Enhancement effect of reduced graphene oxide and silver nanocomposite supported on poly brilliant blue platform for ultra-trace voltammetric analysis of rosuvastatin in tablets and human plasma†

Marwa R. El-Zahry * and Marwa F. B. Ali

The enhancement effect of reduced graphene oxide (rGO) combined with silver nanocomposite supported on poly brilliant blue (PBB) platform was investigated for ultra-trace analysis of rosuvastatin (RS). Herein, *in situ* electrochemical deposition of the silver nanoparticles (AgNPs) and rGO hybrid was performed on the surface of the polymerized brilliant blue (PBB) platform. The developed (AgNPs-rGO/PBB) electrode showed an enhanced catalytic activity toward the oxidation of RS. The modified electrodes AgNPs-rGO/PBB and AgNPs/PBB required an overpotential of 0.68 and 1.06 V to achieve a current density of 10 mA cm⁻², and their corresponding Tafel slopes were calculated to be 70 and 105 mV dec⁻¹, respectively. Further, rGO and silver nanocomposites properties were characterized by scanning electron microscopy (SEM), cyclic voltammetry (CV), square wave voltammetry (SWV), linear sweep voltammetry (LSV), and electrochemical impedance spectroscopy (EIS). Additionally, the formation of GO and AgNPs-rGO was confirmed by Raman spectroscopy and Fourier transform infrared spectroscopy (FT-IR). Under the optimized conditions, the electrochemical sensor showed a remarkable response for quantitation of RS over a wide range of concentrations 5 × 10⁻⁹ to 5 × 10⁻⁷ mol L⁻¹ (*r* = 0.9988), with a limit of detection 2.17 × 10⁻⁹ mol L⁻¹. The electrochemical performance of the studied electrode showed high reproducibility and suitability for tablets and human plasma.

Introduction

Recently, bi- and multi-layered modified electrodes have attracted much attention for the analysis of pharmaceutical and environmental samples due to their high sensitivity, selectivity and electro-catalytic activity.¹

Graphene is a source of most graphitic materials and contains one single layer of carbon atoms. The most interesting properties of graphene are high mechanical strength and tunable optical properties. Among the various methods of graphene exfoliation, oxidation of graphite using strong oxidizing agents forming graphene oxide (GO), a non-conductive hydrophilic material, received great attention due to its simple synthetic protocol. Hummer's method was commonly used for the oxidation of graphite.² To retain the aromatic backbone, GO was reduced either chemically using different reagents or electrochemically by applying more negative potential to reduce the

oxygen functional group present on the surface of GO.³ It was reported that the electrochemically reduced graphene oxide will be more conducting than that prepared from chemical reduction.⁴

Incorporation of metal nanostructures with graphene or rGO greatly influences the electrochemical biosensors which accompanied by an improvement in biosensor sensitivity due to the synergistic effect between rGO and the metal nanostructures. In this study; silver nanoparticles (AgNPs) were selected due to their high conductivity, high surface reaction activity, high catalytic efficiency, strong adsorption ability, high spectral properties and ease of preparation.^{5,6}

Brilliant blue (BB), is a triphenylmethane dye widely used for protein staining in analytical biochemistry field. BB was chosen as a combined valence compound applied on the electrode surface *via* electro-polymerization forming electro-active layers of poly brilliant blue (PBB). The well-organized layers of PBB over the surface of pencil graphite electrode (PGE) act as a platform for dispersion of the *in situ* deposited AgNPs-rGO hybrid nanocomposites.

Rosuvastatin (RS) is a highly effective anti-hyperlipidemic drug acts by inhibiting 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase enzyme, which catalyzes the conversion

of HMG-CoA to mevalonate in cholesterol biosynthesis.⁷ RS reduces low-density lipoprotein (LDL), inhibits hepatic synthesis of very-low-density lipoprotein (VLDL) and lowers triglycerides levels in hypertriglyceridemic patients.⁸ RS has shown a great effect to reduce the rate of mortality in coronary patients and prevent cardiovascular events in ischemic heart disease patients. Owing to its importance, several techniques were reported for determination of RS such spectrophotometry,^{9–12} spectrofluorimetry,¹³ capillary electrophoresis,¹⁴ HPTLC,^{15–17} electrochemistry,^{18–23} and HPLC.^{24–29} Electrochemical techniques exhibited a recent interest owing to its high sensitivity, good selectivity, reproducibility, and rapidity when compared with other analytical methods. Hence, the presented article selected square wave voltammetric (SWV) technique as the technique of choice for detection of RS in different matrices.

Moreover, PGE was selected in the present investigation because of its high electrochemical reactivity, low background current, good mechanical rigidity, disposability, low cost and commercial availability. It offers renewal surface which is simpler and faster than polishing procedures, ease in modification and more environmentally friendly.^{30,31}

In the present work, an electrochemical sensing platform based on *in situ* electro-deposition of AgNPs-rGO (outer layer) on PBB surface (inner layer) was fabricated to modify a graphite electrode (PGE). The presented modified electrode showed an excellent sensitivity compared with other reported electrochemical and HPLC methods.^{18–29}

The main aim of this study is to investigate the role of rGO in facilitating the charge transfer between the AgNPs and the polymerized BB on PGE surface. The modified electrode was characterized by cyclic voltammetry (CV), square wave voltammetry (SWV), linear sweep voltammetry (LSV), electrochemical impedance spectroscopy (EIS). Scanning electron microscope (SEM) was used to follow the morphological properties of the electrode after each preparation step. The formation of GO and AgNPs-rGO was confirmed using Raman and FT-IR spectroscopy. The proposed SWV method was optimized, validated and successfully employed for determination of RS in pharmaceutical tablet and human plasma following ICH guidelines.³²

Experimental

All chemicals, instruments and the preparation steps were mentioned in the ESI.† The fabrication process of the newly developed electrode was shown in Scheme 1.

Results and discussion

Characterization of AgNPs-rGO/PBB modified electrode

FT-IR and Raman spectroscopy characterization of AgNPs-rGO hybrid nanocomposite. GO was prepared following the modified Hummer's procedure,² the synthesized GO powder was characterized using FT-IR and Raman spectroscopic techniques. As shown in Fig. S1A (shown in ESI†), the FT-IR spectrum of graphite exhibited no significant peak indicating the chemical inertness of graphite, while GO spectrum showed

Scheme 1 Schematic presentation of the steps involved in fabrication of AgNPs-rGO/PBB and AgNPs/PBB bi-layered modified electrodes.

various functional groups. An intense peak at 3430 cm^{-1} is attributed to O–H stretching vibration indicating the presence of OH or COOH groups in GO structure. The peak at 1732 cm^{-1} is due to stretching vibration of carbonyl group (C=O), while O–H deformation is observed at 1410 cm^{-1} and C–O stretching vibration of alkoxy group (1050 cm^{-1}) is also observed.³³

In situ deposition of AgNPs-rGO on the electrode surface was achieved electrochemically *via* reduction of oxygen groups present on the surface of GO. The fabricated AgNPs-rGO electrode was further characterized by monitoring Raman spectra of both GO and AgNPs-rGO. Fig. S1B† shows the recorded Raman spectrum of GO which displays two main peaks at 1349 and 1595 cm^{-1} corresponding to D and G bands, respectively.³¹ Comparing with GO, the Raman spectrum of AgNPs-rGO was recorded in which D and G bands were shifted to lower wavenumbers at 1347 and 1591 cm^{-1} which is attributed to the reduction of GO during the electrodeposition process. Additionally, the Raman spectrum of AgNPs-rGO showed a greater intensity compared to GO, which confirms the incorporation of AgNPs to rGO nanocomposite and the surface enhanced Raman scattering (SERS) produced by AgNPs.³⁴ The electrochemical deposition was carried out using cyclic voltammetric technique, where different factors such as the GO concentration and deposition potential were optimized. The maximum current peak of RS was obtained using 0.25 mg mL^{-1} GO using potential ranged from 0 V to -1.5 V at 100 mV s^{-1} scan rate.

Scanning electron microscopy (SEM) characterization. In order to follow the morphological changes that appear on the surface of PGE during the preparation procedures, SEM images of bare PGE, PBB layer and AgNPs-rGO/PBB surfaces were collected. Fig. 1A shows the characteristic features of bare PGE surface with wrinkling and overlapped sheets. After polymerization of BB monomers on PGE surface (Fig. 1B); a rough and porous surface is clearly seen with the formed flocculated structures indicating the formation of PBB platform. In Fig. 1C, there are bright particles formed after the *in situ* electro-deposition of AgNPs-rGO on PBB platform which provides a good dispersion of AgNPs all over the surface of the electrode.

Fig. 1 Schematic diagram of the bi-layered modified electrode accompanied with SEM images of the boundaries surface of (A) bare PGE, (B) PBB/PGE and (C) AgNPs-rGO/PBB.

Electrochemical behavior of AgNPs-rGO/PBB toward RS electro-oxidation. To demonstrate the electrochemical performance of the modified electrodes, cyclic voltammograms of RS were scanned using bare PGE, rGO/PBB and AgNPs-rGO/PBB electrodes (Fig. 2A). Comparing with rGO/PBB and bare PGE, the enhancement effect of AgNPs-rGO/PBB modified electrode on the oxidation current peak of 3.5×10^{-7} mol L⁻¹ RS was observed at 1.15 V (*vs.* Ag/AgCl). Additionally, SWV technique was utilized to investigate the electrocatalytic oxidation behavior of RS using bare PGE and glassy carbon electrode (GCE).

It can be revealed that rGO enhances the electroactive properties of the studied electrode; this behavior may be attributed to the synergistic effect of rGO incorporated with silver nanocomposites. The improved performance is based on facilitating the electron transfer between the outer layer AgNPs-rGO and the inner PBB layers through the conducting material rGO. Additionally, increase the surface active area of the studied electrode caused by AgNPs incorporation could be another reason for the improved electroactive properties.³⁵

In order to demonstrate rGO significance on the electrode performance, an overlay of another modification, AgNPs/PBB electrode without using rGO, was constructed and compared electrochemically with AgNPs-rGO/PBB toward electro-oxidation of RS (Fig. 2B). The AgNPs/PBB exhibited a lower activity towards RS oxidation. This decline in the electrical response confirms the significance of rGO as a conducting element providing an excellent charge transfer between the presented layers.³⁶

Optimization of the inner poly brilliant blue layer (PBB). As the thickness of the polymer layer affects the electro-catalytic activity of the modified electrode, the optimal conditions of BB polymer growth on the modified electrode were investigated. From the obtained results (Fig. 3A–C), it was found that the optimum potential range of the BB electro-polymerization process is -0.5 V to 1.5 V using 100 mV s⁻¹ scan rate for 7 multiple cycles.

Effect of scan rate and the suggested electro-oxidation mechanism of RS. The effect of scan rate ranged from 0.05 V to 1.0 V s⁻¹ was investigated at AgNPs-rGO/PBB modified

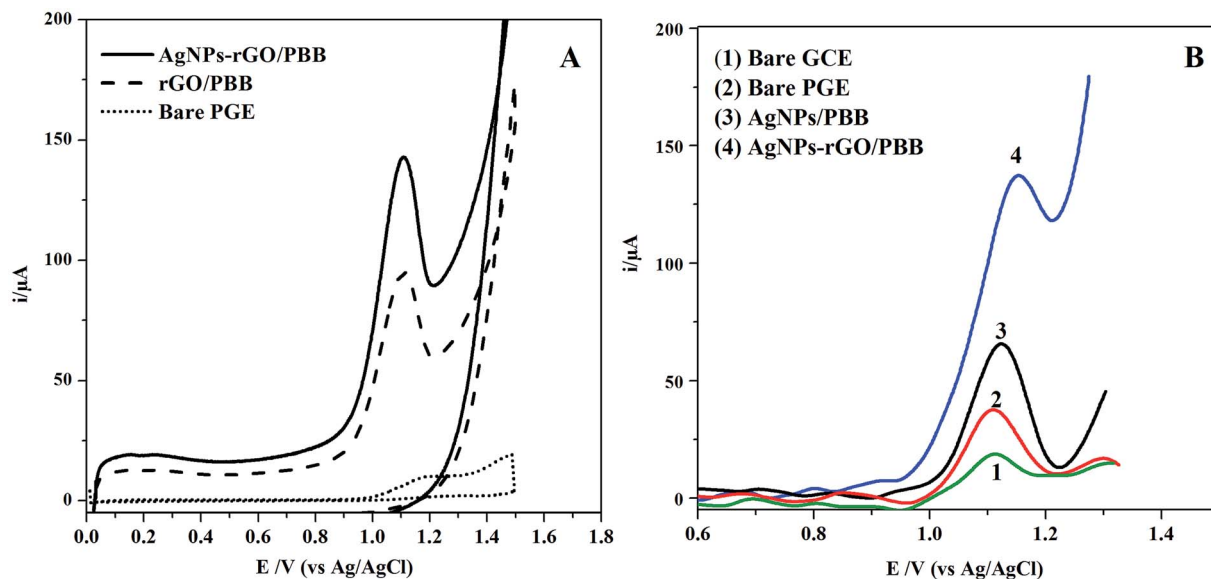

Fig. 2 (A) CV curves of RS recorded at bare PGE, rGO/PBB and AgNPs-rGO/PBB in $0.15 \text{ mol L}^{-1} \text{ H}_2\text{SO}_4$ under the optimum conditions and (B) SWV curves of $3.5 \times 10^{-7} \text{ mol L}^{-1}$ of RS at different electrodes.

electrode. According to Randles-Ševčík equation, the peak current is directly proportional to the scan rate.³⁷ Fig. 4 shows an increase in the anodic peak current accompanied with a shift in the anodic peak potential to more positive values with increasing the scan rate, which is observed when the oxidation reaction is irreversible. A good linearity was obtained upon plotting the anodic peak current against the studied range of scan rate following the equation below:

$$I_p (\mu\text{A}) = 105.5 + 31.5\nu, (R = 0.9972)$$

Fig. 5 describes the linear plot of $\log I_p$ versus logarithm of scan rate ($\log \nu$) which can be described by the following regression equation:

$$\log I_p (\mu\text{A}) = 2.09 + 0.473 \log \nu, (R = 0.9949)$$

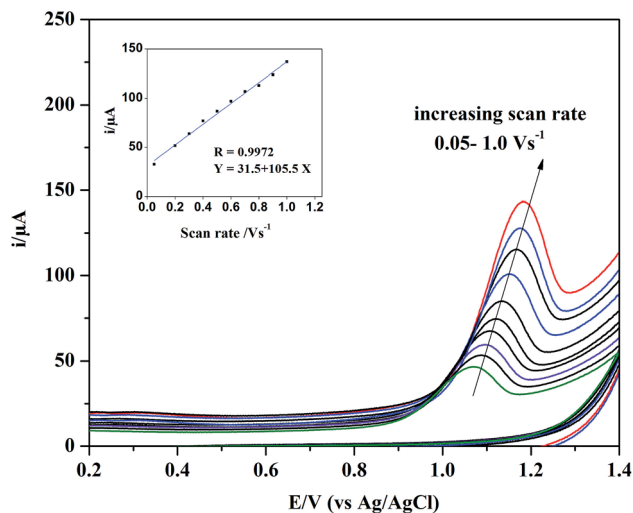

Fig. 4 The effect of different scan rates on CV curve of $3.5 \times 10^{-7} \text{ mol L}^{-1}$ RS. Inset: dependence of oxidation peak current ($I_p/\mu\text{A}$) of RS on scan rate (V s^{-1}).

Fig. 5 Dependence of the logarithm of peak current ($\log I_p/\mu\text{A}$) and the oxidation peak potential (E/V) on logarithm of scan rate (V s^{-1}).

The slope of the above linear equation was calculated to be 0.47, a result close to the theoretical value of 0.5 predicted by Randles–Ševčík's equation for the diffusion-controlled process. Additionally, the relationship between the peak potential E and logarithm of scan rate ($\log \nu$) was plotted and provided a linear regression equation as follow:

$$E (\text{V}) = 1.14 + 0.087 \log \nu, (R = 0.9969)$$

Based on Laviron equation,³⁸ a relationship between the potential and the scan rate, the number of electron (n) transferred in the rate limiting step can be calculated as given by the following equation:

$$\text{Slope of the plot } E \text{ versus } \log \nu = 2.2303RT/\alpha nF$$

R is the universal gas constant ($8.314 \text{ J mol}^{-1} \text{ K}^{-1}$), taking T with 298 K, α is the transfer coefficient ($=0.5$ in totally irreversible reactions) and F is the Faraday constant ($96.480 \text{ C mol}^{-1}$). After substitution the slope with 0.087, the value of αn will be equal to 0.62 and the number of electron is estimated to be 1.2 (≈ 1.0 electron) which is in agreement with the previously reported researches discussing electro-oxidation of RS.^{19–21} As it previously reported, the electro-oxidation process of RS is based on Kolbe electrolysis reaction of the carboxylic acid group. This reaction is based on decarboxylation dimerization of two carboxylate ions. The protonated carboxyl group loses one electron and one proton in an irreversible oxidation reaction with the formation of a carboxyl radical. Due to the instability of this radical, it rapidly loses carbon dioxide (CO_2), producing a C-centered radical. Finally, the C-centered radicals suffer a coupling to produce the dimer.³⁹ The scheme as reported for the RS oxidation reaction is shown in ESI (Fig. S2†).

Electrochemical characterization of the modified electrode using potassium ferricyanide. The electrochemical performance of the bare and modified PGE electrodes were evaluated using the redox activity of 1.0 mmol L^{-1} potassium ferricyanide $\text{K}_3[\text{Fe}(\text{CN})_6]$ in 0.5 mol L^{-1} of KCl using CV technique (Fig. 6A). The enhanced performance of AgNPs-rGO/PBB modified electrode was clearly shown in terms of higher peak current intensities of the reduction–oxidation peak of potassium ferricyanide redox system. This behavior was further confirmed by carrying out electrochemical impedance spectroscopy (EIS) experiments that showed lower series resistance for each of the modified electrodes than the bare one.

The interfacial properties of the modified electrodes were studied using EIS method. Fig. 6B represents the Nyquist plots of the three different studied electrodes, namely (1) bare PGE, (2) AgNPs/PBB and (3) AgNPs-rGO/PBB. It was performed at a potential amplitude of 10 mV at frequency range of 1.0 Hz and 10 KHz. R_{ct} is the diameter of the semi-depressed circle and corresponds to charge transfer process across PGE electrode, W_s is the generalized Warburg impedance for finite diffusion of the reactants. The Nyquist plot describes the charge transfer resistance (R_{ct}) and its relationship with the charge transfer across the electrode surface. R_{ct} values were calculated using Zview software (Z-view version 3.5d). The diameter of the semi-depressed circle is the smallest in case of AgNPs-rGO/PBB. The small values of R_{ct} indicate the enhancement of the electrical conductivity and the speed of the electron transfer. The Nyquist plots of the modified electrodes show linear curves indicating a diffusion behavior comparing with the bare electrode which shows a clear circular curve. Fig. 6C represents the change in charge transfer resistance of potassium ferricyanide redox system as a result of different treatment on the PGE electrode.

The overpotential (η) required at the current density (mA cm^{-2}) is considered a benchmark to evaluate the electrocatalytic activity of the proposed electrode.⁴⁰ As shown in Fig. 7A, the modified electrode AgNPs-rGO/PBB achieved a lower overpotential $\sim 0.68 \text{ V}$ to reach 10 mA cm^{-2} current density as compared to AgNPs/PBB ($\sim 1.06 \text{ V}$). The lower overpotential value of AgNPs-rGO/PBB contributes to the higher

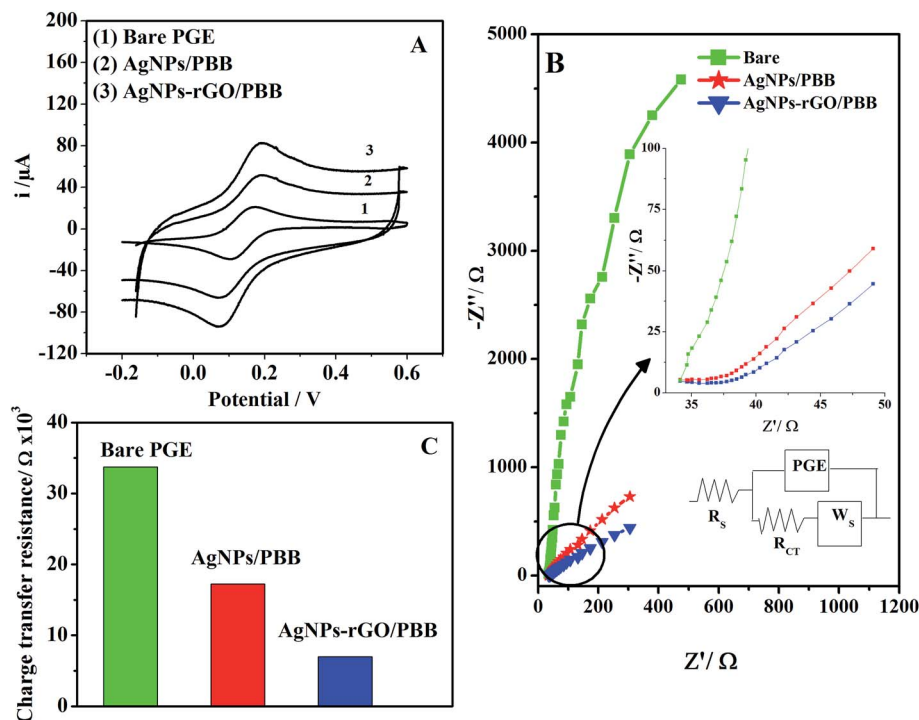

Fig. 6 (A) CV curves, (B) Nyquist plots of 1.0 mmol L^{-1} potassium ferricyanide in 0.5 mol L^{-1} KCl monitored on (1) bare PGE, (2) AgNPs/PBB and (3) AgNPs-rGO/PBB electrode. Inset: enlarged view at lower frequency range, and (C) the corresponding histogram of change in charge transfer resistance. Working conditions: scan rate 100 mV s^{-1} and potential range -0.2 V to 0.6 V .

electrocatalytic activity. For better understanding the catalytic kinetics of the studied electrodes, the Tafel plots ($\log j$ vs. η) were constructed for the studied electrodes by monitoring linear scan voltammetry (LSV) (Fig. 7B) at scan rate 10 V s^{-1} and fitted into the Tafel equation,

$$\eta = a + b \log j$$

where η is overpotential and j is the current density. The fitted Tafel plots of the bare PGE and the modified electrodes are presented in Fig. 7C. AgNPs-rGO/PBB shows Tafel slope of 70 mV dec^{-1} lower than that of AgNPs/PBB (105 mV dec^{-1}) suggesting that AgNPs-rGO/PBB exhibits the best electrocatalytic behavior over the other studied electrodes.

According to Randles-Sevcik equation, the surface active areas of the studied electrodes have been calculated after each modification step:

$$I_{pa} = (2.69 \times 10^5) n^{3/2} A_{\text{eff}} D_R^{1/2} C_0 \nu^{1/2}$$

where n is the number of electron transfer, A_{eff} is the surface area of the electrode (cm^2), D_R is the diffusion coefficient ($\text{cm}^2 \text{ s}^{-1}$), ν is the scan rate (V s^{-1}) and C_0 is the concentration of potassium ferricyanide (mol cm^{-2}). The surface active areas of bare, AgNPs/PBB and AgNPs-rGO/PBB were calculated to be: 44, 86 and 182.2 mm^2 , respectively. The results in Fig. 7D indicate the enhancement effect of the incorporated rGO layer with AgNPs supported on PBB platform causing a cumulative increase in the surface active area and hence in the oxidation peak current of RS on the fabricated electrode.

Effect of supporting electrolyte pH and voltammetric parameters. In order to develop a highly sensitive and selective response of the modified electrode, several parameters such as pH of supporting electrolyte and various instrumental parameters that affect the electro-oxidation of RS have been optimized. The pH of the supporting electrolyte has a significant effect on the electro-oxidation of RS at the modified electrode. The electro-oxidation of RS ($2.5 \times 10^{-7} \text{ mol L}^{-1}$) was investigated over pH range 2.5–8.0 in different electrolytes. It was found that oxidation peak current increases with decreasing pH value until it reaches pH 2.5. Therefore, different acid solutions such as sulphuric, hydrochloric, acetic and phosphoric acid were tested, and sulphuric acid showed the highest results. Further, different concentrations of sulphuric acid over the range $0.05\text{--}0.25 \text{ mol L}^{-1}$ were tried. Sulphuric acid of 0.15 mol L^{-1} was selected as the optimum concentration for RS determination which well agreed with the previously reported method.²¹ In addition, different SWV parameters were optimized, including; pulse height, step height, frequency, initial potential and deposition time. Table 1 summarized the investigated parameters and the obtained results that give the maximum response after optimization.

Validation of the proposed method

Linearity and detection limit. Under the optimum conditions; SWV method was utilized for construction of RS calibration plot over the concentration range of 5×10^{-9} to $5 \times 10^{-7} \text{ mol L}^{-1}$ using a scan rate of 40 mV s^{-1} (Fig. 8). The limit of detection (LOD = $3S_b/m$) and the limit of quantitation (LOQ =

| Parameters | Studied range | Best response |
|-----------------------|---------------|---------------|
| Pulse height (mV) | 3 to 30 | 15 |
| Step height (mV) | 1 to 30 | 10 |
| Frequency (Hz) | 50 to 250 | 200 |
| Initial potential (V) | -0.6 to 0.6 | 0.0 |
| Deposition time (s) | 10 to 180 | 30 |

$10S_b/m$); where S_b is the standard deviation of the intercept and m is the slope of the calibration line are equal to 2.17×10^{-9} and $6.66 \times 10^{-9} \text{ mol L}^{-1}$, respectively. All the linear regression parameters of the proposed method are presented in Table 2.

Precision. To investigate the stability of the AgNPs-rGO/PBB performance, the precision of the proposed method was studied through inter- and intra-day repeatability measurements. Intra-day precision was evaluated by repeating the analysis of three different concentration levels of RS working solution. This study was repeated over a period of three working days to study the inter-day repeatability. The intra- and inter-day precision were expressed as relative standard deviation (% RSD) which was found to be less than 3.96%, indicating high stability, good repeatability and reproducibility of the modified electrode (Table 2).

Interference study. In order to estimate the selectivity of the modified electrode for determination of RS, the effect of different interfering compounds have been investigated. Hence, $2.5 \times 10^{-7} \text{ mol L}^{-1}$ of RS solution was determined using the proposed

Fig. 8 Linear plot between the oxidation peak current and different concentrations of RS. Inset: SWV curves of RS monitored on the studied modified AgNPs-rGO/PBB electrode.

modified electrode in the absence and presence of the following substances: ascorbic acid, citric acid, starch, glucose, sucrose, uric acid and magnesium stearate. As presented in Table 3, the ratio of RS/concomitant has been adopted to be 1 : 10 and 1 : 100. The adopted ratio 1 : 100 is much higher than that found in RS pharmaceutical dosage forms, as these substances are used in pharmaceutical formulations at a mass concentration of 2–5% m/m. From the presented results in Table 3, it can be inferred that there is no significant interference from these matrices on the voltammetric determination of RS.

Determination of RS in pharmaceutical tablets and human plasma. In order to demonstrate the applicability of the modified electrode as a sensing probe of RS in complicated matrices, RS concentrations were monitored in two different matrices; pharmaceutical dosage forms and human plasma. Initially, three pharmaceutical tablets with different RS contents were purchased from local market and analyzed using the modified electrode. The accuracy was studied and good recoveries were obtained (96.6–99.5%) with good agreement with the claimed amounts as shown in Table 4. The obtained results were statistically compared to those obtained by another reported method of RS determination.¹² The calculated *t* and *F* values at 95% confidence level were less than the tabulated ones indicating the high accuracy of the developed voltammetric method.

The recovery of RS from human plasma samples was measured by spiking the plasma sample with known amount of RS standard solution at four different concentration levels. Table 4 shows the found amounts and the calculated recovery percentages of RS quantitation in human plasma samples after simple liquid–liquid extraction method. The obtained recoveries, ranged from 97.2 to 101.2%, indicate the analytical utility and the potentiality of the modified electrode to be used as an ultra-sensor for voltammetric determination of RS with excellent sensitivity and reproducibility.

Comparative study of the proposed and the previously reported methods. The sensitivity of the proposed method was compared with different reported methods for determination of RS

either in pharmaceutical dosage forms or in biological fluids. As shown in Table 5, the proposed method is considered the superior in sensitivity compared with all electroanalytical methods and most of the previously reported chromatographic methods for RS determination. Moreover, PGE provides another advantage of the proposed method, as it is simple, with high electrochemical reactivity, cost effective and more environmentally friendly electrode.

Conclusion

An electrochemical sensing platform was constructed using rGO and silver nanocomposites to modify pencil graphite electrode. The AgNPs-rGO/PBB bilayered sensor was developed using *in situ* electro-deposition of rGO and AgNPs hybrid. The modified electrode was characterized using different methods; CV, SWV, LSV, electrochemical impedance, SEM images, FT-IR spectroscopic and Raman spectroscopic methods. The electro-catalytic behavior of the studied electrodes has been further evaluated by calculating the overpotential at current density 10 mA cm^{-2} and the Tafel slopes from the fitted Tafel plots. It has been concluded that the *in situ* electrochemical deposition of AgNPs-rGO over PBB platform enhanced the performance of the studied electrode. This behavior may be attributed to the synergistic effect of the conducting properties of rGO and increasing the surface active area as a result of silver nanocomposites incorporation. The increase in the contacted area of the studied analyte on the electrode surface was confirmed by calculating the surface active area using Randles-Sevcik equation. The obtained electrochemical sensing platform was successfully applied for the ultra-trace determination of RS in pure, pharmaceutical dosage forms and human plasma with detection limit of $2.17 \times 10^{-9} \text{ mol L}^{-1}$.

Ethical approval

The application on human plasma samples was performed in accordance with the Declaration of Helsinki and approved by the Egyptian Network of Research Ethics Committees (ENREC). Informed consents were obtained from human participants of this study.

Conflicts of interest

The authors report no conflicts of interest.
