A one-pot cyanation of 2,4-arylquinazoline with NIS and malononitrile has been developed. The one-pot reaction includes two steps. The Rh-catalyzed selective C–H activation/iodization of 2,4-diarylquinazoline with NIS, and then Cu-catalyzed cyanation of the corresponding iodinated intermediate with malononitrile to selectively give 2-(2-cyanoaryl)-4-arylquinazolines or 2-(2,6-dicyanoaryl)-4-arylquinazolines in good to excellent yields.

Introduction

Aromatic nitriles have broad applications in agrochemicals, pharmaceuticals and materials science. The nitrile moiety also serves as a pivotal precursor for a multitude of conversions into a great number of other functional groups, such as hydrolysis into carboxyl or amide, reduction into aldehydes or amines, cycloaddition into heterocycles, *etc.*[1] Consequently, a number of methods have been developed to introduce a cyanogen group to an aromatic ring. Various catalytic systems and cyanating agents have been established. Of these transformations, transition-metal-catalyzed cyanation of aryl halides[2a] or aromatic C–H bond activation/cyanation was an elegant route to arylnitriles.[2b] $Cu(CN)_2$,[3] $Zn(CN)_2$,[4] NaCN and KCN,[5] CuSCN,[6] cyanogen halides,[7] TMSCN,[8] NaN_3,[9] and $K_4[Fe(CN)_6]$[10] have been used as cyanation agents to introduce CN into organic molecules. Organic cyanide sources and their combined cyano-groups, such as CH_3NO_2,[11] acetone cyanohydrin,[12] *N*-cyano-*N*-phenyl-*p*-toluenesulfonamide (NCTS),[13] aryl(cyano)iodonium triflates,[14] amine/DMSO,[15] DMF,[16] formamide,[16f,16g] ethyl cyanoacetate,[17] ethyl(ethoxymethylene)cyanoacetate,[18] benzyl cyanide,[19] *tert*-butyl nitrite (TBN),[20] isocyanides,[21] and acetonitrile[22] have been used in cyanation for more solubility in organic solvents.

Recent, malononitrile, being more inexpensive, readily industry available, less toxic, stable and easy-to-handle, had been used as an alternative organic cyano-group source.[23] Although attempts have been made to utilize malononitrile as the cyano-group source in several aryl halogens cyanation reactions (Scheme 1a),[23] there is no report about utilizing it as

a cyano-group source in one-pot C–H bond activation/cyanation.

On the other hand, quinazoline core structure exhibits a wide range of important potential biological activities.[24,25] For example, Erlotinib and Gefitinib are well-known lung cancer drugs.[26] Prazosin is used for curing high blood pressure[27] and Trimetrexate has been used in the treatment of pneumocystis pneumonia[28] (Fig. 1). Thus tremendous efforts have been devoted to develop new synthetic methods for the construction of diverse quinazoline architectures and evaluate their bioactivities.[29] In the past few years, our group has focused extensively on the development methods for the synthesis of quinazoline skeletons and the late-stage functionalization of the quinazoline core with a wish to construct a quinazoline-based molecular library for bioactivity assay.[30]

However, the construction of quinazoline core coupling-nitrile moiety had been rarely reported. In 2013, we reported palladium catalyzed cyanation of quinazoline-4-tosylates with CuCN for access to quinazoline-4-nitriles (Scheme 1b).[31] In 2017, we disclosed quinazoline-directed selective *ortho*-iodination of 2,4-diarylquinazolines for the synthesis of 2-(2-iodoaryl)-4-arylquinazolines (Scheme 1c).[32] Very recently, iodination of 2,4-diarylquinazoline with NIS catalyzed by rhodium, and then trifluoromethylthiolation of the corresponding iodides for the synthesis of SCF_3-substituted 2,4-diarylquinazolines was reported in our group (Scheme 1d).[33] Base on these, we here reported selective synthesis of 2-(2-cyanophenyl)-4-phenylquinazolines and 2-(2,4-dicyanophenyl)-4-phenylquinazolines by one-pot C–H activation iodination/cyanation using malononitrile as a cyano-group source (Scheme 1e).

Results and discussion

Our interest in this particular on the regioselective C–H activation/cyanation of 2,4-diarylquinazolines originated from our recent studies that $[RhCp^*Cl_2]_2/AgSbF_6$ catalyzed iodination of 2,4-arylquinazoline.[33] Here, we first optimize the reaction conditions of one-pot C–H iodination/cyanation of 2,4-phenylquinazoline. To avoid produce mixture of mono- and bis-functionalization products, 2-(*o*-methyl)phenyl-4-(*p*-methyl) phenyl quinazoline **1a**, which one of *ortho* position was blocked by a methyl, was chosen as the model substrate for the optimization of the one-pot cyanation conditions. According to our previous work,[33] the standard iodination protocol was carried out by using **1a** (1.0 eq.), NIS (*N*-iodosuccinimide, 1.5 eq.), $[RhCp^*Cl_2]_2$ (1.0 mol%) and $AgSbF_6$ (8.0 mol%) in DCE at 85 °C for 30 min. When the iodination reaction was finished, the DCE solvent was removed under reduced pressure, and the mixture of malononitrile (2.0 eq.), catalyst-system Cu_2O (10 mol%)–**L** (20 mol%), *t*-BuOK (2.0 eq.) and DMF (2.0 mL) as the solvent were added and then reacted at 120 °C. To our delight, the target product **3a** was isolated in a yield of 25% (Table 1, entry 1). Various of bases, such as K_2CO_3, KOH, Cs_2CO_3, and NaOH, were screened, and *t*-BuOK was found to be the best one (entries 1–5). Different copper salts were then examined, and Cu_2O was proved to be the best selected, which resulted in a yield of 58% (entries 6–12). The results of solvents tested indicated that trace amount of product was detected in H_2O or acetone (not listed in Table 1); low yield of 47% and 49% were obtained in DMAC or DMSO (entries 13 and 14). Additive KF found to be beneficial to the reaction, and gave a yield up to 63% (entry 15). Among the ligands used, $\mathbf{L_4}$ (Bathocuproine) was found to be more facilitating to the reaction than the others (entries 16–18). Excitingly,

[a] Optimized conditions are denoted in bold. [b] Reaction conditions: **1a** (0.1 mmol), NIS (1.5 eq.). $[RhCp^*Cl_2]_2$ (1.0 mol%)–$AgSbF_6$ (8 mol%), malononitrile (2.0 eq.) [Cu] (10 mol%)–ligand (20 mol%), base (2.0 eq.), in solvent (2.0 mL) at 120 °C. [c] Isolated yield. [d] NIS was replaced by NBS.

adding 50 v% of water in DMF can improve the yield to 84% (entries 19–21) and short the reaction time from 18 h to 3 h. Finally, when NBS (*N*-bromosuccinimide) was used as the reactant instead of NIS under the standard reaction conditions, only trace amount of the desired product was detected.

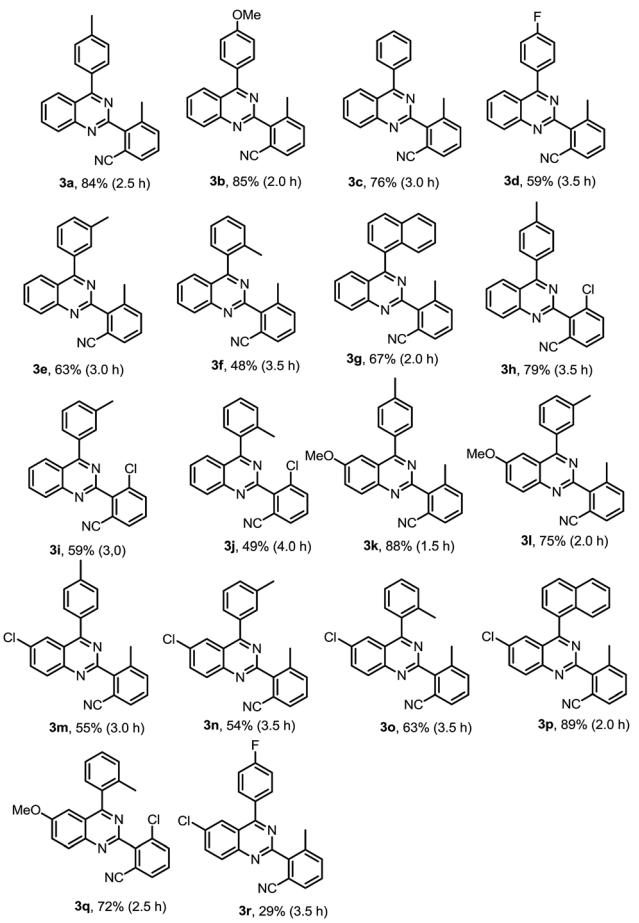
We then started to investigate the scope and the generality of this reaction under optimized conditions [NIS (1.5 eq.), $[RhCp^*Cl_2]_2$ (1.0%), $AgSbF_6$ (8.0 mol%), malononitrile (2.0 eq.), Cu_2O (10 mol%), Bathocuproine (20 mol%), *t*-BuOK (2.0 eq.), KF (2.0 eq.) in the solvent of DMF : H_2O = 2 : 1, at 120 °C for 3.5 hours]. The results are listed in Table 2.

As shown in Table 2, a variety of 2-(*o*-canyophenyl)-4-arylquinazolines were generated under the standard experimental conditions. In general, the electron-donating R^1, R^2, R^3 group substituent fascinated the reactions, and gave higher yields than that of electron-withdrawing ones. For examples, when R^2 is a methyl, and R^1 is *p*-methyl or *p*-methoxyl, the corresponding products **3a** and **3b** were obtained in excellent of yields of 84% and 85%. The reaction of electron-withdrawing fluorinated substrate **1d** gave good yield of 59%. The substituent group at the *meta* or *ortho* position of 4-phenyl, due to the steric hindrance, finished the corresponding products **3e**, **3f** and **3g** in a yield of 63%, 48% and 67%, respectively. When R^2 is chloro, the reactions gave the corresponding products **3h–3j** in good yields 79–49%.

Subsequently, the effects of substituent on the phenyl moiety of quinazoline mother ring were then examined. Pleasingly, methoxy and chloro functionalities were all tolerated, providing the desired products **3k–3q** in good to excellent yields. **3r** was obtained in a low yield due to double electron-withdrawing substituent effect.

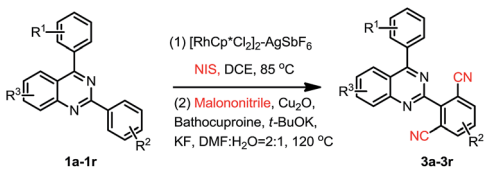
As we seen, when R^2 is H, the reaction may produce mono-cyanation and bis-cyanation selectivity. In our previous work, exclusively generate mono-iodination on the 2-aryl group was obtained catalyzed by $PbCl_2$–PPh_3, and then cyanation of the corresponding 2-(2-iodoaryl)quinazolines using conventional procedure[1e] could selective giving 2-(2-mono-nitrile) quinazolines. Thus, here we focus our attention on selective to produce bis-cyanation quinazolines in one-pot reaction. The results are listed in Table 3.

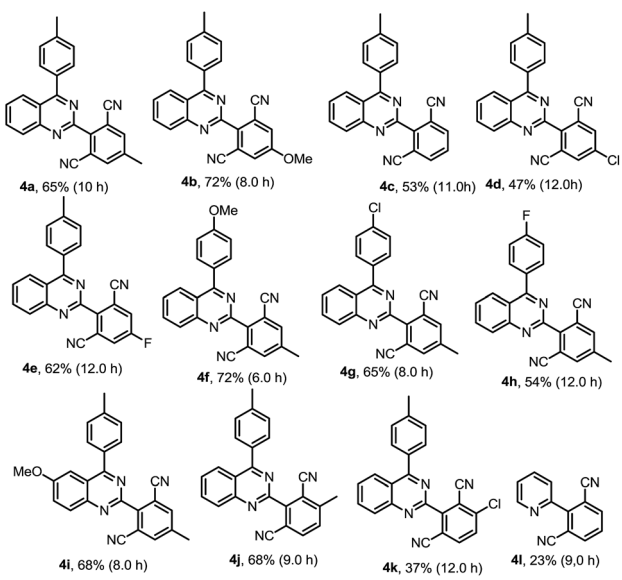
Table 2 Substrate scope exploration[a,b]



[a] Reaction conditions: **1a** (0.2 mmol), NIS (1.5 eq.), $[RhCp^*Cl_2]_2$ (1.0 mol%), $AgSbF_6$ (8.0 mol%), DEC 2.0 mL, malononitrile (2.0 eq.), Cu_2O (10 mol%), Bathocuproine (20 mol%), *t*-BuOK (2.0 eq.), KF (2.0 eq.), DMF : H_2O = 2 : 1 (3.0 mL). [b] Isolated yield.

Table 3 Substrate scope exploration[a,b]





[a] Reaction conditions: (0.2 mmol), NIS (3.0 eq.). $[RhCp^*Cl_2]_2$ (2.0 mol%), $AgSbF_6$ (16 mol%), DEC (2.0 mL); malononitrile (4.0 eq.), Cu_2O (20 mol%), Bathocuproine (40 mol%), *t*-BuOK (4.0 eq.), KF (4.0 eq.), DMF : H_2O = 2 : 1 (3.0 mL). [b] Isolated yield.

When 2,4-di-(*p*-methyl)phenylquinazoline **1aa** was selected as the model substrate, and the corresponding regents were adding double of the standard protocol above, the corresponding bis-cyanation product **4a** was obtained in a yield of 65% (Table 3). The electron-donating R^1, R^2, R^3 group substituent also fascinating the reactions, and gave higher yields (**4a**, **4b**, **4f** and **4i**) than that of electron-withdrawing ones (**4d**, **4e**, **4g** and **4h**). Interestingly, dicyano-compounds were obtained in reasonable yields (**4j** and **4k**) when *m*-substituted of 2,4-diarylquinazolines were used.

In order to further explore the substrate scope, 2-phenylpyridine was then investigated under the standard conditions, however, the corresponding product **4l** was obtained in 23% yield. This result again disclosed that the directing properties of diazine in quinazoline are distinctive from that of pyridine.

To demonstrate the potential synthetic utility of this transformation, a gram-scale reaction of 2-(*o*-methyl)phenyl-4-(*p*-methyl)phenylquinazoline (**1a**) was carried out. As shown in Scheme 2a, the cyanation product (**3a**) was isolated in an 71% yield.

To further understand the reaction mechanism, a controlled experiment was conducted. When 2-(2-iodo-6-methylphenyl)-4-(*p*-methyl)phenylquinazoline (**2a**) was used as the reactant under the standard reaction conditions in Scheme 2b, the cyanation product (**3a**) was isolated in an 92% yield.

In view of the above results, a plausible mechanism was disclosed in Scheme 3. The one-pot iodination/cyanation reaction include two catalytic cycles. In the first catalytic cycle I, the reaction of $[Cp^*RhCl_2]_2$ and $AgSbF_6$ forms $[Cp^*Rh(SbF_6)_2]_2$, which reacted with **1** through C–H activation to give five-membered rhodacycle **A**, and then was oxidation adduction with NIS to provide the Rh(IV) intermediate **B**, followed reductive eliminated to give iodide intermediate product **2** along with the Rh(III) **C**, which was acidized to regenerate catalyst $[Cp^*Rh(SbF_6)_2]_2$ and finish catalytic cycle I.

In the second catalytic cycle II, the ligand was incorporated with Cu^IX to form the catalyst LCuX, and then incorporate with malononitrile to provide the complex **D**, which was reacted with *t*-BuOK to give intermediate **E**, and then undergoes transmetalation to generate the active species LCu^ICN. The LCu^ICN subjected to oxidative adduction with **2** to form five-membered cyclic Cu(III) **G**, and followed reductive eliminated to give product **3**, and release the LCu^IX catalyst and finish the catalytic cycle.

In summary, we here have developed methods for one-pot process for selective the synthesis of 2-(2-cyano)aryl-4-aryiquinazolines or 2-(2,6-dicyano)aryl-4-arylquinazolines. The one-pot reaction include two steps, the Rh-catalyzed selective C–H activation iodization of 2,4-diarylquinazoline with NIS, and then Cu-catalyzed cyanation of the corresponding iodide intermediate with malononitrile to give 2-(*o*-cyanoaryl)-4-arylquinazolines or 2-(2,6-dicyano)aryl-4-arylquinazolines in good to excellent yields.

Experimental section

Unless otherwise noted, commercial reagents were purchased from Aldrich, Alfa, or other commercial suppliers. All solvents were dried and distilled according to standard procedures before use. Reactions were conducted in standard techniques on vacuum line. Analytical thin-layer chromatography (TLC) was performed using glass plates pre-coated with 0.25 mm 230–400 mesh silica gel impregnated with a fluorescent indicator (254 nm). Flash column chromatography was performed using silica gel (60 Å pore size, 32–63 μm, standard grade). Organic solutions were concentrated on rotary evaporators at ~20 torr (house vacuum) at 25–35 °C. Nuclear magnetic resonance (NMR) spectra are recorded in parts per million (ppm) from internal standard tetramethylsilane (TMS) on the δ scale.

General procedure for preparation of 2-(*o*-cyanoaryl)-4-arylquinazoline 3 (3a as an example)

A mixture of 2,4-phenylquinazolines **1a** (0.2 mmol), NIS (0.3 mmol, 1.5 eq.), $[RhCp^*Cl_2]_2$ (1.0 mol%), $AgSbF_6$ (8.0 mol%) in DCE (2.0 mL) was stirred at 85 °C, until **1a** was completed consumed (detected by TLC). The solvent was removed under reduced pressure. A mixture of malononitrile (2.0 eq.), Cu_2O (10 mol%), Bathocuproin (20 mol%), *t*-BuOK (2.0 eq.), KF (2.0 eq.) and DMF and water (3.0 mL 2 : 1) was added and stirred at 120 °C for 3 h. After completion of the reaction as indicated by TLC, the mixture was cooled to room temperature. The solvent was evaporated, residue was diluted with EtOAc (10 mL), washed with H_2O (10 mL), dried by anhydrous Na_2SO_4. Evaporation of the solvent followed purification by column chromatograph over silica gel provided the corresponding product **3a**.

General procedure for preparation of 2-(*o*-dicyanoaryl)-4-arylquinazoline 4 (4a as an example)

A mixture of 2,4-phenylquinazolines **1aa** (0.2 mmol), NIS (0.6 mmol. 3.0 eq.), $[RhCp^*Cl_2]_2$ (2.0 mol%), $AgSbF_6$ (16 mol%) and in DCE (2.0 mL) was stirred at 85 °C for 0.5 h, until **1a** was completed consumed. The solvent was removed under reduced pressure. A mixture of malononitrile (4.0 eq.), Cu_2O (20 mol%), Bathocuproin (40 mol%), *t*-BuOK (4.0 eq.), KF (4.0 eq.) in DMF
