**Objective:** Platelets catalyze the development of hyperinflammation and microthrombosis and contribute to increases in accumulation of circulating platelet-leukocyte complex, the key event in the development of disseminated infection.

**Subjects and methods:** To determine the relationships of platelet activity in diabetic patients with invasive *Klebsiella pneumoniae* liver abscess syndrome (IKLAS), a total of 175 diabetic patients with community-acquired *Klebsiella pneumoniae* (KP) bacteremia were included in this study. We compared the platelet reactivity of 40 patients with IKLAS, 40 patients with non-IKLAS, and eight healthy controls using a whole-blood flow cytometry-based assay.

**Results:** Patients who were infected with strains expressing K<sub>1</sub>/K<sub>2</sub> serotype (adjusted odds ratio [AOR], 8.81; 95% CI, 2.18–35.53) and those with HbA<sub>1c</sub> ≥9% (AOR, 4.97; 95% CI, 1.73–14.23) were more likely to present with IKLAS, whereas those who had recent therapy with aspirin (AOR, 0.17; 95% CI, 0.04–0.79) were less likely to present with IKLAS. Among patients with IKLAS, patients with a poor glycemic control were more likely to present with hepatic venous thrombophlebitis than those with suboptimal or good glycemic control ( $P=0.03$ ). Patients with IKLAS had a higher median fluorescence intensity of the platelet membrane expression of P-selectin than those with non-IKLAS (78.0 vs 28.0,  $P<0.001$ ) and controls (78.0 vs 22.0,  $P<0.001$ ). The IKLAS group also demonstrated a significantly higher platelet-monocyte aggregation and higher plasma levels of PF-4 than the non-IKLAS group (47.0 vs 18.0 and 47.0 vs 4.0, respectively, both  $P<0.001$ ) and controls (46.0 vs 24.0 and 46.0 vs 13.0, respectively, both  $P<0.001$ ).

**Conclusion:** Diabetic patients with IKLAS demonstrated platelet hyperreactivity, which may be associated with a higher risk for vascular complications.

**Keywords:** Bacteremia, Glycated hemoglobin, vascular complications, Thrombophlebitis, Aspirin

## Introduction

*Klebsiella pneumoniae* (KP) is a common cause of community-acquired or hospital-acquired infections such as urinary tract infections and pneumonia. A clinical manifestation of KP infection known as invasive *Klebsiella pneumoniae* liver abscess syndrome (IKLAS), defined as liver abscess with contemporaneous metastatic KP infections at other body sites, has been increasingly reported,<sup>1–3</sup> particularly in Asia for decades<sup>4</sup> and recently worldwide.<sup>2,3</sup> IKLAS typically infects patients with diabetes mellitus (DM),<sup>1,4</sup> causing various metastatic infections such as meningitis, endophthalmitis, lung abscess, or fasciitis.<sup>4,5</sup>

KP is classically defined as an extracellular pathogen. We recently reported that the serotype K1 of this species, the causative agent of IKLAS, could survive

within neutrophils and trigger the delay in apoptosis.<sup>6</sup> We suggested that the KP serotype K1 can extend the lifespan of neutrophils, making them suitable host cells for bacterial survival and multiplication after infection occurs. This organism may use neutrophils as “Trojan horses” for subsequent infection of other cells. Hence, further studies are needed to identify the factors other than neutrophils that can trigger the development of disseminated infections due to KP.

Previous studies revealed that *Staphylococcus aureus* or *Salmonella* spp. can release toxins and/or use surface proteins that subsequently bind to platelet receptor, which can lead to platelet hyperreactivity and contribute to a higher risk for vascular complications.<sup>7</sup> In patients with invasive KP infection, the number of thrombotic complications is striking.<sup>8</sup> Although the essential role of platelets is to maintain vascular integrity and contribute to homeostasis, platelets can also contribute to the innate immune response.<sup>9</sup> These platelet-leukocyte aggregates have the capacity to act as circulating platforms for generation of a thrombus, producing clots that may lodge in the microvasculature, obstructing the blood flow, and leading to dissemination. Thus, this study aimed to describe the risk factors of IKLAS among DM patients with community-acquired KP bacteremia. In addition, we compared the features of computed tomography (CT) of the abdomen of the patients with IKLAS to ascertain possible predictors of IKLAS among DM patients with different glycemic control. We also studied the platelet reactivity, platelet-monocyte aggregate (PMA), and activation of plasmatic coagulation in a cohort of diabetic patients with KP bacteremia who had either IKLAS or non-IKLAS.

## Subjects and methods

### Study design and participants

DM patients who were admitted to Kaohsiung Chang Gung Memorial Hospital (KCGMH) between January 1, 2013, and December 31, 2016, with community-acquired monomicrobial bacteremia caused by KP were enrolled in this study to investigate the risk factors of IKLAS. Only the KP isolates from the patients' first blood collection were used in this study. Peripheral blood samples were collected for the whole-blood flow cytometry-based assay as described later from eight healthy male volunteers aged between 25 and 40 years and 80 of the participants after KP bacteremia was confirmed randomly. All protocols used in the present study have been approved by the institutional review board of KCGMH (201601500B0). The patients were

made anonymous to maintain confidentiality of the data. All participants including eight healthy male volunteers provided their written informed consent to participate in the study.

The diagnosis of IKLAS was made in patients with liver abscess who developed contemporaneous metastatic KP infections at other body sites such as renal abscess, splenic abscess, meningitis, empyema, mycotic aneurysm, necrotizing fasciitis, or endophthalmitis.<sup>10</sup> To investigate the predisposing factors of IKLAS, the following clinical variables were assessed: age, sex, comorbidities (including cardiovascular diseases, liver cirrhosis, malignancy, chronic renal failure, alcoholism, and biliary tract disease), and a history of receiving high-dose steroids (>20 mg of prednisolone daily for >3 weeks) or aspirin in the previous month prior to the collection of their first KP-positive blood culture. To assess the glycemic control in these DM patients, the HbA<sub>1c</sub> was determined. The impact of glycemic control on various outcomes of interest was evaluated by grouping all patients into three categories on the basis of HbA<sub>1c</sub> levels: HbA<sub>1c</sub> ≤7% (good glycemic control), HbA<sub>1c</sub> 7%–9% (suboptimal glycemic control), and HbA<sub>1c</sub> ≥9% (poor glycemic control).<sup>11</sup>

### Bacterial isolates and serotype determination

All KP isolates were identified using standard methods. Capsular genotyping of seven clinically significant capsular types (K<sub>1</sub>, K<sub>2</sub>, K<sub>5</sub>, K<sub>20</sub>, K<sub>54</sub>, K<sub>57</sub>, and K<sub>N1</sub>) was performed with the use of PCR assay. Briefly, PCR was performed using primers designed for the *cps* variable region. Genomic DNA was extracted by boiling selected colonies in distilled water for 10 minutes. The PCR conditions were 96°C for 3 minutes, followed by 30 temperature cycles of 96°C for 30 seconds, 53°C for 15 seconds, and 72°C for 30 seconds.<sup>12</sup>

### Characteristics of clinical imaging

All patients with IKLAS underwent contrast-enhanced CT of the abdomen. In some patients, CT studies were performed during follow-up to monitor complications. We only reviewed the first imaging studies. The following features were recorded: 1) number of abscesses (single or multiple); 2) unilocular or multilocular (presence of >1 mm thick septations); 3) solid or cystic appearance in most of the sections showing the cavity with abscess; 4) gas within the cavity with abscess; 5) thrombophlebitis (hypodense filling defects in the contrast-enhanced hepatic veins, their tributaries, and/or the inferior vena cava); 6) septic pulmonary embolism

(focal or multifocal lung infiltrates); and 7) presence of pleural effusion.

## Platelet reactivity

Platelet reactivity reflected by P-selectin expression as markers of platelet degranulation was determined by flow cytometry.<sup>13</sup> Platelet reactivity was measured in unstimulated samples and after ex vivo platelet stimulation by ADP (low dose: 7.8  $\mu$ M and high dose: 31.2  $\mu$ M; Sigma-Aldrich, St Louis, MO, USA). Whole blood was added to a mixture of 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid-buffered saline and saturated concentrations of PE-labeled anti-CD62P (P-selectin; BioLegend, San Diego, CA, USA) and PC7-labeled anti-CD61 (platelet identification marker; Beckman Coulter, Villepinte, France). After 20 minutes of incubation at room temperature, 0.2% paraformaldehyde was added and samples were analyzed. Platelets were gated based on their forward- and sideward-scatter properties and positivity for CD61, which was defined as a median fluorescence intensity (MFI) exceeding that of its matched isotype control.

## PMA

The formation of PMA, which is considered as a sensitive marker for platelet activation, was determined by incubating citrated whole blood with PC7-labeled anti-CD61 and PE-labeled anti-CD14 (a glycosylphosphatidylinositol-linked membrane glycoprotein; BioLegend) as a monocyte identification marker.<sup>14</sup> The platelet-monocyte complex formation was quantified based on the MFI of CD61 on CD14-positive cells.

Platelet-poor plasma was harvested from citrate anticoagulated whole blood by centrifugation (1,500 $\times$  *g* without brake, 15 minutes, 20°C). The plasma concentrations of PF-4 (R&D systems, Abbingdon, UK) were measured using ELISA.<sup>15</sup>

## Statistical analyses

The categorical variables of patients' characteristics were compared using the chi-squared test or Fisher's exact test, as appropriate, while the continuous variables were expressed as mean values $\pm$ SDs and compared using the Mann-Whitney *U* test or Student's *t*-test. A multivariate logistic regression model was used to evaluate the predisposing factors of IKLAS by calculating the OR and 95% CI of each clinical variable. Hosmer-Lemeshow goodness-of-fit tests were performed to evaluate the predictive performance of the logistic regression model. Differences in CT features across the groups were compared using ANOVA with posttests or

chi-squared test. Data on platelet reactivity, PMA, and plasma markers levels were expressed as medians with IQR. The experimental data between multiple groups were compared using nonparametric Kruskal-Wallis test with Dunn's post test. All statistical computations were performed using SPSS Statistics version 17.0 (SPSS Inc., Chicago, IL, USA). A two-sided *P*-value of <0.05 was considered as statistically significant in all analyses.

## Results

### Risk factors for invasive KP liver abscess syndrome

Of the 175 DM patients with community-acquired mono-KP bacteremia during the study period, 41 (23.4%) had IKLAS. Based on the results of the serotype determination by PCR assay, the K1/K2 serotype was identified in 22 (12.6%, including 20 K1 and two K2) isolates. As presented in Table 1, IKLAS occurred more often in patients infected with K1/K2 serotype KP strains than in those infected with non-K1/K2 serotype KP strains (43.9% vs 3.0%, *P*<0.01). The proportion of IKLAS was significantly higher among DM patients with HbA<sub>1c</sub>  $\geq$ 9% than among those with HbA<sub>1c</sub> <9.0% (78.0% vs 54.4%, *P*=0.01). In all, 24 (13.7%) patients had received aspirin a month prior to the diagnosis of KP infection, and they were less likely to develop IKLAS than those who had not received aspirin (2.4% vs 17.1%, *P*=0.02; Table 1). In multivariate analysis, IKLAS developing in DM patients with community-acquired bacteremia was associated with bacteremia due to K1/K2 serotype strains (adjusted odds ratio [AOR], 8.81; 95% CI, 2.18–35.53; *P*<0.01), poor glycemic control (AOR, 4.97; 95% CI, 1.73–14.23; *P*<0.01), and recent treatment with aspirin (AOR, 0.17; 95% CI, 0.04–0.79; *P*=0.02). There was adequate goodness of fit (Hosmer and Lemeshow test:  $\chi^2=0.50$ ; *P*>0.99). The receiver operating characteristic (ROC) curve analysis indicated that the predictive performance of the logistic regression model was adequate (area under the curve [AUC]=0.77). Hence, there was no significant evidence of lack of fit for any of the final models.

### Imaging study of invasive KP liver abscess syndrome

The characteristics of abdominal CT of 41 DM patients with different glycemic control who developed IKLAS are summarized in Table 2. A single abscess was found in 19 (46.3%) patients and multiple abscesses in 22 (53.7%) patients. Among the patients with multiple abscesses, the average number of lesions per patient was 2.2 $\pm$ 0.78. The

**Table 1** Comparisons of characteristics between diabetic patients with community-acquired KP bacteremia who developed invasive syndrome and those who did not develop invasive syndrome

Characteristics, n (%)	Invasive syndrome (%)		P-value <sup>a</sup>
	Yes (n=41)	No (n=134)	
K <sub>1</sub> /K <sub>2</sub> serotype of KP	18 (43.9)	4 (3.0)	<0.01 <sup>b</sup>
Male	17 (41.5)	47 (35.1)	0.47
Age ≥60 years	19 (46.3)	65 (48.5)	0.86

Hepatic venous thrombophlebitis	0	0	15 (46.8)	0.03 <sup>a</sup>
Septic pulmonary embolism	1 (25.0)	0	10 (31.3)	0.40
Pleural effusion	2 (50.0)	3 (60.0)	22 (68.8)	0.73

**Note:** <sup>a</sup>Diabetic patients with IKLAS in the group with poor glycemic control (47%) had a significant probability of developing hepatic venous thrombophlebitis than those patients with suboptimal or good glycemic control ( $P=0.03$ ).

**Abbreviations:** CT, computed tomography; IKLAS, invasive *Klebsiella pneumoniae* liver abscess syndrome.

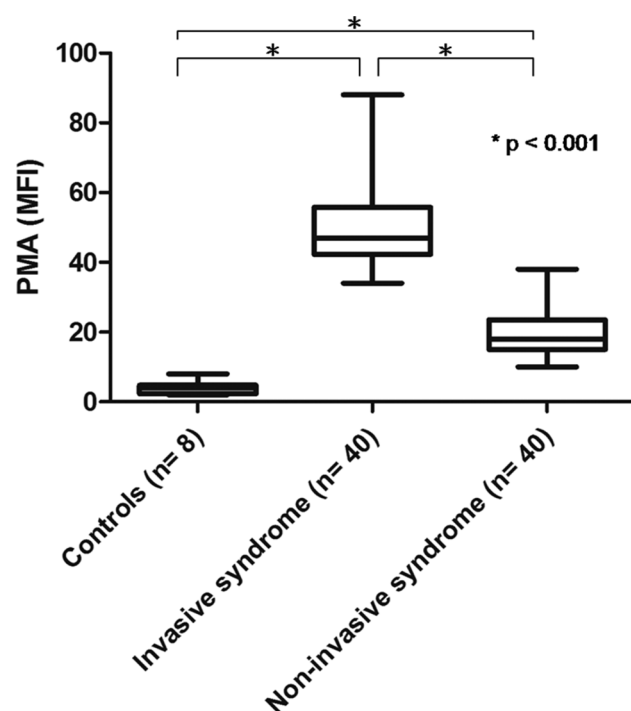

abscesses were predominantly solid in eight (19.5%) patients and cystic in 33 (80.5%) patients. Unilobar involvement was seen in 13 (31.7%) patients, and multilocular abscess was present in 28 (68.3%) patients. Gas in the abscess cavity was present in 17 (41.5%) patients, and hepatic venous thrombophlebitis was present in 15 (36.6%) patients. There

were 11 (26.8%) patients with septic pulmonary emboli and 27 (65.9%) patients with pleural effusion. In a subgroup analysis, hepatic venous thrombophlebitis was more likely to be found in DM patients with IKLAS who had poor glycemic control than in those with suboptimal or good glycemic control ( $P=0.03$ ; Table 2).

## Analysis of platelet reactivity to KP infection

We further studied the platelet reactivity, PMAs, and soluble platelet proteins, which are sensitive markers for platelet activation, in this cohort of DM patients with community-acquired KP bacteremia. The randomly selected patient characteristics in both groups (40 patients in the IKLAS group and another 40 patients in the non-IKLAS group) were similar, including the intervals between the homeostatic testing and blood cultures performed ( $42 \pm 18$  vs  $36 \pm 20$  hours,  $P=0.45$ ) or antibiotic treatment initiation ( $24 \pm 8$  vs  $22 \pm 12$  hours,  $P=0.64$ ). The C-reactive protein levels measured when the homeostasis assays were performed were comparable between the patients in the IKLAS group and those in the non-IKLAS group ( $124 \pm 86$  vs  $102 \pm 74$  mg/L;  $P=0.55$ ). A group of eight healthy volunteers were enrolled as controls. However, the mean age of the controls was lower than that of the patients in the IKLAS and non-IKLAS groups.

The IKLAS group had a significantly higher MFI of PMA than the non-IKLAS group and controls (Figure 1). The median MFI values (IQR) of the platelet marker CD61

**Figure 1** PMAs in diabetic patients with IKLAS and in those with non-IKLAS.

**Notes:** PMAs are depicted as the MFI of the platelet marker CD61 on CD14-positive cells in healthy controls ( $n=8$ ), in patients with IKLAS ( $n=40$ ), and in patients with non-IKLAS ( $n=40$ ). Data depicted are medians with IQR, minimum, and maximum values.

**Abbreviations:** PMA, platelet-monocyte aggregate; IKLAS, invasive *Klebsiella pneumoniae* liver abscess syndrome; MFI, median fluorescence intensity.

on CD14-positive cells were  $47.0$  ( $42.3$ – $55.8$ ) in the IKLAS group compared with  $18.0$  ( $15.0$ – $23.5$ ) in the non-IKLAS group ( $P<0.001$ ) and  $4.0$  ( $2.3$ – $4.8$ ) in controls ( $P<0.001$ ; Figure 1). Moreover, patients in the IKLAS group had a significantly higher median MFI of the platelet membrane expression of P-selectin ( $78.0$ ; IQR,  $76.2$ – $81.8$ ; Figure 2) upon stimulation with a high-dose ADP than those in the non-IKLAS group ( $28.0$ ; IQR,  $26.0$ – $30.0$ ;  $P<0.001$ ) and controls ( $22.0$ ; IQR,  $18.8$ – $23.4$ ;  $P<0.001$ ). The plasma concentrations of PF-4 were statistically significantly higher in the IKLAS group than those in the non-IKLAS group and healthy controls (Figure 3); the median (IQR) concentrations of PF-4 in these respective groups were  $46.0$  ng/mL ( $32.5$ – $57.0$  ng/mL),  $24.0$  ng/mL ( $18.0$ – $26.0$  ng/mL), and  $13.0$  ng/mL ( $10.5$ – $15.5$  ng/mL).

We performed a subanalysis of DM patients in the IKLAS group (Figure 2) and found that those with poor glycemic control ( $HbA_{1c} \geq 9.0\%$ ) had a significantly higher MFI of PMA than those with suboptimal glycemic control ( $HbA_{1c} 7\%$ – $9\%$ ) and good glycemic control ( $HbA_{1c} < 7.0\%$ ). The MFI (IQR) values of PMA were  $48.0$  ( $41.3$ – $56.0$ ) in the poor glycemic control subgroup,  $24.0$  ( $18.0$ – $26.0$ ) in the suboptimal glycemic control subgroup, and  $14.0$  ( $10.5$ – $25.8$ ) in the good glycemic control subgroup (Figure 4). Aspirin treatment decreased the PMA in these tested patients. The MFI (IQR) values of PMA were  $38.0$  ( $18.0$ – $48.0$ ) in patients with aspirin treatment compared with  $18.0$  ( $14.3$ – $24.0$ ;  $P<0.001$ ) in those without aspirin treatment (Figure 5). No significant correlation was observed between PMA and the time interval between hemostatic testing and the initiation of antibiotic therapy, Spearman's rank ( $R^2$ )= $0.07$ ,  $P=0.09$ .

**Figure 2** Platelet reactivity in diabetic patients with IKLAS and in those with non-IKLAS.

**Notes:** Platelet membrane expression of P-selectin is depicted as MFI in arbitrary units, at baseline and after stimulation with two concentrations of the platelet agonist ADP in healthy controls ( $n=8$ ), in patients with IKLAS ( $n=40$ ) and in patients with non-IKLAS ( $n=40$ ). Data depicted are median values with IQR.

**Abbreviations:** IKLAS, invasive *Klebsiella pneumoniae* liver abscess syndrome; MFI, median fluorescence intensity.

**Figure 3** Plasma concentrations of PF-4 in diabetic patients with IKLAS and those with non-IKLAS.  
**Notes:** Data from healthy controls (n=8), patients with IKLAS (n=14), and patients with non-IKLAS (n=14). Data depicted are median values with IQR, minimum, and maximum values.  
**Abbreviations:** IKLAS, invasive *Klebsiella pneumoniae* liver abscess syndrome.

**Figure 5** PMA in aspirin and non-aspirin using diabetic patients with community-acquired KP bacteremia.  
**Notes:** PMA is depicted as the MFI of the platelet marker CD61 on CD14-positive cells. Data depicted are median values with IQR, minimum, and maximum values.  
**Abbreviations:** PMA, platelet-monocyte aggregate; KP, *Klebsiella pneumoniae*; MFI, median fluorescence intensity.

**Figure 4** PMA in diabetic patients with IKLAS, stratified with different glycemic control.  
**Notes:** PMA is depicted as the MFI of the platelet marker CD61 on CD14-positive cells. Data depicted are median values with IQR, minimum, and maximum values. The glycemic control was stratified into three categories: good glycemic control (HbA<sub>1c</sub> ≤7%, n=4), suboptimal glycemic control (HbA<sub>1c</sub> 7%–9%, n=5), and poor glycemic control (HbA<sub>1c</sub> ≥9%, n=31).  
**Abbreviations:** PMA, platelet-monocyte aggregate; IKLAS, invasive *Klebsiella pneumoniae* liver abscess syndrome; MFI, median fluorescence intensity.

## Discussion

The inflammatory response during sepsis involves both platelet and endothelial cell activation. Bacteria can either support platelet adhesion or induce platelet aggregation.<sup>16</sup> P-selectin is a glycoprotein stored in Weibel–Palade bodies of endothelial cells or α-granules of platelets. Upon stimulation, the expression of P-selectin increases. The surface P-selectin can be downregulated by internalization and degradation or by shedding soluble P-selectin in plasma. The activation of platelets leads to the formation of platelet-leukocyte aggregates, which is both platelet and endothelial cell P-selectin dependent.<sup>17</sup> de Stoppelaar et al<sup>18</sup> reported that P-selectin-deficient mice infected with KP via the airways to induce sepsis displayed 10–1,000-fold higher bacterial burdens in the lungs, blood, and distant organs, and P-selectin deficiency was associated with decreased platelet-monocyte complexes and increased cytokine release, which suggests that P-selectin is involved in the host defense against sepsis caused by KP, with protective roles for both platelet and endothelial cell P-selectins.<sup>18</sup> In this current study, we found that DM patients in the IKLAS group had a significantly higher PMA and platelet P-selectin expression and higher plasma PF-4 concentration than those in the non-IKLAS group and controls. The IKLAS group had a higher platelet reactivity

than the non-IKLAS group. These differences were observed despite comparable plasma C-reactive protein concentrations, suggesting that inflammation is not a major driving force in KP-induced platelet activation.

Regional venous thrombophlebitis is a complication of various local infectious diseases that can spread throughout the body. In sepsis, microthrombi form in the blood capillaries.<sup>19</sup> Hepatic venous thrombophlebitis frequently occurs in patients with liver abscesses and appears as non-enhancing linear structures or gas without expanding the lumen on contrast-enhanced CT.<sup>20</sup> The hepatic venous thrombophlebitis may facilitate the seeding of microorganisms into the blood circulation, which might result in hematogenous metastatic infection in patients with liver abscess caused by KP.<sup>21</sup> Evidence suggests that DM patients have a higher platelet reactivity and baseline activation than healthy controls.<sup>22</sup> Furthermore, a close relationship between poor glycemic control and increased platelet activity in these DM patients was noted.<sup>23</sup> We found that DM patients with a poor glycemic control have higher rates of developing hepatic venous thrombophlebitis and invasive syndrome (Tables 1 and 2). In agreement with the previous report,<sup>24</sup> hepatic venous thrombosis is considered as an important sign of metastatic infection in DM patients. Wang et al<sup>24</sup> reported that hepatic venous thrombophlebitis was associated with 72.7% of metastatic infections. They also revealed that poorly controlled diabetes was associated with liver abscess caused by KP.<sup>24</sup> In this study, we postulated that the KP might activate the platelet activity especially in DM patients with poor glycemic control and form a septic thrombosis, which can lead to seeding of microorganisms with metastatic infection.

With regard to aspirin therapy on platelet reactivity, lower soluble P-selectin levels were found in patients with stable coronary disease after a percutaneous coronary intervention under aspirin therapy.<sup>25</sup> In addition, 1 week of low-dose aspirin therapy could attenuate platelet activation in HIV-infected adults.<sup>26</sup> Furthermore, a well-conducted, retrospective study from the Mayo Clinic has shown significantly reduced rates of embolism in patients with infective endocarditis who had been taking aspirin prior to the diagnosis.<sup>27</sup> These findings were also supported by a prospective investigation showing a significant reduction in the frequency of *S. aureus* bacteremia in patients with indwelling hemodialysis catheters who had been taking long-term aspirin.<sup>28</sup> The capsular polysaccharide surrounding the KP bacteria enables the bacteria to evade phagocytosis. We found that the reduction in capsular polysaccharide by salicylates, the major metabolite of aspirin, may therefore attenuate the pathogenicity of KP stains.<sup>29</sup> In

this study, several patients used aspirin that inhibits platelet activation via the COX-1 pathway,<sup>30</sup> leading to decreased platelet reactivity, which may contribute to lower the patients' risk for developing IKLAS.

Our study had several limitations. Peripheral blood samples were collected randomly from 80 participants after KP bacteremia. Differences among these selected participants in this approach to blood test may have resulted in ascertainment bias. The case number of the patients in each group remained small, and the hemostatic assays were only performed once in patients with positive blood cultures. KP isolated from patients in the non-IKLAS group was likely to be rapidly killed by antibiotics, despite the similar time intervals between hemostatic testing and performance of blood cultures or antibiotic treatment initiation among patients in the IKLAS and non-IKLAS groups. Still, increased platelet activation was observed among patients in the IKLAS group related to persistent bacteremia could not to be excluded in this current study. Finally, any potential contribution of other medications except aspirin taken by the patients might influence the platelet activity in the IKLAS group cannot be excluded in this study.

## Conclusion

KP bacteremia complicated with IKLAS is associated with marked platelet activation, which may contribute to the occurrence of vascular complications seen in these infections. Given the role of platelets in immunity and host defense, further studies are needed to investigate the potential role of platelet inhibition in preventing the development of IKLAS in diabetic patients with KP bacteremia.

## Acknowledgments

We thank Dr Chien-Ching Hung at the Department of Internal Medicine, National Taiwan University Hospital, for his critical review of this manuscript. This work was funded by grants from the Ministry of Science and Technology of Taiwan (MOST 106-2314-B-182A-137).

## Disclosure

The authors report no conflicts of interest in this work.

## Infection and Drug Resistance

### Publish your work in this journal

Infection and Drug Resistance is an international, peer-reviewed open-access journal that focuses on the optimal treatment of infection (bacterial, fungal and viral) and the development and institution of preventive strategies to minimize the development and spread of resistance. The journal is specifically concerned with the epidemiology of antibiotic

resistance and the mechanisms of resistance development and diffusion in both hospitals and the community. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
