Received 19 December 2008; accepted 8 January 2009

Key indicators: single-crystal X-ray study;  $T = 293\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$ ; disorder in main residue;  $R$  factor = 0.045;  $wR$  factor = 0.126; data-to-parameter ratio = 9.3.

In the title compound,  $\text{H}_3\text{O}^+\cdot\text{C}_8\text{H}_7\text{O}_8\text{P}_2^-$ , the anions form inversion dimmers by way of pairs of  $\text{O}-\text{H}\cdots\text{O}$  hydrogen bonds involving the phosphonic functions and *via* the hydronium cation. Further  $\text{O}-\text{H}\cdots\text{O}$  links involving the hydronium cation play a prominent part in the cohesion of the crystal structure by building bridges between bisphosphonate pairs, forming infinite ribbons along the *b*-axis direction and by cross-linking these ribbons perpendicularly along the *a*-axis direction, forming an infinite three-dimensional hydrogen-bond network. The benzene ring and the  $\text{C}=\text{O}$  atoms of the furan ring are disordered over two sets of positions of equal occupancy.

### **Comment**

The title compound,  $C_8H_8O_8P_2$ , belongs to the bisphosphonate family (or 1-hydroxymethylene-1,1-bisphosphonic acids or HMBPs). These compounds are synthetic structural analogues of pyrophosphate and are characterized by an enzymatically stable P—C—P group instead of the P—O—P. They are known to have a wide range of applications. They are clinically used in treatment of various bone diseases, such as Pagets disease, osteoporosis, tumor osteolysis or hypercalcemia of malignancy (Heymann *et al.*, 2004; Rodan & Martin, 2000). They are known to induce inhibition of breast and prostate cancer cell proliferation and more recently to inhibit angiogenesis *in vitro* and *in vivo* (Fournier *et al.*, 2002; Hamma-Kourbali *et al.*, 2003; Wood *et al.*, 2002). In addition, HMBPs have also activity against several trypanosomatid and apicomplexan parasites (Martin *et al.*, 2001; Martin *et al.*, 2002; Sanders *et al.*, 2003). HMBPs are usually obtained from two different synthetic methods (Lecouvey & Leroux, 2000). Unfortunately, these methods are not always suitable for fragile, aromatic or functionalized substrates. Recently we developed a new method of HMBP synthesis from silylated phosphite and acid chlorides (Lecouvey *et al.*, 2003a,b; Monteil *et al.*, 2005) (or acid anhydrides (Guénin *et al.*, 2004)) that gave an easy access to the obtaining of aromatic and functionalized HMBPs. Using phthalic anhydride as a substrate, a new and original cyclic bisphosphonate was described (Guénin *et al.*, 2004). The cyclic structure of this compound was provided indirectly by IR measurements and further opening of the cycle in basic media. Here we undoubtedly proved this cyclic structure, the hydroxy function being part of a lactone. This compound presents a real biological interest as it could act as a prodrug. The hydroxy function which is essential to the HMBP biological properties is in this particular case totally hidden, but could be reformed in the cell by esterase activity. Such acyloxymethyl bis(phosphonate) prodrugs have already been described and the protection shown to be reversible (Vachal *et al.*, 2006).

Bisphosphonate are compounds with super-acid properties, and they easily crystallize as mono salts of sodium or potassium (Sylvestre *et al.*, 2001) or as well characterized solvates (Lecouvey *et al.*, 2002) where crystals generally include water.

The asymmetric unit of the title compound is built up from one deprotonated HMBP anion and a  $H_3O^+$  cation (Fig. 1) which are linked through OW—H···O hydrogen bonds (Table 1). The crystal structure consists of hydrophilic layers that enclose the hydronium cation and bisphosphonate function where molecules linked by pair and less hydrophilic layers made of aromatic rings attached to the cyclic bisphosphonate structure.

### **Experimental**

Synthesis of (3-Oxo-1-phosphono-1,3-dihydro-isobenzofuran-1-yl)-phosphonic acid] was done according to the published procedure (Guénin *et al.*, 2004, compound 3 h). Briefly two equivalents of tris(trimethylsilyl)phosphite were added under  $N_2$  to phthalic anhydride in freshly distilled THF at room temperature. The resulting mixture was then heated at 50°C for 12 h. After evaporation of volatile fractions methanol was added to the residue. After 1 h stirring and methanol evaporation the title compound was washed several times with dimethyl ether. Crystallization was done by slow evaporation at room

temperature from a concentrated methanol/ water (9/1) solution to give colorless crystal with max. size 0.3 mm, suitable for diffraction.

## Refinement

All H atoms attached to C or O atoms were fixed geometrically and treated as riding with C—H = 0.93 Å (aromatic) or 0.96 Å (methylene) and O—H = 0.82 Å (hydroxyl) with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$  (aromatic) and  $1.5U_{\text{eq}}(\text{O})$  for others. Owing to the fact that each of the P2—O22 and P2—O23 bonds seems to be a mixture of single and double bonds and that solvent molecule was 3 times hydrogen donor, the solvent molecule was refined as  $\text{H}_3\text{O}^+$  and the bisphoshonate as the basic form. H atoms of the hydronium were located in difference Fourier syntheses and initially refined using restraints ( $\text{O}-\text{H}=0.93$  (1) Å) with  $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{O})$ . In the last stage of refinement they were treated as riding on the parent O atom.

Disorder of the cyclic structure was modeled with two different positions per disordered atom with occupation factors of 0.5. The two disordered part were refined using the tools, PART and SAME, available in SHELXL-97 (Sheldrick, 2008).

## Figures

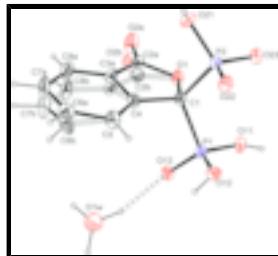

Fig. 1. Molecular View of the title compound. Displacement ellipsoids are drawn at the 30% probability level. H atoms are represented as small spheres of arbitrary radii.

Monoclinic, $C2/c$	Mo $K\alpha$ radiation
Hall symbol: -C 2yc	$\lambda = 0.71069 \text{ \AA}$
$a = 26.2271 (9) \text{ \AA}$	Cell parameters from 2338 reflections
$b = 7.2913 (3) \text{ \AA}$	$\theta = 0.4\text{--}25.4^\circ$
$c = 15.2621 (6) \text{ \AA}$	$\mu = 0.40 \text{ mm}^{-1}$
$\beta = 124.103 (2)^\circ$	$T = 293 (2) \text{ K}$
$V = 2416.66 (16) \text{ \AA}^3$	Parallelepipedic, colourless
$Z = 8$	$0.30 \times 0.10 \times 0.10 \text{ mm}$

### Data collection

Nonius KappaCCD diffractometer	2139 independent reflections
--------------------------------	------------------------------

Radiation source: fine-focus sealed tube	1627 reflections with $I > 2\sigma(I)$
Monochromator: graphite	$R_{\text{int}} = 0.071$
Detector resolution: 9 pixels mm <sup>-1</sup>	$\theta_{\text{max}} = 25.4^\circ$
$T = 293(2)$ K	$\theta_{\text{min}} = 3.0^\circ$
$\varphi$ and $\omega$ scans	$h = -31 \rightarrow 30$
Absorption correction: none	$k = -8 \rightarrow 8$
14205 measured reflections	$l = -18 \rightarrow 17$

### Refinement

Refinement on $F^2$	Secondary atom site location: difference Fourier map
Least-squares matrix: full	Hydrogen site location: inferred from neighbouring sites
$R[F^2 > 2\sigma(F^2)] = 0.045$	H-atom parameters constrained
$wR(F^2) = 0.126$	$w = 1/[\sigma^2(F_o^2) + (0.0625P)^2 + 4.0148P]$ where $P = (F_o^2 + 2F_c^2)/3$
$S = 1.05$	$(\Delta/\sigma)_{\text{max}} = 0.001$
2139 reflections	$\Delta\rho_{\text{max}} = 0.33 \text{ e \AA}^{-3}$
229 parameters	$\Delta\rho_{\text{min}} = -0.37 \text{ e \AA}^{-3}$
21 restraints	Extinction correction: none
Primary atom site location: structure-invariant direct methods	

### Special details

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
