Purpose: Color preferences vary among normal individuals and psychiatric patients, and this might be related to their different levels of hypnotic susceptibility. We hypothesized that individuals with higher hypnotic susceptibility prefer more arousing colors such as red.

Patients and methods: Out of 440 participants, we selected 70 with higher (HIGH) and 66 with lower (LOW) hypnotic susceptibilities, and asked them to undergo the Stanford Hypnotic Susceptibility Scale: Form C (SHSSC) test, then to order their preferences of 11 colors.

Results: The HIGH group preferred red more and scored higher on the total SHSSC. The preference order of black was negatively predicted by the SHSSC Taste hallucination but positively by Arm rigidity, and the preference of yellow was positively predicted by Posthypnotic amnesia and Taste hallucination in the HIGH group.

Conclusion: The red preference and the SHSSC associations with black and yellow preferences in participants with high hypnotic susceptibility help to clarify the individual difference of color preference and provide research hints for behavioral studies in normal individuals and psychiatric patients.

Keywords: color perception, healthy people, the Stanford Hypnotic Susceptibility Scale: Form C (SHSSC)

Introduction

Color is a fundamental aspect of human perceptual experience of external world.¹ Color preference, as a part of many consumer and aesthetic choices in daily lives, is crucial for understanding people's behavior; for instance, it has an effect on judgments and decisions of an individual, such as which clothes to wear or which product to buy.^{2,3} Investigators are trying to figure out colors people preferring and the reasons for doing so. For instance, some scholars have shown that the average color preference followed a relatively smooth and curvilinear function, with a peak at blue and a trough around yellow or yellow-green.³⁻⁷ Other scholars have found a cross-cultural pattern of sex difference on the color preference, eg, men preferred green and women preferred red.^{4,8}

There are also some models which might explain the pattern of color preference. One model is the ecological valence theory,⁵ which describes people like/dislike colors to a degree that is associated with the liked/disliked objects in these respective colors. The association might have an ecological and adaptive function through the individual learning mechanism, which is the repeated pairing of color and particular concepts, messages, and experiences over time.⁹ However, the ecological valence theory is challenged by the results that the color preference varies between different cultures.¹⁰ Some scholars have described different symbolic and conceptual

associations of colors in several cultures.^{7,11} Indeed, when people frequently encounter situations where different colors are accompanied by particular objects or experiences, they would form specific associations to those colors. Therefore, the culture-specific personal experiences would influence his/her color preference.

Further, other factors, such as personality traits, are related to the color preference. Fetterman et al¹² found that people preferring red over blue were more interpersonally hostile, which might be due to that red was linked to anger metaphorically and physiologically. Another study has shown that the connections between color preference and personality traits fit into a social structural layout, for example, males preferred stimulating colors such as yellow in order to elevate their sociability levels.¹³ On the other hand, mental disorders or psychopathological alterations also influence the color preference.¹⁴ For instance, one study has shown psychotic patients preferred green,¹⁵ another has shown patients with mild depression preferred black and brown.¹⁶

Furthermore, the hypnotic susceptibility is a stable ability of responsiveness to suggestions for changes in subjective experience, and for alterations in perception, sensation, emotion, thought, or behavior.^{17,18} High hypnotizables were reported to have increased accessibility to affective events and exaggerated emotional feelings.¹⁹ Considering color preference is determined by the average affective response to everything the individual associates with the color,⁵ it might be influenced by individual hypnotizability. Similar to personality function, which varies from normal to diseased conditions, the hypnotic susceptibility also displays a continuum from low to high states; therefore, different states of hypnosis might be associated with different patterns of color preference. Previous studies have demonstrated that the hypnotic susceptibility is correlated with normal personality traits such as the openness to experience.^{20,21} Interestingly, red as an arousing color^{22,23} is correlated mostly with the trait of thrill and adventure seeking.²⁴ Moreover, higher hypnotic susceptibility has been reported in patients suffering from posttraumatic stress disorder,²⁵ and lower hypnotic susceptibility has been reported in schizophrenia patients,²⁶ who preferred black, red, and white²⁷ or brown.²⁸ These outcomes again imply that color preferences are different in individuals with different hypnotic susceptibilities.

In the current study, we have hypothesized that individuals with higher hypnotic susceptibility prefer more arousing colors such as red than those with lower one do. We therefore have invited participants with either high or low hypnotic susceptibility to undergo hypnosis, and later to undergo

the color preference test. There are many scales assessing hypnotic susceptibility, and in the current study we chose the Stanford Hypnotic Susceptibility Scale: Form C (SHSSC),²⁹ which is one of the most widely used measures of this kind.³⁰ Consistent with previous studies,^{13,31} we chose eleven basic colors, ie, white, gray, black, red, green, blue, yellow, orange, pink, brown, and purple, to measure the color preference of our participants.

Patients and methods

Participants

The first three SHSSC items, ie, the Hand lowering, Moving hands apart, and Mosquito hallucination (see the “Hypnosis test” section), were used for screening participants due to the ascending order of item difficulty and the good predictions of the first three items for the full SHSSC test.³² Those who either had passed two items (high susceptibility) or had failed to pass any item (low susceptibility) were enrolled into the current study, as per the procedure in a previous report.²¹ Altogether 440 participants from university or community were invited, only 136 participants succeeded to be enrolled: 70 were classified into the high hypnotic susceptibility group (HIGH; 27 men, mean age: 21.04 years \pm 1.65 SD, ranged 18–25 years); and 66 into the low hypnotic susceptibility group (LOW; 28 men, mean age: 21.06 \pm 1.62, ranged 18–26). There was no age ($t=0.06$, $df=134$, $p=0.95$) or gender ($\chi^2=0.21$, $p=0.65$) difference between groups. Participation was restricted to individuals with normal color vision as verified on the color vision test. A semi-structured interview was performed for each participant in order to ascertain that they were not suffering or had not suffered from any psychiatric problems, including personality disorder. All participants were naive to the study design and had normal or corrected-to-normal visual acuity. The study has been approved by the Ethics Committee of Zhejiang University College of Medicine, and all participants gave their written informed consents to participate in the study.

Procedures

Hypnosis test

The Chinese version of the SHSSC used previously was applied in the current study.^{21,33} The SHSSC consists of 12 dichotomously scored items including direct ideomotor (eg, arm heaviness), challenge motor (eg, arm immobilization), and cognitive–perceptual (eg, auditory hallucination) suggestions, with scores ranging from 0 to 12. The internal α (reliability) of SHSSC was 0.85 in the current study.

If a participant got one point on an item, we referred to it as “s/he has passed the item,” otherwise as “s/he has failed to pass the item.” We defined “passing rate” of each item as the percentage of participants who had passed that item.

Color preference test

The participant was positioned about 50 cm from the monitor in a dark room with the illumination consisting of the direct, diffused light from 40 W fluorescent lamps. The colors were presented on a computer monitor (1,280×800 pixels, vertical refresh rate, 75 Hz). The background color of the screen was kept constantly in gray (Red: 153; Green: 153; Blue: 153; Hue: 0; Saturation: 0; Brightness: 60). The color was formulated using the Adobe Photoshop CS3 extended edition software (Adobe Systems, San Jose, CA, USA). At the beginning of the experiment, participants were given 3 minutes to adapt to the background color, and 3 minutes later for the 11 target colors presented against the gray background. All target colors (ie, white, gray, black, red, green, blue, yellow, orange, pink, brown, and purple) were displayed as rectangular patches (2.5×2.5 cm² each), and the chromatic scheme values of Red-Green-Blue and of Hue-Saturation-Brightness for these colors were in accordance with the former study.¹³ Each color was presented in one patch for 1 minute in the middle of the screen against a gray background, and the patch presentations were randomized among participants. Then the participants were asked to write down their preference orders of these colors, from 11 to 1, beneath the name of these colors on a piece of paper, with the bigger number representing the more preferred one. There was no time limitation on the response, but participants were asked to select as quickly as possible without cogitation

and particularly without reference to any other color-vectors outside the monitor.

Statistical analyses

The χ^2 test was used to evaluate the differences of SHSSC item passing rates in the LOW and HIGH groups. The differences of the color preference rank orders between the two groups were tested with Mann–Whitney *U* test. The relationships between scores of SHSSC and the preference orders were assessed by multiple linear regression analysis (stepwise method) in a given group. The *p*-value <0.05 was considered to be significant.

Results

The Mann–Whitney *U* test detected significant group differences with regard to the color red ($U=1,572.00$, $p=0.001$), but showed no difference in other colors (Figure 1). The HIGH group preferred Red (7.79 ± 3.14) more than the LOW group (6.08 ± 3.06) did. Not surprisingly, the total SHSSC score in the HIGH group (8.77 ± 0.84) was higher ($t=42.25$, $df=134$, $p<0.05$) than that in the LOW group (2.09 ± 1.00). Comparing the passing rates of SHSSC items, the HIGH group passed all significantly more often than the LOW group did (Table 1).

In HIGH group, the preference order of black was negatively predicted by the SHSSC Taste hallucination (adjusted $R^2=0.12$, $\beta=-0.31$, standard error (SE) =1.06, $p=0.008$, 95% confidence interval (CI) = [-5.02 to -0.80]) and positively by Arm rigidity ($\beta=0.25$, SE =1.20, $p=0.033$, 95% CI = [0.21–5.01]). The preference order of yellow was positively predicted by Posthypnotic amnesia (adjusted $R^2=0.11$, $\beta=0.30$, SE =0.66, $p=0.012$, 95% CI = [0.38–3.00])

Figure 1 Color preference orders in the HIGH (rhombus, $n=70$) and LOW (square, $n=66$) groups.

Notes: * $p<0.05$ vs HIGH group. HIGH group consisted of participants with higher hypnotic susceptibilities; LOW group consisted of participants with lower hypnotic susceptibilities.

Table 1 Distribution of participants who passed the SHSSC test in the two groups of participants

SHSSC item	Number, rate, %		χ^2
	HIGH (n=70)	LOW (n=66)	
Hand lowering	61, 87.1	22, 33.3	41.4
Moving hands apart	65, 92.9	17, 25.8	63.9
Mosquito hallucination	64, 91.4	14, 21.2	68.5
Taste hallucination	62, 88.6	13, 19.7	65.1
Arm rigidity	64, 91.4	15, 22.7	65.9
Dream	42, 60.0	3, 4.5	47.2
Age regression	67, 95.7	36, 54.5	31.3
Arm immobilization	63, 90.0	4, 6.1	95.8
Anosmia to ammonia	37, 52.9	5, 7.6	32.6
Hallucinated voice	21, 30.0	3, 4.5	15.1
Negative visual hallucination	47, 67.1	5, 7.6	51.0
Posthypnotic amnesia	21, 30.0	1, 1.5	20.3

Notes: All *p*-values <0.01 vs LOW group. HIGH group consisted of participants with higher hypnotic susceptibilities; LOW group consisted of participants with lower hypnotic susceptibilities.

Abbreviation: SHSSC, Stanford Hypnotic Susceptibility Scale: Form C.

and Taste hallucination ($\beta=0.27$, SE =0.94, $p=0.023$, 95% CI = [0.32–4.08]). Some colors could be predicted by the SHSSC items, but these associations were not reported here due to their lower determination coefficients (adjusted $R^2<0.10$, Table 2).

Discussion

Compared to the LOW group, the HIGH group preferred red more in our study, which confirmed our hypothesis. The HIGH group also scored higher on the total SHSSC as we expected. However, the weak associations between the preference of red and the SHSSC items offered little explanation for the red preference in the HIGH group. Nonetheless, the preference order of black was negatively predicted by Taste hallucination but positively by Arm rigidity, while the preference order of yellow was positively predicted by Posthypnotic amnesia and Taste hallucination in the HIGH group.

Red is the color of blood and fire, and is considered a signal conveying danger and provoking avoidance,³⁴ which seems to be of particular significance for survival.^{23,35} In competitive contexts, red functions as a dominance cue and might enhance performance accordingly.²² In other circumstances, red is considered as healthy,³⁶ attractive, and sexually desirable.⁹ In these normal situations, red color has a high arousal level which is connected with adventure seeking,^{23,24} this might help to explain our finding of the higher red preference in the HIGH group.²¹ In clinics, the high hypnotizability was correlated with posttraumatic stress disorder³⁷ and dissociative disorder,³⁸ and also children²⁷ and veterans³⁹ with posttraumatic stress disorder consistently preferred the color red.

Some previous studies support the associations between the preference of black and Taste hallucination (–) and Arm rigidity found in the HIGH group. Black is associated with negative concepts such as evil and death, and it was found to have association with aggression;⁴⁰ while Taste hallucination involves experience of sweet and sour tastes and either one strong or one with movements, which demands much devotion and fantasy.^{29,33} Although we failed to record the aggression trait in our participants, the preference of black might reflect that these participants did not comply with the induction of cognitive alteration. Therefore, the preference order of black was negatively predicted by Taste hallucination in the HIGH group. Arm rigidity is a motor challenge item, which requires the participant to imagine her/his arm to be stiff and rigid and thus they cannot overbend it.²⁹ It is an easier one to pass since the individual needs to do nothing during the hypnosis induction,⁴¹ which might particularly be the case in our participants with high hypnotic susceptibility.

In our HIGH group, the associations between the preference of yellow and Posthypnotic amnesia and Taste hallucination were also supported by previous results.

Table 2 Stepwise multiple regression among color preferences and the SHSSC items in the HIGH (n=70) and LOW (n=66) groups

Group	Color preference	SHSSC predictor	Adjusted R ²	β	SE	<i>p</i> -value	95% CI
HIGH	Black	Taste hallucination	0.12	–0.31	1.06	0.008	–5.02 to –0.80
		Arm rigidity		0.25	1.20	0.033	0.21–5.01
HIGH	White	Arm rigidity	0.05	0.24	1.05	0.042	0.08–4.26
HIGH	Brown	Anosmia to ammonia	0.07	0.29	0.54	0.014	0.29–2.46
HIGH	Pink	Posthypnotic amnesia	0.04	–0.24	0.76	0.046	–3.05 to –0.03
HIGH	Yellow	Posthypnotic amnesia	0.11	0.30	0.66	0.012	0.38–3.00
		Taste hallucination		0.27	0.94	0.023	0.32–4.08
HIGH	Purple	Negative visual hallucination	0.07	–0.29	0.64	0.015	–2.87 to –0.32
LOW	Blue	Moving hands apart	0.06	0.28	0.79	0.025	0.24–3.41

Notes: HIGH group consisted of participants with higher hypnotic susceptibilities; LOW group consisted of participants with lower hypnotic susceptibilities.

Abbreviations: CI, confidence interval; SE, standard error of the mean; SHSSC, Stanford Hypnotic Susceptibility Scale: Form C.

Posthypnotic amnesia examines if one can recall three or fewer items from before the instruction of memory-retrieving was given after the hypnosis test.²⁹ It was positively associated with extroversion trait and negatively with openness to experience.²¹ Extroverts preferred yellow since they considered the color exciting.⁴² Similarly, sociability trait was negatively associated with the preference of yellow in males.¹³ The Posthypnotic amnesia score was found positively associated with scores on schizoid personality disorder,³³ and individuals with this disorder are characterized by unsocial and introverted features.⁴³ Moreover, during an electroencephalogram test, the extraverts followed the test instructor with less attention;⁴⁴ the ignoring of the instruction details might facilitate the participants to pass the Taste hallucination test in our HIGH group.

Conclusion

However, there are several design limitations of the current study which should be noted. First, we conducted a rank-ordering task to evaluate color preferences, and this might suffer from the ceiling effect since most favorite colors, such as blue and green, are highly preferred ones. Second, we did not record either normal or disordered personalities of our participants, and so whether these traits influence our current results remains unclear. Third, the majority of our participants were university students, and so the current study results cannot be directly generalized to other age ranges. Fourth, all participants were Chinese and the sample sizes for each group were small; thus, whether our findings are unique to Chinese culture remains unanswered. Nevertheless, we have demonstrated that individuals with higher hypnotic susceptibility preferred red more and some of their hypnotic aspects contributed to their preferences of black and yellow. Our study might open new ways to evaluate the characteristics of individuals who are hypnotized, to identify other elements that influence the color preference, and to provide hints for using color arrangements to help the application of cognitive-behavioral therapy to different psychiatric patients with different levels of hypnotic susceptibility.
