Received 9 July 2009; accepted 11 August 2009

Key indicators: single-crystal X-ray study;  $T = 200$  K; mean  $\sigma(C-C) = 0.002$  Å;  $R$  factor = 0.029;  $wR$  factor = 0.071; data-to-parameter ratio = 38.8.

The centrosymmetric binuclear complex,  $[Cu_2(C_{13}H_{13}N_2O)_2(NCS)_2]$ , formed *via* phenolate oxygen bridges, involves the  $Cu^{II}$  atoms in a distorted square-pyramidal coordination [ $\tau = 0.197$  (1)]. A  $Cu \cdots Cu$  separation of 3.2281 (3) Å is observed. The in-plane  $Cu-O_{phenolate}$  distance [1.9342 (8) Å] is shorter than the axial distance [2.252 (8) Å]. The  $Cu-N_{amine}$  and  $Cu-N_{py}$  distances are similar [2.0095 (10) and 2.0192 (10) Å, respectively]. The  $Cu-N_{thiocyanate}$  distance [1.9678 (11) Å] is in the range found for  $Cu-N$  distances in previously determined structures containing coordinated thiocyanate anions. There is an intermolecular hydrogen bond between the amine H atom and the S atom of a coordinated thiocyanate anion.

**Comment**

The synthesis and structure determination of copper complexes containing potentially bridging or ambidentate ligands, such as the thiocyanate anion, is of wide interest. The different possible coordination modes of the thiocyanate anion can involve bridging or ambidentate functions. A major obstacle to a more comprehensive study of thiocyanate polynuclear complexes is the lack of rational synthetic procedures. One convenient synthetic strategy is use displacement of weakly coordinated anions such as perchlorate or trifluoromethanesulfonate. In this instance some control over resulting stereochemistry can be achieved.

The present complex was synthesized by displacement of weakly coordinated perchlorate anions from a structurally determined complex (Assey *et al.*, 2009). The crystal structure of the resulting complex, bis{ $\mu$ -O-[2-((pyridin-2-ylmethylamino)methyl)phenolato]thiocyanatocopper(II)} has been determined. In this instance, two thiocyanate ligands were ligated to the copper(II) complex as a result of displacement of weakly coordinated perchlorate ligands. This method of ligand substitution has been used in the area of chemical sensors such as: competitive assay method involving the displacement of an indicator ligand (Sharma *et al.*, 2008), fluorescence displacement method involving determination of receptor-ligand binding constants (Kuzmic *et al.*, 1992), luminescence molecular sensing based on analyte coordination to the transition metal complexes (Rogers & Wolf, 2002), and the use of ligand substitution for fluorescence sensing in detection of NO in biological aqueous solution (Lim *et al.*, 2006).

The complex contains a reduced Schiff base, 2-[[pyridine-2-ylmethyl]amino]methylphenolato and thiocyanate coordinated to copper. The phenolate O atoms bridge the two copper centres and the two thiocyanate anions are terminally coordinated to each copper through their N donors (Fig. 1 and Table 1). The resulting complex reveals a centre of inversion. The coordination geometry about each Cu<sup>II</sup> is distorted square pyramidal ( $\tau = 0.197$  (1), Addison *et al.*, 1984) with the bridging O, N<sub>amine</sub>, N<sub>pyridine</sub> and N<sub>thiocyanate</sub> forming the base and a bridging O forming the apex. The Cu—O<sub>base</sub> and Cu—O<sub>apex</sub> distances are 1.9342 (8) and 2.2526 (8) Å respectively. The Cu—N<sub>thiocyanate</sub> distance [1.9678 (11) Å] is in the range observed for other copper(II) complexes containing coordinated thiocyanate (Wang & Li, 2005; You & Zhu, 2004; You, 2005; You & Zhu, 2005). The bond distances to the central copper [Cu—N(1) 2.0095 (10) Å, Cu—N(2) 2.0292 (10) Å, Cu—O 1.9342 (8) Å] are comparable to those observed for related complexes (Shakya *et al.*, 2005) and (Biswas *et al.*, 2005).

**Experimental**

The complex was synthesized in a three-step process. 1. The ligand (2-pyridylmethyl)(2-hydroxybenzyl)amine ( $L^1H$ ) was synthesized as described below (Yisgedu, 2001). To 5.4 g (50 mmol) of 2-(2-aminomethyl)pyridine in 10 ml of ethanol was added 6.1 g (50 mmol) of salicylaldehyde in 15 ml of ethanol which resulted in a deep yellow colour. The solution was left to stir for 30 m. A sodium borohydride solution (3 g NaBH<sub>4</sub>, 0.4 g NaOH, and 40.0 ml of H<sub>2</sub>O) were added dropwise. The solution changed to colourless and was left to stir for 1 h after adding all the NaBH<sub>4</sub> solution. The volume of the solution

## supplementary materials

---

was reduced to 20 ml after extracting three times with chloroform (3 x 40 ml). The extracts were combined and dried in anhydrous Na<sub>2</sub>SO<sub>4</sub> overnight. The Na<sub>2</sub>SO<sub>4</sub> was filtered and the filtrate concentrated to give a colourless oil (9.3 g, 87%).

2. Copper(II) perchlorate precursor complex was synthesized as follows (Yisgedu, 2001): 1.64 g (7.7 mmol) of *L*<sup>1</sup>H was mixed with 2.86 g (7.7 mmol) of Cu(ClO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O in 25 ml MeOH and 1.75 ml NaOCH<sub>3</sub>. The solution mixture was stirred overnight and a green filtrate of precipitate (2.7 g) was obtained. This was washed with EtOH/MeOH (2:1), then crystallized from CH<sub>3</sub>CN/CH<sub>3</sub>NO<sub>2</sub>.

3. Cu(II) thiocyanate complex was synthesized as follows: 0.1 mmol (0.0835 g) of the dinuclear Cu<sup>II</sup> perchlorate complex was dissolved in 15 ml s of EtOH and reacted with 0.25 mmol (0.0203 g) of NaSCN dissolved in 10 ml s EtOH. The mixture was stirred for 18.5 h. A mixture of solids and supernatant were obtained at the end of the reaction. The supernatant was decanted and the solids were re-dissolved in 7.5 ml of DMF, filtered and layered with diethyl ether and left to crystallize. Dark-green crystals suitable for X-ray diffraction were obtained and used for X-ray structure determination.

### Refinement

H atoms were placed in geometrically idealized positions and constrained to ride on their parent atoms with C—H distances of 0.95 and 0.99 Å  $U_{iso}(H) = 1.2U_{eq}(C)$ . The H atom attached to N was idealized with an N—H distance of 0.93 Å.

## supplementary materials

---

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
