Received 13 October 2011; accepted 15 October 2011

Key indicators: single-crystal X-ray study; $T = 100$ K; mean $\sigma(C-C) = 0.007 \text{ \AA}$; R factor = 0.043; wR factor = 0.135; data-to-parameter ratio = 22.8.

The asymmetric unit of the title Co^{III} complex, $[\text{Co}(\text{NO}_2)_2(\text{C}_{16}\text{H}_{32}\text{N}_4)]\text{ClO}_4 \cdot 0.5\text{H}_2\text{O}$, comprises two complex cations, two perchlorate anions and a water molecule of crystallization. The Co^{III} atoms exist within distorted octahedral N_6 geometries defined by four N atoms of the macrocycle ligand and *trans*-N atoms derived from the nitrite anions. Systematic variations in the Co–N bond lengths are correlated with the presence of intramolecular N–H···O(nitrite) hydrogen bonds. In the crystal, water-O–H···O(perchlorate) hydrogen bonds, involving one of the independent perchlorate anions only, lead to supramolecular chains along the *b*-axis direction. The three-dimensional architecture is consolidated by numerous C–H···O interactions. The crystal studied was a non-merohedral, racemic twin.

Comment

The title complex, (I), was investigated as a part of continuing studies into the biocidal potential and structural properties of macrocyclic metal complexes (Roy *et al.* 2006; Hazari *et al.*, 2008).

The asymmetric unit of (I) comprises two independent complex cations, two perchlorate anions and a water molecule of crystallization, Fig. 1. The Co^{III} atom is coordinated by the four nitrogen atoms of the macrocycle and two nitrogen atoms derived from the nitrite anions. The resulting N₆ coordination geometry is based on an octahedron. The Co—N distances span a relatively narrow range, *i.e.* 1.926 (4) to 2.009 (4) Å, Table 1. The shortest and longest Co—N distances involve Co—N(nitrite) bonds, and it is notable that one Co—N(nitrite) bond is systematically longer than the other in each complex cation. This feature of the bonding is readily explained by the presence of intramolecular N—H···O(nitrite) hydrogen bonds, Table 2. In each complex cation, one nitrite group (*i.e.* N5- and N12-) is orientated to optimize the formation of N—H···O hydrogen bonds as each nitrite-O atom is aligned with an amine-H atom, which lie to the same side of the CoN₄ plane. The relative lengthening of the Co—N5, N12 bonds compensates for the weakening of the respective N—O bonds. Only small differences in the molecular structures are manifested: the r.m.s. deviations in bond distances and angles are 0.0132 Å and 0.928°, respectively (Spek, 2009). In terms of conformations, a small difference in the relative orientations in the nitrite anions is noted. Thus, for the Co1 complex, the dihedral angle formed between these is 55.1 (4)° which compares to 62.6 (4)° in the Co2 complex.

In the crystal packing, the water molecule of solvation bridges two Cl1-perchlorate anions, forming donor O—H···O interactions, Table 2. The result of this hydrogen bonding is the formation of supramolecular chains along the *b* axis comprising alternating water molecules and Cl1-perchlorate anions. The water-O atom exists in a pocket of C-bound hydrogen atoms and the closest C—H···O(water) contact is weak, Table 2. The remaining intermolecular interactions are of the type C—H···O, Table 2, which serve to consolidate the three-dimensional architecture, Fig. 2. Globally, the crystal structure comprises layers of complex molecules in the *ab* plane comprising alternating rows of Co1- and Co2-containing complex molecules. Interspersing layers of complex cations are alternating layers comprising the Cl1-perchlorate anions and water molecules or Cl2-perchlorate anions.

Experimental

The macrocycle, *L*, (Curtis & Hay, 1966) and precursor complex (Bembi *et al.*, 1984) were prepared as described in the literature. Sodium nitrite (0.069 g, 1.0 mmol) and *trans*-[CoLCl₂](ClO₄) (0.252 g, 0.5 mmol) were suspended in methanol (20 ml). After heating the mixture on a water-bath for 15 minutes, the yellow solution was filtered while hot. The filtrate was concentrated on a water bath until crystallization commenced. After cooling, the yellow product *trans*-[CoL(NO₂)₂](ClO₄) was filtered off, washed with dry ethanol, followed by diethyl ether and finally dried *in vacuo*. *M.pt.*: 495–497 K. Yield 76.2%. FT—IR (KBr, cm⁻¹): 3120 (s, vN-H); 1649 (s, vC=N); 1079, 622 (*versus*, vClO₄); 519 (s, vCo-N); 1175(m, vC—C);

supplementary materials

2920 (vw, vCH); 1380 (s, vCH₃); 1396 (*versus*, v_{asym}NO₂); 1310 (*versus*, v_{sym}NO₂). Orange blocks of the title hemihydrate were prepared by slow evaporation of its acetonitrile and ethanol (1:1) mixture.

Refinement

The N- and C-bound H-atoms were placed in calculated positions (N—H = 0.88 Å and C—H = 0.98–0.99 Å) and were included in the refinement in the riding model approximation, with $U_{\text{iso}}(\text{H})$ set to $1.2U_{\text{equiv}}(\text{N,C})$. The water-H atoms were located from a difference map, fixed in these positions are refined with $U_{\text{iso}}(\text{H}) = 1.5U_{\text{equiv}}(\text{O})$. Several of the atoms (*i.e.* N4, N5, N7, C2, C5, C7, C9, C10, C11, C12 and C29) exhibited large displacement parameters and these were refined to be nearly isotropic with the ISOR command in *SHELXL97* (Sheldrick, 2008). The crystal is a non-merohedral, racemic twin. The two twin domains were separated by the diffractometer software and the intensities were integrated simultaneously; the two domains were scaled separately. The proportion of the twin domains refined to 0.644 (1): 0.356 (1). The Flack parameter refined to 0.509 (17) from 8210 Friedel pairs, *i.e.* the crystal is a racemic twin.

Figures

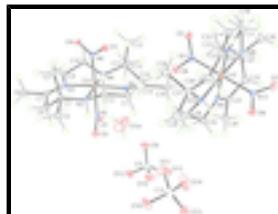

Fig. 1. The molecular structures of the components comprising the asymmetric unit of (I) showing displacement ellipsoids at the 50% probability level.

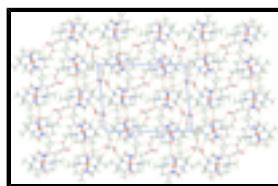

Fig. 2. A view in projection down the *b* axis of the unit-cell contents of (I) showing the alternating layers of complex cations and anions stacking along the *c* axis. The O—H···O (largely obscured) and C—H···O interactions are shown as blue and orange dashed lines, respectively.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
