Keywords: crystal structure; 3-methyl-6-propynyloxymethyl-1,4-dioxane-2,5-dione; lactide; synthesis.**CCDC reference:** 1555000**Supporting information:** this article has supporting information at journals.iucr.org/e

The number of known asymmetrically substituted hemilactides, important precursors for obtaining regular derivatives of polylactide polymers, is still limited and structural characterization of most of them is incomplete. In the title racemic 1,4-dioxane-2,5-dione derivative, C₉H₁₀O₅, the hemilactide heterocycle exhibits a twist-boat conformation. The bulkier propynyloxymethyl group is in an axial position with a *gauche* conformation for the CH₂–O–CH₂–C segment. In the crystal, molecules are linked by pairs of C–H···O hydrogen bonds, forming inversion dimers. The dimers are linked by further C–H···O contacts, forming a three-dimensional structure.

1. Chemical context

Cyclic dilactides, or hemilactides, close structural analogs of 1,4-dioxane-2,5-dione (glycolide) with methyl- or methylene-containing substituents at the *sp*³ C atoms, are the most important precursors for obtaining polylactide polymers, which are widely employed in biodegradable plastics and in the food and biomedical industries due to their intrinsic biocompatibility and biodegradability (Gerhardt *et al.*, 2006). Well-tuned architectures of substituted hemilactides lead to the creation of new polylactide materials with regular structures that allow clarification of polymer behaviour at the supramolecular level, as well as achieving new useful properties (Fuoco *et al.*, 2016; Trimaille *et al.*, 2007; Zhang & Song, 2014). Nevertheless, the further development of the field is hampered by the fact that asymmetrically substituted hemilactides still constitute a very limited group of compounds, the structural characterization of most of which remains incomplete. In this context, the goal of the present study was to elaborate a reliable protocol for obtaining 3-methyl-6-[(propynyloxy)methyl]-1,4-dioxane-2,5-dione, **1**.

Figure 1

The atom-numbering diagram of the molecule of **1**. C and O atoms are shown as displacement ellipsoids at the 50% probability level and H atoms are shown as spheres of arbitrary radius.

2. Structural commentary

The molecule of the final product (Fig. 1) possesses a 1,4-dioxane-2,5-dione six-membered ring, as well as the two different substituents, *i.e.* methyl and propynyloxymethyl groups, linked to atoms C1 and C3, respectively, determining the aimed architecture of **1**. In general, the bond lengths and angles are in normal ranges for organic carbohydrates. The hemilactide heterocycle exhibits a twisted boat conformation, where atoms C1, C2 and O1 are in one plane and atoms C1, C3, C4 and O2 are in another plane; the planes are inclined at a dihedral angle of 27.9 (2)°. The values of the observed puckering parameters [$\theta = 84.8$ (3)° and $\varphi = 308.2$ (3)°] deviate slightly from those corresponding to an ideal boat conformation ($\theta = 90^\circ$ and $\varphi = 300^\circ$). Two stereocentres represented by the C1 and C3 atoms have opposite chirality, *i.e.* *R,S* (and *S,R* in the centrosymmetric counterpart), the substituents at which adopt a *trans* configuration with respect to the ring, by minimizing repulsive interactions. The bulkier propynyloxymethyl

Table 1

Hydrogen-bond geometry (Å, °).

$D-H\cdots A$	$D-H$	$H\cdots A$	$D\cdots A$	$D-H\cdots A$
C3—H3 \cdots O4 ⁱ	0.92 (2)	2.60 (2)	3.247 (3)	127.8 (16)
C3—H3 \cdots O5	0.92 (2)	2.49 (2)	3.033 (2)	118.1 (16)
C6—H6B \cdots O3 ⁱⁱ	0.99 (3)	2.47 (2)	3.369 (3)	151.0 (19)
C7—H7A \cdots O3 ⁱⁱⁱ	0.98 (2)	2.66 (2)	3.627 (3)	169.1 (18)
C9—H9 \cdots O4 ^{iv}	0.88 (3)	2.58 (3)	3.412 (3)	156 (2)

Symmetry codes: (i) $-x+1, -y+1, -z+1$; (ii) $-x+2, y-\frac{1}{2}, -z+\frac{1}{2}$; (iii) $x-1, y, z$; (iv) $-x+1, -y, -z+1$.

group is located above the ring, *i.e.* in the axial position with a *gauche* conformation for the C6—O5—C7—C8 segment, at a dihedral angle of 71.3 (2)°. A similar conformation has been observed in *meso*-3,6-dipropargyloxymethyl-1,4-dioxane-2,5-dione (Zhang *et al.*, 2015).

3. Supramolecular features

In the crystal cell of **1** (Fig. 2), all the 1,4-dioxane-2,5-dione rings are located in parallel planes at a distance of approximately 2.0 Å, but do not tend to form molecular stacks and organize the rings neither into columns, as reported for hemilactides bearing relatively small substituents, such as 3,6-dimethyl-1,4-dioxane-2,5-dione (van Hummel *et al.*, 1982) and 3-bromo-3,6-dimethyl-1,4-dioxane-2,5-dione and 3-methylene-6-methyl-1,4-dioxane-2,5-dione (Fiore *et al.*, 2010), nor into supramolecular formations where one half of the parallel plane is perpendicular to the other, as reported in the cases of 3-benzoyloxymethyl-6-methyl-1,4-dioxane-2,5-dione (Kooijman *et al.*, 2005) and 3,6-diphenyl-1,4-dioxane-2,5-dione (Lynch *et al.*, 1990). In addition, the crystal packing shows some short C—H \cdots O contacts (Table 1) leading to the pairwise molecular binding, *i.e.* by hydrogen bonds. It is assumed that the packing is mostly determined by the contact involving the acid acetylenyl H9 and ketone O4 atoms (Fig. 2), analogous to the centrosymmetric interactions reported for symmetric *meso*-3,6-dipropargyloxymethyl-1,4-dioxane-2,5-dione (Zhang *et al.*, 2015). It is worthy of note that the unit cell contains no residual solvent-accessible voids.

Figure 2

A view along the *b* axis of the crystal packing of **1**. Weak C—H \cdots O contacts involving the acetylenyl H and ketone O atoms are shown as dotted lines.

Figure 3
Scheme of the chemical synthesis of the title compound 3-methyl-6-[(propynyloxy)methyl]-1,4-dioxane-2,5-dione (**1**).

4. Database survey

A search in the Cambridge Structural Database (Version 5.38 with two updates; Groom *et al.*, 2016) for pure and functionalized lactides (*i.e.* glycolides with one methyl substituent) returned 25 entries, including different lactide stereoisomers (Kooijman *et al.*, 2014; Fedushkin *et al.*, 2009; van Hummel *et al.*, 1982) and other derivatives (Zhang *et al.*, 2015; Fiore *et al.*, 2010; Kooijman *et al.*, 2005; Bolte *et al.*, 1994; Lynch *et al.*, 1990).

5. Synthesis and crystallization

The desired product **1** was obtained from the initial *rac*-1-chloropropane-2,3-diol (**2**) via a three-step pathway (see Fig. 3) inspired partly by general protocols (Bredikhina *et al.*, 2014; Trimaille *et al.*, 2004; Nagase *et al.*, 2008), comprising the oxidation of **2** to *rac*-3-chloro-2-hydroxypropanoic acid (**3**) followed by the etherification with propargyl alcohol to 2-hydroxy-1-(propynyloxymethyl)propanoic acid (**4**) and the final double esterification of **4** with bromopropionyl bromide. The final purification of **1** was performed by auto-flash-chromatography on silica, using chloroform as eluent to give, after evaporation under reduced pressure, a white crystalline solid (see supporting information for more details on the synthesis and structural characterization of the intermediate and final products).

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. H atoms were located from Fourier difference maps and fully refined.

 Extinction coefficient: 0.0045 (17)

Special details

Experimental. X-ray crystallographic data for I were collected from a single crystal sample, which was mounted on a loop fiber. Data were collected using a Bruker Venture diffractometer equipped with a Photon 100 CMOS Detector, a Helios MX optics and a Kappa goniometer. The crystal-to-detector distance was 4.0 cm, and the data collection was carried out in 1024 x 1024 pixel mode.

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
