to the kidney had been well elucidated by earlier studies [8,13]. Likewise, the distortion of metabolic stability through the consumption of petroleum tainted diets has been reported by Okpoghono et al. [10]. This study reports similar dysfunction of the kidney owing to intake of crude petroleum tainted diets evidenced by rising serum creatinine and urea in rats not treated with any dose of the BLME but fed crude petroleum tainted diets (Table 2). Rising serum creatinine and urea is an established indicator of poor glomerular filtration and has been established as a significant clinical marker for kidney dysfunction and loss of kidney integrity [8,31]. The present study, although observed no significant rise in serum sodium ion concentrations, there were significant increases in both serum potassium ion concentration and calcium ion concentration owing to consumption of petroleum tainted diets (Table 2). These results are in agreement with the studies of Orisakwe et al. [15] and Uboh et al. [16]. The observed high levels of calcium and potassium ions have been reported to be linked with the disruption of certain ion pumps and transmembrane ATPases owing to increased lyses within the kidney and the liver [32,33]. The study also observed a reduction of chloride ion concentration in rats owing to crude petroleum contamination of the diets relative to the control was not in agreement with those reported in

the study of Ita and Edagha [34] which reported increased serum chloride ions due to oral consumption of crude petroleum. Although the treatment of rats fed tainted diets indicated observed reduction in the serum calcium, potassium and chloride ion concentration relative to those not treated, it is indicative that the BLME extract had some level of efficacy in balancing the observed distortion in electrolyte derangement.

A significant observation of this study was the ability of the BLME at both doses to reduced serum electrolyte concentrations (Na<sup>+</sup>, K<sup>+</sup>, Ca<sup>+</sup> and HCO<sub>3</sub><sup>-</sup>) relative to the normal control which implies that the BLME may have the capability of improving glomerular filtration even in the absence of toxicants (Table 2). This observation, however is not in agreement with studies done with other plant extracts such as *Aframomum sceptrum* and *Aframomum malagueta* which showed elevation of

serum and renal electrolytes (Na<sup>+</sup>, K<sup>+</sup> and HCO<sub>3</sub><sup>-</sup>) relative to control [31,35]. The renal improvement potential possessed by the BLME in the absence of any toxicant and in the presence of the toxicological effects of crude petroleum tainted diets may have been conferred on the BLME due to its high antioxidant defence capacities as reported by Ijeh and Ejike [11]. They are said to have a rich potential for antioxidants such as flavonoids, alkaloids and polyphenols.

Tissue lipid peroxidation has been identified as one significant marker of oxidative stress status of any organism that has been associated with the deleterious effects of petroleum contamination in plants and animals [36,37]. The process of lipid peroxidation, often times preceded by disruption of the natural antioxidant defence, which in several cases are signalled by the depletion of both enzymatic and non-enzymatic antioxidants [38]. Increase in lipid peroxidation is closely linked with the induction of cytosolic enzymes such as the oxidases (sulphite, aldehyde, xanthine and monoamine) needed for the clearance of increasing sulfoxides, N-oxides, and aromatic nitro compounds and 1,2-benzisoxazole derivatives; that are associated with environmental toxicants [39]. In this study, the administration of BLME to rats fed with crude petroleum tainted diet gave rise to increased lipid peroxidation and the concomitant increase in the activities of oxidative enzymes: sulphite oxidase, aldehyde oxidase, monoamine oxidase and xanthine oxidase relative to control (Table 3). More so, reduction in lipid peroxidation at a dose of 100 mg kg<sup>-1</sup> body weight of BLME and concomitant increase in the activities of oxidative enzymes across the two doses (Table 3) were observed. This may be due to the preventive effects of BLME against crude petroleum nephrotoxicity. Although the administration of BLME at the 200 mg kg<sup>-1</sup> dosage to rats fed tainted diet indicated increased MDA level relative to rats not treated with BLME, this may be indicative of the negative effects of high dose of plant extracts which was submitted by Ogbekwe et al. [31] that when plant extracts are administered in the right dose it will remain effective in conferring protection to tissues in situations of metabolic stress but when administered in the wrong dosage however, it ends up in the continued induction of metabolic stress. The positive effects of BLME observed at the 100 mg Kg<sup>-1</sup> body weight on petroleum tainted diets are similar to those conferred on petroleum induced nephropathy in the study of Achuba and Ogwumu [7]. The BLME which is said to be a rich source of catechin and several polyphenols and essential mineral elements and remains significant in the enhancement of vascular nitric oxides (NO) activity which is significant for the mechanistic control of oxidative stress and several signal transduction pathways [40].

Key: a= Control fed normal diet; b= Normal diet+ 100mg/Kg body weight of BLME; c= Normal diet+ 200mg/Kg body weight of BLME; d = Normal diet+ 4 mL crude petroleum ; e = Normal diet+ 4mL crude petroleum +100mg/Kg body weight of BLME; f = Normal diet+ 4 mL crude petroleum +200mg/Kg body weight of BLME

**Fig. 1.** Effect of Bitter Leaf methanol extracts (BLME) on prevention of renal toxicity induced by crude petroleum contaminated diets (Haematoxylin and eosin X 100).

As regards antioxidant defence, this study indicated a significant ( $P < 0.05$ ) increase in FRAP in rats fed with crude petroleum tainted diets and treated with BLME (Table 4). Also, significant ( $P < 0.05$ ) depletion in GSH relative to normal control and rats not exposed to tainted diets but treated with BLME was also observed (Table 3). Increased FRAP level is a significant indicator of an improved antioxidant capacity and the presence of elements that have the ability to neutralize the negative effects of increasing peroxy and alkoxy radicals which constitute significant reducing agents and oxygen quenchers [41]. GSH on the other hand is an important antioxidant in the scavenging of the reactive oxygen species and peroxides [42,43]. Reduced glutathione (GSH) was significantly depleted in the tissues of rats exposed to crude petroleum tainted diets relative to control but increased relative to the rats fed tainted diets without treatment. This observed trend is in agreement with those reported by Azeez et al. [1], Alisi et al. [44] and Odewabi et al. [45] who used animal models as well as gasoline station attendants exposed to petroleum fumes in their studies. An insight to the justification of increased GSH levels in treated rats relative to untreated rats has been earlier reported in the study of Huang et al. [46] who stated that there is an increase in the levels of tissue glutathione during early stages of tissue regeneration. It is important to note that matured bitter leaf has been reported to have a level of glutamic acid, one of the amino acids essential for the synthesis of glutathione [47,48]. GSH has also been identified as a significant factor in the maintenance of the concentrations of exogenous antioxidants such as vitamins C and E in their reduced (active) forms. This may be a justification for the observed increase in the concentrations of vitamin C in the kidney of rats fed tainted diets and treated with BLME relative to those not treated after been exposed to tainted diets

The results of the enzymatic antioxidants indicated a significant

reduction in the activities of SOD, CAT, GSTs and GPx in untreated rats relative to control, however, the eventual enhancement of these enzymes' activities by BLME in the tissues of rats exposed to petroleum tainted diets and untainted diets relative to the untreated rats gives credence to the antioxidative properties possessed by the bitter leaf (Table 5) and its capabilities to enhance the enzymatic antioxidant defence mechanistic activities as reported by Iwalokun et al. [49]. Also this study recorded the ability of BLME to confer protection on the kidney ultra-structure due to the negative effects of petroleum tainted diets. The consumption of petroleum tainted diets has been previously reported to induce tissue injury by Achuba and Ogwumu [7]; and Okpogho et al. [10]. In line with their studies which utilized palm oil and *Monodora myristica*, the administration of BLME was able to enhance the gradual healing and clearance of the observed tissue necrosis and inflammation in the kidney. This observation is also given credence by the wound healing properties of BLME earlier reported by Kambizi and Afolayin [50]. As presented by the histopathological examination (Fig. 1), rats treated with both doses of BLME were observed to show visible regeneration and clearance of the observed tissue necrosis in rats not treated with BLME

## 5. Conclusions

This study indicated that the consumption of crude petroleum contaminated diets induced kidney damage and consequent malfunction. However, the administration of bitter leaf extract offered defence against the induced negative effects of crude petroleum and ameliorated and restored the lost renal function capabilities by conferring protection on tissue ultra-structure.
