Key indicators: single-crystal X-ray study;  $T = 171$  K; mean  $\sigma(C-C) = 0.004$  Å;  $R$  factor = 0.026;  $wR$  factor = 0.040; data-to-parameter ratio = 18.1.

The Ir<sup>III</sup> atom of the title compound, [Ir(C<sub>11</sub>H<sub>8</sub>N)<sub>2</sub>Cl(CH<sub>3</sub>CN)], displays a distorted octahedral coordination. The pyridyl groups are in *trans* positions [N–Ir–N = 173.07 (10) $^\circ$ ], while the phenyl groups are *trans* with respect to the acetonitrile and chloride groups [C–Ir–N = 178.13 (11) and C–Ir–Cl = 176.22 (9) $^\circ$ ]. The pyridylphenyl groups only show a small deviation from planarity, with the dihedral angle between the planes of the two six-membered rings in each pyridylphenyl group being 5.6 (2) and 5.8 (1) $^\circ$ . The crystal packing shows intermolecular C–H $\cdots$ Cl, C–H $\cdots$  $\pi$ (acetonitrile) and C–H $\cdots$  $\pi$ (pyridylphenyl) contacts.

### (Acetonitrile- $\kappa N$ )chloridobis[2-(pyridin-2-yl)phenyl- $\kappa^2 C^1, N$ ]iridium(III)

F. Blasberg, J. W. Bats, M. Wagner and H.-W. Lerner

#### Comment

One of the highlights of our group's work is the synthesis and characterization of redox active ligands for transition metal catalyzed reactions and applications in material science. Up to now we have applied electro-active ligands with poly(pyrazol-1-yl)borate (Jäkle *et al.*, 1996; Guo *et al.*, 2001), diimine (Margraf *et al.*, 2006; Kretz *et al.*, 2006; Phan *et al.*, 2011) and bis(pyrazol-1-yl)methane (Scheuermann *et al.*, 2008; Scheuermann *et al.*, 2009; Blasberg *et al.*, 2010) donor groups. So far, ferrocenyl and mainly *para*-quinonyl units (quinone is used if the oxidation state is not defined) were used as the redox-active element. But recently our attention turned to *ortho*-quinone derivatives, since they should allow for efficient bridging of two different transition metal centers in redox-switchable catalysis. In this context, synthesis of the hetero-bimetallic complex **3** with an *ortho*-hydroquinone-derived bis(pyrazol-1-yl)methane ligand, a catalytically active palladium(II) and a light-switchable iridium(III) center was attempted (see Fig. 1). This molecule might allow for light-driven redox-reactions, which in turn can switch catalysis on or off. The palladium(II) complex **1** (Blasberg *et al.*, 2010; Blasberg *et al.*, 2011) was deprotonated twice with lithium t-butoxide ( $\text{LiOtBu}$ ) in a tetrahydrofuran solution in a glove box and subsequently tetrakis-[2-(pyridin-2-yl)phenyl]-dichlorido-diiridium(III) **2** (Lowry *et al.*, 2004) was added to the resulting dianion. After stirring overnight and recrystallization of the resulting crude material from acetonitrile, the only obtained product was (acetonitrile- $N$ )-chlorido-bis[2-(pyridin-2-yl)phenyl- $C,N$ ]iridium(III) **4**, instead of the expected compound **3**.

The molecular structure of the title compound is shown in Fig. 2. The Ir(III) atom displays octahedral coordination (Table 1). The pyridyl groups are in *trans* positions and the phenyl groups in *cis* positions with respect to the central metal atom. A *trans* position of the pyridyl groups also has been observed in dimer **2** (McGee & Mann, 2007; Garces *et al.*, 1993) and in related compounds (Shu *et al.*, 2011). The bond lengths involving the Ir atom are very similar to the values reported for a closely related molecule (Yang *et al.*, 2009). The pyridylphenyl groups only show a small deviation from planarity. The angle between the planes of the two six-membered rings is 5.6 (2) and 5.8 (1) $^\circ$ , respectively, for the two different pyridylphenyl groups. The crystal packing shows two intermolecular C—H $\cdots$ Cl contacts, an intermolecular C—H $\cdots$  $\pi_{\text{acetonitrile}}$  and an intermolecular C—H $\cdots$  $\pi_{\text{pyridylphenyl}}$  contact (Table 2). The C—H $\cdots$  $\pi_{\text{acetonitrile}}$  contact points closer towards atom C23 than towards the midpoint of the C≡N triple bond. The C—H $\cdots$  $\pi_{\text{pyridylphenyl}}$  contact does not point towards the center of one of the six-membered rings. It rather points towards the midpoint of the C17—C18 bond.

#### Experimental

Dichlorido-[1-(bis-1*H*-pyrazol-1-ylmethyl)-benzene-3,4-diol-*N,N'*]palladium(II) (50 mg, 0.12 mmol; Blasberg *et al.*, 2011) was reacted with 19 mg (0.23 mmol) of lithium t-butoxide in tetrahydrofuran (4 ml) for 5 min, after which 62 mg (0.12 mmol) of tetrakis-[2-(pyridin-2-yl)phenyl]-dichlorido-diiridium(III) was added. After stirring overnight, the suspension which had formed, was separated by centrifugation and dried by evaporation. Recrystallization of the tan-colored powder from acetonitrile yielded yellow-brown blocks of the title compound.

## *Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
