**Abstract:** 10-deoxoartemisinin is a semisynthetic derivative of artemisinin that lacks a lactone carbonyl group at the 10-position, and has stronger antimalarial properties than artemisinin. However, 10-deoxoartemisinin has limited utility as a therapeutic agent because of its low solubility and bioavailability. Hydroxylated 10-deoxoartemisinins are a series of properties-improved derivatives. Via microbial transformation, which can hydroxylate 10-deoxoartemisinin at multiple sites, the biotransformation products of 10-deoxoartemisinin have been investigated in this paper. Using ultra-performance liquid chromatography-electrospray ionization-quadrupole time-of-flight mass spectrometry (UPLC-ESI-Q-TOF-MS<sup>E</sup>) combined with UNIFI software, products of microbial transformation of 10-deoxoartemisinin were rapidly and directly analyzed. The hydroxylation abilities of nine microorganisms were compared using this method. All of the microorganisms evaluated were able to hydroxylate 10-deoxoartemisinin, and a total of 35 hydroxylated products were identified. These can be grouped into dihydroxylated 10-deoxoartemisinins, monohydroxylated 10-deoxoartemisinins, hydroxylated dehydrogenated 10-deoxoartemisinins, and hydroxylated hydrogenated 10-deoxoartemisinins. *Cunninghamella echinulata* and *Cunninghamella blakesleeana* are able to hydroxylate 10-deoxoartemisinin, and their biotransformation products are investigated here for the first time. *Cunninghamella elegans* CICC 40250 was shown to most efficiently hydroxylate 10-deoxoartemisinin, and could serve as a model organism for microbial transformation. This method could be used to generate additional hydroxylated 10-deoxoartemisinins for further research.

**Keywords:** 10-deoxoartemisinin; microbial transformation; hydroxylation ability; UPLC-ESI-Q-TOF-MS<sup>E</sup>

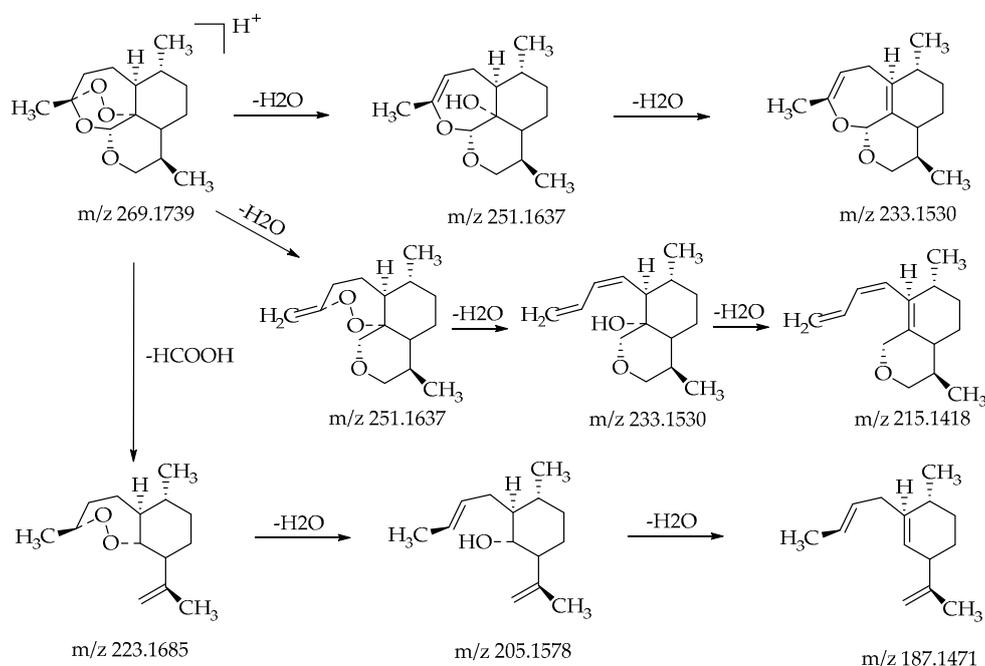

## 1. Introduction

Artemisinin is a first-line antimalarial agent, which is first derived from Chinese herb by Professor Tu [1]. 10-deoxoartemisinin is a bioactive derivative of artemisinin, first prepared by the simple transformation in 1990 [2]. It lacks the C-10 lactone carbonyl group of artemisinin, but retains its antimalarial endoperoxide activity [3]. Compared with artemisinin, the derivate was eight times more active against multidrug-resistant malaria in vitro [2]. However, poor solubility and bioavailability are the barriers for further application in the clinic. Moreover, 10-deoxoartemisinin also has impressive antitumor and antiangiogenesis activities [4–6]. As a part of our ongoing projects [7–10], novel 10-deoxoartemisinin derivatives with improved the properties are attractive to develop for further research. Hydroxylation, as the main modification route, could not only improve chemical properties, but provide candidates of novel drug development.

**Figure 2.** Ultra-performance liquid chromatography-electrospray ionization-quadrupole time-of-flight mass spectrometry (UPLC-ESI-Q-TOF-MS<sup>E</sup>) spectra and fragmentation diagram of 10-deoxoartemisinin.

## 2.2. Identification of Microbial Transformation Products

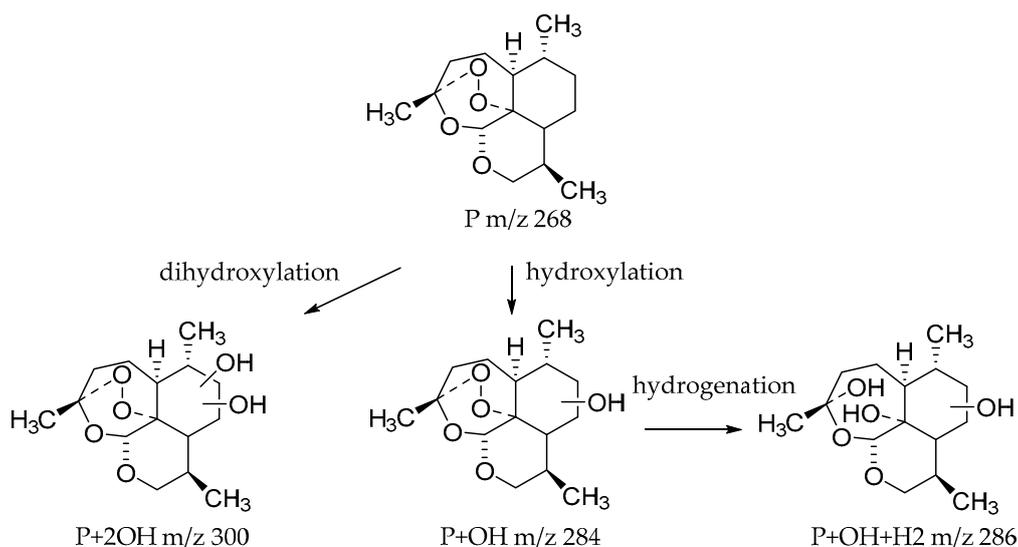

Microbial transformation products were identified using the characteristic mass spectrometric behavior of 10-deoxoartemisinin, including parent ions, internal cleavage of the ion, and retention times. Altogether, 35 transformation products were identified; primarily dihydroxylated 10-deoxoartemisinin, monohydroxylated 10-deoxoartemisinin, hydroxylated dehydrogenated 10-deoxoartemisinin, and hydroxylated hydrogenated 10-deoxoartemisinin. While all strains tested were able to produce hydroxylated 10-deoxoartemisinins, **MT1** produced the most derivatives, with 18 distinct products. The 18 hydroxylated products from **MT1** all had a peroxide bridge. These results demonstrate that **MT1** is an ideal microorganism model to obtain hydroxylated 10-deoxoartemisinin for further research. Meanwhile, the biotransformation products from *Cunninghamella echinulata* and *Cunninghamella blakesleeana* are first to be investigated. The identified microbial transformation products are shown in Table 1, and the structures of predicted transformation products are shown in Figure 4.

Table 1. Cont.

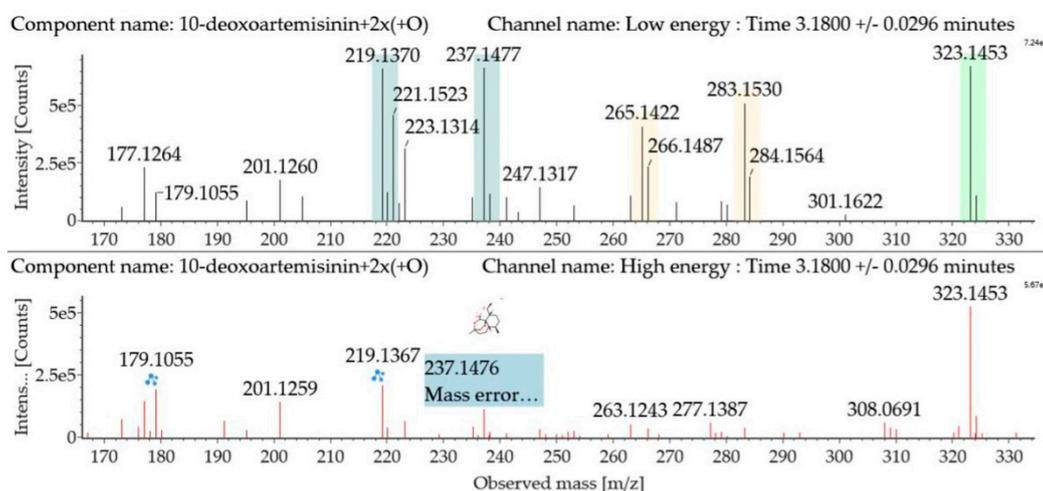

NO.	Component Name	Formula	RT (min)	Major Fragments	MT1	MT2	MT3	MT4	MT5	MT6	MT7	MT8	MT9
31	P+O-2H	C <sub>15</sub> H <sub>22</sub> O <sub>5</sub> + H <sup>+</sup>	4.97	305, 283, 265, 247, 237, 219	+								
32	P+O-2H	C <sub>15</sub> H <sub>22</sub> O <sub>5</sub> + H <sup>+</sup>	4.50	305, 285, 267, 249, 231, 221, 203							+		
33	P+O-2H	C <sub>15</sub> H <sub>22</sub> O <sub>5</sub> + H <sup>+</sup>	4.41	283, 265, 247, 237, 219	+								
34	P+O-2H	C <sub>15</sub> H <sub>22</sub> O <sub>5</sub> + H <sup>+</sup>	4.65	305, 283, 265, 249, 237, 231, 219	+

P represents 10-deoxoartemisinin.

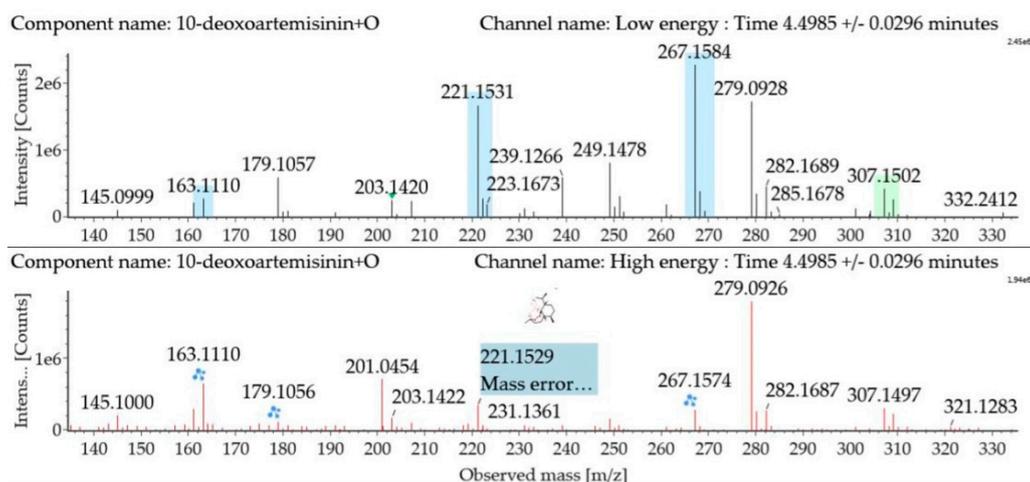

**Figure 4.** Structures of predicted transformation products.

Dihydroxylated 10-deoxoartemisinin transformation products were detected between 2.83 and 4.41 min, and the parent ions were detected at  $m/z$  323 ( $[M + Na]^+$ ) and  $m/z$  301 ( $[M + H]^+$ ). The products were identified by comparing their parent ions to 10-deoxoartemisinin, which showed a series of fragment ions resulting from  $H_2O$  and  $CO$  loss. The dihydroxylated products were more likely to lose two water molecules compared with 10-deoxoartemisinin, and the fragment ions at  $m/z$  265 and 247 were generated by successive water loss from  $m/z$  283. The fragment ion at  $m/z$  237 was generated by  $CO$  loss from  $m/z$  265 or  $HCOOH$  loss from  $m/z$  283. The fragment ion at  $m/z$  219 was generated by water loss from  $m/z$  237. Mass spectra and the fragmentation diagram for dihydroxylated 10-deoxoartemisinin products are shown in Figure 5.

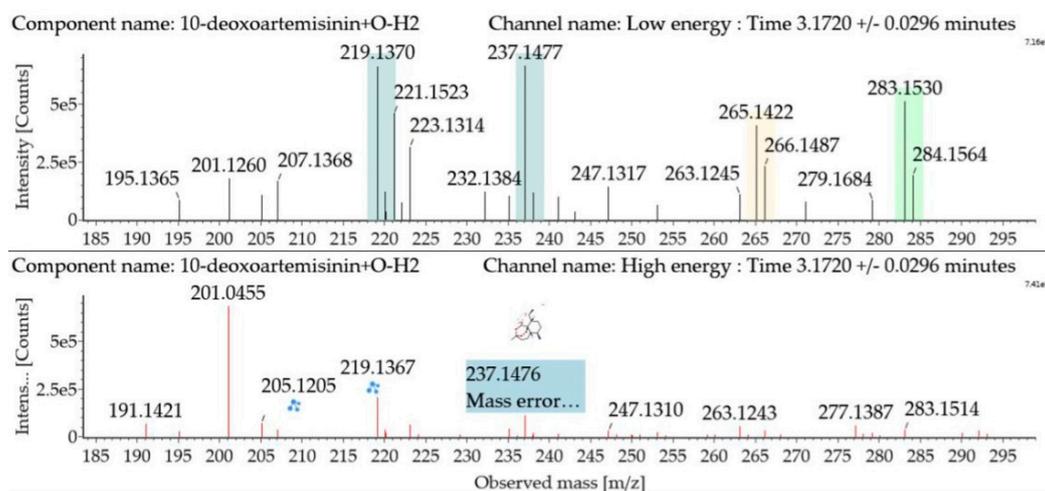

**Figure 5.** UPLC-ESI-Q-TOF-MS<sup>E</sup> spectra and the fragmentation diagram of dihydroxylated 10-deoxoartemisinin.

Monohydroxylated 10-deoxoartemisinin transformation products were detected between 3.14 and 6.91 min. The products were identified by comparing their parent ions to 10-deoxoartemisinin, with a 16 Da mass shift attributed to an oxygen atom. The molecular ion at  $m/z$  307 ( $[M + Na]^+$ ) was observed. The fragment ion at  $m/z$  267 resulted from water loss from  $m/z$  285. The fragment ions at  $m/z$  249 and  $m/z$  231 were generated by water loss from  $m/z$  267 and  $m/z$  249, respectively. The fragment ion at  $m/z$  221 resulted from  $CO$  loss from  $m/z$  249. Mass spectra and the fragmentation diagram for monohydroxylated 10-deoxoartemisinin products are shown in Figure 6.

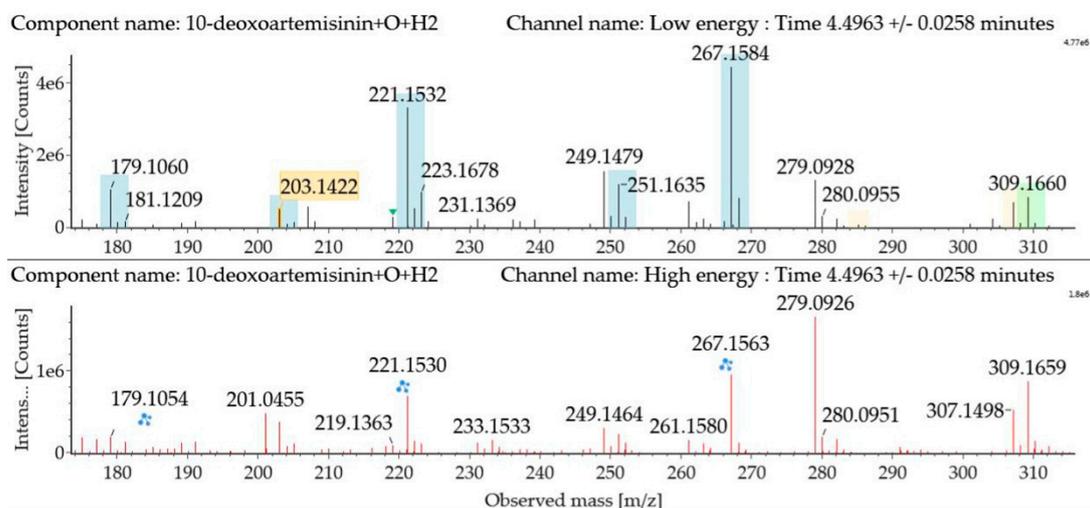

**Figure 6.** UPLC-ESI-Q-TOF-MS<sup>E</sup> spectra and the fragmentation diagram of monohydroxylated 10-deoxoartemisinin.

Hydroxylated dehydrogenated 10-deoxoartemisinin products were detected between 2.83 and 5.57 min. The molecular ion at  $m/z$  283 ( $[M + H]^+$ ) was observed. Consistent with 10-deoxoartemisinin, these products showed a series of fragment ions resulting from the loss of  $H_2O$ ,  $CO$ , or  $HCOOH$ . Mass spectra and the fragmentation diagram for hydroxylated dehydrogenated 10-deoxoartemisinin products are shown in Figure 7.

**Figure 7.** UPLC-ESI-Q-TOF-MS<sup>E</sup> spectra and the fragmentation diagram of hydroxylated dehydrogenated 10-deoxoartemisinin.

Hydroxylated hydrogenated 10-deoxoartemisinin products were detected at about 4.50 min. The fragment ions were similar to monohydroxylation products of 10-deoxoartemisinin. The parent ion was detected at  $m/z$  309 ( $[M + Na]^+$ ). Fragment ions at  $m/z$  249 and 231 were generated by successive water loss from  $m/z$  267. The fragment ion at  $m/z$  221 was generated by  $CO$  loss from  $m/z$  249 or  $HCOOH$  loss from  $m/z$  267. The fragment ion at  $m/z$  203 resulted from water loss from  $m/z$  221. The mass spectra and the fragmentation diagram for hydroxylated hydrogenated 10-deoxoartemisinin products are shown in Figure 8.

**Figure 8.** UPLC-ESI-Q-TOF-MS<sup>E</sup> spectra and the fragmentation diagram of hydroxylated hydrogenated 10-deoxyartemisinin.

### 3. Discussion

Hydroxylation is the main route for molecular modification and also a primary metabolic reaction in vivo involving artemisinin and its derivatives [20,26]. Hydroxylated 10-deoxyartemisinins are a series of products that have a peroxide bridge and may retain antimalarial activity, with better physiological solubility compared with unmodified 10-deoxyartemisinin. Meanwhile, these hydroxylated compounds provide the new reactive site to link another functional group for developing a novel active drug.

Microbial transformation is an increasingly popular method used to modify small molecules, particularly adept at generating hydroxylated derivatives, because many enzymes catalyze hydroxylation reactions, and a variety of microorganisms can be used in this method. The microbial transformation was used in this study to find out novel hydroxylated 10-deoxyartemisinins. The hydroxylation abilities of nine microorganisms from the genera *Cunninghamella* and *Mucor* was evaluated, because previous studies have shown that species in these two genera are rich in hydroxylases [27]. Additionally, *C. elegans*, *C. echinulata*, *C. blakesleeana*, and *M. circinelloides* have been successfully employed to hydroxylate other substrates [28–30]. The hydroxylation ability of these microorganisms was estimated by identifying and comparing their hydroxylation products. A total of 35 hydroxylated products were identified from the nine microorganisms.

Strains **MT1–MT9** produced 18, 1, 4, 15, 1, 9, 14, 7, and 3 distinct hydroxylated 10-deoxyartemisinins, respectively. These hydroxylated 10-deoxyartemisinins were categorized as ehydroxylated 10-deoxyartemisinins, monohydroxylated 10-deoxyartemisinins, hydroxylated dehydrogenated 10-deoxyartemisinins, and hydroxylated hydrogenated 10-deoxyartemisinins. Strains **MT1**, **MT4**, **MT6**, and **MT7** had the best hydroxylation abilities, generating more than ten hydroxylated products each, with products from all four of the above categories. Strains **MT2** and **MT5** showed only weak hydroxylation, producing only one monohydroxylated 10-deoxyartemisinin each. In addition, strains **MT3** and **MT9** only produced monohydroxylated 10-deoxyartemisinins. **MT1** (*C. elegans* CICC 40250) exhibited the best hydroxylation ability, with 18 hydroxylated products identified. **MT1** could serve as a model organism for this process and could also produce novel hydroxylated 10-deoxyartemisinins. Overall, *Cunninghamella* hydroxylates 10-deoxyartemisinin better than *Mucor*.

The rapid and direct analysis method developed in this paper is significant for efficiently screening numerous of Microorganisms transformation. The results could be the guidance for further isolation research to obtain more derivatives. This work is foundational for producing novel, potentially bioactive, hydroxylated 10-deoxyartemisinins.

## 4. Materials and Methods

### 4.1. Materials and Reagents

10-deoxoartemisinin was synthesized from artemisinin, as previously described [2]. *M. circinelloides* CGMCC 3.3421, *M. circinelloides* CGMCC 3.49, *C. blakesleeana* CGMCC 3.910 and 3.5802, *C. echinulata* CGMCC 3.5771, *C. echinulata* 3.4879, and *C. elegans* CGMCC 3.4832 were obtained from the China General Microbiological Culture Collection Center (Beijing, China). *C. elegans* CICC 40250 was obtained from the China Center of Industrial Culture Collection (Beijing, China). *C. elegans* ATCC 9245 was obtained from the American Type Culture Collection (Virginia, United States). Acetonitrile and methanol were purchased from Fisher (Geel, Belgium), and formic acid, EtOAc (ethyl acetate), and other chemicals used in this research were purchased from Beijing Chemical Works (Beijing, China).

### 4.2. Culture and Biotransformation Procedure

Culture and biotransformation experiments were conducted in a medium composed of 20 g Sabouraud Dextrose Broth (Oxoid, Basingstoke, UK), 10 g peptone (Solarbio, Beijing, China), 15 g sucrose (Solarbio, Beijing, China), and 1000 mL deionized water [31,32].

Two-stage fermentation was employed in this study [33,34]. The substrate was dissolved in MeOH at a concentration of 25 mg/mL, and 2 mL of the solution was added into each flask after the second fermentation stage, producing a 10-deoxoartemisinin concentration of 0.5 mg/mL. Cultures were incubated at 28 °C and shaken at 180 rpm for 14 days. Mycelia and broth were then separated by filtration. The filtrate was extracted with EtOAc (1:1, *v/v*) three times, and the extract was evaporated under vacuum to produce a brown residue, which was dissolved in MeOH for LC-MS analysis.

### 4.3. LC-MS<sup>E</sup> Conditions and Data Processing

Mass spectrometry conditions were established in previous studies [32]. The UPLC-ESI-Q-TOF-MS<sup>E</sup> system consisted of a Waters ACQUITY I-class UPLC and Xevo G2-XS Q-TOF Mass Spectrometer (Waters, Manchester, UK). Chromatography was conducted using an Acquity UPLC BEH C<sub>18</sub> (2.1 mm × 100 mm, 1.7 μm (Waters, Manchester, UK)). The mobile phase consisted of solvent A (H<sub>2</sub>O containing 0.1% formic acid, *v/v*) and solvent B (acetonitrile containing 0.1% formic acid, *v/v*). The gradient program included three segments: 5%–100% B from 0 to 15 min; 100%–5% B from 15 to 17 min; followed by a 3 min post-run for column equilibration. The flow rate was 0.4 mL/min, and the temperature was 25 °C throughout the analysis.

The MS was operated in positive ionization mode across a scan range of 50 to 1200 *m/z*. The low collision energy was set at 6 eV, and the high collision energy was ramped from 12 to 25 eV. MS<sup>E</sup> analysis was conducted using multiple reactions monitoring positive-ion electrospray ionization.

All data processing was performed using UNIFI 1.9 (Waters, Manchester, UK). Components were identified using the following 3D peak detection features: Low-energy limits of 150 and high-energy limits of 20, isotope clustering, and high-to-low energy association within a 0.5 fraction of the chromatographic and drift peak width, with a mass accuracy of ± 2 mDa. The maximum number of allowed fragment ions per match was set to 10.

## 5. Conclusions

This research establishes microbial transformation as a method for obtaining various hydroxylated products. Transformation products from nine microorganisms were identified using UPLC-ESI-Q-TOF-MS<sup>E</sup>, and the hydroxylation ability of the nine microorganisms was evaluated. Transformation products of 10-deoxoartemisinin were categorized as hydroxylated 10-deoxoartemisinins, hydroxylated dehydrogenated 10-deoxoartemisinins, and hydroxylated hydrogenated 10-deoxoartemisinins. **MT1** (*C. elegans* CICC 40250) exhibited the best hydroxylation ability among the selected microorganisms, and could be used as a transformation model to prepare

hydroxylated 10-deoxoartemisinins for further research. Additionally, this study was the first to investigate the transformation products of 10-deoxoartemisinin from *C. echinulata* and *C. blakesleeana*.

**Author Contributions:** L.Y. and Y.M. conceived the idea for this project, designed, and conducted experiments. Y.B. collected and analyzed the data and wrote the manuscript with contributions from other authors. D.Z. participated in research design and assisted in the data analysis. Y.Z. and X.C. participated in performing the microbial transformation experiments. P.S. contributed to the writing.

**Funding:** This work was supported by the emergency management program of the National Natural Science Foundation of China (Grant No. 81841001), major science and technology project for ‘Significant New Drugs Creation’ (Grant No. 2017ZX09101002-002), the Fundamental Research Funds for the Central public welfare research institutes (Grant No. ZXKT19023).
