This study aimed to evaluate disease and injury trends among wintering members of the Japanese Antarctic Research Expedition. Obtained information is indispensable to the advancement of medical system and research. Summation was performed based on medical records of reports prepared by each expedition over the period 1956-2016. The clinical department's classification methods of the names of injuries and diseases varied among expeditions, but the names were integrated following the same classification. Of 1734 members (29 women), 6837 disease or injury cases (4 cases/person) were recorded. The rates of cases were as follows: surgical-orthopaedic (45.3%), internal medical (21.7%), dental (11.6%), dermatological (8.4%), ophthalmological (5.8%), otorhinolaryngological (5.3%), psychiatric (1.6%), and urological (0.1%) cases. There was no major change in rates by type of medical case in each expedition. This analysis made it possible to prepare medical facilities, content of physical examinations to select members, training of physicians before departure, preventive hygiene at sites, and medical research themes.

Antarctica; medicine; morbidity; disease distribution; health survey; medical evacuation

#### Introduction

Japanese Antarctic research activities initiated in 1956 have reached the 59th expedition (until December 2017), and the total number of Japanese Antarctic Research Expedition (JARE) members who participated has exceeded 1800. Japan has performed various scientific observations at Syowa Station and the surrounding areas. Syowa Station is the mother station of JARE at 69°00'S and 39°35'E in East Antarctica. where it is isolated from its surroundings even in Antarctica. Some expedition members had travelled to Dome Fuji Base (S77°190, E 39°420, altitude of 3810 m) which was built inland about 1000 km away from Syowa Station in 1995. The members of the wintering team stay in Antarctica for 14 months. In Syowa Station, there is no supply of food and living goods from the outside world from February to November because the ship cannot keep pace with the thick ice mass and air routes are closed due to stormy weather conditions and extreme darkness. The wintering members have no chance of leaving Antarctica in this period. Therefore, it is important for wintering doctors to understand the disease tendency in Syowa Station for preventing health problems in the wintering team.

Several countries continuously survey injuries and diseases at the Antarctic [1-5]. In Japan, Ohno et al. analysed a total of 4233 medical cases from the 1st-39th expeditions [6]. Otani et al. assessed 4760 cases, including additional data for the 40th expedition [7], and analyses have been reported each year thereafter. In this study, diseases and injuries that occurred during the 40th-56th expeditions from February 1999 to January 2016 were summed up. By integrating the classification methods of injuries and diseases with those in previous reports, the injury and disease statistics were updated.

To carry out medical care research at the Antarctic, investigation of all medical types' trends during winter is essential, and the findings will help in the preparation of medical facilities, content of physical examinations to select members, training of physicians before departure, preventive hygiene at sites, and medical research themes. Therefore, this study aimed to evaluate disease and injury trends among wintering members of JARE to Antarctica. Obtained information is indispensable to the advancement of medical system and research.

### **Materials and methods**

This retrospective review was performed based on medical records of reports prepared by each of the 40th-56th expeditions active between February 1999 January 2016. Data on diseases and injuries encountered by the JARE team from the 1st to 56th expedition were collected from the annual report of National Institute of Polar Research (NIPR). For the 1st-39th expeditions (1956–1999), analytical data were provided by Ohno, the author of the report from 2000 [5]. The clinical department's classification methods of injuries and diseases varied among expeditions, but the names were integrated following Ohno's classification which was classified in Table 1. Excluding the 2nd and 6th expeditions without habitation and the 1st and 24th expeditions without descriptions of the numbers of injuries and diseases, data of 52 expeditions were integrated and analysed.

There were a total of 1156 members (2 women) in the 1st–39th expeditions and 578 members (27 women) in the 40–56th expeditions, and a total of 1,734 members (29 women) were included in the analysis. The range and mean age in each expedition are shown in Figure 1. All members were men until two women initially joined in the 39th expedition. The mean age for all periods was 34.1 years and that after the 38th expedition was between 35 and 39 years. This research was approved by NIPR through Project Research no. KZ-32.

#### **Results**

# Injuries and diseases by expedition and by type of medical case

Table 1 shows the details of diseases and injuries by expedition and by type of medical case. In the newly analysed 40th-56th expeditions, the number of injuries and diseases was 2604 and that per person was 4.5/expedition. After integration with previous reports, the total number of injuries and diseases in the 1st–56th expeditions was 6837 and there were 4 cases per person. The rates by type of medical case are shown in Figure 2. The rates of cases were as follows: surgical-orthopaedic (45.3%), internal medical (21.7%), dental (11.6%), dermatological (8.4%), ophthalmological (5.8%), otorhinolaryngological (5.3%), psychiatric (1.6%), and urological (0.1%) cases. In successive expeditions, no major change was noted in the rates based on the type of medical case (Figure 3).

# Statistics for injuries and diseases by month and by type of medical case

The details of the classification and number of injuries and diseases by month and by type of medical case are

shown in Table 2. Data were described by season, such as every 3 months, but were not described by months in the 1st–39th expeditions (two expeditions at Syowa Station, one expedition at Asuka Station, and one expedition at Dome Fuji). Excluding these, the summation period was set at 12 months from February to January of the following year. As the habitation period was changed in some expeditions, the total monthly number of injuries and diseases was 6502. The monthly number of episodes was almost constant.

#### Severe cases, surgical cases, and group infection

There was one accidental death due to blizzard, but it was not due to an injury or disease. Two cases of surgery under lumbar anaesthesia were performed, and both were appendectomy. Surgery under general anaesthesia had never been performed. Three cases caused by an accident on snow vehicle in the 29th expedition (1987-1989) and one case of arrhythmia in the 46th (2004–2006) expedition were evacuated by aircraft in the summer period. No severe case requiring medical evacuation occurred in the wintering period, but in the 25th expedition (1983-1985), there was one case of pelvic fracture and urethral injury by a snow vehicle in November. The patient required hospitalisation for 3 months at Syowa Station until the research vessel "Shirase" arrived. In the 38th expedition (1996-1998), a vesicostomy was performed under local anaesthesia for acute renal failure associated with urinary retention. In this case, dialysis was considered. "Shirase" directly rushed to the Syowa Station without performing science on the outward route. Fortunately, this patient's general condition was not getting worse.

In the summer period, medical reports contained special notes on two groups of infections. In the 41st expedition (1999–2001), common colds accompanied by influenza-like symptoms and digestive symptoms were prevalent in May, which affected 18 of 29 members. In April, acute gastroenteritis with diarrhoea as the main symptom developed in many members of the 43rd expedition (2001–2003).

#### **Discussion**

In this study, we found that the mean age of members in each expedition gradually increased and exceeded 37 years old after the 50th expedition, demonstrating ageing of members compared with those in previous expeditions. The participating medical cases slightly varied among the expeditions, but surgery and orthopaedics were the most frequent,

Department	Disease and injury	February	March	April	May	June .	luly /	August	September	October	November	December	Jan.	Total

followed by internal medicine. These were similar to past reports [1-5]. The number of medical episodes required for treatments per member varied among expeditions, but this may have been because the number of facilities varied and drugs were provided in mild cases as self-management during some expeditions.

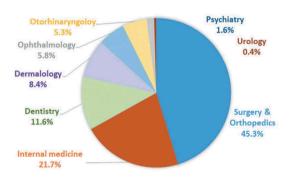

According to the monthly statistics of injuries and diseases by department, regarding changes in disease onset during the 12-month period from initiation of habitation in February to January of the following year, some diseases had seasonal changes, but other disease were almost constantly observed. Afflictions of motor organs and the digestive system, bruises, sprains, cuts and contusions, and lower back pain occurred almost every month. In contrast, periods with frequent disease development were noted: the frequency of frostbite was high in May (accounting for 22.0% of all cases in the 12-month period) and August-September (39%), insomnia in May-August (59%), headache in July-August (22%) and October (16%), ocular foreign body in February-April (47%), otitis in August-October (45%), and alcohol-related cases in May-July (44%). In addition, 88% of carbon monoxide poisoning cases developed in May-October, which may have occurred in snow vehicles during outdoor activities. This had not occurred after the 21st expedition (1979-1981) since the vehicles had changed.

Fortunately, there were no serious cases requiring medical evacuation in the winter period. Even if it was necessary, it was impossible because the Syowa Station was isolated and separated from other countries' bases. Hasegawa et al. reported an international comparative study of winter medical services from a total of 18 stations from 13 countries in 2007 [8]. Each station has 4-37 wintering members, and the average age was 36.4 years in 2004-2006. The Syowa Station had two medical doctors, and other stations had one each. About 60% of the stations had medical facilities for operations under general anaesthesia. In the past, 32 operations including 14 appendectomies have been performed at 9 stations. There have been 18 deaths at 9 stations. Most were accidental deaths, and 2 were caused by acute myocardial infarction. At 11 stations, there were 21 medical evacuations in summer, and 2 in winter, including 11 cases of orthopaedic disease and 3 cases of acute appendicitis. Medical evacuation has made remarkable progress with an airlift in summer, but JARE had no experience and no evacuation program in the winter.

This review has some limitations. The classification was integrated because the records and classification

**Figure 1.** Range and average age of members in each expedition. The bar graph represents the age range, and the red line graph represents the average age. The mean age of members in each expedition gradually increased and exceeded 37 years old after the 50th expedition. The 2nd and 6th expeditions were not overwintering.

**Figure 2.** Rate of diseases by medical departments. The cases and their rates were as follows: surgical-orthopaedic, 45.3%; internal medical, 21.7%; dental, 11.6%; dermatological, 8.4%; ophthalmological, 5.8%; otorhinolaryngological, 5.3%; psychiatric, 1.6%; and urological, 0.1% cases.

of clinical departments and names and sites of injuries were different among expeditions, but it may differ from the original record. Variation in diagnosed diseases due to differences in the specialties of medical care members was also considered. Moreover, judgement of the classification and severity based on International Classification of Diseases 10 was

difficult. It was not possible to investigate the incidences of injuries and diseases by age because age information of the patients could not be obtained. However, in addition to treatment, methods to prevent injuries and diseases may be a task to be solved as members aged. A remote medical system between Syowa Station and Japan through satellite was introduced in the 47th expedition (2005–2007), which enabled consultation with a physician specialising in the corresponding field. Further utilisation of this system may be useful to secure quality medical care and promote preventive medicine regardless of the speciality of medical members.

Even in Antarctica, medical treatments that can be provided have made progress. However, there are few reports on clinical data collected since the 2000s. For all countries, this latest analysis made it possible to prepare medical facilities, update content of physical examinations to select members, training of physicians before departure, preventive hygiene at sites, and medical research themes. We believe that these data will be useful to promote medicine in the Antarctic region in the future.

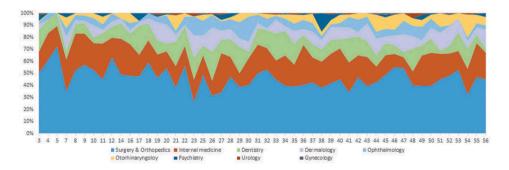

Figure 3. Change in rate based on departments. No major change was noted in the rates based on departments.

Table 2. Details of the classification and number of diseases and injuries by month and by type of medical case in 1956–2016 excluding the 2nd and 6th expeditions without habitation and the 1st and 24th expeditions without descriptions of the numbers of injuries and diseases.
