ARTICLE INFO	A B S T R A C T
Keywords: Migraine Patent foramen ovale closure PFO Right-to-left shunt	<i>Background:</i> The potential correlation between patent foramen ovale (PFO) and migraine has been previously reported, but whether PFO closure plays a role in reducing migraine burden has not reached an agreement. <i>Method:</i> We searched PubMed, Embase, China National Knowledge Infrastructure (CNKI), Wanfang Database, VIP Science Technology Periodical Database and China Biology Medicine Database (CBM) through September 30, 2021 to identify associations between PFO closure and outcome of migraine burden. The control groups consisted of drug treatment or sham procedure. <i>Result:</i> Three randomized clinical trials (RCT) and 9 case-control studies were eligible for inclusion (1754 participants), of which 7 reported nonrecurrence of migraine, 4 reported reduced migraine-frequency and migrainedays, and 5 reported HIT-6 score and 4 reported MIDAS score. The mean (SD) age of participants was 40.68 (3.81) years and 1340 (76.39%) were women. PFO closure was significantly associated with a reduced risk of migraine-recurrence by 4.47 (95% CI, 2.94–6.80; $I^2 = 12\%$), frequency of migraine by 0.35 (95% CI, 0.17–0.53; $I^2 = 0\%$) and monthly migraine days by 0.28 (95% CI, 0.10–0.46), and decreased score of HIT-6 (SMD 1.23, 95 % CI 0.52–1.95, $I^2 = 93\%$). <i>Conclusion:</i> Transcatheter PFO closure is significantly associated with burden reduction of migraine headache.

1. Introduction

Migraine is one of the most prevalent neurological disorders with a one-year prevalence among adults ranged from 6.0% to 14.3% in East Asia, leading to an impaired quality of life and substantial financial cost [1]. Approximately one-third of migraineurs are preceded by aura, the most common visual symptoms, that is a brief episode of neurological dysfunction [2]. Patent foramen ovale (PFO) is a common congenital defect of the heart, causing an interatrial slit-like channel [3]. Several studies have shown that migraine has a close relationship with right-to-left shunt, notably in migraine with aura patients [4–6]. It has been suggested that various factors increasing neuronal excitability are possible mechanisms for this association, including paradoxical emboli, vasoactive substances and neurotransmitters and so on [7–9].

The results of the three main randomized clinical trials (RCT) showed that PFO closure not yet could cure migraine completely, but the frequency of attacks and monthly headache-days could be reduced [10–12]. The effects of transcatheter PFO closure on migraine, therefore, are controversial. Because existing studies are limited by the statistical power with the small sample size of the available datasets and the findings are inconsistent, we performed a systematic review and *meta*-analysis to detect the impact of PFO closure on migraine.

2.2. Selection criteria

We searched PubMed, Embase and China National Knowledge Infrastructure (CNKI), Wanfang Database, VIP Science Technology Periodical Database and China Biology Medicine Database (CBM) for articles published from databases inception until September 30, 2021. The search terms included "patent foramen ovale", "transcatheter closure", "right-to-left shunting", "migraine" and "headache". The search strategies were designed to identify published reports of clinical trials and case-control studies to evaluate the long-term impact of PFO closure on migraine. According to the eligibility criteria, two researchers (LW and ZW) independently screened the titles and abstracts and then full-text articles against the inclusion and exclusion criteria. Disagreements were resolved by discussion or consultation with a third author (YZ).

Studies were considered eligible if they were randomized clinical trial (RCT), and case-control study, compared with drug treatment or sham procedure, had at least 6 months of follow-up, published in the English or Chinese language and assessed outcomes including migraine-free, the monthly number of migraine attacks, the mean number of migraine days per month, headache impact test-6 (HIT-6) scores and migraine disability assessment survey (MIDAS) scores [13-15]. Literature review, conference abstract and case report, comment, *meta*-analysis and controlled before-after study were excluded.

2.3. Data extraction and study quality assessment

We extracted the following data using a standardized form: study characteristics (first author, year of publication, country, sample size, and duration of follow-up), baseline characteristics of participants (age, sex), interventions (drug treatment, PFO closure and sham procedure), outcomes and postprocedural therapy. Methodological quality was assessed using the Newcastle-Ottawa Scale (NOS) for non-randomized studies and the Jadad scale for randomized controlled trials (RCTs) [16,17]. A descriptive analysis of each study is shown in Table 1.

2.4. Statistical analysis

For dichotomous outcomes, odds ratios (ORs) and 95% CIs were estimated for each study. For continuous outcomes, the standard mean difference and corresponding 95% CIs were calculated. Both fixed-effects and random-effects model *meta*-analyses were performed, and in case of substantial heterogeneity, the random-effects model was used.

Heterogeneity was tested by Chi-squared test and was quantified by the I² statistic, with I² values>50% suggesting significant heterogeneity. Statistical analyses were performed using the "Metafor" package in R statistical software, version 4.0.3. A 2-side P < 0.05 was considered statistically significant.

3. Results

eFigure 1 shows that 1214 potentially relevant articles are retrieved after duplicates removal. After reviewing 77 full-text articles for eligibility, three RCT, one non-randomized concurrent control-trial and eight case-control studies meet the eligibility criteria. In total, 1754 participants were enrolled. The mean (SD) age of participants was 40.68 (3.81) years and 414 participants were men. Table 1 shows the characteristics of the included trials. Trials were performed in the Italy (N = 4),[18-21] China (N = 5),[22-26] England (N = 1)[10] and America (N = 1),[12] and a multicenter trial performed at 20 centers[11]. One trial compared a sham procedure,[10] one trial compared a combination treatment with drug treatment and sham procedure[12], and other ten trials compared drug treatment.[11,18-28] Seven trials reported on complete cessation of migraine, [10-12,18,19,21,23] four trials reported on

frequency of migraine attack and migraine days per month, [10-12,25] five trials reported on HIT-6 score, [10,22-25] and four trials reported on MIDAS score [10,11,20,21].

3.1. Risk of bias

The funnel plot depicting the potential publication bias between the complete arrest of migraine analyzed as a categorical variable and PFO closure was shown in eFigure 2. To correct the asymmetry of the funnel plot, two additional studies (the hollow circle) were needed. Among the total, three articles found to be moderate quality (NOS score: 6-7; Jadad score: 3-4) and nine were high quality (NOS score > 7; Jadad score > 4).

3.2. PFO closure and migraine-free

Seven trials reported the incidence of complete arrest of migraine. [10-12,18,19,21,23] Compared with medical therapy or sham procedure, PFO closure significantly increased the rate of migraine-free by 4.47 (95% CI, 2.94–6.80). Heterogeneity was low to moderate ($I^2 = 12\%$, P = 0.33), so the common-effect model was used. (Fig. 1).

3.3. PFO closure with migraine frequency and migraine days

Four trials reported on frequency of migraine attack and migraine days per month. [10-12,25] Compared with the drug therapy group, patients with PFO closure treatment showed a significant reduction in monthly migraine days by 0.28 (95% CI, 0.10–0.46), with low heterogeneity ($I^2 = 0\%$, P = 0.53). And monthly migraine attacks were statistically decreased by 0.35 (95% CI, 0.17–0.53), with low heterogeneity ($I^2 = 0\%$, P = 0.61). (Fig. 2).

3.4. PFO closure and change in activities of daily living score

A random-effects model was selected due to the high heterogeneity among the studies ($I^2 = 93\%$, P < 0.01). HIT-6 score was significantly decreased in the transcatheter closure patient group (SMD 1.23, 95 %CI 0.52–1.95). However, there was no statistically significant difference in MIDAS score between both groups (SMD 0.96, 95 %CI -0.55–2.47). (Fig. 3).

4. Discussion

Migraine, the second leading cause of disability worldwide, [29] is a paroxysmal disease characterized by complex sensory dysfunction and headache, and accompanied by aura in approximately one in four migraine patients [30]. It is possible that many factors are associated with migraine, including menstruation, emotional stress and weather changes, poor sleep and right-to-left shunting and so on [29,31]. Besides, a large cohort study found that migraine may increase risk of ischemic stroke with an adjusted hazard ratio of 2.26 [32].

A study from part of the Northern Manhattan Study found that there was no significant difference in the prevalence of PFO between subjects with migraine and those without migraine, and no relationship was demonstrated between PFO and self-reported migraine [33]. However, a study that divided migraine into those with and without aura indicated that PFO presence is more prevalent in migraine patients with aura than without aura or controls [34,35]. Furthermore, several controlled before-and-after studies proved that percutaneous closure of interatrial septal defect could be beneficial to reduce intensity, frequency and duration of migraine [36–39]. No residual right-to-left shunt is an important factor in reducing the burden of migraine.

Our findings are consistent with these previous *meta*-analyses that transcatheter closure can significantly improve symptoms of migraine patients on headache duration and frequency [6,40,41]. And studies providing HIT-6 scores and MIDAS scores were also included in our analysis, which were not involved in previous studies; second, this is the

Fig. 3. Associations of PFO closure with change in activities of daily living score. (A: HIT-6 score; B: MIDAS score).

IJC Heart & Vasculature 39 (2022) 100992

meta-analysis that has included the most relevant literature so far, and publication bias was included in the analysis. We demonstrated that PFO occlusion could reduce headache severity, of the five studies included, only the MIST (Migraine Intervention with STARFlex Technology) trial reported no improvement in severity of headache was realized. The possible reason may be the residual amount of shunt and absence of shunt related to substantial reduction in migraine [42]. And there may be a dose–effect relationship between residual shunt and migraine symptoms.[42,43] Besides, due to the subjective nature of the HIT-6 questionnaire, HIT-6 scores are heavily influenced by the variability of pain tolerance across individuals [23].

The procedure of PFO occlusion is not complicated, and the operation can be performed in less than half an hour, and the patient can be discharged from hospital in 3-4 days. The results of this meta-analysis suggest that the clinical indications for PFO occlusion should be strictly selected, and that the use of foramen ovale occlusion can effectively relieve migraine symptoms, reduce pain of patients and improve their overall quality of life. The possible mechanisms by which patients with PFO are prone to migraine are as follows. First, right-to-left shunt may allow serotonin or other vasoactive substances such as neurotransmitters or endothelin circumventing the lungs, instead of being metabolized by lung monamine oxidase, and directly entering the cerebral circulation [9,44]. These may lead to stimulation of trigeminal and cerebrovascular, because large amounts of serotonin exposed to the brain [45,46]. Second, subclinical emboli across a PFO may be responsible for migraine, especially for migraine with aura [7]. paradoxical emboli generated into the occipital area, causing the visual aura and subsequent headache [47] paradoxical emboli generated into Furthermore, oral aspirin and clopidogrel reduced the frequency of migraine after transcatheter PFO closure.[48].

5. Limitation

There are several limitations of this study. First, due to the retrospective nature of studies, recall bias and reporting bias cannot be entirely ruled out. The second is heterogenicity, especially in casecontrol studies. Third, further subgroup stratification analysis by aura is not conducted, because of the limited number of published studies. And different studies have used different evaluation index, therefore causing some clinical endpoints are only applicable to the included studies.

6. Conclusion

The collective evidence confirmed that migraine could be effectively improved after transcatheter PFO closure, in particular when patients are at risk for paroxysmal embolism or visual aura. In order to testify the prognostic values of PFO closure to improve migraine burden, more large samples, multi-center prospective randomized controlled trial are required.

Author contributions

JX, XRL conceived and designed the study. YLW, FZW contributed generation of the manuscript. RZL, JWJ helped revise the manuscript. All authors contributed to the editing of the manuscript.

Funding

This study was supported by the National Natural Science Foundation (Grant Numbers 82071187, 81870821, 81471215), The National Key Research and Development Program of China (2021YFC2500103), Beijing Youth Talent Team Support Program (2018000021223TD08), National key research and development program (2019YFC01209028) and Beijing Natural Science Foundation grant (L182055).

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.
