Abstract

We compared the Ca^{2+} responses to reactive oxygen species (ROS) between mouse endothelial cells derived from large-sized arteries, aortas (aortic ECs), and small-sized arteries, mesenteric arteries (MAECs). Application of hydrogen peroxide (H_2O_2) caused an increase in cytosolic Ca^{2+} levels ($[\text{Ca}^{2+}]_i$) in both cell types. The $[\text{Ca}^{2+}]_i$ rises diminished in the presence of U73122, a phospholipase C inhibitor, or *Xestospongin C* (XeC), an inhibitor for inositol-1,4,5-trisphosphate (IP_3) receptors. Removal of Ca^{2+} from the bath also decreased the $[\text{Ca}^{2+}]_i$ rises in response to H_2O_2 . In addition, treatment of endothelial cells with H_2O_2 reduced the $[\text{Ca}^{2+}]_i$ responses to subsequent challenge of ATP. The decreased $[\text{Ca}^{2+}]_i$ responses to ATP were resulted from a pre-depletion of intracellular Ca^{2+} stores by H_2O_2 . Interestingly, we also found that Ca^{2+} store depletion was more sensitive to H_2O_2 treatment in endothelial cells of mesenteric arteries than those of aortas. Hypoxanthine-xanthine oxidase (HX-XO) was also found to induce $[\text{Ca}^{2+}]_i$ rises in both types of endothelial cells, the effect of which was mediated by superoxide anions and H_2O_2 but not by hydroxyl radical. H_2O_2 contribution in HX-XO-induced $[\text{Ca}^{2+}]_i$ rises were more significant in endothelial cells from mesenteric arteries than those from aortas. In summary, H_2O_2 could induce store Ca^{2+} release via phospholipase C- IP_3 pathway in endothelial cells. Resultant emptying of intracellular Ca^{2+} stores contributed to the reduced $[\text{Ca}^{2+}]_i$ responses to subsequent ATP challenge. The $[\text{Ca}^{2+}]_i$ responses were more sensitive to H_2O_2 in endothelial cells of small-sized arteries than those of large-sized arteries.

Introduction

Vascular endothelial cells *in vivo* are constantly exposed to ROS that are released from neutrophils, macrophages, and vascular smooth muscle cells [1,2]. Moreover, endothelial cells themselves are generators of ROS [1,2]. The main ROS that are produced include superoxide anions, H_2O_2 , hydroxyl radicals and peroxynitrite. Functionally, ROS play a key role in physiological and pathological processes in endothelial cells. For example, H_2O_2 at physiological concentration serves as an endothelium-derived hyperpolarizing factor (EDHF), mediating vascular relaxation [3]. However, excessive production of ROS causes extensive damage to the structure and function of endothelial cells, leading to endothelial dysfunction [1]. Evidence indicates that ROS-induced endothelial function and dysfunction are often preceded by an alteration in endothelial $[\text{Ca}^{2+}]_i$ [4], which serves as an important second messenger to induce diverse responses.

Reports showed that superoxide anions [5], H_2O_2 [6–9], and hydroxyl radical [5,10] are all capable of inducing $[\text{Ca}^{2+}]_i$ rises in vascular endothelial cells. The $[\text{Ca}^{2+}]_i$ rises could result from ROS actions on the plasma membrane ion channels [11], IP_3 production [7,12], IP_3 receptors [13,14], and/or endoplasmic reticulum Ca^{2+} -ATPase [6]. In addition to their direct action on endothelial $[\text{Ca}^{2+}]_i$, ROS treatment may alter the $[\text{Ca}^{2+}]_i$

responses of endothelial cells to a variety of physiological agonists including ATP and bradykinin [7,9,12]. However, the results of these studies are often controversial. In some studies, ROS treatment was found to enhance the agonist-induced $[\text{Ca}^{2+}]_i$ rises [12], whereas in other studies ROS were found to attenuate [9,15] or have no effect [7] on the agonist-induced $[\text{Ca}^{2+}]_i$ responses.

Although there have been a great number of studies investigating the ROS effect on $[\text{Ca}^{2+}]_i$ in endothelial cells, most of these reports only investigated the endothelial cells derived from large-sized arteries [5–10,12,15]. The role of ROS on $[\text{Ca}^{2+}]_i$ in endothelial cells of small-sized arteries has received little attention [but see 8]. It is unclear whether there is any difference in ROS-induced $[\text{Ca}^{2+}]_i$ responses in endothelial cells from different-sized arteries. Large-sized arteries and small-sized arteries differ in their function. Small-sized arteries such as mesenteric arteries are resistance arteries that play a key role in blood pressure control. Vasoactive factors in small-sized arteries are often different from that in large-sized arteries. For example, while nitric oxide is the major vasodilator in large arteries, EDHFs often play a more important role as vasodilators in small-sized arteries [16].

In the present study, we compared the effect of H_2O_2 on $[\text{Ca}^{2+}]_i$ in endothelial cells from large-sized arteries, aortas (aortic ECs), and small-sized arteries, mesenteric arteries (MAECs). We found that H_2O_2 stimulated IP_3 production to induce store Ca^{2+} release

in both cell types. H₂O₂ treatment depleted intracellular [Ca²⁺]_i stores, resulted in a decreased [Ca²⁺]_i response to subsequent ATP challenge. The Ca²⁺ store depletion was more sensitive to H₂O₂ in endothelial cells of small-sized arteries than those of large-sized arteries.

Results

Both Ca²⁺ entry and store Ca²⁺ release contributed to H₂O₂-induced [Ca²⁺]_i rises

The effect of H₂O₂ on [Ca²⁺]_i was investigated in aortic ECs and MAECs. H₂O₂ at 5 mM caused marked [Ca²⁺]_i rises in both types of cells that were bathed in normal physiological saline solution (N-PSS) containing 1 mM Ca²⁺ (Figure 1A–1D). The amplitude of [Ca²⁺]_i rises to H₂O₂ reduced when bath Ca²⁺ was decreased to 0.5 mM or to nominal Ca²⁺-free (0Ca²⁺-PSS), suggesting a contribution of Ca²⁺ entry to the H₂O₂-induced [Ca²⁺]_i rises. Significant [Ca²⁺]_i rises to H₂O₂ could still be observed even when bath was Ca²⁺-free, suggesting that store Ca²⁺ release also contributed to the H₂O₂-induced [Ca²⁺]_i rises.

H₂O₂ enhanced IP₃ production and store Ca²⁺ release

It is well documented that IP₃-sensitive Ca²⁺ stores are the major intracellular Ca²⁺ stores, and that the Ca²⁺ release from the stores hinges on the production on IP₃, which is generated through activity of phospholipase C (PLC) [17]. Figure 2A–2D show that treatment of the cells with XeC, an IP₃ receptor inhibitor, at 10 μM for 20 min almost abolished the H₂O₂-

induced [Ca²⁺]_i rises in both aortic ECs and MAECs. Furthermore, a PLC inhibitor U73122 (10 μM) markedly reduced the H₂O₂-induced [Ca²⁺]_i rises, whereas its inactive analog U73343 (10 μM) had no effect (Figure 3A–3D). These results suggest that the action of H₂O₂ mediated through IP₃, which binds to IP₃ receptors to release Ca²⁺ from intracellular Ca²⁺ stores. This was confirmed by experiments that measures IP₃ production (Figure 4). Treatment of cells with H₂O₂ caused a H₂O₂ concentration-dependent increase in IP₃ levels in both types of endothelial cells (Figure 4).

H₂O₂ reduced the [Ca²⁺]_i responses to ATP in a H₂O₂ concentration and incubation time dependent manner

We next examined the effect of H₂O₂ treatment on agonist (ATP)-induced [Ca²⁺]_i rises. The cells were first pre-incubated with H₂O₂ (500 μM or 1 mM) for 30 min, followed by 30 μM ATP application to evoke [Ca²⁺]_i responses. Figure 5A and 5B show the representative traces of [Ca²⁺]_i rises in response to ATP in aortic ECs and MAECs that were pre-incubated with different concentrations of H₂O₂. A marked difference was found between aortic ECs and MAECs. While both cells lost the [Ca²⁺]_i responses to ATP after 1 mM H₂O₂ treatment, a relatively low concentration of 500 μM H₂O₂ could abolish the ATP responses in MAECs but had no effect in aortic ECs (Figure 5A–5D). To further confirm the difference between aortic ECs and MAECs, time series experiments were carried out. 500 μM H₂O₂ caused a time dependent decrease in the [Ca²⁺]_i responses to ATP in MAECs (Figure 5F) but not in aortic ECs (Figure 5E).

doi:10.1371/journal.pone.0025432.g002

H₂O₂ induced Ca²⁺ store depletion

The reduced [Ca²⁺]_i responses to ATP could result from a decreased Ca²⁺ entry or a reduced Ca²⁺ release from intracellular Ca²⁺ stores. To focus on the store Ca²⁺ release alone, we next studied the ATP (30 μM)-induced [Ca²⁺]_i rises in cells bathed in a nominal Ca²⁺-free solution (Figure 6). Under this condition, [Ca²⁺]_i rises could only be attributed to the store Ca²⁺ release. The results show that ATP still triggered large [Ca²⁺]_i responses, which could be abolished by pre-treating aortic ECs for 25–30 min with 1 mM H₂O₂ but not 500 μM H₂O₂ (Figure 6A and 6C). For MAECs, treatment with a lower concentration (500 μM, 26–30 min) was enough to abolish the [Ca²⁺]_i responses to ATP (Figure 6B and 6D).

To further confirm the findings, Mag-fluo4/AM, a dye that stains Ca²⁺ in intracellular Ca²⁺ stores, was used to directly measure the store Ca²⁺ content. As shown in Figure 6E–6F, treatment with 500 μM H₂O₂ for 26–30 min caused a marked reduction of store Ca²⁺ content by 33 ± 6% (n = 3) in MAECs but had no significant effect in aortic ECs. These data suggest that MAECs were more sensitive to H₂O₂ treatment than aortic ECs with regard to their responses in Ca²⁺ store depletion and ATP-induced [Ca²⁺]_i rises. The controls in Figure 6E and 6F were time controls, in which the cells went through 30 min incubation in the absence of H₂O₂. In time control, Mag-fluo4 fluorescence only decreased by 8 ± 6% (n = 3) in MAECs and by 3 ± 7% (n = 3) in aortic ECs. The small reduction in Mag-fluo4 fluorescence in the control experiments could be due to light-sensitive quenching of Mag-fluo4 as described elsewhere [18].

[Ca²⁺]_i responses to ATP in the absence of H₂O₂

We also compared ATP-induced Ca²⁺ store release in aortic ECs and MAECs in the absence of H₂O₂ pretreatment. Cells bathed in a nominal Ca²⁺-free solution were challenged with different concentrations of ATP. In both cell types, ATP evoked [Ca²⁺]_i rises in a concentration dependent manner (Figure 7). Furthermore, the [Ca²⁺]_i response in MAECs was more sensitive to ATP than that in aortic ECs (Figure 7).

Non-involvement of hydroxyl radical

The effect of H₂O₂ on [Ca²⁺]_i could result from the action of H₂O₂ itself or from its metabolic product hydroxyl radical. Catalase was used to remove H₂O₂ and DMSO was used to scavenge hydroxyl radical. Pretreatment of cells with 2000 U/ml catalase for 30 min abolished the H₂O₂-induced [Ca²⁺]_i rises in both types of endothelial cells, whereas 2% DMSO had no effect (Figure 8A–8D). Our data suggest hydroxyl radical was not involved in the H₂O₂-induced [Ca²⁺]_i rises in both types of endothelial cells.

HX-XO-induced [Ca²⁺]_i rises were caused by superoxide anion and hydrogen peroxide

Effect of HX-XO on [Ca²⁺]_i was also studied. HX-XO reacts to yield superoxide anions, which may spontaneously or enzymatically dismutate into H₂O₂ [4]. Application of HX-XO (200 μM and 20 mU/ml, respectively) evoked rapid [Ca²⁺]_i rises in both types of endothelial cells. Pre-incubation of the cells for 20 min

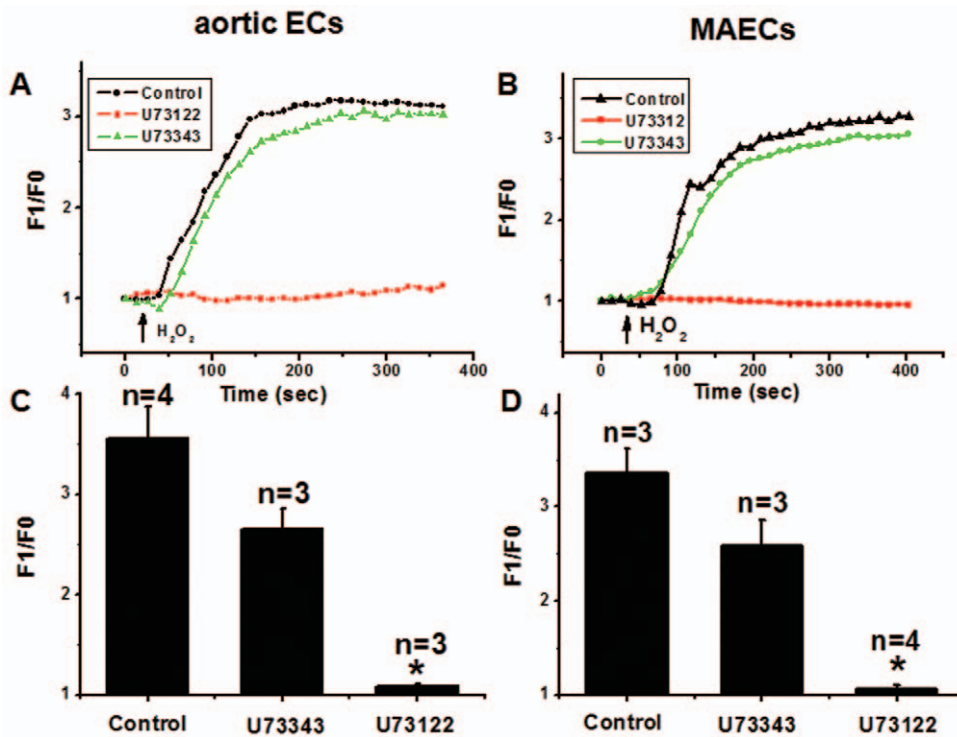

Figure 3. Effect of U73122 on H₂O₂-induced [Ca²⁺]_i rises in aortic ECs and MAECs. A and B. Representative traces showing the [Ca²⁺]_i rises in response to 5 mM H₂O₂ with or without U73122 or U73343. The cells were pre-treated with or without 10 μM U73122 or 10 μM U73343 for 30 min in N-PSS. Control had no U73122 and U73343. Fluorescence intensity before H₂O₂ application was normalized to 1 as F₀. **C and D.** Summary of data showing the effect of 10 μM U73122 or 10 μM U73343 on H₂O₂-induced maximal [Ca²⁺]_i rises in aortic ECs (C) and MAECs (D) as expressed in F₁/F₀. Mean ± SEM of 3 to 4 independent experiments (10 to 15 cells per experiment). *, *P*<0.05 as compared to U73343. doi:10.1371/journal.pone.0025432.g003

with 250 U/ml superoxide dismutase (SOD), an enzyme that causes superoxide dismutation, reduced the [Ca²⁺]_i rises (Figure 9A–9D). Pretreatment with catalase (2000 U/ml, 30 min) also reduced the HX-XO-induced [Ca²⁺]_i rises (Figure 9A–9D). Catalase had a larger effect on the HX-XO-

induced [Ca²⁺]_i responses in MAECs (reduction by 71±0%, n=13) than in aortic ECs (reduction by 47±0%, n=10) (Figure 9C and 9D). Combined treatment of SOD and catalase almost completely abolished the HX-XO-induced [Ca²⁺]_i rises in both types of endothelial cells (Figure 9A–9D).

Figure 4. H₂O₂-induced IP₃ production in a H₂O₂ concentration-dependent manner in aortic ECs and MAECs. The intracellular IP₃ production was measured in aortic ECs and MAECs after different concentration of H₂O₂ challenge (500 μM, 2 mM and 5 mM), according to the protocols described in Methods. Mean±SEM of 3 independent experiments. doi:10.1371/journal.pone.0025432.g004

Discussion

[Ca²⁺]_i change is an important early signal for ROS-induced endothelial function and dysfunction. However, only a few studies have investigated ROS-induced Ca²⁺ signaling in the endothelial cells derived from small-sized arteries [8,19] and it is unclear whether there is any difference in ROS-induced [Ca²⁺]_i responses in endothelial cells from different-sized arteries. In the present study, we compared the effect of H₂O₂ on [Ca²⁺]_i in endothelial cells from large-sized arteries and small-sized arteries. The results show that H₂O₂ stimulated [Ca²⁺]_i rises in both cell types. The H₂O₂-induced [Ca²⁺]_i rises could be blocked by U73122 and XcC, suggesting that the signaling cascade involves phospholipase C activity, IP₃ production, and Ca²⁺ release through IP₃ receptors. The increased IP₃ production following H₂O₂ treatment was confirmed by IP₃ measurement. It is well documented that Ca²⁺ release from IP₃-sensitive Ca²⁺ stores would stimulate Ca²⁺ influx through store-operated Ca²⁺ entry mechanism [20]. Indeed, we found that H₂O₂ treatment could enhance Ca²⁺ entry when the bath solution contained Ca²⁺.

There are conflicts in reports as to how ROS treatment would affect the [Ca²⁺]_i responses to subsequent agonist challenge in endothelial cells [7,9,12,15]. In some studies, H₂O₂ and superoxide anions were found to reduce the agonist-

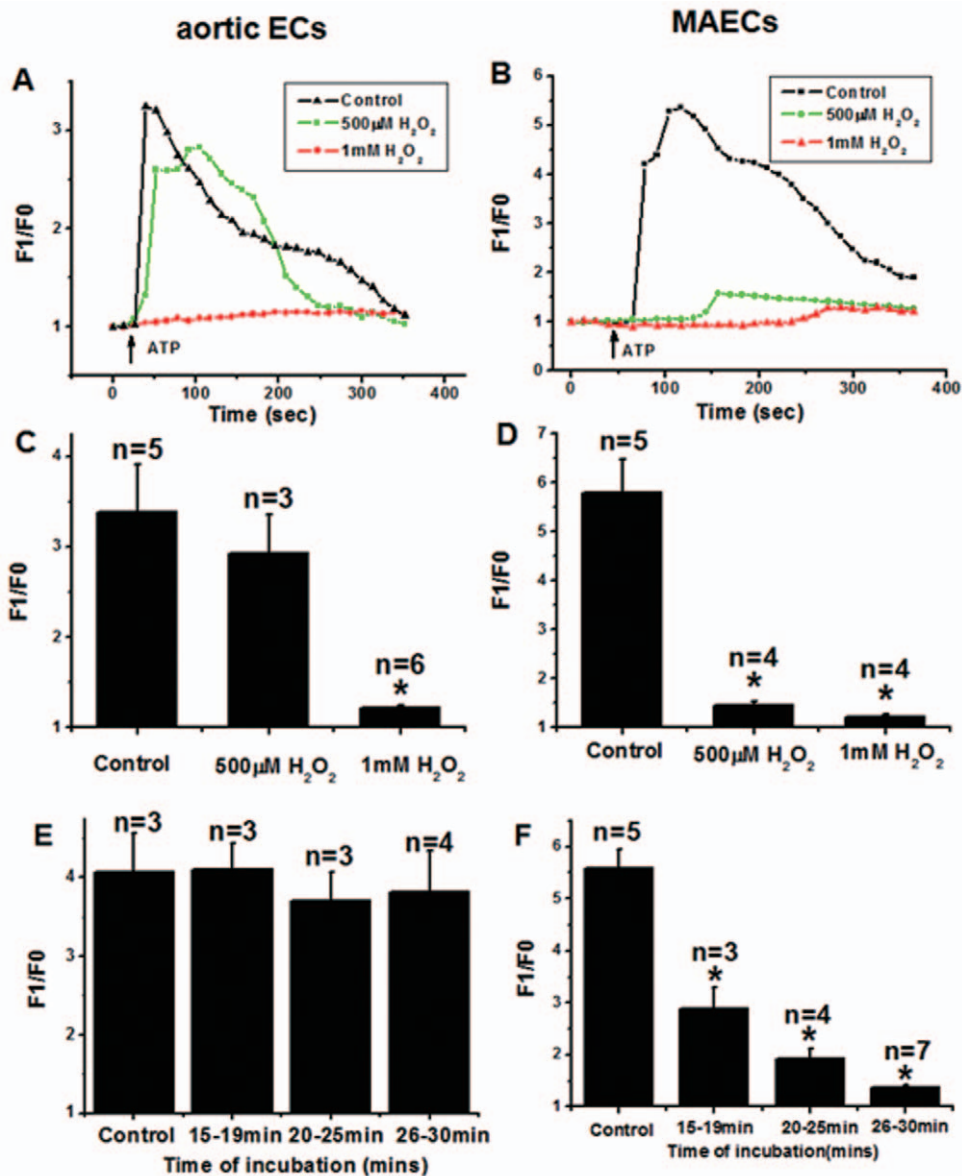

Figure 5. Effect of H₂O₂ pre-treatment on ATP-induced [Ca²⁺]_i rises in aortic ECs and MAECs. **A and B.** Representative traces showing the [Ca²⁺]_i rises in response to 30 μM ATP. The cells were pre-treated with or without H₂O₂ (500 μM or 1 mM as indicated) in N-PSS for 30 min, followed by ATP challenge. Control had no H₂O₂ treatment. Fluorescence intensity before ATP application was normalized to 1 as F₀. **C and D.** Summary of data showing the ATP-induced maximal [Ca²⁺]_i rises as in A and B, expressed in F1/F₀. **E and F.** Summary of data showing the ATP-induced maximal [Ca²⁺]_i rises after the cells were treated with 500 μM H₂O₂ for different period of time in N-PSS. Mean ± SEM of 3 to 7 independent experiments (10 to 15 cells per experiment). *, *P* < 0.05 as compared to control. doi:10.1371/journal.pone.0025432.g005

induced [Ca²⁺]_i rises [9,15]. In other studies, ROS treatment was found to enhance [9,12] or have no effect on the agonist-induced [Ca²⁺]_i responses [7]. In the present study, we found that H₂O₂ treatment reduced the [Ca²⁺]_i responses to ATP in H₂O₂ concentration-dependent and H₂O₂ incubation time-dependent manners in mouse aortic ECs and MAECs. The reduced [Ca²⁺]_i responses to ATP were due to a pre-depletion of intracellular Ca²⁺ stores during H₂O₂ treatment. Two lines of evidence support this: 1) After H₂O₂ treatment, the store Ca²⁺ release in response to ATP became much smaller. 2) Direct measurement of store Ca²⁺ content by Mag-fluo4 demonstrated a reduction in store Ca²⁺ content after H₂O₂ treatment. Interestingly, our data clearly indicate that endo-

thelial cells from small-sized arteries (MAECs) were more sensitive to H₂O₂ treatment than those of large-sized arteries (aortic ECs) with regard to their store Ca²⁺ release and subsequent [Ca²⁺]_i responses to ATP. This type of differential sensitivity/response of store Ca²⁺ release to ROS treatment could explain some data conflicts in the literature. For example, Volk et al., reported that, in rat liver artery endothelial cells, ROS treatment had no effect on the [Ca²⁺]_i responses to subsequent ATP or histamine challenge [7]. But they used a relatively low concentration of ROS [7]. It is possible that such a low concentration of ROS might not be sufficient to cause marked store Ca²⁺ depletion. As a result, no change in [Ca²⁺]_i responses to agonists would be expected.

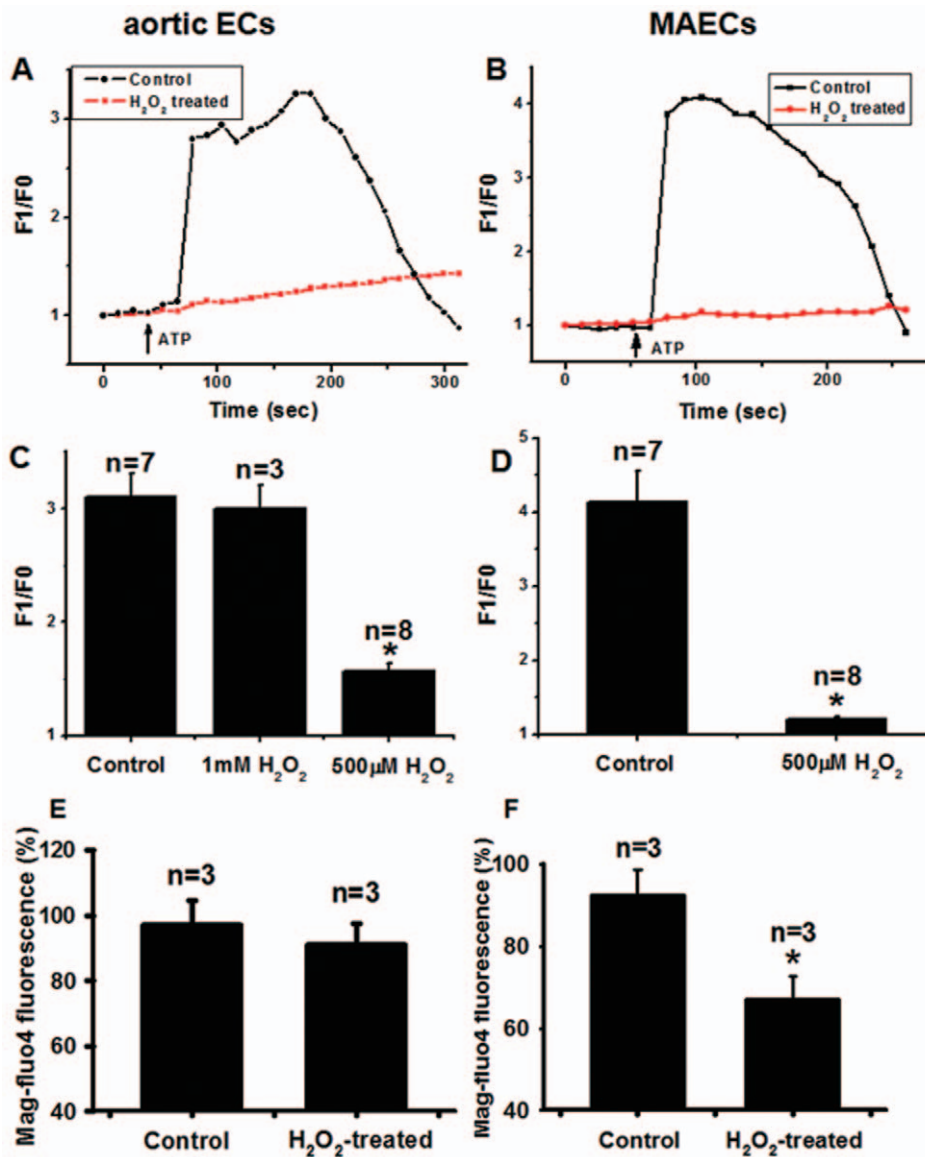

Figure 6. Depleting effect of H₂O₂ on store Ca²⁺ content in aortic ECs and MAECs. A and B. Representative traces showing the [Ca²⁺]_i rises in response to 30 μM ATP. The cells were pre-treated with or without 1 mM H₂O₂ for 30 min in N-PSS. Control had no H₂O₂ treatment. Cells were transferred to 0Ca²⁺-PSS and then challenged by ATP. Fluorescence intensity before ATP application was normalized to 1 as F₀. **C and D.** Summary of data showing the effect of H₂O₂ (500 μM or 1 mM as indicated) on ATP-induced maximal [Ca²⁺]_i rises in aortic ECs and MAECs as expressed in F₁/F₀. **E and F.** Summary of data showing the effect of H₂O₂ treatment on store Ca²⁺ content as determined by Mag-fluo4 fluorescence in aortic ECs and MAECs. The cells were treated with or without 500 μM H₂O₂ for 30 min. Mean ± SEM of 3 to 17 independent experiments (10 to 15 cells per experiment). *, *P* < 0.05 as compared to control. doi:10.1371/journal.pone.0025432.g006

What could be the underlying cellular mechanism for the higher sensitivity of [Ca²⁺]_i responses to H₂O₂ in MAECs than in aortic ECs? H₂O₂-induced IP₃ production was similar in MAECs and aortic ECs, therefore IP₃ production was not the reason. Alternatively, this could be due to more abundant IP₃ receptor expression and/or a higher IP₃ receptor sensitivity to IP₃ in MAECs than in aortic ECs. If this is true, [Ca²⁺]_i responses to other agonists is also expected to be higher in MAECs than in aortic ECs. Indeed, we found that similar high sensitivity of intracellular store Ca²⁺ release to ATP in MAECs than in aortic ECs (Figure 7). Therefore, we speculate that MAECs may express more IP₃ receptors and/or the sensitivity of IP₃ receptors to IP₃ may be higher in MAECs than in aortic ECs.

The higher sensitivity of [Ca²⁺]_i responses to H₂O₂ in the endothelial cell of small-sized arteries could have physiological and/or pathological implication. At physiological concentration, H₂O₂ is a vasodilator and it causes endothelium-dependent and endothelium-independent vascular dilation [3,23,24]. The effect of H₂O₂ as a vascular dilator is often found in small-sized arteries and arterioles [3,25]. In contrast, in large-sized arteries nitric acid is a more important vascular dilator [26]. Because [Ca²⁺]_i rises endothelial cells often trigger vascular dilation, a more sensitive [Ca²⁺]_i response to H₂O₂ in endothelial cells would allow H₂O₂ to serve as a more effective vascular dilator in small-sized arteries and arterioles. On the other hand, a high [Ca²⁺]_i sensitivity to H₂O₂ could also have pathological consequence. Excessive Ca²⁺

Figure 7. ATP-induced store Ca²⁺ release in endothelial cells in the absence of H₂O₂ pretreatment. Shown were the maximal [Ca²⁺]_i changes to different concentration of ATP (1 μM, 10 μM, 30 μM, 100 μM) in aortic ECs and MAECs as expressed in F1/F0. Cells were bathed in 0Ca²⁺-PSS in the absence of H₂O₂ pretreatment. Mean ± SEM of 3 to 7 independent experiments (10 to 15 cells per experiment). *, *P* < 0.05 as compared to aortic ECs. doi:10.1371/journal.pone.0025432.g007

accumulation may lead to endothelial cell apoptosis and cell death [4]. Therefore, it is possible that endothelial cells in small-sized arteries or arterioles might be more vulnerable to ROS-induced cell damage.

H₂O₂ can be converted to hydroxyl radical in the presence of Fe²⁺ [4]. However, in the present study the effect of H₂O₂ on [Ca²⁺]_i rises in endothelial cells could not be attributed to hydroxyl radical, because the H₂O₂ effect was not affected by DMSO, which is an efficient hydroxyl radical scavenger [21]. In contrast, H₂O₂ effect was abolished by catalase, which converts H₂O₂ to O₂ and H₂O, suggesting a direct action of H₂O₂. We also investigated the effect of HX-XO on [Ca²⁺]_i in mouse aortic ECs and MAECs. HX-XO is one of most widely used methods to generate superoxide anions, which may in turn dismutate into H₂O₂ spontaneously or enzymatically [4]. We found that the HX-XO-induced [Ca²⁺]_i rises could be attributed to involvement of superoxide anions and H₂O₂ but not hydroxyl radicals in both types of endothelial cells, because the response was reduced by SOD and catalase but not by DMSO. There were relatively more H₂O₂ contribution in HX-XO-induced [Ca²⁺]_i rises in endothelial cells of small-sized arteries (MAECs) than in those of large-sized arteries (aortic ECs). Previously, different reports have claimed different ROS, including H₂O₂ [5,7,10], hydroxyl radical [10], and/or superoxide anions [5,10], to be the contributing factors that were involved in HX-XO provoked-[Ca²⁺]_i rises in endothelial cells. The discrepancy in results could be due to a variety of factors including endothelial cell sources and/or culture conditions.

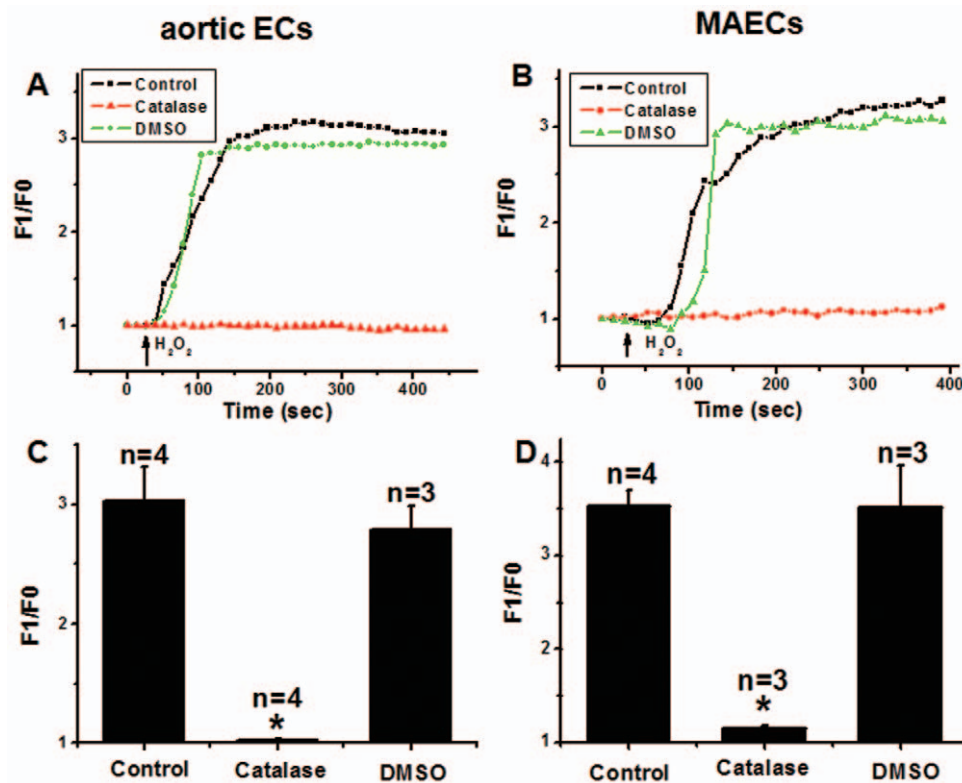

Figure 8. Effect of catalase and DMSO on H₂O₂-induced [Ca²⁺]_i rises in aortic ECs and MAECs. **A and B.** Representative traces of H₂O₂-induced [Ca²⁺]_i rises in the presence or absence of catalase or DMSO in N-PSS. 2000 U/ml catalase or 2% DMSO was added 30 min prior to the addition of H₂O₂ (5 mM). Fluorescence intensity before application of H₂O₂ was normalized to 1 as F0. **C and D.** Summary of data showing the effect of 2000 U/ml catalase and 2% DMSO treatment on H₂O₂-induced maximal [Ca²⁺]_i rises in aortic ECs (C) and MAECs (D) as expressed in F1/F0. Mean ± SEM of 3 to 4 independent experiments (10 to 15 cells per experiment). *, *P* < 0.05 as compared to control. doi:10.1371/journal.pone.0025432.g008

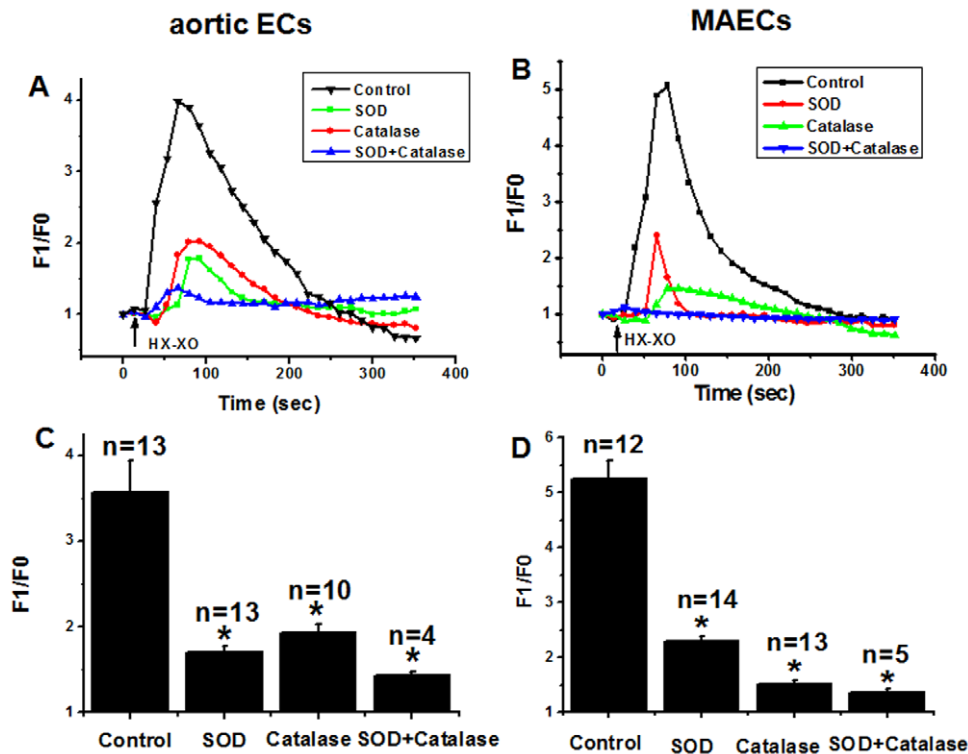

Figure 9. Effect of SOD and catalase on HX-XO-induced $[Ca^{2+}]_i$ rises in aortic ECs and MAECs. A and B. Representative traces of the $[Ca^{2+}]_i$ in response to HX-XO (200 μ M HX; 20 mU/ml XO). The cells were pre-treated with or without 250 U/ml SOD for 20 min or 2000 U/ml catalase for 30 min prior to the addition of HX-XO in N-PSS. Mean \pm SEM of 4–13 independent experiments (10 to 15 cells per experiment). *, $P < 0.05$ as compared to control. doi:10.1371/journal.pone.0025432.g009

In conclusion, we found both Ca²⁺ entry and store Ca²⁺ release contributed to the H₂O₂-induced $[Ca^{2+}]_i$ rises in endothelial cells. H₂O₂ treatment depleted the intracellular Ca²⁺ stores, resulting in reduced $[Ca^{2+}]_i$ responses to subsequent agonist challenge. The store Ca²⁺ release and subsequent $[Ca^{2+}]_i$ responses to ATP were more sensitive to H₂O₂ treatment in endothelial cells of small-sized arteries than those of large-sized arteries. This study highlights the similarity and difference of ROS-induced $[Ca^{2+}]_i$ responses in endothelial cells from large-sized arteries and small-sized arteries.

Methods

Ethics statement

We followed Guide for Animal Care and Use of Laboratory Animals published by the US National Institute of Health. The protocols for animal experiments were approved by Animal Experimentation Ethics Committee, The Chinese University of Hong Kong (approval number# 09/060/MIS).

Primary Cell Culture

Animals were supplied by the Laboratory Animal Service Center of the Chinese University of Hong Kong (Hong Kong, China). We followed Guide for Animal Care and Use of Laboratory Animals published by the US National Institute of Health. The protocols for animal experiments were approved by Animal Experimentation Ethics Committee, The Chinese University of Hong Kong (approval number# 09/060/MIS). Male C57 mice (8–12 weeks) were sacrificed by inhalation of CO₂.

Primary cultured aortic endothelial cells (aortic ECs) and mesenteric artery endothelial cells (MAECs) were dissociated from mouse aorta and mesenteric arteries of the first to tertiary branches (internal diameter = 60–200 μ m), respectively, using the methods described elsewhere [27]. Aortic ECs and MAECs were cultured in endothelial cell growth medium supplemented with 1% bovine brain extract.

$[Ca^{2+}]_i$ Measurement

Cells were prepared and loaded with a membrane permeant fluorescence dye Fluo4/AM (Molecular Probes, Inc., NJ) for observing their $[Ca^{2+}]_i$ responses to H₂O₂ or HX-XO or ATP. Briefly, the cells were seeded on circular glass discs at 37°C overnight supplemented with the culture medium. For the fluorescence dye loading, cells were incubated for 1 hr in dark at room temperature with 10 μ M Fluo4/AM and 0.02% Pluronic acid F-127 in normal physiological saline solution (N-PSS), which contained in mM: 1 CaCl₂, 140 NaCl, 1 KCl, 1 MgCl₂, 10 glucose, and 5 Hepes at pH 7.4. The circular discs containing the endothelial cells were then pinned in a specially designed chamber. The chamber was placed on the stage of an inverted microscope (Nikon Diaphot 200). During experiments, cells were bathed in N-PSS or 0.5Ca²⁺-PSS or 0Ca²⁺-PSS. The composition of 0.5Ca²⁺-PSS and 0Ca²⁺-PSS was similar to N-PSS except for Ca²⁺ concentration (0.5 mM CaCl₂ for 0.5Ca²⁺-PSS, and nominal Ca²⁺-free for 0Ca²⁺-PSS). All agents were applied directly to the bath along the side of the chamber. Solutions were then mixed by pipetting gently up and down for a few times. Experiments were

performed at room temperature. Fluorescence signals were recorded by MRC-1000 Laser Scanning Confocal Imaging System with MRC-1000 software (Bio-Rad) with the excitation wavelength of 488 nm and a 515 nm-long pass emission filter. The Ca²⁺ responses were displayed as the ratio of fluorescence relative to the intensity before H₂O₂ or ATP or HX-XO (F₁/F₀). Due to variation in [Ca²⁺]_i responses between different batches of cells, each series of experiments had its own control.

Measuring Ca²⁺ Content in Intracellular Ca²⁺ Stores

Cells were loaded with fluorescence dye Mag-fluo4/AM (Molecular Probes, Inc., NJ) for observing the Ca²⁺ level in intracellular Ca²⁺ stores. Briefly, cells were seeded on circular glass plates at 37°C overnight supplemented with the culture medium. As for the fluorescence dye loading, cells were incubated with 5 μM Mag-fluo4/AM in dark at 37°C for 45 min, and 0.02% Pluronic acid F-127 in N-PSS. Cells were then washed with the indicator-free N-PSS and incubated at 37°C for 45 min to unload the Mag-fluo4 from cytoplasm. The circular discs containing the endothelial cells were then pinned down in a specially designed chamber. The chamber was placed on the stage of an inverted microscope (Nikon Diaphot 200). Mag-fluo4 fluorescence was recorded by MRC-1000 Laser Scanning Confocal Imaging System with MRC-1000 software (Bio-Rad) with the excitation wavelength of 488 nm and a 515 nm-long pass emission filter. The cells were then treated with or without H₂O₂ for 30 minutes. Because Mag-fluo4 fluorescence was reported to be light-sensitive and could be quenched by light exposure, laser emission to samples was cut off during the period of H₂O₂ treatment. Fluorescence signals were then collected before and after 30-minute H₂O₂ treatment. The change in store Ca²⁺ content is displayed as Mag-fluo4 intensity change in percentage.

IP₃ measurement

The amount of IP₃ was measured using HitHunter™ IP₃ Assay Fluorescence Polarization Detection-Green Kits (DiscoverX Tech,

Fremont, CA, USA), a reliable and convenient methodology based on competitive binding between an IP₃ fluorescence tracer and unlabeled IP₃ from the cell lysates or standards. Free IP₃ competes at the IP₃ binding protein and allows the IP₃ tracer to rotate freely upon excitation with plane polarized light. The polarized signal is inversely proportional to the amount of the free unlabelled IP₃. Thus, polarization signal is decreased when the concentration of free IP₃ is increased [22]. Briefly, aortic ECs and MAECs were treated with different concentrations of H₂O₂ (500 μM, 2 mM, 5 mM) for 5 min in black 96-well plates. The cellular reactions were terminated by placing cells on ice followed by addition of 0.2 N perchloric acid to lyse the cells. The plate was then shaken at 650 rpm for 5 min. The IP₃ tracer was subsequently added to each well, followed by IP₃ binding protein. The polarized fluorescence from the IP₃ tracer (fluorescein) was read using a Wallac EnVision™ Microplate Reader (Perkin Elmer, Wallac, EnVision, Finland) with a polarization mirror, a 485 nm excitation filter and a 530 nm emission filter. IP₃ concentration was calculated from the IP₃ standard curve and expressed as pmole/1 × 10⁶ cells.

Data Analysis

Data Analysis was performed with Software Confocal Assistant and Metafluor. All representative traces were plotted by using Prism 3.0 (GraphPad, San Diego, CA, USA). Summarized data were expressed as the mean ± SEM and analyzed with two-tailed Student's t test at a p < 0.05 level of significance.

Author Contributions

Conceived and designed the experiments: LS H-YY O-CL XY. Performed the experiments: LS O-CL XY. Analyzed the data: LS O-CL XY. Contributed reagents/materials/analysis tools: LS O-CL XY. Wrote the paper: LS XY O-CL YH.
