The title compound, hexakis[μ_3 -1,2-bis(trifluoromethyl)ethene-1,2-dithiolato]-octahedro-hexapalladium(II), $[\text{Pd}(\text{C}_4\text{F}_6\text{S}_2)]_6$, crystallizes as its benzene solvate, $[\text{Pd}(\text{tfd})]_6 \cdot 2.5\text{C}_6\text{H}_6$, where tfd is the dithiolene $\text{S}_2\text{C}_2(\text{CF}_3)_2$. The molecular structure of $[\text{Pd}(\text{tfd})]_6$ is of the hexametallic cube type seen previously in three examples of hexameric homoleptic palladium monodithiolene structures. All structures have in common: (a) the cluster closely approximates a cube containing six Pd^{II} atoms, one at the centre of each cube face; (b) 12 S atoms occupy the mid-points of all 12 cube edges, providing for each Pd^{II} atom an approximately square-planar S_4 environment; (c) each S atom is part of a dithiolene molecule, where the size of the dithiolene ligand necessitates that only sulfur atoms on adjacent cube edges can be part of the same dithiolene. This general cube-type framework has so far given rise to two isomeric types: an S_6 -symmetric isomer and a C_2 -chiral type (two isomers that are enantiomers of each other). The structure of $[\text{Pd}(\text{tfd})]_6$ is of the C_2 -type. Out of the 12 CF_3 groups, three are rotationally disordered over two positions. Further, we answer the question of whether additional, previously undiscovered, isomers could follow from the cube rules (a) through (c) above. An exhaustive analysis shows that no additional isomers are possible and that the list of isomers (one S_6 isomer, two C_2 enantiomers) is complete. Each isomer type could give rise to an unlimited number of compounds if the specific dithiolene used is varied.

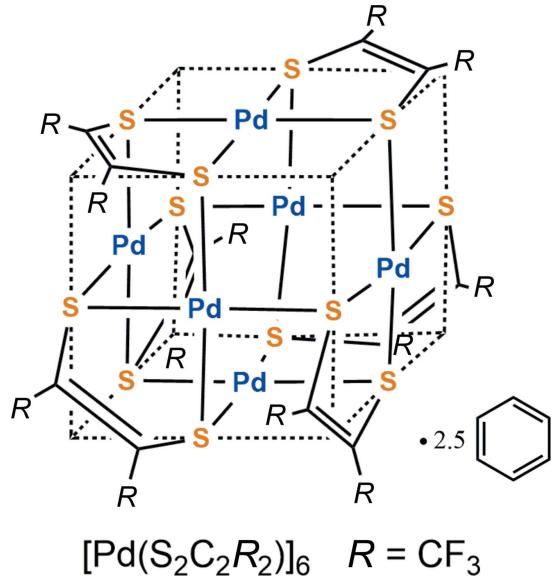

1. Chemical context

Metal-dithiolene complexes (dithiolene = $\text{S}_2\text{C}_2\text{R}_2$) are relevant for a host of new materials and several metalloenzymes (Stiefel, 2004; Harrison *et al.*, 2006). Homoleptic complexes normally contain two or three dithiolenes per metal, for bis-dithiolenes $M(\text{dithiolene})_2$ or trisdithiolenes $M(\text{dithiolene})_3$. Monomeric homoleptic monodithiolenes of the composition $M(\text{dithiolene})_1$ are unstable and polymerize or oligomerize. A dimeric complex $[\text{Ni}(\text{S}_2\text{C}_2(\text{CF}_3)_2)]_2$ was recently computed (Dang *et al.*, 2013). The class of hexameric homoleptic palladium monodithiolenes $[\text{Pd}(\text{dithiolene})]_6$, where dithiolene = $\text{R}_2\text{C}_2\text{S}_2$ with any substituent R was suggested by Stiefel and co-workers (Beswick *et al.*, 2002), and a charge-neutral hexanuclear complex was crystallographically characterized (as its toluene solvate) using the dithiolene $\text{S}_2\text{C}_2(\text{COOMe})_2$. The partially reduced complex, with a tetraphenylphosphonium counter-ion, was later structurally characterized by Stibrany (2012). A charge-neutral complex $\text{Pd}(\text{dithiolene})_6$ with the

OPEN ACCESS

dithiolene $\text{S}_2\text{C}_6\text{H}_2(\text{OMe})_2$ was reported by Rawson and co-workers (Wrixon *et al.*, 2015). In this work, we generated $[\text{Pd}(\text{tfd})]_6$ [where tfd is the dithiolene $\text{S}_2\text{C}_2(\text{CF}_3)_2$] from tfd and the dibenzylideneacetone (dba) complex Pd_2dba_3 as described below. A crystal was obtained, and the structure was determined by X-ray crystallography.

2. Structural commentary

The molecular structure of $[\text{Pd}(\text{tfd})]_6$ is shown in Fig. 1, where the second position for the rotationally disordered trifluoromethyl groups (attached to C1, C13, and C14), the second position for disordered atom C15, as well as the benzene solvate molecules are not displayed. The structure has approximate, non-crystallographic, C_2 symmetry (C_2 through Pd2 and Pd4). The gross features of this cube-like structure will be discussed first, followed by details such as bond lengths. The structure is of the hexameric homoleptic palladium monodithiolenes characterized by Stiefel and co-workers (Beswick *et al.*, 2002), Stibrany (Stibrany, 2012), and Rawson and co-workers (Wrixon *et al.*, 2015). All structures have in common: (a) the cluster closely approximates a cube containing six Pd^{II} atoms, one at the centre of each cube face; (b) 12 S atoms occupy the midpoint of all 12 cube edges, providing for each Pd^{II} atom an approximately square-planar S_4 environment; (c) each S atom is part of a dithiolene molecule, where the size of the dithiolene ligand requires that only sulfurs on adjacent cube edges can be part of the same dithiolene. This general cube-type framework has so far given rise to two isomer types: one S_6 -symmetric isomer seen for the charge-neutral palladium complex of $\text{S}_2\text{C}_2(\text{COOMe})_2$ (Beswick *et al.*, 2002) and for a partially reduced complex involving the same ligand (Stibrany, 2012). The charge-neutral complex $\text{Pd}(\text{dithiolene})_6$ with the dithiolene $\text{S}_2\text{C}_6\text{H}_2(\text{OMe})_2$ was found by Rawson and co-workers (Wrixon *et al.*, 2015) to have a different, C_2 -symmetric, structure. The two isomeric types are shown here schematically, inscribed into a cube (Fig. 2).

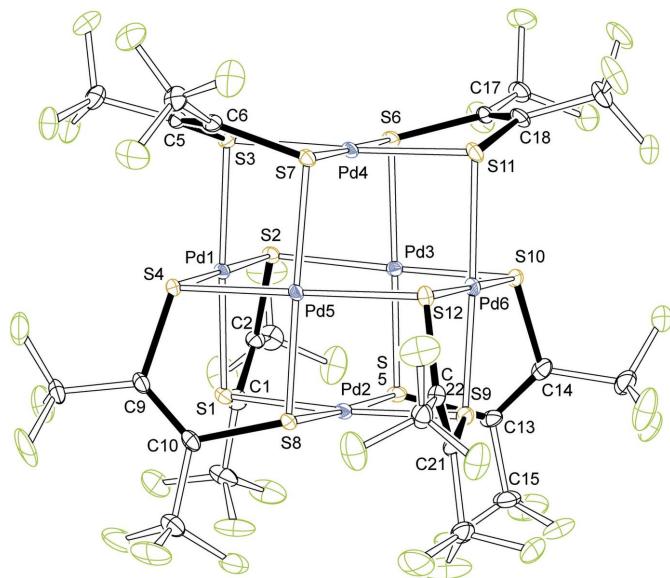

Figure 1

A view of the molecular structure of $[\text{Pd}(\text{tfd})]_6$. Anisotropic displacement ellipsoids are shown at the 30% probability level. The ligand backbones are highlighted.

The question of whether additional isomers are possible remained open and is answered here (Figs. 3 and 4). The starting point is the constraint that 12 donor atoms (such as sulfur) reside at the midpoint of the 12 cube edges and that metal atoms (such as Pd) occupy the centres of all cube faces. The ligand length constraint forbids *trans*-spanning placement of a chelate bridge, and chelates can only bridge the short distance between adjacent edge positions. All possible isomers following from this framework are explored in an exhaustive fashion (Figs. 3 and 4), following the initially arbitrary placement of the first bridge. It results that no additional isomers are possible and that the list of isomers (one S_6 isomer, two C_2 enantiomers) is complete. It is worthwhile noting that the S_6 isomer cannot have a dipole moment, by virtue of its inversion centre, while the C_2 isomer has a dipole.

With these general results for homoleptic square-planar metal-based short-span chelates in the form of hexameric cubes $[M(L_2)]_6$ in hand, we return to discussing the details of the structure of $[\text{Pd}(\text{tfd})]_6$ (Fig. 1). It is notable that not all Pd–S distances are the same. Shorter distances, on average 2.294 Å (12 values; standard deviation = 0.008 Å), are found for the Pd–S distances within an approximately planar $\text{C}_2\text{S}_2\text{Pd}$ five-

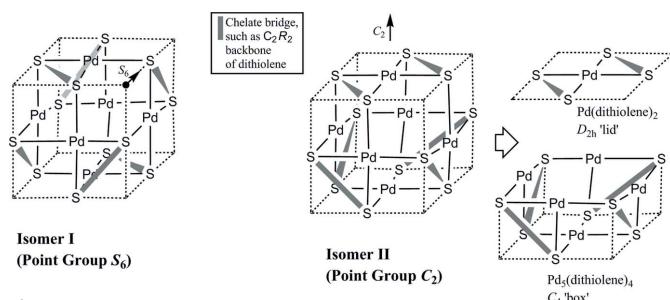

Figure 2

Isomers for $[\text{Pd}(\text{dithiolene})]_6$.

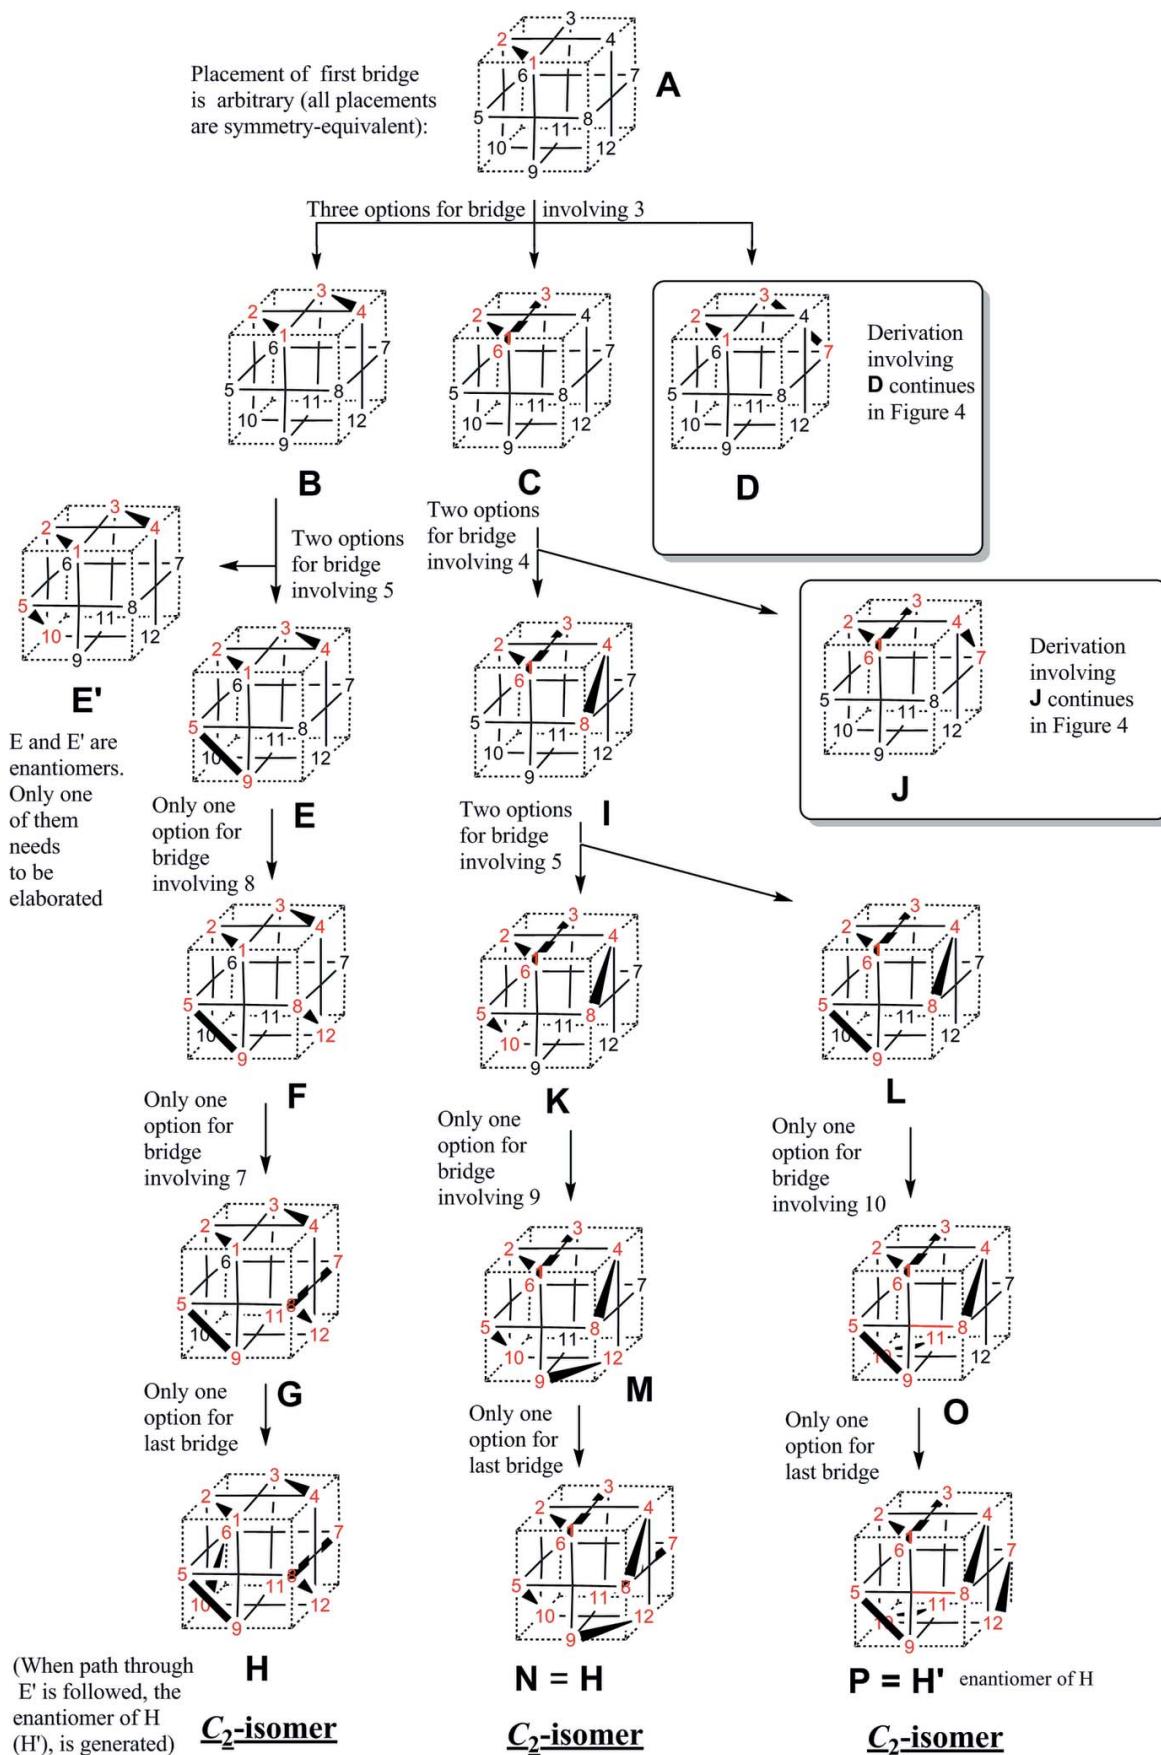

Figure 3

Graphical proof that only one S_6 isomer and two (enantiomeric) C_2 isomers are possible for homoleptic palladium monodithiolenes in the form of hexameric cubes, given the 'cube rules' discussed in the text. Continues in Fig. 4.

membered ring. Longer distances, on average 2.364 Å (12 values; standard deviation = 0.01 Å) are found for coordination of an S atom outside its own C₂S₂Pd ring onto a different Pd^{II} atom at an approximately right angle to the five-membered ring. All bonds to Pd₂, the Pd atom at the bottom of the Pd₅(tfd)₄ C₄-symmetric ‘box’ (Fig. 2) are long. All bonds to Pd₄, the Pd^{II} atom in the Pd(tfd)₂ ‘lid’ are short. The charge on the tfd ligand can be seen from the C–C distance within the chelate ring, which is short (double bond) for the dianion (ene-dithiolate; C–C distance of 1.35 Å or shorter expected) and long for monoanionic tfd (C–C bond order = 1.5; C–C distance of 1.38 Å expected), as is known from Tang *et al.* (2009) and Kogut *et al.* (2006) (see analysis in Hosking *et al.*, 2009). The chelate C–C bond distances in the current structure of [Pd(tfd)]₆ average to 1.339 Å (six values; standard deviation = 0.006 Å) and indicate a dianionic chelate. Charge balance necessitates that all palladium atoms are in the oxidation state 2+, which is also supported by the coordination geometry around each Pd^{II} atom, which is approximately square-planar, as expected for a *d*⁸ metal centre. The structure may thus be described as a charge-neutral C₄-symmetric Pd₄(dithiolene)₄ tiara capped on one side with a Pd²⁺ dication and on the other side with a Pd(tfd)₂²⁻ dianion. While the structure is likely more charge balanced than this zwitterionic description implies, this description suggests a direction of the dipole moment.

3. Supramolecular features

Molecules of [Pd(tfd)]₆ and benzene solvate molecules pack *via* contacting van der Waals surfaces. There are no particularly short intermolecular distances (such as hydrogen bonds).

4. Database survey

The three structures discussed (EGIDIH: Beswick *et al.*, 2002; XARMOU: Stibrany, 2012; YUQHUP: Wrixon *et al.*, 2015) are the only structures for hexametallic compounds of the type [Pd(dithiolene)]₆ in CSD (Groom *et al.*, 2016), Version 5.38 including updates up to Feb 2017.

5. Synthesis and crystallization

General specifications: All manipulations were carried out under an inert (N₂) atmosphere using standard glove box (M. Braun UniLab) and Schlenk techniques. NMR solvents were obtained from Cambridge Isotope Laboratories. Solvents were purified prior to use by vacuum distillation from purple sodium benzophenone ketyl. NMR data were obtained on a Bruker Avance III 400 MHz spectrometer. Pd₂dba₃ was obtained from Sigma-Aldrich. S₂C₂(CF₃)₂ (tfd) was synthesized as in Harrison *et al.* (2006).

Synthesis: A pyrex reaction vessel containing 10 ml of toluene, 80 mg of Pd₂dba₃ (175 µmol of Pd) and 80 µl (350 µmol) of tfd was heated to 353 K overnight. At the end of the reaction, the dark-red solution had turned an intense brown. Solvent and volatiles were removed under vacuum at

Computer programs: APEX2 and SAINT (Bruker, 2014), SHELXS97 and SHELXTL (Sheldrick, 2008), SHELXL2014 (Sheldrick, 2015) and ORTEP-3 for Windows (Farrugia, 2012).

room temperature, followed by heating to 383 K for 4 h, also under vacuum. NMR spectroscopy (C₆D₆ solvent) showed a complex mixture, as indicated by multiple ¹⁹F resonances, chiefly two intense quartets (*J*_{F-F} = 14.5 Hz) at -58.7 ppm and -59.3 ppm but also a large number of overlapping signals between -56 and -58 ppm. C₂-[Pd(tfd)]₆ is clearly not the only species in solution, as it would give rise to six distinct fluorine signals (quartets) in equal intensity. It seems likely that multiple species are in equilibrium in the reaction mixture, and C₂-[Pd(tfd)]₆ might crystallize from non-polar solvents relatively early due to its dipole moment, which makes it less soluble in non-polar solvents compared to non-polar species. Dissolving the sample in a minimal amount of benzene, followed by storage at 285 K for one week, led to the formation of crystals suitable for X-ray crystallography.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. The F atoms of three of the -CF₃ groups were refined as disordered over two sets of sites with the ratios of refined occupancies being 0.898 (6):0.102 (6) for F1/F2/F3, 0.784 (7):0.216 (7) for F19/F20/F21 and 0.749 (9):0.251 (9) for F22/F23/F24. Both the major and minor compo-

nents were refined with anisotropic displacement parameters. In the $-CF_3$ group containing F19/F20/F21, the attached atom C15 was also refined over two sets of sites with occupancies of 0.784 (7) and 0.216 (7). The SIMU command in *SHELXL* (Sheldrick, 2015) was used to restrain the anisotropic displacement parameters of the disordered atoms. The asymmetric unit contains 2.5 benzene solvent molecules. One benzene molecule is disordered about an inversion centre and hence has 0.5 occupancy. The RIGU command in *SHELXL* was used to restrain the anisotropic displacement parameters of the 0.5 occupancy benzene molecule. The H atoms bonded to C atoms were placed in calculated positions $C-H = 0.95 \text{ \AA}$ and included in the refinement in a riding-motion approximation with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$.

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
