Previous studies reported on the association between physical activity (PA) and cardiovascular diseases (CVD<sub>s</sub>) among the Western population. However, evidence on the association between different patterns of PA and the risk of CVD<sub>s</sub> among Chinese population are limited. This study aims to evaluate the association of different PA types and the risk of CVD<sub>s</sub> in a Chinese adult population. A total of 3568 community residents were recruited from Jiangsu Province of China using a stratified multistage cluster sampling method. The latent class analysis method was employed to identify the types of PA, and the Framingham risk score (FRS) was used to estimate the risk of CVD<sub>s</sub> within 10 years. Three types of PA were identified: CLASS1 represented participants with high occupational PA and low sedentary PA (32.1% of male, 26.5% of female), CLASS2 represented those engaging in low occupational PA and high leisure-time PA (27.0% of male, 14.2% of female), and CLASS3 represented low leisure-time and high sedentary PA (40.9% of male, 59.3% of female). The average of FRS in males was higher than that in females across PA types. CLASS1 (OR = 0.694, 95%CI 0.553–0.869) and CLASS2 (OR = 0.748, 95%CI 0.573–0.976) were both found to be protective against CVD<sub>s</sub> in males; however, such associations were not statistically significant among females. Therefore, higher occupational or leisure-time PA appear to be associated with decreased risk of CVD<sub>s</sub>, while more sedentary behaviors may increase the risk of CVD<sub>s</sub>, particularly for male Chinese adults.

### Abbreviations

Increasing in the number of the aging population and the acceleration of urbanization have significantly increased the prevalence of cardiovascular diseases (CVDs), including coronary heart disease, cerebrovascular disease, rheumatic heart disease, and other conditions<sup>1</sup>. According to the *National Report on Cardiovascular Diseases (2018)* in China<sup>2</sup>, the number of patients with CVDs in China have reached 290 million. The main causes of CVDs are unhealthy lifestyle behavior and reduced physical activity<sup>3</sup>. Previous studies revealed that regular physical activity (PA) was critical in preventing chronic diseases, including CVDs<sup>4,5</sup>. Bennett et al. proposed that PA can be categorized as occupational, commuting, household, and recreational<sup>6</sup>. *The Global Burden of Diseases Report* estimated that low levels of PA accounted for 1.26 million premature deaths and 2.37 million disability-adjusted life-years worldwide in 2017<sup>7</sup>. Meanwhile, high levels of either occupational or leisure-time PA have been found to be associated with a lower risk of CVDs in high-income countries<sup>8</sup>. However, the association between different types of PA and the risk of CVDs among different subgroups of the population in China, so far, have been rarely reported<sup>6,9</sup>.

Latent class analysis (LCA) uses the latent class model (LCM) to explain the relationship between explicit class variables with intrinsic latent class variables<sup>10</sup>. LCA can identify subgroups of people who share common characteristics so that people within the subgroups have a similar scoring pattern on the measured variable, while the difference in scoring patterns between subgroups is as distinctly different as possible<sup>11</sup>. LCA analysis uses a mixture of distributions to identify the most likely model describing the heterogeneity of data as a finite number of classes (subgroups), also known as finite mixture models<sup>12</sup>. LCA was used for modelling the “lifestyle” variable in Miranda’s study to assess the lifestyle of female adolescents based on measurements of behavioral variables<sup>13</sup>. Moreover, in two community samples in Breslau, LCA aimed to empirically examine the structure underlying post-traumatic stress disorder (PTSD) criteria symptoms and identify discrete classes with similar symptom profiles<sup>14</sup>. Similar attempts have also been made in a cohort study, which used data during 2003–2008 from the National Violent Death Reporting System, and included 28,703 suicide decedents from 12 US states<sup>15</sup>. In the present study, we used LCA to estimate the latent PA types of adult residents in Jiangsu province of China and explored the associations of different latent PA types with CVDs risk.

## Materials and methods

**Participants.** A multistage stratified cluster sampling method was employed to select participants. Within the seven counties (in rural areas) or districts (in urban areas) of the *Chinese National Disease Surveillance System for Chronic Diseases and Risk Factors* in northern and middle areas of Jiangsu Province of China<sup>16</sup>, five towns /streets were randomly selected from each county/district. Then, two villages/communities were randomly selected from each town/street, followed by sixty households being randomly selected from each village/community. Finally, using the KISH table method, one adult resident aged 18 years or above was selected from each household<sup>17</sup>.

4200 individuals were recruited for participation. We excluded 574 participants whose age did not meet the Framingham Scoring criteria (i.e., 30–74 years old)<sup>18</sup>, 52 participants who had pre-existing CVDs, cancer or other severe comorbidities, and 6 participants who did not have complete laboratory data. Finally, a number of 3568 participants were included in this study.

**Questionnaire survey.** A standard questionnaire which designed based on the *Questionnaire for the Chinese Chronic Non-communicable Disease and Risk Factor Surveillance (2010)*<sup>16</sup> was used to collect information on demographic information (i.e., residence, gender, age, educational level, marital status), behavioral factors (i.e., tobacco smoking, alcohol drinking, physical activity and daily sedentary behaviors), and health condition (i.e., hypertension, diabetes, and dyslipidemia). All surveys were conducted face-to-face by interviewers, who had received proper training and passed relevant assessment. The *Global Physical Activity Questionnaire (GPAQ)*<sup>19</sup> was used to assess the frequency and duration of several components of PA in different components, including: (1) occupational, agriculture, and housework activity; (2) commuting related physical activity; (3) leisure-time physical activity; (4) sedentary behaviors. Levels of agreement with objective measurements indicated that the GPAQ was a valid measure of moderate-to-vigorous physical activities<sup>20</sup>.

**Anthropometric measurements.** Height, body weight, waist circumference, and blood pressure were measured by anthropometric investigators using unified brands and models instruments. All investigators successfully completed a training program that introduced them with the specific tools and methods used in this study, as well as with the aims of this study. Briefly speaking, height was measured by a height meter with a maximum range of 2.0 m and a minimum scale of 0.1 cm. The body weight was measured by an electronic scale with a maximum range of 150 kg and an accuracy of 0.1 kg. The waist circumference was measured by a leather tape, which was measured at the midpoint between the lowest rib margin and the lower 12th costal margin. Blood pressure was measured 3 times using an automated device (OMRON HEM-7207)<sup>21</sup> at the left-arm according to

the standard measuring protocol. All sphygmomanometers were calibrated by the manufacturer and checked by the national quality assurance team department. The mean value of the three measurements was used as the final blood pressure values. Details of the anthropometric measurements had been documented elsewhere<sup>22</sup>.

**Blood sample collection and laboratory tests.** A volume of 4–5 ml venous blood sample was collected in a vacuum tube containing sodium fluoride in the morning, after overnight fasting of at least 10 h. Fasting plasma glucose (FPG) was measured by glucose oxidase or hexokinase methods within 12 h after collecting in an accredited laboratory. Serum total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and triglycerides (TG) were measured using auto-analyzers (Abbott Laboratories) in Jiangsu Province Center for Disease Control and Prevention, which was certificated by The National Laboratory Certification of China.

**Measurement of the risk of CVD<sub>s</sub>.** In this study, we used the Framingham Risk Score (FRS) to estimate a person's chance of developing a CVD<sub>s</sub> event in the next ten years. The FRS, expressed as a percentage, was calculated based on the prediction equation known as the “Framingham Risk Equation”, which consisted of age, TC, HDL-C, SBP, treatment for hypertension, smoking status, and diabetic status<sup>18</sup>. The risk of CVD<sub>s</sub> was categorized as: “low” if the FRS ≤ 10%; “intermediate” if the FRS was between 11 and 20%; “high” if the FRS > 20%<sup>23</sup>.

**Classification of physical activity.** In this study, the PA of participants was classified using the LCA, an analysis method established on the basis of probability distribution and a log-linear model. It can make up for the traditional statistical methods that only focus on a single variable and play a role of considering the comprehensive effect of multiple factors. The model of LCA was judged using the following test standards<sup>24</sup>: (1) Akaike information criterion (AIC), Bayesian information criterion (BIC), and adjusted Bayesian information criterion (aBIC). The smaller the three indexes, the better the model fitting effect could be; (2) Entropy, the larger the value, the higher the accuracy of the classification could be; (3) In combination with the adjusted Lo-Mendell-Rubin likelihood ratio test (LMR) and the bootstrap-based likelihood ratio test (BLRT), the model of K categories was significantly better than the model of K-1 categories, while it indicates  $P < 0.05$  of these indicators. The best classification was determined by considering all above indicators and relevant professional knowledge was used for the interpretation of results.

**Definitions of other involved variables.** Body mass index ( $\text{kg}/\text{m}^2$ ) was calculated as weight divided by height squared. Participants were categorized as: underweight ( $\text{BMI} < 18.5 \text{ kg}/\text{m}^2$ ), normal ( $18.50 \leq \text{BMI} < 24.00 \text{ kg}/\text{m}^2$ ), overweight ( $24.00 \leq \text{BMI} < 28.00 \text{ kg}/\text{m}^2$ ), and obese ( $\text{BMI} \geq 28.00 \text{ kg}/\text{m}^2$ ) according to the standard made by the working group on obesity in China for Chinese population<sup>25</sup>. Central obesity was defined as: males with a waist circumference  $\geq 90 \text{ cm}$  or females with a waist circumference  $\geq 85 \text{ cm}$ <sup>26</sup>.

Hypertension was defined as having a self-report history of hypertension, receiving BP-lowering treatment, or having an average measured systolic BP of at least 140 mmHg or a diastolic BP of at least 90 mmHg (or both) during the study period<sup>27</sup>.

Diabetes mellitus was defined as  $\text{FPG} \geq 7.0 \text{ mmol}/\text{L}$ , or 2-h OGTT  $\geq 11.11 \text{ mmol}/\text{L}$ , or having a self-report history of diabetes, or taking hypoglycemic drugs during the study period<sup>28</sup>. Dyslipidemia was defined as  $\text{TC} \geq 6.22 \text{ mmol}/\text{L}$ , and/or  $\text{TG} \geq 2.26 \text{ mmol}/\text{L}$ , and/or  $\text{LDL-C} \geq 4.14 \text{ mmol}/\text{L}$ , and/or  $\text{HDL-C} \leq 1.04 \text{ mmol}/\text{L}$ <sup>29</sup>.

Current smoking was defined as having smoked at least 100 cigarettes, or equivalent other tobacco products in one's lifetime, and currently smoking cigarettes. Drinking alcohol more than once per month over the past 12 months prior to the interview was defined as current drinking<sup>16</sup>.

**Statistical analysis.** General descriptive analysis and  $\chi^2$  test were used to compare the potential differences of categorical variable among groups. The effects of different PA types on the risk of CVD<sub>s</sub> were analyzed by ordinal logistic regression. Given that age, blood pressure, smoking status, and other factors have been included in the calculation of the FRS, these variables were not adjusted in the ordinal logistic regression analysis. A two-side  $P$ -value  $< 0.05$  was considered statistically significant. All these analyses were performed using SPSS statistical software (v23.0), while the MPLUS statistical software (v8.0) was used to analyze the potential categories of PA (Latent Classes).

**Ethics approval and consent to participate.** Informed written consent was obtained from all participants. The procedures were in accordance with the standards of the ethics committee of Jiangsu Provincial Center for Disease Control and Prevention and with the Declaration of Helsinki (1975, revised 2013). This study protocol was approved by the ethical review committee at the Jiangsu Province Center for Disease Control and Prevention (the committee's reference number: **SL2017-B002-01**). Individual person's data have not been contained in any form (including any individual details, images, or videos) in this manuscript.

## Results

**Characteristics of participants.** Of the 3568 participants (men, 43.0%), the average age was 52.04 years ( $\text{SD} = 11.08$ ). Compared with females, males had a higher percentage of higher education or having a job. Males were more likely to be smokers, to consume alcohol, or to have hypertension, whilst females were more likely to have central obesity or dyslipidemia (Table 1).

**Table 1.** Characteristics of participants by gender.

**Identification of PA types using LCA method.** In the LCA of PA, 10 variables were included in the GPAQ, including high occupational PA, medium–low occupational PA, commuting PA, high leisure-time PA, medium–low leisure time PA, sedentary PA, TV PA, computer PA, reading PA, and sleeping PA. Five latent class models were fitted for both men and women (Table 2). As was shown in Table 2, with the increase in model categories, Log-likelihood (Log (L)), AIC, BIC, and aBIC decreased. In males, BIC value of 3 category model reached the minimum and *P*-value for the LMR was 0.004, however fitting four category model, *P*-value for the LMR was 0.680. Therefore the three category model had the best fitting degree. Similarly, in females the three category model had the best fitting degree. According to the results of the conditional probability distribution of each item in three categories of each gender (Fig. 1), the performance of Latent CLASS1 was high occupational PA, low sedentary PA; the performance of Latent CLASS2 was low occupational and high leisure-time PA; the performance of Latent CLASS3 was low leisure-time PA, high sedentary PA. There were 492 (32.1%), 414 (27.0%) and 628 (40.9%) male participants in these three classifications, respectively, while there were 539 (26.5%), 288 (14.2%) and 1207 (59.3%) female participants, respectively.

**Comparison of the characteristics in different Latent Classes of PA.** The baseline characteristics of participants were given by classifications in Tables 3 and 4. There were significant differences in age, education status, marital status, BMI, work status, sleep duration, smoking status, low HDL-C, high TG, hypertension, hyperglycemia and central obesity among the three Latent classes of male PA (*P*<0.05). There were significant differences in age, education status, marital status, BMI, work status, sleep duration, alcohol consumption, high TG, low HDL-C, Hypertension, and Central obesity among the three Latent classes of female PA (*P*<0.01).

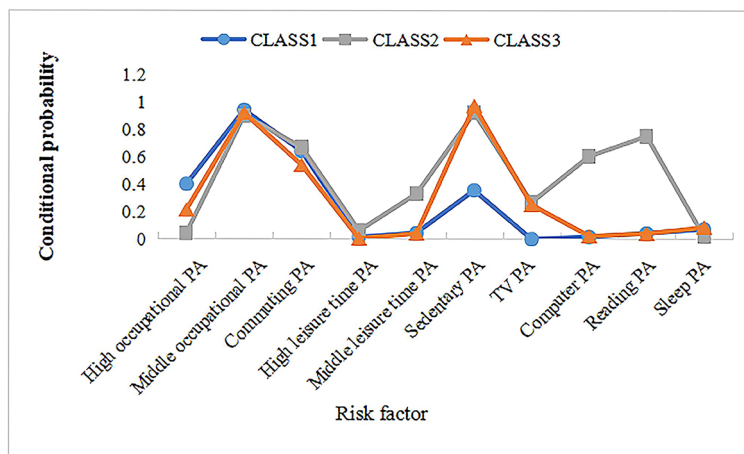

**Relationships between PA types and the risk of CVD<sub>5</sub>.** Comparison analysis among the three PA types in males revealed significant differences in their 10-year FRS. As shown in Table 5, the FRSs of males

were higher than that of females. Among males, the FRS for CLASS1 and CLASS2 were lower than that of CLASS3, which had the largest number of participants. CLASS1 (OR=0.654, 95%CI 0.526–0.813) and CLASS2 (OR=0.544, 95%CI 0.432–0.685) were found to be protective against the risk of CVD<sub>s</sub> compared to CLASS3. After adjusting for potential confounding factors, the relationship between CLASS 1 (OR=0.694, 95%CI 0.553–0.869) and CLASS 2 (OR=0.748, 95%CI 0.573–0.976) and the risk CVD<sub>s</sub> was slightly attenuated but remained

**Table 3.** Comparison of characteristics among different potential categories of PA for males.

statistically significant. Among females, CLASS2 was inversely correlated with CVD<sub>s</sub> (OR = 0.451, 95%CI 0.316–0.643), but such association disappeared after adjusted for potential confounders.

## Discussion

The China Kadoorie Biobank (CKB) study<sup>30</sup> reported that total levels of PA was strongly, and inversely, associated with CVD<sub>s</sub>-related mortality in Chinese population<sup>31</sup>. Like in many other developed countries, the standard of living in China greatly improved, leading to drastic lifestyle changes, for example, transferring from a labor-intensive lifestyle to a sedentary lifestyle<sup>3</sup>. A prospective cohort study of 487,334 subjects conducted by Bennett et al<sup>6</sup> in 10 regions of China showed that higher occupational or non-occupational PA was significantly associated with a lower risk of major CVD<sub>s</sub> events among Chinese adults. In this study, we classified PA in three groups (Latent Classes), i.e., CLASS1 (high occupational and low sedentary PA), CLASS2 (low occupational and high leisure-time PA), and CLASS3 (low leisure-time and high sedentary PA). Several previous LCA studies provided limited and inconsistent findings in different fields, such as sociology, biology, medicine, and psychology<sup>32</sup>. To the best of our knowledge, this is among the first studies to explore the associations between CVD<sub>s</sub> and PA types using LCA among Chinese adults with representative data.

**Table 5.** FRS among different PA types and associations of PA types and the risk of CVDs. \*Adjusted for education, work, drinking, BMI, dyslipidemia, central obesity, and overweight/obesity; <sup>#</sup>median (25th percentile, 75th percentile).

This study found that CLASS3 accounted for a big proportion in the three categories of PA (40.9% of males and 59.3% of females). CLASS3 was manifested as high sedentary and low leisure-time activity behavior. A previous survey of nine provinces in China from 1991 to 2011<sup>33</sup> found that for both adult men and women in China, occupational and domestic PA were the largest contributors to the total PA; meanwhile, this study also revealed that the overall PA of community residents significantly declined in the two decades, and active leisure and travel PA were fairly low. Some studies have shown that the occupational PA, rather than the leisure PA, is the main source for total daily PA<sup>34,35</sup>. Inadequate total daily PA has become one of the major risk factors for China's CVD<sub>s</sub> death and disease burden<sup>36</sup>. Similarly, physical inactivity and obesity are the biggest public health threats, with 53.5% of adults being physically inactive in Canada<sup>37</sup>. Sedentary PA is also a threat to Americans' physical health, which is why the *2018 Physical Activity Guidelines for Americans, 2nd* edition highlights the shift from sitting time to being more active, ideally by doing moderate- or vigorous-intensity physical activity<sup>38</sup>.

This study explored the relationship of 10-year risk of CVD<sub>s</sub> predicted by the Framingham risk scoring system with three types of PA. The current data demonstrated that the 10-year risk of CVD<sub>s</sub> incidence was higher in males compared to females in across the three categories. Previous studies indicated that males had a higher risk to have CVD<sub>s</sub> events, which may be related to differences in exposure levels, sensitivities of risk factors for CVD<sub>s</sub> between genders, and sex hormone differences<sup>39,40</sup>. In this study, CLASS3 was associated with higher CVD<sub>s</sub> risk in both genders compared to CLASS1 and CLASS2. The CLASS1 (OR = 0.694, 95%CI 0.553–0.869) and CLASS2 (OR = 0.748, 95%CI 0.573–0.976) were found to be related to lower risk of CVD<sub>s</sub> with 10-year. These results were consistent with previous studies<sup>8,41</sup>. As a result, the 2018 PA guidelines for Americans<sup>38</sup> emphasize that increasing PA and reducing sedentary time are appropriate for all populations and that even a little increase in PA can bring health benefits. In addition, the American college of sports medicine (ACSM)<sup>42</sup> suggest that regular PA (for example, exercise, cycling) may reduce insulin levels and renal sympathetic nerve tension by sodium retention and foundation, vasodilator substances by skeletal muscle release cycle, and improve blood pressure, blood lipid, blood glucose and other risk factors of CVD<sub>s</sub><sup>43</sup>.

The LCA method takes into account the comprehensive effect of multiple factors. It can reveal the characteristics of various groups of people and provide a scientific basis for the designation of targeted intervention and prevention measures. However, several limitations of the study should be considered. First of all, the LCA takes the qualitative data into consideration instead of the comprehensive analysis of its frequency and duration. Second, in this study, a questionnaire survey was used to collect physical activity information, rather than using objective measurements (e.g., pedometers to calculate the exact daily steps), which may lead to recall bias. Nevertheless, the use of a tool with proven validity and reliability, i.e., the GPAQ, together with adequate staff training, can minimize such bias. Third, the FRS was used to estimate the 10-year CVD<sub>s</sub> risk in this study, which may has neglected important information on the possible effects of ethnicity on the findings. As this was a cross-sectional study, the causal relationship between PA and the risk of CVD<sub>s</sub> could be hardly established. Consequently, further longitudinal research with robust design is warranted to test this relationship.

To summarize, results from this study revealed potential associations between CVD<sub>s</sub> and PA types among Chinese adults. Lower occupational and leisure-time PA and higher sedentary PA were associated with increased risk of CVD<sub>s</sub>. Accordingly, we suggest relevant sectors in China to strengthen evidence-based interventions in order to increase the levels of PA of people and reduce the time of sedentary behaviors. Findings from this study can be used to advance public health, particularly in the management of public policies that promote PA and bring more health benefits.

## Acknowledgements

We would like to thank the investigators from the ten investigation areas (Yulong District in Xuzhou, Donghai County in Lianyungang, Sucheng District in Suqian, Hongze County in Huaian, Xiangshui County in Yancheng, Hanjiang District in Yangzhou, Rugao County in Nantong, Jiangyan County in Taizhou, Pukou District in Nanjing and Runzhou District in Zhengjiang) for all their work and support. We also thank Professor Zhang

Yongqing (Jiangsu Center for Disease Control and Prevention) and Professor Ling Ping (Jiangsu Center for Disease Control and Prevention) for providing constructive suggestion.

### Author contributions

Q.X., Z.Z., C.C., Y.Q., Z.W. conceptualized study concept and design; C.C., J.L., S.L., G.D., J.W., Q.X. collected the data; C.C., J.L., S.L., G.D., J.W., Y.Q., Q.X., X.W. analyze and interpret data; C.C., J.L., S.L., Y.Q., X.W., Q.X. drafted the manuscript; C.C., J.L., S.L., Y.Q., Q.X. revised the manuscript that had important intellectual content; C.C., J.L., S.L., Y.Q., G.D., J. Wang conducted statistical analysis; Q.X. obtained funding; S.L., Y.Q., X.W., Z.Z., C.C. provided technical, or material support; Q.X. studied supervision. All authors reviewed the manuscript.

### Funding

This work was supported by the Natural Science Foundations of China (81973005) and the Natural Science Foundation of Jiangsu Province (BK20151593).

### Competing interests

The authors declare no competing interests.
