P001 THE FEASIBILITY STUDY OF CHEMICALLY ASSISTED ENDOSCOPIC SUBMUCOSAL DISSECTION USING MESNA FOR SUPERFICIAL OESOPHAGEAL SQUAMOUS NEOPLASMS

A. Dobashi[1,*], K. Goda[1], M. Kobayashi[1], K. Sumiyama[1], H. Toyoizumi[1], T. Kato[1], H. Tajiri[1,2]. [1]*Endoscopy,* [2]*Gastroenterology and Hepatology, THE JIKEI UNIVERSITY OF MEDICINE, Tokyo, Japan*

INTRODUCTION: In Western countries, ESD was not commonly performed because the submocosal dissection is technically challenging. We reported that the injection of mesna solution (sodium-2-mercaptoethanesulfonate) made submucosal connective tissues chemically softened and facilitated mechanical dissection of the submucosal layer in the stomach [1]. Our previous study suggested that mechanical dissection with mesna might make an ESD for gastric cancer safer and easier. There has been no study to evaluate the feasibility of mechanical dissection with mesna for superficial oesophageal squamous neoplasms (SOSNs).
AIMS&METHODS: The aim of this study was to evaluate the feasibility and safety of chemically assisted ESD using mesna in 20 consecutive patients with SOSNs. Submucosal fluid cushion was made by 0.4% sodium hyaluronate and then the lesion was circumferentially isolated from surrounding normal mucosa as a conventional ESD method with needle knife (Dual knife, Olympus medical systems). After that, 4 to 8 mL of 10% mesna solution was injected into the submucosal layer and mechanical submucosal dissection was performed by cleaving the submucosal layer with the tip of a cap-fitted endoscope. The number of electrosurgical incision as well as coagulation for hemostasis by stepping the foot switch of high-frequency wave apparatus (VIO 300, ERBE) and the procedural time were recorded by dedicated software (VIO Doku, ERBE) in real time. We also performed conventional ESD without mesna for each consecutive10 SOSNs as control during before and after mesna ESD. Operators and lesion size matched paired t test was analyzed by comparing each result of mesna and conventional ESD groups.
RESULTS: The mean size of resected sample was 31.1 ± 8.6 mm, with an en bloc resection rate of 100%. The number of electrosurgical incision during submucosal dissection procedure in mesna group was significantly smaller than that in conventional group (mean; 89.8 ± 82.3 vs. 232.4 ± 150.9 times, $p < 0.01$). The procedural time of submucosal dissection in mesna group tended to be shorter than that in conventional group (mean; 10.5 vs. 17.3 minutes, p=0.056) while there was no significant difference. There was also no significant difference between mesna and conventional groups in the number of coagulation for hemostasis (mean; 7.1 vs. 3.8 times, p=0.19). There was no perforation and no uncontrollable hemorrhage. Ulcerations healed normally within 2 months.
CONCLUSION: The mechanical submucosal dissection with mesna for SOSNs deem safe and may facilitate procedure of conventional ESD.

P002 ENDOSCOPIC SUBMUCOSAL DISSECTION OF SPORADIC NON-AMPULLARY DUODENAL SUPERFICIAL NEOPLASMS - EVOLUTION OF THE TECHNIQUE TOWARDS THE DECREASE OF THE COMPLICATION RATE

J. Cyrany[1,*], H. Ivekovic[1], R. C. P. Yeung[1], A. Jouret-Mourin[2], H. Piessevaux[1], P. H. Deprez[1]. [1]*Gastroenterology,* [2]*Pathology, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

INTRODUCTION: Endoscopic submucosal dissection (ESD) technique enables treatment of lesions untreatable by conventional mucosal resection (such as incomplete lifting and residual lesions) and makes en-block resection more feasible. ESD in the duodenum is more challenging and has higher risk of complications than in the other parts of the digestive tract.
AIMS&METHODS: Endoscopic database in a single tertiary university centre was cross-examined to identify sporadic non-ampullary duodenal neoplasms treated by ESD between 1/2006 and 3/2013, ESD being only used in case of poor lifting during mucosal resection. Procedure was qualified as ESD when any type of an endoscopic knife was used: either as pure ESD (when the en-block resection was achieved) or as hybrid endoscopic procedure (when polypectomy snare was also used in a piecemeal manner). Procedures were divided into two halves according to the order of the procedure. Results were expressed as medians, first and third quartiles and were compared using Student's t-test and Fisher's exact test.
RESULTS: 26 ESD procedures in 25 patients were identified (out of a total of 110 duodenal non-ampullary mucosectomies): the first 13 in the group A, the rest in the group B. There were no significant differences between two groups in terms of age (66 [63-67] vs. 63 [58-69], p=0.2); sex (8 vs. 9 females; p very close to 1); lesion size (20 [15-30] vs. 25 [20-30], p=0.9) and presence of high grade dysplasia (2 vs. 5; p=0.4). 3 procedures in both groups were pure ESDs, prophylactic closure of the mucosal defect was used significantly more often in the group B (2 vs. 10 cases, p=0.005). The length of the procedure did not differ between groups (111 [80-149] vs. 96 [67-143] min, p=0.6). There were 4 (31%) vs. 2 (15%) intra-procedural perforations, 2 (15%) vs. 1 (8%) post-procedural bleedings and 2 (15%) vs. 0 post-procedural perforations. Sum of the complications was significantly reduced in the group B (8 [62 %] vs. 3 [23 %], p=0.05). No difference in the length of hospital stay was observed (3 [3-4] vs. 4 [3-5] days, p=0.6). Post-procedural complications were significantly reduced in prophylactic closure cohort (regardles of the order of procedures): 0 vs. 5 (36 %), p=0.04.
CONCLUSION: ESD in the duodenum is a laboured procedure with a significant risk of complications. During 7 years experience prophylactic closure of the mucosal defects was introduced without prolongation of the operation time and with a significant reduction of bleedings and perforations.

P003 USEFULNESS OF THE OROPHARYNGEAL INVERSION METHOD BY MEANS OF NASAL ENDOSCOPY

K. K. Kawada[1,*], T. Okada[1], J. Swangsri[1], H. Fujiwara[1], K. Saito[1], N. Fujiwara[1], S. Ohta[1], Y. Miyawaki[1], Y. Tokairin[1], Y. Nakajima[1], Y. Kumagai[1], K. Nagai[1], T. Kawano[1]. INTRODUCTION: Accompanying the progress in endoscopy, the number of discoveries of superficial carcinoma in the head and neck region has increased, but with oral-route endoscopy, there are areas that have proven to be difficult to view.
AIMS&METHODS: As a technique for observing in detail the root of tongue, which is an area that is difficult to observe, an oropharyngeal inversion method by means of nasal endoscopy is proposed. We intend to clarify the usefulness of such a method. The scopes used were EG-580NW and EG-530NW (Fujifilm, Tokyo). The image quality was good, and the angular field of view was wide-angle, at 140 degrees, with FICE used as standard equipment. An upward angle of 210° and significant flexing of the scope tip were possible.The subjects consisted of 172 cases in which the oropharyngeal inversion method by means of nasal endoscopy was performed, from April to October, 2012. After observation of the buccal cavity, the endoscope was inserted through the nose, and around where the endoscope passed the uvula, the patient was asked to open the mouth wide, stick the tongue forward as much as possible, and make a sound like "ayyy", whereupon the endoscope was set to its full upward angle, inverted, and observation was carried out. Recording was performed on a video recording device, and it was studied whether it was possible to obtain observations from the lingual root to the lingual apex.
RESULTS: Observation up to the lingual apex was possible in 160 cases (93%). It is now easier to obtain a frontal view of the vallate papillae, which until now could only be observed tangentially, using the oral route. We have found two superficial carcinomas of the root of tongue in half a year.
CONCLUSION: The oropharyngeal inversion method by means of nasal endoscopy is thus considered to be useful for observing the oropharynx.

P004 MAGNIFICATION ENDOSCOPY IN COMBINATION WITH ACETATE INSTILLATION AND A NARROW-BAND IMAGING SYSTEM FOR PREDICTING HISTOLOGIC CHARACTERISTICS OF GASTRIC MUCOSAL NEOPLASMS

K. Shibagaki[1,*], Y. Amano[2], N. Ishimura[3], H. Taniguchi[1], H. Fujita[1], K. Kobayashi[4], Y. Kinoshita[3]. [1]*Gastroenterology, Tottori Municipal Hospital, Tottori,* [2]*Endoscopy, Kaken Hospital, International University of Health and Welfare, Ichikawa,* [3]*Gastroenterology, Faculty of Medicine, Shimane University, Izumo,* [4]*Pathology, Tottori Municipal Hospital, Tottori, Japan*

INTRODUCTION: Magnification endoscopy with narrow-band imaging (NBIME) that enables a detailed visualization of the capillary patterns (CP) of superficial gastric neoplasms is useful for predicting their histologic types, although CP is often difficult to interpret. NBIME with acetate enhancement (acetate-NBIME) is effective for the observation of mucosal microstructure patterns (SP) of gastric mucosa.
AIMS&METHODS: The aim of this prospective study is to compare the predictability of acetate-NBIME and NBIME for the histologic types of gastric mucosal neoplasms. We photographed 147 gastric lesions (35 adenomas, 96 differentiated and 16 undifferentiated adenocarcinomas) with NBIME and acetate-NBIME. CP by NBIME was classified into the following four groups: Type C1: capillaries with homogenous diameters and distributions form round or oval networks, or grow within the regular microstructures, Type C2: capillaries with heterogeneous diameters and irregular distributions form a polygonal or incomplete network, or grow within the irregular microstructures, Type C3: capillaries with heterogeneous diameters and distributions grow in disorder with unclear mucosal microstructure, and Type C4: capillaries are invisible or obviously decreased. SP by acetate-NBIME was classified into the following three

groups: Type S1: glandular crypts are homogeneously sized, shaped and arranged, Type S2: glandular crypts are heterogeneous, and Type S3: glandular crypts are absent or severely decreased. Three experts independently reviewed the endoscopic images, and judged CP and SP. The correlations of CP and SP agreed by two or all of three reviewers with each histologic type were statistically analyzed, and the predictability of the histologic types was compared between both modalities.

RESULTS: The kappa values of interobserver agreement for CP and SP diagnosis were 0.61(0.57-0.64) and 0.63(0.55-0.71), showing good diagnostic concordances. Adenomas, differentiated, and undifferentiated mucosal adenocarcinomas were statistically related to type C1, C2, and C3 ($P<0.01$) in NBIME and to type S1, S2, and S3 ($P<0.01$) in acetate-NBIME, respectively. Type C4 was difficult to use as an indicator of specific histologic types. The kappa values of diagnostic concordance between each CP and SP and their related histologic types were 0.45(0.30-0.59) and 0.77(0.68-0.87), showing a statistical difference.

CONCLUSION: Acetate-NBIME shows a good clinical feasibility and the superiority to NBIME in predicting the histologic types of gastric mucosal neoplasms.

P005 ENDOSCOPIC SUB-MUCOSAL DISSECTION WITH A WATER JET SYSTEM ALLOWING INJECTION OF DIFFERENT VISCOUS SOLUTIONS: COMPARISON VERSUS SALINE ON EX-VIVO PIG STOMACHS

M. Pioche[1,2,*], M. Ciocrilan[3], V. Lépilliez[1], N. Gonon[4], C. Pinset[4], O. Guillaud[1], T. Ponchon[1]. [1]*Endoscopy unit, Edouard Herriot Hospital,* [2]*U1032, Inserm, Lyon, France,* [3]*Gastroenterology, Carol Davila Institute, Bucarest, Romania,* [4]*Reserch and development, Nestis, Lyon, France*

INTRODUCTION: Long lasting lifting is a key factor during ESD and can be obtained by water-jet injection of saline or by injection of viscous macromolecular solutions. These 2 techniques have never been used simultaneously. A new water-jet system with a high-pressure generator allowing injection of viscous solutions, even with retroflexed endoscope, has been developed.

AIMS&METHODS: We assessed the ability of this new system to inject viscous solutions in direct viewing and in retroflexion and we then compared injection of saline or hyaluronate 0.5% to perform ESD on ex-vivo pig stomachs. Using the jet-injector, four viscous solutions were tested. 10 ESD larger than 25 mm (5 in direct viewing and 5 in retroflexion) and one of more than 10 cm were performed with each solution. ESD with hyaluronate jet-injection was then compared to ESD with saline jet-injection performing 50 ESD in each group. A single low experienced operator conducted all the procedures.

RESULTS: All 145 resections were complete including all marking points with two perforations. We performed 11 jet ESD with hydroxyethyl starch, glycerol mix, hyaluronate sodic (0.5%) or poloxamer mix without injection issue. In the second part of the study, when compared to saline, significant benefit of hyaluronate was observed on dissection speed (0.80 cm2/min versus 1.08 cm2/min).

Solution	**Saline Serum**	Hyaluronate 0.5%	Statistics
Mean Maximal diameter	4.0 cm	4.2 cm	p=0.242
Mean duration	12.9 min	10.7 min	p=0.002
Surface (ellipse area)	9.9 cm^2	10.8 cm^2	p=0.483
Speed (surface/time)	0.80 cm^2/min	1.08 cm^2/min	$p<0.001$
Perforations	**1**	**0**	NS
Injection issue	**0**	**0**	NS

CONCLUSION: This is the first report on a water jet system allowing injection of macromolecular viscous solutions even with retroflexed scope. Dissection speed using jet injection of hyaluronate was significantly higher than using jet injection of saline. This jet injection of macromolecular solutions should be now tested on humans to evaluate the effect on morbidity.

P006 "TORNADO ESD": A NOVEL ESD TECHNIQUE WITH ROBUST AND ADJUSTABLE TISSUE TRACTION USING OVER-TUBE WITH A WORKING CHANNEL

M. Kato[1,*], M. Yamasaki[2], M. Hirota[2,3], Y. Miyazaki[2,3], N. Kawai[4], T. Yamada[1,5], M. Tsujii[6], T. Takehara[1], M. Mori[2], Y. Doki[2], K. Nakajima[2,3]. INTRODUCTION: Adequate tissue traction is a key to success in any kinds of advanced endoscopic intervention as well as surgical intervention. A simple over-tube, compatible with currently available flexible gastrointestinal endoscopes and instruments, has been newly developed to improve tissue traction.

AIMS&METHODS: The aim of this study was to evaluate this new over-tube in performing esophageal ESD using porcine models.

The prototype is a polyvinyl chloride tube (19mm OD and 22cm length) with a built-in side-channel (3mm OD), where a standard grasping forceps is passed for tissue traction. The strength and direction of traction is controlled by rotating the over-tube around the endoscope (i.e. "tornado technique"), while keeping the forceps grasping the tissue, and also by adjusting the depth of the grasping forceps inside the side-channel. After confirming its feasibility on bench tests, the prototype device was evaluated in acute porcine models (n=5). Two 20-mm virtual lesions were created in each animal (n=10). The "tornado ESD" was attempted on each lesion using a grasping forceps (FG-6L-1, Olympus) via side-channel, and a scissors-type electrosurgical knife (SB knife, Sumitomo Bakelite) via biopsy channel. Measured outcomes were completion rate of procedure, incident rate of any complication, rate of en bloc resection, and procedure time.

RESULTS: Esophageal ESD was successfully performed without any complications. En bloc resection was accomplished in all 10 lesions. Median procedure time for submucosal dissection was 22 minutes (ranged 10-50 minutes). The "tornado technique" was robust, adjustable, reproducible and effective in obtaining adequate tissue counter-traction during mucosal cutting and submucosal dissection.

CONCLUSION: The study revealed that "tornado technique" might contribute to safer and more efficient ESD by providing robust and adjustable tissue traction. This inexpensive technique may become an attractive option in standardizing technically demanding endoscopic interventions.

INTRODUCTION: The esophageal vascular system has been studied for long time as an *ex vivo* evaluation but with the advent of the endoscopy a clear direct view of the esophageal wall has been achieved, moreover with the NBI-magnifying endoscopy.

AIMS&METHODS: A comprehensive evaluation of all the esophageal vasculature from the endoscopists' point of view using advanced endoscopic techniques is here proposed.Images from 39459 upper GI endoscopies and 519 endoscopic treatment, performed at a single institution from may 2008 to august 2012, were collected and analyzed. To confirm the results achieved, an immunostained histological analysis was performed in 8 esophageal non-pathological specimens with the evaluation of the expression of CD34 and D2-40.

RESULTS: The entire esophageal wall is organized, from the lumen to outside, into five layers (epithelium, lamina propria with lamina nuscularis mucosa, submucosa, muscle layer, adventitia) with different vascular system belonging to each of them and connecting each other: Mucosa with the IPCL (Intra Papillary Capillary Loop) in the epithelium and the SECN (Sub-Epithelial capillary network) in the lamina propria and at the LES (Lower esophageal Sphincter) level also with the palisade vessels; Submucosa with the drainage vessels and the spindle veins just under the LES; Muscle layer with the perforating vessels; periesophageal veins in Adventitia. Advanced endoscopy allows the direct visualization of all these structures (Fig 1). Histopathologically, all (8/8) the specimens analyzed showed a high expression of CD34 in the areas corresponding with the IPCL, SECN and branching vessels.

Fig. 1 Schematic illustration of vascularization in the esophageal wall and at the esophago-gastric junction with the endoscopic corresponding images. Vessels are indicated with black arrows.

A: perforating vessel from the outer esophagus to the submucosa; image captured during POEM B: submucosal drainage vessel C: submucosal vessels connecting the drainage veins with the mucosal (lamina propria) branching vessels; D: Spindle veins immediately below the gastro-esophageal junction; E and F: white light and NBI of the Branching vessels. G: Palisade vessels, in the same level of branching vessels (lamina propria).

CONCLUSION: Magnifying endoscopy and operative endoscopy enable direct observation of esophageal wall vasculature in vivo from epithelium to adventitia.

P008 FABRICATED ALLOGENEIC EPIDERMAL CELL SHEET IN PORCINE MODEL: CELL TISSUE ENGINEERING APPROACH FOR THE PREVENTION OF ESOPHAGEAL STRICTURE AFTER CIRCUMFERENTIAL ESD

S. Kobayashi[1,2,*], N. Kanai[3], M. Yamato[2], T. Hosoi[2,4], N. Tanaka[2], T. Okano[2], S. Eguchi[1]. [1]*surgery, Nagasaki university graduated school, Nagasaki,* [2]*Institute of advanced biomedical engineering and science, Tokyo women's medical university,* [3]*Institue of advanced biomedical engineering and science, Tokyo women's Medical University,* [4]*Tokyo university of science, Tokyo, Japan*

INTRODUCTION: Sever stricture is one of the major problems of endoscopic submocosal dissection (ESD) for widespread superficial esophageal carcinoma. There are no effective preventive measures or treatment for this complication. We recently developed the fabricated epidermal cell sheet. The fabricated autologous epidermal cell sheet could inhibit esophageal constriction after circumferential ESD in swine model[1)]. For the standardization of this approach, it is important to evaluate not only autologous but also allogeneic transplantation.

AIMS&METHODS: We evaluated whether fabricated allogeneic epidermal cell sheets are safety and effectiveness for the prevention of severe esophageal constriction after circumferential ESD in swine model.

Firstly, fabricated epidermal cell sheet was optimized, and the function of epidermal cell sheet was histologically evaluated.

Secondly, fabricated epidermal cell sheets were transplanted after circumferential esophageal ESD and evaluated the effectiveness for the prevention of esophageal constriction after circumferential ESD. In more detail, after circumferential ESD of esophagus, allogeneic epidermal cell sheets were endoscopically transplanted to 3 pigs without immunosuppression referred as transplanted group. Other 3 pigs were only performed circumferential ESD and they referred as control group. Endoscopic and histological analyses were performed at 2 weeks after ESD.

RESULTS: Epidermal cells were cultured in temperature-responsive cell culture insert for 2 weeks at 37°C. After epidermal cell sheets were incubated at 20°C for 20 minutes, they were noninvasively harvested. Fabricated epidermal cell sheet was consisted of 3-5 layers and has a basement membrane-like extracellular matrix. Cytokeratin patterns of epidermal cell sheet were similar to the cytokeratin pattern of native epidermis. Labeled epidermal cell sheet was transplanted on the ulceration surface of esophageal ESD. Labeled epidermal cell sheet was histologically detected at 1 postoperative day.

In transplantation experiments, all pigs of transplanted group kept their clinical conditions in contrast to control group. Endoscopic and histological analysis demonstrated that allogeneic epidermal cell sheets promoted the healing of the artificial ulcer after ESD and prevented the esophageal stricture after ESD.

CONCLUSION: Fabricated allogeneic epidermal cell sheets have the potential for the prevention of esophageal constriction after extensive ESD.

P009 NARROW BAND IMAGING-BASED MAGNIFYING ENDOSCOPY POTENTIALLY PREDICTIVE OF EARLY GASTRIC CANCER IN BORDERLINE LESIONS BEFORE ESD

T. Maehata[1,*], Y. Sato[1], R. Morita[1], M. Suzuki[1], S. Nakatsu[1], S. Ishigooka[1], S.-I. Ozawa[1], K. Hosoya[1], Y. Watanabe[1], H. Yasuda[1], F. Itoh[1]. [1]*Gastroenterology and Hepatology, St. Marianna Univercity School of Medicine, Kawasaki, Japan*

INTRODUCTION: Endoscopic resection (ER) includes endoscopic submucosal dissection (ESD) is widely accepted as standard treatment for early gastric cancer (EGC) without lymph node metastasis. The procedure has some advantage that minimally invasive, safe, and convenient. Especially, large lesions can be resected en bloc by ESD technique. However, some incomplete resection will happen because we still do not have any appropriate diagnostic tool for decide benign-malignant borderline lesion. Recently, we have seen that narrowband imaging-based magnifying endoscopy (M-NBI) is more accurate than conventional white-light imaging (C-WLI) in diagnosis of gastric cancer. Our goal is to clarify potentially useful findings to predict the existence of gastric cancer in borderline lesions diagnosed by M-NBI, we retrospectively analyzed certain endoscopic features.

AIMS&METHODS: We diagnosed 168 consecutive gastric benign-malignant borderline lesions (152 cases) by C-WLI and M-NBI before ESD treatment. After we resected EGC lesions by ESD, we compared M-NBI diagnosis of borderline with pathological findings. M-NBI diagnosis was classified according to VS (vessel plus surface) classification system.

RESULTS: The final diagnosis for 149 lesions (88.7%) was adenocarcinoma, and for 19 lesions (11.3%) was adenoma. 168 lesions include 115 of mucosal and 34 of submucosal cancer. 156 of 168 (92.8%) lesions could successfully diagnose of the tumor by M-NBI. There was no significant difference of diagnostic accuracy in tumor size (>20mm, 54/62: < 20mm, 102/106). However, we found 12 mismatch (M-NBI and pathological findings) lesions that were mostly slightly depressed type (9 lesions of slightly depressed type, 3 lesions of flat type). Moreover, we pathologically found intraluminal bridge form in one mismatch case.

CONCLUSION: We were able to distinguish all protruded types of cancer. Endoscopic findings using VS classification system were potentially predictive of EGC in borderline lesions diagnosed by M-NBI before ESD.

P010 PENTAX I-SCAN™ WITH ELECTRONIC MAGNIFICATION FOR THE REAL-TIME HISTOLOGICAL PREDICTION OF COLONIC POLYPS: A PROSPECTIVE STUDY USING A NEW DIGITAL CHROMOENDOSCOPY SETTING

C. Robles-Medranda[1,*], R. Del Valle[1], H. Pitanga Lukashok[1], C. Robles-Jara[1]. [1]*ENDOSCOPY, INSTITUTO ECUATORIANO DE ENFERMEDADES DIGESTIVAS, UNIVERSITY HOSPITAL OMNI, ESPIRITU SANTO UNIVERSITY, Guayaquil, Ecuador*

INTRODUCTION: *i*-Scan is a digital chromoendoscopy (DCE) tool that has the potential for in vivo optical diagnosis of colonic polyps. EPK-I processors permits the combination of DCE with electronic magnification (EM). EPK-I combine 6 DCE post-processing settings (d, e, c, g, r and b) called tone enhancement (TE) with different levels of Contrast (CE) and Surface enhancement (SE) resulting in 216 possible combinations. However, 3 established modes (*i*-Scan 1, 2, 3) are available, leading to an under use of other setting combinations

AIMS&METHODS: AIM: to evaluate the DCE-settings available in EPK-I processors establishing ''New ISCAN Setting'' (NIS) modes and measuring its effectiveness with EM for the real-time histological prediction of colonic polyps. After approval by the ethics committee a single-center, prospective study was performed in 255 consecutive patients undergoing screening colonoscopy from Oct-2011/Sept-2012. Exclusion criteria were: <18 years; pregnancy, history of IBD, coagulopathy, absence of polyps and bad bowel preparation. To determine the NIS modes, initially 10 lesions were recorded as HD quality images with EM for each DEC setting combination, including the original settings and HD white light image. Analysis of all images was done using a visual analogue scale VAS (bad: 1 - excellent: 10) assessing the quality of image regarding the pit and vascular mucosal pattern rated by 3 endoscopists to determine the parameters of the *i*-Scan settings based on the highest VAS scores. Finally, an histological prediction of neoplastic (N) and non-neoplastic (NN) polyps using the unified NICE classification for pit and vascular pattern was done using the three highest score NIS modes and the established *i*-Scan modes. Results were compared with histology as the gold standard

RESULTS: 2170 HD images were analyzed and 3 settings were identified: NIS 1, 2, 3 showing a statistical significance ($p > 0.05$) for pit and vascular mucosal pattern compared to original setting (mean VAS: 9.2 vs. 4.16). 183 patients were excluded. Finally 72 patients with 122 polyps were analyzed, 34 males, mean age 59.3 (ranges: 18-91). NIS diagnosed 19/20 N and 102/102 NN lesions and *i*-Scan 16/20 N and 95/102 NN. The NIS was more precise to predict N and NN lesions when compared with *i*-Scan showing a sensitivity of 95% vs. 80%, specificity 100% vs. 93%, PPV 100% vs. 70% ($p < 0.05$), NPV 99% vs. 96% (p 0.2)

CONCLUSION: Identification of under-utilized *i*-Scan modes was possible regarding analyses of mucosal pattern. NIS is effective for real-time histological prediction of colonic polyps and warrants further study

P011 ENDOCYTOSCOPY IS AN EFFICIENT TOOL FOR DIFFERENTIATING AMONG TYPES OF SERRATED POLYPS

M. Kutsukawa[1,2,*], S.-E. Kudo[1], N. Ikehara[1], Y. Ogawa[1], K. Wakamura[1], Y. Mori[1], K. Ichimasa[1], K.-I. Takeda[1], M. Misawa[1], T. Kudo[1], Y. Wada[1], T. Hayashi[1], H. Miyachi[1], H. Inoue[1]. [1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama,* [2]*Department of Gastroenterological Internal Medicine, Yokosuka Kyosai Hospital, Yokosuka, Japan*

INTRODUCTION: Accurate endoscopic criteria are needed to differentiate among serrated polyps, including hyperplastic polyp (HP), sessile serrated adenoma/polyp (SSA/P), and traditional serrated adenoma (TSA), because some are precursors of colorectal cancers.

AIMS&METHODS: The aim of this study was to determine the endocytoscopic features of each type of serrated polyps, especially the shapes of lumens and nuclei. The endoscopic and pathological database of Showa University Northern Yokohama Hospital was searched for serrated polyps removed from May 2005 to December 2012. Lumen shapes were assessed as straight, star-like, oval, serrated and villous, and nucleus shapes were assessed as small round and fusiform.

RESULTS: Of the 58 eligible lesions, 27 were classified as HP, 12 as SSA/P, and 19 as TSA. Most HPs (77.8%) had star-like lumens, and most SSA/Ps (83.3%) had oval lumens. The lumens of TSA were serrated (31.6%) or villous (68.4%), with both shapes seen only in TSA. Most HPs (92.6%) and SSA/Ps (75.0%) had small round nuclei, and all TSAs had fusiform nuclei. Features significantly differentiating TSAs from HPs and SSA/Ps were the presence of fusiform nuclei ($P < .001$) and villous ($P < .001$) and serrated ($P = .002$) lumens. The presence of oval lumens was significantly characteristic of SSA/Ps ($P < .001$), and the presence of star-like lumens was significantly characteristic of HPs ($P < .001$).

CONCLUSION: The shape of lumens and nuclei on endocytoscopy can efficiently differentiate among the different types of serrated polyps.

P012 EFFICACY OF COLOR INTENSITY ANALYSIS USING A NOVEL AUTO-FLUORESCENCE IMAGING SYSTEM FOR PREDICTING DEPTH OF INVASION IN COLORECTAL NEOPLASIA

N. Tamai[1,*], H. Inomata[1], D. Ide[2], T. R. Ohya[1], H. Aihara[1], K. Sumiyama[1], S. Saito[1], H. Imazu[1], T. Kato[1], H. Tajiri[1,2]. [1]*Department of Endoscopy,* [2]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan*

INTRODUCTION: The effectiveness of auto-fluorescence imaging (AFI) systems in distinguishing colorectal non-neoplastic lesions from neoplastic lesions has been reported. Recently, a novel high-resolution AFI system with a noise reduction algorithm was developed.
AIMS&METHODS: The purpose of this study was to evaluate the efficacy of color intensity analysis of AFI images using the novel AFI system to predict depth of invasion of colorectal neoplasia. A total of 96 consecutive patients with colorectal neoplasia were examined using the novel AFI system from May 2011 to December 2012, and the results were retrospectively reviewed. The neoplasias were resected endoscopically or surgically at the Jikei University Hospital and pathological assessments were conducted. First, the regions of interest (ROI) were determined based on findings from chromoendoscopy under white light imaging, then color tone sampling from the ROI in the AFI images was conducted using software which enables the analysis of each color intensity. Finally, the green/red (G/R) ratio for the ROI was calculated. The G/R ratio was compared between the intra-mucosal neoplasia or submucosal (SM) superficial (less than 1,000 μm from the muscularis mucosae) cancer and SM deep (1000 μm or more from the muscularis mucosae) cancer. The endoscopic diagnosis for predicted depth of invasion of colorectal neoplasia (regardless of whether the cancer was SM deep) based on the findings of magnifying chromoendoscopy was also retrospectively reviewed using electronic medical records.
RESULTS: The mean G/R ratios $\pm$ standard deviations were 0.796 $\pm$ 0.062 in intra-mucosal neoplasia or SM superficial cancer and 0.671 $\pm$ 0.069 in SM deep cancer. The G/R ratio of intra-mucosal neoplasia or SM superficial cancer were significantly higher than those of SM deep cancers ($P < 0.001$), and the area under the receiver operating characteristic (ROC) curve was 0.9164. If a cut-off value for the G/R ratio of < 0.70 was applied to this result to determine SM deep cancers, the sensitivity, specificity, positive predicting value (PPV), and negative predicting value (NPV) were 75.0%, 92.5%, 66.7%, and 94.8%, respectively. Regarding the endoscopic diagnosis for SM deep cancers, the sensitivity, specificity, PPV, and NPV were 56.3%, 88.3%, 69.2%, and 91.6%, respectively.
CONCLUSION: Color intensity analysis using the novel AFI system was considered an effective modality to determine the depth of invasion of colorectal neoplasia.

P013 ADDITIONAL DIAGNOSTIC VALUE OF ENDOCYTOSCOPY TO MAGNIFYING CHROMOENDOSCOPY FOR COLORECTAL NEOPLASMS: A LARGE RETROSPECTIVE ANALYSIS

S.-E. Kudo[1,*], Y. Mori[1], K. Wakamura[1], N. Ikehara[1], K. Ichimasa[1], Y. Wada[1], M. Kutsukawa[1], M. Misawa[1], T. Kudo[1], T. Hayashi[1], S. Hamatani[1], H. Inoue[1]. [1]*Digestive Disease Center, Northern Yokohama Hospital, Yokohama city, Japan*

INTRODUCTION: Pit pattern (PIT) diagnosis with magnifying chromoendoscopy is effective diagnostic method for predicting a massively invasive submucosal colorectal cancer (SMm) which has possibility of metastasis, whereas endocytoscopy (EC) is recently reported to provide excellent diagnostic ability by enabling *in vivo* visualization of cells and nuclei.
AIMS&METHODS: The aim was to assess the additional diagnostic value of EC to PIT for diagnosing colorectal lesions. We conducted a retrospective comparative study using a prospectively recorded database in a referral hospital. The subjects were 538 patients who were detected of a colorectal lesion with use of a magnifying colonoscope with EC capability. Each detected lesion was initially diagnosed by PIT findings followed by EC diagnosis by the on-site endoscopist. The main outcome measures were the diagnostic abilities of PIT and EC in predicting neoplastic change and SMm.
RESULTS: Overall, 514 lesions from 455 patients were available for analysis. Of them, there were 58 non-neoplastic lesions, 352 adenomas, 15 slightly invasive submucosal cancers, and 89 SMm. The diagnostic abilities of predicting neoplastic change were comparable between PIT and EC diagnosis: sensitivity was 97.8% versus 97.4%, specificity was 91.4% versus 89.7%, and accuracy was 97.1% versus 96.5%. Regarding those of predicting SMm, EC diagnosis showed additional specificity and accuracy to PIT diagnosis: specificity was 99.1% versus 97.6% (P=0.041), and accuracy was 96.3% versus 93.8% (P=0.004).
CONCLUSION: Though PIT has feasible diagnostic ability for predicting both neoplastic change and SMm, EC provides additional diagnostic value to PIT diagnosis for predicting SMm.

INTRODUCTION:
Previous studies have yielded conflicting results on the polyp detection rate with narrow band imaging (NBI) compared with white light imaging (WLI).
AIMS&METHODS:
To overcome the confounding factors of these studies, we aimed to evaluate the colon polyp detection rate with NBI versus that with WLI by using a next-generation NBI system (EVIS LUCERA ELITE, OLYMPUS) with/ without wide angle (WA) colonoscopy.
Design: A 2 $\times$ 2 factorial designed prospective, multicenter randomized controlled trial.
Setting: This study was conducted at five academic centers in Japan.
Interventions: Patients were allocated to 1 of 4 groups: (1) WLI without WA – colonoscopy using WLI with standard colonoscopy (H260AZI); (2) NBI without WA–colonoscopy using NBI with standard colonoscopy (H260AZI); (3) WLI with WA–colonoscopy using WLI with WA colonoscopy (CF-HQ290); and (4) NBI with WA–colonoscopy using NBI with WA colonoscopy (CF-HQ290). All polyps were removed except polyps less than 5mm in size diagnosed hyperplastic lesion endoscopically in the recto-sigmoid colon.
Main outcome: The difference in polyp detection rate (number of detected polyps per patient) between the WLI with/without WA and NBI with/without WA.
RESULTS:
After recruiting for 454 patients, a total 449 patients who consent to join the study, were included. A total 18 patients were excluded due to exclusion criteria. Finally 431 patients, mean aged 65 (26-86), including 287 (67%) male patients were enrolled (WLI without WA: 119 Pts, NBI without WA: 100 Pts, WLI with WA: 99 Pts, and NBI with WA: 113 Pts). A total number of polyps (hyperplastic/ SSAP/ adenoma/ invasive carcinoma) detected in the WLI without WA, NBI without WA, WLI with WA, and NBI with WA were 164 (10/ 1/ 150/ 3), 176 (22/ 1/ 150/ 4), 188 (22/ 5/ 159/ 2), and 241 (22/ 6/ 209/ 4), respectively. The polyp detection rate in the NBI group was significantly higher than in the WLI group (2.01 vs. 1.56; P =. 032). The polyp detection rate in the colonoscopy with the WA group did not show higher rates than in that with standard group (1.97 vs. 1.61 P =. 089).
CONCLUSION:
REFERENCES:
1. UMIN000007150
Although a wide angle colonoscopy did not eliminate polyp detection rate, next-generation brighter narrow band imaging colonoscopy represented a significant improvement in the detection of colonic polyps.

P015 LAPAROSCOPY-ASSISTED TRANSGASTRIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY FOR THE MANAGEMENT OF BILIOPANCREATIC DISORDERS IN BARIATRIC ROUX-EN-Y GASTRIC BYPASS PATIENTS

C. Snauwaert[1,*], M. Buset[2], P. Laukens[3], B. Dillemans[4], D. De Looze[1], P. Deprez[5], J. Himpens[6], A. Badaoui[7]. [1]*Gastroenterology and Hepatology, Ghent University Hospital, Ghent,* [2]*Gastroenterology and Hepatology, Saint-Pierre University Hospital, Brussels,* [3]*Gastroenterology and Hepatology,* [4]*General and Gastrointestinal Surgery, AZ Sint-Jan Brugge-Oostende, Bruges,* [5]*Gastroenterology and Hepatology, Saint-Luc University Hospital, Brussels,* [6]*General and Gastrointestinal Surgery, Sint Blasius General Hospital, Dendermonde,* [7]*Gastroenterology and Hepatology, Mont-Godinne-Dinant University Hospital, Yvoir, Belgium*

INTRODUCTION: Endoscopic retrograde cholangiopancreatography (ERCP) in Roux-en-Y gastric bypass (RYGB) patients is technically challenging. The success rate of the balloon enteroscopy-assisted ERCP technique is about 60% in most of the literature whereas ERCP by laparoscopic transgastric access (ERCP-LTA) provides a direct access to the biliary tract which may lead to higher technical success rates[§]. In addition, many post-RYGB patients with biliary complications will still have a gallbladder in place. Hence, in these cases, combining ERCP-LTA and cholecystectomy (CCE) is a valuable strategy.
AIMS&METHODS: The goal of the present study is to assess the feasibility of ERCP-LTA after RYGB. We retrospectively analysed the data of post-RYGB patients who underwent an ERCP-LTA in the study centres from May 2008 to April 2013. The ERCP-LTA technique was similar in all cases, except for some subtle differences. A purse-string suture was fashioned around a gastrotomy on the anterior wall of the gastric remnant 5 cm proximal to the pylorus. A side-viewing endoscope was introduced through a 15 or 18 mm trocar placed into the gastrotomy and ERCP was completed under fluoroscopic guidance.
RESULTS: A total of 20 patients were identified (mean age 53 years, range 26-80). 3 patients had a history of open surgery, 17 patients were operated laparoscopically. 6 patients had a history of prior CCE. Indications included ascending cholangitis (n=1), cholecystitis and cholangitis (n=1), radiologically proven choledocholithiasis (n=14), recurrent biliary pancreatitis (n=3) and combination of a typical pain syndrome, cholelithiasis, elevated liver enzymes and a dilated common bile duct on ultrasound (n=1). 14 patients underwent concomitant

CCE, 9 prior to and 5 after ERCP completion. Laparoscopic access was converted to a minilaparotomy in 1 patient due to severe adhesions. ERCP findings included papillary stenosis (n=1), normal cholangiogram (n=1), choledocholithiasis (n=17) and biliary sludge (n=1). All patients successfully underwent biliary cannulation and sphincterotomy. The mean endoscopic procedure time was 53 minutes (range 15-120). No ERCP-related complications occurred. Mean hospital stay was 3.3 days (range 2-5).

CONCLUSION: ERCP-LTA is a feasible approach in the treatment of biliopancreatic disorders in post-RYGB patients and allows for ERCP and CCE to be performed consecutively in a single procedure, without major complications in our series.

P016 THE SAFETY AND EFFICACY OF PANCREATIC DUCT STENT PLACEMENT IN THE EMERGENCY ERCP OF ACUTE BILIARY PANCREATITIS BUT DIFFICULT SPHINCTEROTOMY

H. Hisai[1,*], Y. Koshiba[1], T. Hirako[1], Y. Arihara[1], Y. Ikeda[1], E. Miyazaki[1]. [1]*Department of Gastroenterology, Japan Red Cross Date General Hospital, Date, Japan*

INTRODUCTION: Several prospective, randomized trials have demonstrated that early ERCP and biliary endoscopic sphincterotomy (ES) with/without stone extraction was superior in reducing the mortality and morbidity rates in acute biliary pancreatitis (ABP) compared with conservative treatment. Prophylactic pancreatic duct (PD) stent placement has been shown to reduce the risk of post-ERCP pancreatitis in high risk patients. However, there are few reports about the safety and efficacy of PD stent placement in the emergency ERCP of ABP.

AIMS&METHODS: The aim of current study was to evaluate the effectiveness of emergency ERCP and PD stent placement in patients with ABP. Between January 2002 and March 2013, 90 patients with ABP referred to our institution. Total 60 consecutive patients were enrolled in the study. The inclusion criteria were as follows: 1) symptoms consistent with ABP, 2) serum amylase or lipase levels at three times over the upper limits, 3) elevated aspartate aminotransferase and alanine aminotransferase or alkaline phosphatase level, 4) radiological and/or EUS evidence of gallstones, 5) the possibility to accomplish ERCP within 48h following the onset of symptoms. Patients were randomly assigned to either the stent group (n=26) or the no-stent group (n=34). In the stent group, 5F, 3cm-long, straight, double-flanged polyethylene stent insertion was applied at initial ERCP. PD stent was safely removed within 3 weeks in majority of cases.

RESULTS: Mean age, gender, initial symptom-to-ERCP times, admission-to-ERCP times, Glasgow scores, Balthazar scores (CT severity index), BISAP scores, serum amylase and CRP levels at admission were not significantly different in the stent group vs. the no-stent group. The initial selective biliary cannulation was achieved in 88.5% (23/26) of the stent group and in 94.1% (32/34) of the no-stent group (P=0.645). Endoscopic sphincterotomy or needle knife sphincterotomy were performed in 73.1% (19/26) of the stent group and in 100% of the no-stent group (P=0.017). There was no statistical difference in pancreatic complication rates (need for endoscopic necrosectomy) between the two groups (3.8% vs. 5.9%). Mortality rates related to ABP were less frequent in the stent group without any significant differences (0% vs. 11.8%, P=0.126).

CONCLUSION: PD stent placement is a safe and effective procedure for ABP, and is recommended for ABP in patients with failed or difficult ES. Prospective controlled studies are required to support this innovating approach.

P017 COMPARISON OF EUS-CD, EUS-HG AND EUS-AG AS TECHNIQUES OF EUS GUIDED BILIARY DRAINAGE (EUS-BD)

A. Bapaye[1,*], N. A. Dubale[2], A. B. Aher[1]. [1]*Department of Digestive Diseases and Endoscopy,* [2]*Deenanath Mangeshkar Hospital and Research Center, Pune, India*

INTRODUCTION: ERCP fails in 5-10% patients due to various causes. EUS guided biliary drainage (EUS-BD) is an alternative. EUS-BD may be as EUS-ERCP rendezvous (EUS-RV); or as purely EUS guided procedure by transmural choledocho-duodenostomy (EUS-CD) or hepatico-gastrostomy (EUS-HG), or antegrade trans-papillary stenting (EUS-AG). EUS-RV is an access technique similar to PTBD rendezvous & is not designed for therapy. Other EUS-BD procedures have differences in technical aspects, success rates & complications.

AIMS&METHODS: To compare technical aspects, success rates, clinical outcomes & complications of EUS-CD, EUS-HG & EUS-AG. Retrospective study. Patients undergoing EUS-CD, EUS-HG or EUS-AG included. Those undergoing EUS-RV excluded. All 3 groups comparable for clinical profile, etiology of biliary obstruction & cause of failed ERCP. All EUS-BD procedures performed by a single endoscopist using a 3.8mm channel therapeutic echoendoscope. Parameters compared - technical & clinical success (defined as 50% reduction in bilirubin level @ 1 week), mean procedure time, need for aggressive track dilatation & complications. Statistical analysis using simple 't' test & Chi square test. P-value < 0.05 considered significant.

RESULTS: 31 EUS-BD procedures in 7 years (2005-12); EUS-CD – 13 (42%), EUS-HG – 9 (29%), EUS-AG – 9 (29%). (Table) Complications – 5/14 in EUS-CD (4 minor leaks), 2/9 in EUS-HG (1 – major – biliary peritonitis & death) & 1/10 in EUS-AG (late stent occlusion).

Parameter		EUS-CD, N = 13 (%)	EUS-HG, N = 9 (%)	EUS-AG, N = 10 (%)	P value
Technical success#		13 / 14 (92.9)	7 / 9 (77.7)	9 / 10 (90)	P > 0.05
Clinical success		11 / 13 (84)	6 / 7 (85.7)	7 / 9 (77.7)	P > 0.05
Failure / conversion		1 Conversion (EUS-AG)	2 1 – conversion (PTBD) 1 Failure	1 Conversion (EUS-HG)	
Median procedure time – min (range)		26 (20 – 40)	38 (30 – 90)	35 (25 – 60)	P > 0.05
Stent (SEMS / PS)		10 / 3	9 / 0	9 / 0	P > 0.05
Track dilatation	**Bougie**		6 / 14 (43)	1 / 9 (11)	9 / 9 (100)
	Balloon (4mm)		2 / 14 (14)	2 / 9 (22)	0 / 9 (0)
	Diathermy (6Fr. cystotome)		6 / 14 (43)	6 / 9 (67)	0 / 9 (0)

CONCLUSION: All 3 EUS-BD techniques– EUS-CD, EUS-HG & EUS-AG are comparable for technical success & clinical efficacy to achieve biliary drainage. EUS-CD had shortest procedure time. Aggressive track dilatation was not required in EUS-AG – possibly preventing immediate complications. EUS-HG was technically more difficult and resulted in one severe complication. Further randomized prospective studies comparing these 3 techniques are needed to confirm these findings.

P018 A COMPARATIVE STUDY IN THE CAPABILITY OF DELINEATION BETWEEN RADIAL AND CURVED LINEAR ARRAYED EUS FOR PANCREAS AND BILIARY TRACT: RESULTS OF A PROSPECTIVE STUDY

K. Akio[1,*], M. Kaneko[1], H. Maguchi[1], K. Yane[1], S. Hashigo[1], T. Kin[1], R. Harada[1], M. Osanai[1], K. Takahashi[1]. [1]*Center for Gastroenterology, Teine-Keijinkai hospital, Sapporo, Japan*

INTRODUCTION: Endoscopic ultrasonography (EUS) is categorized into radial and curved linear array EUS based on the difference in scanning methods. Few studies have reported the difference in the capability of delineation between the two techniques.

AIMS&METHODS: The aim of this study is to prospectively compare the capability of delineating the pancreas and biliary tract between radial EUS(R) and curved linear array EUS(C). A total of 201 consecutive cases that required EUS examination from May 2011 to December 2012 were studied in our center. Exclusion criteria were as follows: (1) history of treatment for pancreaticobiliary or upper intestinal disease; (2) suspected intestinal obstruction or stenosis; (3) if patient consent was not obtained. The endpoint of the study was the capability of the system to delineate 11 regions in the pancreas and biliary tract (the head, neck, body and tail of pancreas, bile ducts, cystic duct, gallbladder, papilla, upper bile duct, porta hepatis, branch of celiac artery and superior mesenteric artery). The observation standards for each region were developed and the capability was rated on a three-graded scale: 2, clearly observable; 1, partly observable; 0, unobservable.

RESULTS: Of 201 consecutive patients, one was found to have undergone gastrectomy during examination and was thus excluded from the evaluation. The remaining 200 patients were divided randomly into two groups, with 99 in the R group and 101 in the C group. No differences were found in the age and sex distribution between the R and C groups. The overall average score was 18.59 points in the R group and 19.62 points in the C group, indicating the superiority of the C group ($P < 0.001$). When the arterial branch was excluded from the assessment, the average was 15.34 points in the R group and 15.62 points in the C group, showing no significant difference between the two groups ($p = 0.13$). For the capability of delineation by regions, the C group was non-inferior to the R group for delineating the head, body and tail of pancreas ($p = 0.63$, N/A, 0.505), while it was superior for the neck of pancreas ($p = 0.008$). In the biliary tract system, the C group was inferior for delineating the ampulla of Vater and gallbladder ($p < 0.001$ for both).

CONCLUSION: There is no significant difference between radial EUS and curved linear array EUS for observations in routine screening. However, the selection of the scope should be taken into consideration for detailed examinations in specific regions.

Disclosure of Interest: None Declared

P019 USE OF ANCILLARY TECHNIQUES IN IMPROVING THE YIELD OF SAMPLES OBTAINED AT EUS-FNA OF THORACIC AND ABDOMINAL LYMPH NODES

M. N. Khan[1], A. Loya[1], M. A. Yusuf[2,*]. [1]*Pathology,* [2]*Internal Medicine, Shaukat Khanum Memorial Cancer Hospital & Research Centre, Lahore, Pakistan*

INTRODUCTION: Imaging techniques such as computed tomography (CT) and positron-emission tomography–CT or PET-CT, can detect enlarged thoraco-abdominal lymph nodes, but cannot predict pathological diagnoses. Endoscopic ultrasound-guided fine needle aspirate (EUS-FNA) is a well-established technique for obtaining tissue, but samples obtained are small, and may be insufficient to result in a definitive diagnosis.
Ancillary techniques, such as special histochemistry (SHC), immunohistochemistry (IHC) and flow cytometry may increase the diagnostic yield of EUS-FNA.
AIMS&METHODS: Between November 2005 and December 2012, 278 patients (age 8-87y, mean 45y) underwent EUS-FNA of enlarged thoracic and abdominal nodes at our institution. All specimens were subjected to rapid on-site evaluation (ROSE) by an experienced cytopathologist. We reviewed data on all patients in whom ancillary techniques were employed.
RESULTS: Ancillary techniques were performed in 111/278 cases. 27/111 were neoplastic while 84/111 were non-neoplastic. Nodes sampled were subcarinal (73; 11 neoplastic), other mediastinal (10; 2 neoplastic), coeliac (11; 7 neoplastic) and other abdominal (17; 7 neoplastic).
IHC was performed in 24 cases - one of these also needed SHC stain. 3 cases required flow cytometry. SHC staining was performed in 84 non-neoplastic cases. IHC aided in reaching a definitive diagnosis in 19/24 (79%) cases. Diagnoses made after IHC were metastatic carcinoma in 7 (29.1%), requiring CK (AE1/AE3), CK7, CK20, CK19, CAM5.2, ER, Hep-Par1, EMA and p63, classic Hodgkin's lymphoma in 6 (25%), which required CD30 and CD15, diffuse large B cell lymphoma (DLBCL) (CD20 and CD3), metastatic gastrointestinal stromal tumour (CD117) and metastatic neuroendocrine tumor (CD56).
Flow cytometry led to a definitive diagnosis in 3 neoplastic cases. These were DLBCL in two cases and chronic lymphocytic leukaemia in one.
SHC stains (Ziehl Neelson (ZN), PAS, GMS and mucicarmine)) were performed in 85 cases, of which 84 were non-neoplastic. These were granulomas in 72 (85.7%), (2 staining positive for acid fast bacilli (AFB) on ZN stain and 1 for Aspergillus on PAS/GMS stain), necrosis/calcified material in 7 (8.3%) and reactive lymphoid hyperplasia in 5 (5.9%). ZN staining for AFB was performed on all cases. Additional PAS stain was performed in two and mucicarmine and GMS stains in one case each.
CONCLUSION: IHC and flow cytometry improved the yield of EUS FNA in 22/111 (20%) of cases. SHC studies provided additional information in a further 3 (2.7%) cases. Ancillary studies in EUS-guided FNA of thoracic and abdominal lymph nodes can significantly improve the yield of this very effective diagnostic tool.

P020 MR ENTEROGRAPHY IN CROHN'S DISEASE – A HOSPITAL EXPERIENCE

B. M. Gonçalves[1,*], A. Caetano[1,2], A. Ferreira[1,2], J. B. Soares[1], P. Bastos[1], C. Rolanda[1,2], A. Machado[1], R. Gonçalves[1]. [1]*Gastroenterology, Hospital de Braga,* [2]*Life and Health Sciences Research Institute, School of Health Sciences, University of Minho, Braga, Portugal*

INTRODUCTION: Magnetic resonance enterography (MR enterography) is important in evaluating Crohn's disease (CD), particularly in assessing the activity and extension of the disease, as well as in revealing extraluminal complications, like abscesses and fistulas.
AIMS&METHODS: The present study proposes to evaluate the impact of MR enterography in the management of these patients. The retrospective study of MR enterography and subsequent management of suspected or diagnosed Crohn's disease patients between January and December of 2011 in our hospital.
RESULTS: MR enterography was performed in 69 patients (48 females and 21 males, with median age of 33.1±12.6 years). For 17 patients with suspected DC, MR enterography confirmed the diagnosis in only 2. To the remaining 52 patients a MR enterography was performed to establish the extent or detect complications of CD. In this group, MR enterography did not change the location of the disease previously diagnosed by endoscopy. In 26 (50%) patients, the exam has shown imagiologic signs of active disease, in 19 (13%) patients the exam has detected 23 complications (18 stenosis, 3 fistulas and 2 abscesses) and in 7 patients the exam was normal. MR enterography was associated with a change in the clinical management of 29 (56%) patients: 24 had therapeutic progression (13 patients started azathioprine and 11 patients anti-TNF therapy); 3 patients required surgery and 2 patients required endoscopic dilatation. Multivariate analysis has shown that positive findings (active disease and/or complications) on MR enterography ($p = 0.0001$) and previously surgery for CD ($p = 0.02$) were associated with management modification. Age, gender, location of CD and medical therapeutic were not significant for management alteration. Twenty-nine imagiologic findings not related with CD were documented.
CONCLUSION: The main role of MR enterography in Crohn's disease is to evaluate disease activity and its complications. As has been shown in this study, MR enterography has a significant impact in the management of these patients.

P021 ENDOSCOPIC RETROGRADE APPENDICITIS THERAPY (ERAT): A MULTICENTER RETROSPECTIVE STUDY IN CHINA

B. Liu[1,*], J. Feng[2], S. R. Ma[3], J. Song[4], X. Ma[4], Z. Yang[3], Z. Feng[2], R. Sun[2], L. Guo[2], W. Liu[2]. [1]*Department of Gastroenterology and Hepatology, THE SECOND HOSPITAL OF HARBIN MEDICAL UNIVERSITY, Harbin,* [2]*Betune International Peace Hospital, Shijiazhuang,* [3]*Shenyang North Hospital, shengyang,* [4]*THE SECOND HOSPITAL OF HARBIN MEDICAL UNIVERSITY, Harbin, China*

INTRODUCTION: Endoscopic retrograde appendicitis therapy (ERAT) proved to be one feasible and effective therapeutic method for the treatment of acute uncomplicated appendicitis.
AIMS&METHODS: This study tried to evaluate the long-term outcomes following ERAT and examined the use of ERAT as an alternative treatment to acute uncomplicated appendicitis. From December 2009 to February 2013, 39 consecutive patients with suspected acute uncomplicated appendicitis who come from three different hospitals recieved ERAT and were reviewed retrospectively. False-positive rate of clinical diagnosis (the rate of patients with incorrectly diagnosed as acute appendicitis proved by appendiceal radiography during ERAT) and outcomes of ERAT were examined.
RESULTS: Endoscopic appendiceal intubation and radiography were successful in 38/39 (97.4%) patients during the procedures. The false-positive rate was 8/38 (21.1%). Immediate appendiceal decompression were performed in all 30 patients, including simple endoscopic cleaning of appendiceal lumen in 19/30 (63.3%) patients, and plastic stent drainage in 11/30 patients (36.7%, including one patient underwent appendiceal fecalith extraction by Dormia basket). Abdominal pain disappeared immediately and abdominal tenderness alleviated within 12 hours in 28/30 patients. Liquid diet was resumed after the procedure. Nine patients recieved ERAT in outpatient clinic without hospitalization. There is not severe complication occurred in any patients, however, 2 patients (5.3%) recurred appendicitis during 36 months follow-up, and then accepted operations.
CONCLUSION: ERAT appears to be a safe, effective and minimally invasive diagnosis and treatment modality for patients suspected with acute appendicitis.

INTRODUCTION: RFA has become the preferable method for elimination of BE, when indicated. Although highly effective, RFA suffers from drawbacks such as the need for precise sizing, multiple deployment steps, and large controller units.
AIMS&METHODS: The aim was to assess the feasibility, safety, and dose-response of a newly developed Cryoballoon Focal Ablation System (CbFAS) in patients with flat BE with or without dysplasia. The system was designed to address many of the limitations of current ablation techniques.
In this multi-center, prospective non-randomized trial, up to 40 patients will be enrolled with each subject receiving up to 2 ablations using the CbFAS using two doses. The CbFAS consists of a TTS catheter with a balloon probe made of a conformable material obviating the need for sizing. The balloon is simultaneously inflated and cooled with cryogenic fluid delivered from a small disposable canister, resulting in ablations of approximately 2 cm^2. Symptoms were assessed directly after and 2 days after CbFA. FU endoscopy with photo documentation and biopsy of the treated areas was scheduled at 6-8 weeks. Primary outcomes were incidence of adverse events, pain, esophageal stricture formation, and ablation response by cryogen dose.
RESULTS: By May 2013, 21 ablations (6s in 10, 8s in 11) were performed in 15 patients. Median (range) procedure time was 12 (3-38) min. Device malfunction was encountered in 1 additional patient. No major adverse events occurred – 2 patients had minor mucosal lacerations that required no additional intervention. Mild pain was reported immediately after the procedure in 2 of 15 patients and in one patient at 2 days. Thirteen (ten 6s, three 8s) ablation areas (10 patients) had reached FU endoscopy. No strictures developed. Squamous regeneration was seen in 7 treated areas (5/10 areas treated with 6s, 2/3 areas treated with 8s).
CONCLUSION: Preliminary results of this multicenter prospective trial suggest that focal cryobablation of BE with the newly developed CbFAS is feasible, safe, and results in squamous regeneration in the majority of patients.

P023 ENDOSCOPIC TREATMENT FOR SUPERFICIAL CARCINOMA OF THE PHARYNX AND BORDERLINE LESIONS BETWEEN THE CERVICAL ESOPHAGUS AND HYPOPHARYNX

H. Kawakubo[1,*], T. Omori[1], R. Nakamura[1], T. Takahashi[1], N. Wada[1], Y. Saikawa[1], H. Takeuchi[1], Y. Kitagawa[1]. [1]*Department Of Surgery, Keio University School 0f Medicine, Tokyo, Japan*

INTRODUCTION: Early diagnosis and early treatment are the best ways to improve cancer patient prognoses and keep QOL of patients after treatment. We developed ELPS (endoscopic laryngo-pharyngeal surgery) as an endoscopic treatment and a minimal invasive surgery for superficial pharyngeal carcinoma. Also we developed a hybrid endoscopic surgery (ESD+ELPS) for borderline lesions between the cervical esophagus and hypopharynx. ELPS is transoral endoscopic surgery for pharyngeal cancer. We lift the larynx by the curved type laryngoscope. After lifting the larynx, the scopist inserts endoscope and the operator inserts forceps and electric device transorally. After the iodine staining, we mark the normal mucosa just 1-2mm out of the cancer margin and inject Epinephrine-added physiological saline solution to the sub-epithelial layer. After the circumferential cutting, we resect the lesion with the forceps and electric device. ELPS was applied for all lesions of the pharynx. However, ELPS has not been applied for cervical esophagus carcinoma because of the narrow working space and interference of endoscopy, forceps and electric device. We applied a hybrid endoscopic surgery (ESD+ELPS) for borderline lesions between the cervical esophagus and hypopharynx.
AIMS&METHODS: The purpose of this study was to examine the usefulness and effectiveness of endoscopic treatment for superficial carcinoma of the pharynx and cervical esophagus. We defined the superficial carcinoma of the pharynx as the carcinoma which depth of tumor invasion is within the sub-epithelial layer. ELPS was performed on 278 patients of superficial carcinoma of the pharynx and hybrid endoscopic surgery (ESD and ELPS) was performed on 10 patients for superficial carcinoma of borderline lesions between the hypopharynx and cervical esophagus during the period from January 2000 to April 2012.
RESULTS: All lesions were completely resected. The complications of ELPS were laryngeal edema for 18 patients, which required overnight intubation or tracheotomy, postoperative bleeding for 3 patients, temporary vocal cord palsy for 11 patients. The complications of hybrid endoscopic surgery (ESD and ELPS) were laryngeal edema for 3 patients, which required overnight intubation, and stricture for 3 patients, which required endoscopic dilation more than 10 times. There were no long-term complications in all patients.
CONCLUSION: The results indicated the usefulness and effectiveness of ELPS for superficial carcinoma of the pharynx and hybrid endoscopic treatment (ELPS+ESD) for superficial carcinoma of borderline lesion between the cervical esophagus and hypopharynx.

P024 LAPAROSCOPY AND ENDOSCOPY COOPERATIVE SURGERY FOR GASTRIC SUBMUCOSAL TUMOR LOCATED NEAR THE ESOPHAGOGASTRIC JUNCTION

T. Hirasawa[1,*], N. Hiki[2], Y. Yamamoto[1], S. Nunobe[2], J. Fujisaki[1], I. Masahiro[1], T. Sano[2], T. Yamaguchi[2]. [1]*Department of Gastroenterology,* [2]*Gastroenterological Surgery, CANCER INSTITUTE HOSPITAL, Tokyo, Japan*

INTRODUCTION: Laparoscopic wedge resections are increasingly applied for gastric submucosal tumors (SMT) such as gastrointestinal stromal tumor (GIST). For tumors located near the esophagogastric junction (EGJ), especially intragastric-type SMT, wedge resection of the stomach is quite difficult. Thus intragastric-type SMT located near the EGJ usually undergo total gastrectomy or proximal gastrectomy.
AIMS&METHODS: This study aimed to introduce a laparoscopy and endoscopy cooperative surgery (LECS) for gastric wedge resection that is applicable for resections of intragastric-type SMT located near the EGJ.
Methods: We retrospectively analyzed 15 patients [7 men and 8 women, mean age 58 years (range, 26-79 years)] who underwent LECS for the resection of intragastric-type SMT located within 2cm from the EGJ at the Cancer Institute Hospital, Tokyo, between June 2006 and April 2013. To decide the precise resection line, both mucosal and submucosal layers around the tumor were circumferentially dissected using endoscopic submucosal dissection (ESD) via intraluminal endoscopy. Subsequently, the seromusclar layer was laparoscopically dissected along the incision line by ESD. After three-fourths of the circumference around the tumor had been resected, the SMT was exteriorized to the abdominal cavity and dissected with a standard endoscopic stapling device.
RESULTS: The mean tumor size was 3.5 cm (range, 2.0–5.0 cm). The mean distance from the lesions to EGJ was 0.5 cm (range, 0-2 cm). All surgical margins were clear. Histopathologic examination of the tumors showed GIST (n = 8), leiomyoma (n = 6), schwannoma (n = 1). The mean operation time was 219 min, and the estimated blood loss was 31 ml. In 11 of 15 cases, the LECS procedure was successful for dissecting out the gastric SMT and the postoperative course was uneventful. The remaining four were converted to open surgery because of extensive resection more than half of circumference of the EGJ. Among the cases converted to open surgery, anastomotic leakage occurred in two cases and anastomotic stenosis occurred in one. No recurrence or death was noted during follow-up (average 26 months).
CONCLUSION: LECS for dissection of intragastric-type SMT located near the EGJ may be performed safely with minimal resection lines, therefore is helpful for preserving cardia. But extensive resection around the EGJ is not feasible.

P026 TRANSNASAL SMALL-CALIBER ESOPHAGOGASTRODUODENOSCOPY IMPROVES SAFETY IN PATIENTS WITH CONGESTIVE HEART FAILURE

M. Yuki[1,*], Y. Komazawa[1], M. Kusumoki[1], Y. Kobayashi[1], Y. Takahashi[1], I. Ikuma[1], T. Shizuku[1]. [1]*Division of Internal Medicine, Izumo-City General Medical Center, Izumo, Japan*

INTRODUCTION: Unsedated transnasal small-caliber esophagogastroduodenoscopy (TN-EGD) is often used to examine the upper gastrointestinal tract.TN-EGD has improved the safety of the endoscopic examination, showing fewer adverse effects on cardiopulmonary function and autonomic nerve function. Although we perform endoscopy on elderly and critically ill patients with increasing frequency, we have little information concerning the relative safety of transnasal small-caliber and transoral conventional EGD (TO-EGD) in these groups. The aim of this prospective, randomized study was to compare the effects of TN-EGD and TO-EGD on cardiac function in patients with risk of congestive heart failure.
AIMS&METHODS: We enrolled 200 patients (mean 71.1 years old) for unsedated diagnostic EGD and randomly allocated them to undergo either TN-EGD or TO-EGD (n=100 per group).All the EGDs were performed without administration of scopolamine butylbromide. We *evaluated cardiac functions by measuring* systolic and diastolic blood pressure (BP), and pulse rate (PR) at the following 3 time points during the endoscopic examination: baseline, 2 minutes after endoscopic intubation, and just after extubation. The rate-pressure product (RPP: PR x systolic BP /100) was also calculated. And in patients with a high risk of heart failure, the autonomic nervous responses were determined employing power spectral analysis (PSA) of heart-rate variations on electrocardiogram using amplitude of the high-frequency component (HF) and low-frequency-to-high-frequency power ratio (LF/HF) as indices of cardiac vagal activity and sympathetic activity. We used BNP levels according to heart failure risk, and divided all patients into 2 groups; high-risk (BNP level $\geq$100 pg/ml) and low-risk (BNP level $<$99 pg/ml).
RESULTS: In the TO-EGD group, RPP levels in patients with a high risk of heart failure were increased at 2 minutes after endoscopic intubation and significantly higher than those in patients without heart failure risk. On the other hand, endoscopic intubation did not influence the RPP levels in any patients in the TN-EGD group. in Further in patients with a high risk of heart failure, PSA revealed a lower increase in LH /HF in TN-EGD than in TO-EGD.
CONCLUSION: In patients with a high risk of congestive heart failure, TO-EGD induced hemodynamic effects, while TN-EGD did not. TN-EGD is considered to be safe, as it is associated with few adverse effects on cardiac function.

P027 CARD15 MUTATIONS AND GASTRIC CANCER IN A PORTUGUESE POPULATION

P. Freire[1], P. Figueiredo[1,2], R. Cardoso[1,*], M. M. Donato[2], A. Sá[3], F. Portela[1], J. M. Romãozinho[1,2], C. Sofia[1,2]. [1]*Department of Gastroenterology, Centro Hospitalar e Universitário de Coimbra,* [2]*Center of Gastroenterology, Faculty of Medicine, University of Coimbra,* [3]*Department of Oncology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: *CARD15* is involved in the innate immune response and mutations of this gene have been linked with increased risk of Crohn's disease and colorectal cancer. The relation between *CARD15* mutations and Gastric Cancer (GC) remains controversial.
AIMS&METHODS: The aim of this study was to assess whether *CARD15* mutations are risk factors for GC in Portugal and whether there are genotype-phenotype correlations in these patients.
The 3 main *CARD15* mutations (3020insC, R702W and G908R) were searched in 150 patients with GC and in 202 healthy controls.
RESULTS: Overall, *CARD15* mutations were found in 28 patients (18.7%) and in 27 controls (13.4%) ($p = 0.176$).
Individually, the incidence of 3020insC was significantly higher in patients than in controls (6.0% *vs.* 1.0%, $p = 0.021$). This polymorphism was linked with an increased risk for the intestinal-type of GC ($p = 0.002$), whilst no association was found with the diffuse and/or mixed types. Genotype frequencies for R702W (10.0% *vs.* 7.9%) and G908R (4.0% *vs.* 4.0%) were not statistically different between the two groups. Similarly, no significant associations were detected between these two polymorphisms and the different histological GC types. No correlations were observed between *CARD15* mutations and family history, mean age at diagnosis or GC stage.
CONCLUSION: The *CARD15* 3020insC variant is a risk factor for intestinal GC in Portugal. *CARD15* variants are not correlated with age of diagnosis or family aggregation of the disease neither with the GC stage.

P028 DOWN-REGULATION OF HSA-MICRORNA135B IN GASTRIC CORPUS

S. Urabe[1,*], H. Isomoto[1], K. Matsushima[1], K. Nakao[1]. [1]*Department of Gastroenterology and Hepatology, Nagasaki University Hospital, Nagasaki City, Japan*

INTRODUCTION: Micro RNAs(miRs) are small molecular, non-cording RNAs which consist of 8-25 bases. MiRs regulate the expression of target genes through translational repression or messenger RNA(mRNA) degradation. Considering miRs participate organ development and differentiation, and cellular growth, they greatly affect various diseases.
AIMS&METHODS: The present study was conducted to determine expression patterns of miR in gastric mucosa, with special reference to differences in expression patterns between the antrum and body. Using endoscopic biopsy specimens, miR expression patterns of gastric antrum and body were determined by microarray. The differentially expressed miRs were quantitated by real-time reverse-transcriptase polymerase chain reaction (RT-PCR) in the test samples. Biopsy specimens were obtained from gastric mucosa of the antrum and body in chronic gastritis patients with or without *H.pylori* infection, and total RNA was isolated.
RESULTS: Upon micro array analysis, certain miRs, such as miR-135b, miR-1, miR-193b, miR-34a, miR-34b and miR-455-5p were differentially expressed (more than 2-fold) between the antrum and body. Among these miRs, miR-135b was one of the most down-regulated miRs in the body irrespective of *H.pylori* status. So, we quantitated miR-135b expression levels via quantitative RT-PCR. RNU48 was employed as the internal control. As a result, in 17 of 20 patients, the miR-135b expression levels were higher in the antrum than in the body. The average of expression ratio with the internal control (miR135/RNU48) was 0.015 in the antrum, while it was 0.006 in the body. Thus, there was a significant difference in miR-135b expression between the antrum and body ($p<0.0001$). Based on in silico analysis representative of TargetScan, miR-135b could repress ADCYAP1 (adenylate cyclase activating polypeptide 1) which stimulates gastric acid secretion by inducing histamine release, implying down-regulation of miR-135b in the acid secretion from gastric body.
CONCLUSION: MiR-135b was differentially expressed within gastric mucosa. Further studies are warrant to explore clinical significance of the down-regulation of miR-135b in gastric body.

P029 GENETIC POLYMORPHISMS OF MAFK ARE ASSOCIATED WITH THE ABERRANT DNA METHYLATION OF CDKN2A IN JAPANESE SUBJECTS

T. Arisawa[1], T. Tahara[2,*], T. Shibata[2], N. Kawada[1], K. Matsunaga[1], M. Nakamura[1]. [1]*Gastroenterology, Kanazawa Medical University, Uchinada-machi,* [2]*Gastroenterology, Fujita Health University, Toyoake, Japan*

INTRODUCTION: CpG island aberrant methylation is shown to be an important mechanism in gene silencing. We have already reported that genetic polymorphisms of NRF2 are associated with the aberrant DNA methylation of CDKN2A in gastric mucosa. An activation of transcription factor Nrf2 is regulated by dimerized with small Maf proteins. MafK, encoded by MAFK gene, is one of the small Maf proteins. Within 20kbp around MAFK gene, there are two linkage disequilibrium blocks, with above 0.05 of HWE p value and above 0.05 of minor allele frequency. In this study, we investigated an association between aberrant DNA methylation of CDKN2A in gastric mucosa and each tag polymorphism, rs4268033G>A and rs3735656 (*910T>C), and the other one rs10226620 (*1506T>C).
AIMS&METHODS: Gastric mucosal samples were obtained from 381 subjects without malignancies. Methylation status of genes ($p14^{ARF}$ and $p16^{INK4a}$) was determined by methylation-specific polymerase chain reaction. Both $p14^{ARF}$ and $p16^{INK4a}$ methylations were defined as CDKN2A methylation. The genotypings of *MAFK* were performed by PCR-SSCP.
RESULTS: Mean age of the subjects was 60.2 years old, male/female ratio was 221/160 and *H. pylori* (HP) positive ratio was 230/381. Methylation of $p14^{ARF}$ and $p16^{INK4a}$ was seen in 126 and 106 of 381 subjects, respectively. The ration of CDKN2A methylation was 45/381. The distribution of rs4268033, rs3735656 and rs10226620 genotypes were 173GG, 175GA and 33AA (HWE p=0.29), 151TT, 184TC and 46CC (HWE p=0.44) and 157TT, 176TC and 48CC (HWE p=1.00). By a logistic regression analysis after adjustment for age, gender and HP infection status, rs4268033 AA, rs3735656 CC and rs10226620 CC homozygous were significantly associated with the susceptibility to CDKN2A methylation (OR, 3.10; 95%CI, 1.14-8.41; p=0.027, OR, 4.55; 95%CI, 1.86-11.1; p=0.0009 and OR, 3.49; 95%CI, 1.47-8.27; p=0.0045, respectively). Regarding as $p14^{ARF}$ methylation, rs3735656 CC homozygous had a significantly increased risk (OR, 2.28; 95%CI, 1.11-4.70; p=0.025). In addition, rs3735656 CC and rs10226620 CC homozygous had also a significantly increased risk for $p16^{INK4a}$ methylation (OR, 2.99; 95%CI, 1.42-6.29; p=0.0039 and OR, 2.37; 95%CI, 1.16-4.82; p=0.018).
CONCLUSION: MAFK polymorphisms are significantly associated with the increased risk for the development of CDKN2A mathylation in non-cancerous gastric mucosa. In particular, rs3735656 *910T>C is closely associated with CDKN2A methylation.

P030 THE EFFECTS OF MDR-1 GENE POLYMORPHISMS ON THE CLINICAL COURSE OF CHRONIC HEPATITIS B INFECTION

H. Sivgin[1,*], A. Yilmaz[2], A. Rustemoglu[3], M. Sagcan[1], B. Ozturk[4], S. Sahin[1], T. Taslıyurt[1]. [1]*İnternal Medicine, Gaziosmanpasa University Medical Faculty, Tokat,* [2]*Gastroenterology, Cumhuriyet University Medical Faculty, Sivas,* [3]*Genetics,* [4]*Medical Oncology, Gaziosmanpasa University Medical Faculty, Tokat, Turkey*

INTRODUCTION: The treatment modilities of chronic HBV infectionand resistance is currently investigated (1). P-glycoprotein(P-gp), the product of multidrug resistance gene(MDR-1), is well-known mechanism of MDR phenotype. MDR gene C1236T polymorphism is associated with decreased P-gp function (2). The mutation of MDR gene can affect the clinical course of disease and response rate to treatment (2,3). It was aimed to investigate the relationship between MDR gene polymorphism and clinical course and treatment responses in chronic HBV infection in our study.
AIMS&METHODS: A total of 90 (male/female:69/21) patients with chronic HBV infection under Lamivudine treatment was enrolled in this study. The patients were categorized as: Treatment responded (group 1: HBV-DNA is negative at 24th week) and treatment refractory (group 2: HBV-DNA is still positive after 24th week). Group 1 was consisted of 51 (M/F: 38/13) and group 2 was consisted of 39 (M/F: 31/9) patients. YMDD mutation was investigated in 19 patients of group 2. Polymerase chain reaction-restriction fragment length polymorphism was used for the detection of C1236T single nucleotide polymorphism. MDR-1 gene C1236T alleles' frequencies and CC, CT, TT genotype distributions were investigated in two groups.
RESULTS: Genotype distributions were as follows: CC, CT, TT genotypes were detected as 8(15.7%), 37(72.5%), and 6(11.8%) in patients at group 1, respectively. CC, CT and TT genotypes were found 13(33.3%), 21(53.8%), and 5(12.8%) in patients at group 2, respectively. CC genotype was more common in group 2 than group 1 (p=0.044). C and T alleles' frequencies in the group 1 and 2 were 51.96% and 60.26%, 48.04% and 39.74%, respectively ($p>0.05$). The patients with YMDD mutation positive at group 2 (n:11), 5(45%) had have CC genotype, 5(45%) had have CT, 1(9%) had have TT genotype. The patients with YMDD mutation negative at group 2(n:8), 3(37%) patients had have CC and 5 (63%) patients had have CT genotype. CC genotype was more common in the patients with YMDD mutation positive than group 1 (p=0.043). Moreover, CC genotype was more common in the patients with HBV-DNA positive at 12nd month of Lamivudine treatment than group 1 (p=0.042).
CONCLUSION: Consequently; MDR-1 and p-gp polymorphisms are important factors in the clinical course of chronic HBV infection and may influence the treatment responses. In the current study, it was found that the CC genotype of MDR-1 gene C1236T was more common in the patients with lamivudine resistant HBV infection.

P031 IMPACT OF INTERFERON LAMBDA GENE POLYMORPHISM ON TREATMENT OF HCV-4 INFECTION IN DIABETIC PATIENTS

A. Monis[1,*], R. AL Swaff[1], M. Saber[2]. [1]*Internal Medicine, Gastroenterology and Hepatology unit, Faculty of Medicine, Ain Shams University, Cairo, Egypt,* [2]*Molecular Biology, Theodore Bilharz Research, CAIRO, Egypt*

INTRODUCTION: IL28B polymorphisms are strongly associated with response to treatment for HCV infection. IL28B acts on interferon-stimulated genes via the JAK-STAT pathway, which has been implicated in development of insulin resistance[1].
AIMS&METHODS: This study aimed to evaluate the Impact of interferon lambda gene polymorphism on treatment of HCV-4 infection in diabetic patients. Occurrence of variants at three IL28B-Related Single Nucleotide Polymorphisms (rs12979860, rs12980275, and rs8099917) was correlated with virologic response to combined treatment with pegylated interferon and ribavirin among 104 HCV - 4 infected Egyptian patients (41 diabetic Vs. 63 non diabetic patients).

RESULTS: IL28B-Related Single Nucleotide Polymorphisms had significant impact on virologic responses to combined treatment among non diabetic patients; CC subtype of rs12979860 and AA subtype of rs12980275 had the highest rapid virologic response rates (p=0.02 and 0.04 respectively).Early virologic response rates were significantly higher among non diabetic patients with CC subtype of rs12979860 (p=0.005), AA subtype of rs12980275 (p=0.04) and TT subtype of rs8099917 (p=0.01).Significant higher percentage of sustained virologic response rates was found among non diabetic patients with CC subtype of rs12979860 (p = 0.003) and AA subtype of rs12980275 (p = 0.004). Strikingly, all the subtypes of the three IL28B-Related Single Nucleotide Polymorphisms (rs12979860, rs12980275, and rs8099917) had no impact on virologic responses to combined treatment among diabetic patients.
CONCLUSION: Non diabetic patients with chronic hepatitis C-4 infection are more likely to benefit from the assessment of IL28B-related SNPs (rs12979860, rs12980275, rs8099917) in the prediction of virologic response to combined treatment than diabetic patients.

P032 DISCOVERY OF POTENTIAL PLASMA BIOMARKERS OF CHOLANGIOCARCINOMA UTILISING SURFACE-ENHANCED LASER DESORPTION/IONIZATION TIME-OF-FLIGHT MASS SPECTROMETRY (SELDI-TOF MS)

C. A. Wadsworth[1,2,*], V. M. Horneffer-van der Sluis[1], A. A. Zabron[1], S. P. Pereira[3], K. M. Boberg[4], S. D. Taylor-Robinson[1], R. J. Edwards[5], S. A. Khan[1]. [1]*Hepatology and Gastroenterology Section, Imperial College London, London,* [2]*Department of Gastroenterology, University Hospital Aintree, Liverpool,* [3]*UCL Institute for Liver and Digestive Health, University College London, London, United Kingdom,* [4]*Section of Gastroenterology, Dept. of Organ Transplantation, Oslo University Hospital, Rikshospitalet, Oslo, Norway,* [5]*Centre of Pharmacology and Therapeutics, Imperial College London, London, United Kingdom*

INTRODUCTION: Cholangiocarcinoma (CC) is a malignant neoplasm of the bile duct. Diagnosis of CC is hampered by the inadequate performance of current plasma markers of disease, particularly in patients with preexisting primary sclerosing cholangitis (PSC). We aimed to identify potential new protein biomarkers of CC
AIMS&METHODS: In an initial discovery study, blood plasma samples from 18 subjects with CC, 17 with PSC and 10 healthy controls were subjected to SELDI-TOF MS. Comparisons of m/z peak intensity were made between groups using the Mann-Whitney U test. Differentiating m/z peaks were then confirmed in a further validation study of 81 subjects with CC, 54 with PSC and 90 healthy controls. Pearson's correlation was used to investigate the relationship of each m/z peak's intensity to routine laboratory indices. Diagnostic performance was investigated using receiver operator characteristic area-under-the curve (ROC-AUC) analyses. Multiple linear regression was used to investigate the performance of combinations of differentiating m/z peaks, as well as the combination of m/z peaks with routine laboratory markers (including CA19-9).
RESULTS: Seven differentially expressed m/z peaks were identified in the CC group and these were subsequently confirmed in the validation study (p=2.6x10-4 to 9.4x10-13). The intensity of the seven m/z peaks of interest did not correlate with creatinine, ALP, bilirubin, CRP, white cell count or CA19-9. A panel of three peaks discriminated CC from PSC subjects with ROC-AUC of 0.76 (sensitivity 75%, specificity 64%). A panel of five peaks discriminated CC subjects from healthy controls with ROC-AUC of 0.90 (sensitivity 95%, specificity 74%). Addition of routine laboratory indices did not change the diagnostic performance of these models significantly.
CONCLUSION: SELDI-TOF has been used to successfully identify seven m/z peaks that are differentially intense in CC subjects (total n=99), when compared to PSC subjects (n=64) and healthy controls (n=107). These peaks appear to be independent of standard markers of renal impairment, cholestasis, sepsis and inflammation, as well as CA19-9. Individually, and more so in combination, these peaks exceed the expected diagnostic performance of CA19-9, particularly in discriminating CC from PSC. Work to identify the proteins represented by these m/z peaks is ongoing.

P033 GENETIC FACTORS AND THEIR INVOLVEMENT IN NONALCOHOLIC FATTY LIVER DISEASE

D. Neagoe[1,*], A. Amzolini[1], G. Ianosi[2], M. Ioana[3], M. Dinca[1], T. Ciurea[1]. [1]*Internal Medicine,* [2]*Surgery,* [3]*Genetics, University of Medicine and Pharmacy of Craiova, Craiova, Romania*

INTRODUCTION: Family and interethnic studies suggested that the genetic variability is implied to be one of the most important factors of NAFLD progression in individual patients.
AIMS&METHODS: The aim of our study was to identify the role of PNPLA3rs738409 in progression of the disease. We included 138 subjects with NAFLD and 125 age and sex matched healthy controls. In both groups we determined anthropometric mesurements, aminotransferases levels, presence or not of diabetes mellitus, insulin resistence, abdominal ultrasound and the PNPLA3 gene polymorphism. The genotyping assays were performed at Molecular and Cellular Biology Department, University of Medicine and Pharmacy from Craiova, using predesigned *TaqMan SNP Genotyping Assays*.
RESULTS: The genotype frequencies for PNPLA3 rs738409 polymorphism in the study group was [CC](59,42%)> [CG](32,41%)> [GG](7,97%). The [CG] genotype carriers had a 1.7 times higher risk of developing hepatic steatosis, compared with the [CC] genotype (p=0.046). The PNPLA3 polymorphism was associated with an increased risk of hepatic steatosis in patients with BMI <30 kg/m2, compared with the control population, when the risk allele [G] carriers were compared with the [C] allele carriers (p=0.038). By comparing the subgroup with steatosis without obesity with the subgroup with steatosis and BMI ≥30 kg/m2, we have noticed that the [G] allele carriers compared to the [CC] homozigotes in the dominant model, have a 2.5 times higher risk of developing hepatic steatosis (p=0.025). [G] risk allele was significantly associated with the risk of hepatic steatosis in patients without metabolic syndrome (p=0,005) and without insulino-resistance (p= 0,033).
CONCLUSION: The risk [G] allele carriers have a 3 times higher risk of developing hepatic steatosis in the absence of obesity, of insulin- resistance and of the metabolic syndrome.

P034 CARD15 MUTATIONS AND ALCOHOLIC LIVER CIRRHOSIS IN THE PORTUGUESE POPULATION

J. M. Carvalheiro[1,*], P. Freire[1], R. Cardoso[1], M. M. Donato[2], S. Lopes[1], C. Agostinho[1], P. Figueiredo[1,2], D. Gomes[1], S. Mendes[1], L. Tomé[1,2], F. Portela[1], C. Sofia[1,2]. [1]*Gastrenterology, Centro Hospitalar e Universitário de Coimbra,* [2]*Center of Gastroenterology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal*

INTRODUCTION: *CARD15* gene is involved in the immune response regulation. *CARD15* mutations were initially linked with increased risk of Crohn's disease and, more recently, have been associated with a higher risk of some infections and neoplasms. In liver cirrhosis, *CARD15* mutations have been related with an increase in the risk of Spontaneous Bacterial Peritonitis (SBP).
AIMS&METHODS: Aims: The aim of this study was to assess whether *CARD15* mutations are risk factors for Alcoholic Liver Cirrhosis (ALC) in Portugal and whether there are genotype-phenotype correlations in these patients. **Methods:** Case-control study involving the research of the 3 main *CARD15* mutations (3020insC, R702W e G908R) in 128 patients with ALC and in 202 healthy controls.
RESULTS: Overall, *CARD15* mutations were found in 25 patients (19.5%) and in 27 controls (13.4%) (p=0.134). The mean age of patients was 61.1 ± 11.9 years old, and 77.3% were males. The average age at diagnosis of ALC was significantly lower in patients with mutation (49.0±12,6 *vs.* 56.7±11.7 years old; p=0.014). The incidence of *CARD15* mutations, especially of the R702W variant, was significantly higher in patients with hepatorenal syndrome (HRS) (overall – 36.3% *vs.* 16.0%; p=0.029; R702W variant – 27.3% *vs.* 10.4%, p=0.034). No significant associations were detected between *CARD15* mutations and SBP (27.3% *vs.* 16.8%, p=0.193), hepatocellular carcinoma (17.6% *vs.* 19.8%, p=0.833), hepatic encephalopathy (22.7% *vs.* 16.1%, p=0.347), gastroesophageal variceal bleeding (18.6% *vs.* 20.0%, p=0,851), acute alcoholic hepatitis (30.0% *vs.* 18.0%, p=0,384), or other infectious intercurrences (18.0% *vs.* 20.5%, p=0.726).
CONCLUSION: Within the portuguese population, *CARD15* mutations are not linked with increase risk of ALC, but are associated with earlier onset of the disease and represent a risk factor for HRS. *CARD15* variants are not correlated with other ALC complications.

P035 FREQUENCY OF ADRENAL FAILURE IN AMBULATORY PATIENTS WITH CIRRHOSIS

J. Paz[1,*], F. Bosques[2], F. J. Lavalle[3], J. Z. Villarreal[3], H. J. Maldonado[2]. [1]*Medicina Interna,* [2]*Gastroenterologia,* [3]*Endocrinologia, Hospital Universitario, Monterrey, Mexico*

INTRODUCTION: Previous studies have shown that adrenal failure is frequent among patients with advanced cirrhosis with septic shock (65%), or in acute liver failure (33%). Although adrenal failure is well documented in critically ill patients with cirrhosis, it's unclear if it's a pre-existing condition or if it's triggered by a critical illness.
AIMS&METHODS: Establish the frequency of adrenal failure in stable cirrhotic patients by insulin tolerance test. In a period between September 2011 and August 2012 patients attending a gastroenterology clinic of a tertiary medical center were evaluated. The study was approved by the local ethics committee and all patients signed informed consent. Patients with sepsis, cancer, adrenal failure, treatment with steroids, ischemic heart disease, arrhythmias, seizures, gastrointestinal bleeding, hepatic encephalopathy grade III-IV or serum creatinine >3mg/dL were excluded. Adrenal failure was identified by the insulin tolerance test. Patients remained sited and medically supervised during the test, hypoglycemia was induced by the administration of a 0.15 U/kg insulin IV bolus. Capillary glucose levels were measured every 15 minutes, until adequate levels of hypoglycemia (50% decrease from basal glucose or <45mg/dL) were reached. Blood samples were obtained at time of 0, 30, 60 and 90 minutes

after the insulin bolus. Serum levels of cortisol were analyzed by *electrochemiluminescence* (Roche diagnostic) with ELECSYS 2010 system. Adrenal failure was defined with a total serum cortisol level <18μg/dl at 30 minutes after the hypoglycemia induced by insulin, patients were classified as responders or non-responders according to levels of cortisol.
RESULTS: A total of 40 insulin tolerance tests were performed, 16 patients (40%) were classified as responders with a serum cortisol level >18μg/dl at 30 minutes of hypoglycemia and 24 patients (60%) were considered non-responders. The values of MELD score were different between groups, responders 9.81+1.25 (IC95%8.56-11.06) vs. non-responders 15.1+2.6 (IC95%12.5-17.7) (p=0.001), also Child-Pugh scores were statistically different 7.18 +0.88 (IC95% 6.3-8.06) vs. 8.87+1.04 (IC95% 7.83-9.91) (p=0.02). In this study patients with a MELD score >12 had an increased risk of adrenal failure (OR 7.22) (IC95% 1.60 a 32.46). Patients with Child class C had an 80% prevalence of adrenal failure.
CONCLUSION: We found that adrenal failure is highly frequent among ambulatory cirrhotic patients in absence of a critical illness, and its frequency is related to hepatic reserve and severity of the disease measured by MELD and Child-Pugh scores.

P036 HEPATITIS VIRUS B INACTIVE CARRIERS: PREDICTIVE FACTORS OF SPONTANEOUS SEROCONVERSION TO ANTI-HBS

M. C. Moura[1,*], A. M. Horta e Vale[2], R. Coelho[2], H. Cardoso[2], A. Sarmento[2], M. Marques[2], P. Pereira[2], S. Lopes[2], G. Macedo[2]. [1]*Internal Medicine,* [2]*Gastrenterology, Centro Hospitalar São João, Porto, Portugal*

INTRODUCTION: Patients infected with hepatitis B Virus (HBV) may evolve to an inactive carrier status (IC): low or undetectable DNA (<2000 UI/mL) and normal liver enzyme levels, which predict a good prognosis. The described spontaneous seroconversion is 1-3% per year.
AIMS&METHODS: Evaluation of patients who seroconverted and their predictors. Retrospective cohort study of 157 IC patients followed as Hepatology outpatient for 15 years (1998-2013). Of those, we exclude 33 previously treated with interferon (n=20 reached seroconversion, n=7 with reactivation). In the sample analyzed (n=124), seroconversion to anti-HBs occurred in 15 patients (12.1%, HBVs), 107 patients (86.3%, HBVns) did not have seroconversion and reactivation occurred in 2 patients (1.6%). We used the Chi-square and Mann-Whitney test and logistic regression to compare groups and to evaluate the predictive factors.
RESULTS: Most of the HBVs were male (n=10) and older (60vs52 years,p=0.002) with genotype A and D. In HBVs no patient presented enough viremias to perform genotype and comparing with HBVns was lower (33vs5350UI/mL,p<0.001) and more uniform (p=0.035). The fibrosis documented in liver biopsy was lower in HBVs (p=0.003) but similar when estimated by fibroscan (5.2vs5.5 KPa,p=0.350). No HBVs patient presented complications, evolution to chronic hepatitis, liver cancer or died. The incidence of seroconversion was 1% patients per year. The follow-up time was longer in HBVs (14vs6 years,p=0.003). The predictive factors of seroconversion were older age (OR 1.07,p=0.004), lower viremias (OR 0.99,p=0.049) and longer follow-up (OR 1.23, p=0.002).
CONCLUSION: Patients with lower viremias and those who performed previous treatment with interferon had higher probability of seroconversion. Those who presented reactivation were only detected because the follow-up was keptand they were treated thereafter.

P037 SIMVASTATIN INHIBITS THE LIPOPOLYSACCHARIDE INDUCED EPITHELIAL-TO-MESENCHYMAL TRANSITION OF HUMAN BILIARY EPITHELIAL CELLS VIA DOWNREGULATION OF TLR4

S. M. Park[1,*], N. Kim[2], E. J. Lee[1], M. Ji[1], J.-W. Choi[3], Y. Kim[4]. [1]*Internal Medicine, Chungbuk National University College of Medicine, Cheongju,* [2]*Internal Medicine, Seoul National University Bundang Hospital, Seongnam,* [3]*Surgery,* [4]*Physiology, Chungbuk National University College of Medicine, Cheongju, Korea, Republic Of*

INTRODUCTION: The epithelial-to-mesenchymal transition (EMT) of biliary epithelial cells (BECs) plays a role in biliary fibrosis and is promoted by lipopolysaccharide (LPS).
AIMS&METHODS: We studied the effects of simvastatin (1mM) on the EMT of BECs induced by LPS or transforming growth factor-β1 (TGF-β1) and investigated the underlying molecular mechanism. Immortalized normal human cholangiocyte line (H69) were exposed to LPS (2μg/mL) or TGF-β1 (5 ng/ml) for 24 h. The expressions of E-cadherin, vimentin, and toll-like receptor 4 (TLR4) were determined by real-time PCR, Western blotting, and confocal microscopy. The effect of simvastatin on the EMT induced by LPS or TGF-b was determined by changes in the expression of E-cadherin, vimentin, and TLR4 and in cell morphology.
RESULTS: BECs stimulated with TGF-β1 or LPS showed EMT changes that occurred by TLR4 upregulation, including increased vimentin and decreased E-cadherin expression at the mRNA and protein levels. Simvastatin inhibited the EMT induced by TGF-β1 or LPS via TLR4 downregulation, manifested as increased E-cadherin and decreased vimentin and a change from a spindle-like to a round morphology. Therefore, LPS or TGF-β1 promoted EMT, and the treatment of the BECs with simvastatin blocked these changes by inhibition of TLR4.
CONCLUSION: Simvastatin inhibits the LPS induced EMT of cultured human BECs and therefore can be considered as a new agent for the prevention of biliary fibrosis associated with the EMT of BECs.

P038 HEREDITARY TRANSTHYRETIN AMYLOIDOSIS AND COMMON MUTATIONS IN GERMANY

Y. Avsar[1,*], T. Todorov[1], A. Zibert[1], I. Kabar[1], V. Cicinnati[1], S. Beckebaum[1], C. Röcken[2], A. Barreiros[3], H. H.-J. Schmidt[1]. [1]*Department of Transplantation Medicine, University Hospital Münster, Münster,* [2]*Department of Pathology, Christian-Albrechts University, Kiel,* [3]*Department of Internal Medicine, Universitätsmedizin Mainz, Mainz, Germany*

INTRODUCTION: Hereditary amyloidosis (familial amyloid polyneuropathy) is composed of a heterogenous group of diseases transmitted as an autosomal dominant trait. The most common form is associated with a mutation of the transthyretin gene (TTR) with so far more than 100 TTR-variants known to form amyloid. The varying mutations are correlated with differing clinical manifestations, which is a significant factor for the outcome of liver transplantation – currently the only curative treatment option. This highlights the importance for identifying the specific mutation involved in order to optimize patient selection. Certain high frequency mutations have been reported in countries such as Portugal, Sweden and Japan. Common TTR-variants in Germany have yet to be identified.
AIMS&METHODS: The mutational pattern of TTR-amyloidosis in Germany was studied. 86 patients with TTR-amyloidosis from 46 unrelated families were included. Diagnosis was confirmed histologically. Mutations were identified by genomic DNA extraction from patient's blood and direct sequencing. Patients were examined for clinical signs and symptoms.
RESULTS: Val30Met, identified in 42 patients from 25 families, was found to be the most prevalent mutation. The Gly47Ala variant was found in 19 patients. However 18 of those patients belonged to one family. Patients with a Val30Met mutation were mainly affected by polyneuropathy, with involvment of other organ systems developing later in the clincial course. A primarily cardiac presentation and a later onset of polyneuropathy was associated with the Gly47Ala variant. Furthermore we identified following mutations: Gly47Glu, Leu58His, Ile107Val, Gly53Ala, Asp39Val, Arg34Thr, Val20Ile, Thr60Ala, Thr59Lys and Glu89Gln. 16/86 patients received a liver transplant and 21/86 patients are currently on treatment with Tafamidis. Outcomes are still being followed.
CONCLUSION: This is the first report on mutational analyisis of amyloidogenic TTR-variants in Germany. Similar to Portugal, Sweden and Japan, areas with the largest FAP foci, Val30Met was found to be the most prevalent mutation. Our ongoing analysis with a growing number of FAP-patients may help to categorize the mutational pattern in Germany and may facilitate to identify prognostic factors for patients treated with Tafamidis or liver transplantation.

P039 NUCLEOTIDE-BINDING OLIGOMERIZATION DOMAIN PROTEIN 2 (NOD2/CARD15) MUTATION P.R702W PREDISPOSES TO A FATAL OUTCOME OF SEVERE ACUTE PANCREATITIS

F. U. Weiss[1,*], A. Guenther[1], R. M. Nijmeijer[2], C. Nitsche[1], A. Aghdassi[1], M. A. Boermeester[3], H.-U. Schulz[4], G. I. Papachristou[5], J. Mayerle[1], H. C. van Santvoort[2], M. Zenker[6], P. Simon[1], E. Weber[1], D. C. Whitcomb[5], M. M. Lerch[1]. [1]*Department of Medicine A, University Medicine, Greifswald, Germany,* [2]*Department of Surgery, University Medical Centre Utrecht, Utrecht,* [3]*Department of Surgery, Academic Medical Center, Amstardam, Netherlands,* [4]*Department of Surgery, Otto-von-Guericke University Magdeburg, Magdeburg, Germany,* [5]*Department of Medicine, University of Pittsburgh, School of Medicine, Pittsburgh, United States,* [6]*Department of Genetics, Otto-von-Guericke University Magdeburg, Magdeburg, Germany*

INTRODUCTION: Acute Pancreatitis is a common non-malignant gastrointestinal disorder and, when severe, burdened with a mortality of up to 20%. Nucleotide-binding oligomerization domain protein 2 (NOD2/CARD15) acts as an intracellular sensor of pathogen-associated molecular patterns (PAMP), namely the peptidoglycan derivate muramyl-dipeptide. Loss-of-function mutations in the NOD2-gene have been identified as a susceptibility factor for several

inflammatory disorders including Crohn's disease, Blau-Syndrome, and early-onset sarcoidosis. We have investigated whether loss-of-function mutations in the NOD2/CARD15-gene affect the risk of developing acute pancreatitis or the patient's survival

AIMS&METHODS: A total of 941 patients with acute pancreatitis were prospectively recruited (761 Europe, 180 US) as well as 926 blood donor controls (662 Europe, 264 US). 59 patients did not survive pancreatitis (overall mortality 6.3%). Genotyping of three established loss-of-function mutations in the NOD2/CARD15 gene. Stratification of patients according to disease severity, complications and survival. A total of 941 patients with acute pancreatitis were recruited (761 Europe, 180 US) as well as 926 blood donor controls (662 Europe, 264 US). 59 patients did not survive pancreatitis (overall mortality 6.3%).

RESULTS: Carrier status for the p.R702W mutation, but not for the p.G908R or the p.L1007fs mutations conferred an increased risk for severe pancreatitis with fatal outcome (11% vs. 4.5%; $p<0.01$ on meta-analysis, odds ratio 2.64; CI 1.35-5.05). Among patients who died from severe pancreatitis 40% carried the p.R702W allele and 16.4% the wild type allele with an odds ratio for death of 2.5 (CI 1.25-5.02) for heterozygous carriers and 9 (CI 0.8-100.93) for homozygous p.R702W carriers. Stratification for different complications found a positive association with multiple organ failure (odds ratio 4.25; CI 1.28-14.3; $p<0.02$) but not for infected necrosis, sepsis of single organ failure.

CONCLUSION: This study identifies the p.R702W mutation in NOD2/CARD15 as a genetic risk factor for developing organ complications and for mortality related to acute pancreatitis. Patients known to carry this allele may require specific measures to prevent multiple organ failure early in their disease process.

P040 THE HIV ENVELOPE PROTEIN GP120 DIRECT ACTIVATES THE INFLAMMASOME COMPLEX THROUGH THE ENGAGEMENT OF CCR5 IN BOTH HUMAN HEPATIC STELLATE CELLS AND FRESH ISOLATED MONONUCLEAR CELLS

A. Cappon[1], R. Bruno[2], S. Gessani[3], A. Masotti[4], **F. Marra**[1,*]. [1]*Dept. of Clinical and Experimental Medicine, University of Florence, Florence,* [2]*University of Florence, Pavia,* [3]*Istituto Superiore di Sanità,* [4]*Ospedale Pediatrico Bambin Gesù, Rome, Italy*

INTRODUCTION: Patients with HCV/HIV co-infection show a faster progression of hepatic fibrosis and more severe inflammation. The HIV envelope protein gp120 has been previously shown to modulate different aspects of hepatic stellate cells (HSCs) biology, including directional migration and expression of profibrogenic cytokines, at least in part via activation of the chemokine receptor CCR5. Recent work has identified the NALP3 inflammasome as a critical pathway in the generation of proinflammatory signals during liver injury, but no information is available on a possible direct link between the inflammasome and HIV proteins.

AIMS&METHODS: Aim of this study is to elucitated the role of HIV envelope protein gp120 to activates inflammsome components in HSCs and PBMCs. Myofibroblastic HSCs were isolated from normal human liver tissue and cultured on plastic until fully activated. freshly isolated mononuclear cells (PBMCs) were separated from human whole blood. Gene expression was measured by qPCR. Protein IL-1β protein levels were assayed by ELISA. Where reported TAK-779 or α-CCR5 were pre-incubated 1h before treatment.

RESULTS: HSCs or PBMCs were exposed to 500 ng/ml recombinant M-tropic gp120 (CN54) for 2, 8 and 24 hours. A time-dependent, significant up-regulation of ASC and NALP3, components critical for the assembly of NALP3-dependent inflammasome was observed in both cell types. This effect was associated with increased expression of caspase-1, which caused conversion of pro-IL-1β into mature IL-1β, in both HSCs and freshly isolated PBMCs. Remarkably, a significant increase in gene expression of IL-1β was observed in both cell types, together with increased protein levels in the supernatant. Notably, preincubation with TAK779, a CCR5 receptor antagonist, or with neutralizing CCR5 antibody significant abolished gp120-mediated IL-1β expression and production by both HSCs and PBMCs. Furthermore, gp120 induced significant up-regulation of pro-inflammatory chemokine IL-8 expression on HSCs and PBMCs, a potent chemokine. Pre-incubation with TAK-779 prevented, at least in part, the mRNA expression of IL-8 in both cellular model, suggesting that also in this case CCR5 is the mainly receptor involved.

CONCLUSION: HIV-gp120 significantly increased the expression of components of the NALP3 inflammasome in human HSCs and PBMCs, mainly through activation of CCR5. These data identify a novel mechanism by which HIV-gp120 may directly influence hepatic necroinflammation and fibrosis during HCV/HIV coinfection, through increased production of the pro-inflammatory cytokine IL-1β.

INTRODUCTION: Obesity and aging are associated with a state of chronic low-grade inflammation, however little is known regarding the mechanisms that trigger the development of non-alcoholic-fatty-liver-disease(NAFLD) in aging.

AIMS&METHODS: To link lipid availability at the cell membrane to inflammation, we hypothesized that a diet-induced increase in fatty acid uptake may underlie the development of hepatic inflammation in obesity and aging.

Mice:To investigate this, we subjected young and aged C57Bl6 mice on a chow diet. Also young and aged mice were fed a high-fat diet (HFD, 60% kcal fat (Research Diets) for 12 weeks.

Human liver biopsies:

- Young ($\leq$ 38 years; n=16) and old ($\geq$ 50 years; n=14) patients with histologically normal liver (NL)
- Young ($\leq$ 42 years; n=11) and old ($\geq$ 52 years; n=15) patients diagnosed with non-alcoholic steatosis (NAS)
- Subjects matched in terms of sex distribution, BMI, insulin resistance, and histological grade of steatosis
- Patients with alcohol intake $>$ 20 g/d, those with NASH, hepatitis B, C and HIV infection, and taking chronic medications were excluded

Analyses: Livers were dissected for gene expression (RT-PCR), immunoblot analyses and histological assessment of steatosis and CD36 expression

RESULTS: As a result, CD36, a long-chain-fatty-acid (LCFA) uptake protein, was increased in livers of aged normal-diet mice compared to young mice. This result correlated with normal-liver (NL) of patients above 50 years age compared to patients below 38 years age. Conversely, CD36 expression was increased at the plasma membrane of hepatocytes of non-alcoholic steatosis (NAS) above 50 years age in opposition to both NAS young and normal liver, confirming an important role for CD36 in the development of NAFLD. Moreover, high-fat feeding in aged mice severely augmented hepatic CD36 expression, TG accumulation and inflammatory signaling.

CONCLUSION: Our data suggest that a diet-induced increase in hepatic CD36 expression may underlie the development of hepatic inflammation in obesity and aging by promoting LCFA uptake.

P042 PIOGLITAZONE-ALOGLIPTIN COMBINATION THERAPY IMPROVES LIVER STEATOSIS IN MURINE NONALCOHOLIC FATTY LIVER DISEASE MODEL COMPLICATED WITH TYPE 2 DIABETES MELLITUS

H. Tobita[1,*], S. Sato[1], T. Miyake[1], T. Saitoh[1], Y. Kinosita[1]. [1]*Gastroenterology and Hepatology, Shimane University Faculity of Medicine, izumoshi, Japan*

INTRODUCTION: Accumulation of visceral fat and insulin resistance are major pathophysiologic abnormalities that occur in patients with nonalcoholic liver disease (NAFLD) and type 2 diabetes mellitus (T2DM), with thiazolidinedione and DPP-4 inhibitor known to be effective for several T2DM pathophysiologic processes. However, since the effectiveness of each drug individually for NAFLD is not adequate, their combination is speculated to provide effective therapy.

AIMS&METHODS: We investigated the effectiveness of combination therapy with thiazolidinedione and DPP-4 inhibitor in NAFLD model mice complicated with T2DM. Twelve-week-old male KK-A^y/TaJcl (KK-A^y) mice were given a choline-deficient (CD) diet supplemented with 0.02% pioglitazone (PIO) and/or 0.03% alogliptin (ALO) for 8 weeks. We assessed biochemical parameters, pathological changes, and hepatic mRNA levels in association with fatty acid metabolism.

RESULTS: Severe hepatic steatosis developed in KK-A^y mice given the CD diet. Although hepatic inflammation and fibrosis were not obvious in these mice, hepatic mRNA levels of monocyte chemoattractant protein-1 (MCP-1) and α-smooth muscle actin (α-SMA) were increased as compared to KK-A^y mice fed a normal diet. Hepatic steatosis was improved in mice that received the CD diet supplemented with PIO and/or ALO, as the level of adiponectin in serum increased and that of triglyceride decreased with that supplementation. Insulin resistance and serum HDL-C level were also improved by supplementing the CD diet with PIO and ALO. Furthermore, the hepatic mRNA levels of carnitine palmitoyltransferase-1a (CPT-1a) and superoxide dismutase-1 (SOD-1) were increased with ALO supplementation of the CD diet, as was Thr172 phosphorylation of AMP-activated protein kinase alpha in the liver. In contrast, the hepatic mRNA levels of sterol regulatory element-binding protein-1c (SREBP-1c) and fatty acid synthase (FAS) were decreased by supplementing with PIO.

CONCLUSION: PIO plus ALO combination therapy improved liver steatosis in NAFLD model mice complicated with T2DM. Also, PIO decreased hepatic mRNA levels for fatty acid synthesis, while ALO increased hepatic CPT-1a mRNA levels for fatty acid β oxidation. Our results suggest that ALO, similar to adiponectin, promotes CPT-1a expression through Thr172 phosphorylation of AMPKα.

P043 NECROPTOSIS IN PRIMARY RAT HEPATOCYTES AND IN PATIENTS WITH CHRONIC LIVER DISEASE

M. B. Afonso[1], D. M. S. Ferreira[1], H. Cortez-Pinto[2,3], R. E. Castro[1,4,*], C. M. P. Rodrigues[1,4]. [1]*Research Institute for Medicines and Pharmaceutical Sciences (iMed.UL), Faculty of Pharmacy, University of Lisbon,* [2]*Gastrenterology, Hospital Santa Maria,* [3]*Institute of Molecular Medicine (IMM), Faculty of Medicine, University of Lisbon,* [4]*Department of Biochemistry and Human Biology, Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal*

INTRODUCTION: Regulated necrosis or necroptosis is arising as a prominent pathological feature of inflammation-driven liver diseases. Bile acids are well-established modulators of inflammatory and cell death processes in the liver, which may play a role in disease pathogenesis and progression.
AIMS&METHODS: The aim of this study was to investigate the role of necroptosis in liver cell injury in vitro and in patients. HepG2 cells and primary rat hepatocytes were incubated with hydrophobic toxic bile acids, free fatty acids, or tumour necrosis factor(TNF)-alpha/cycloheximide, in the presence or absence of pan-caspase inhibitor, zVAD-fmk, and/or with therapeutic ursodeoxycholic acid (UDCA) or necroptosis inhibitor necrostatin-1. Cytotoxicity and caspase-3/7 activity were assessed at 24 h. High-mobility group box 1 protein (HMGB1), extracellular marker of necrosis, was analysed by immunoblotting. Expression of receptor interacting protein 3 (RIP3) was evaluated by immunofluorescence in cultured cells and patient liver tissue.
RESULTS: In HepG2, cell death induced by toxic bile acids was completely abolished by inhibition of caspases. Conversely, toxic bile acids, free fatty acids or TNF-alpha plus zVAD-fmk induced caspase-3-independent cell death in primary rat hepatocytes, which was inhibited by both necrostatin-1 and UDCA; cellular leakage of HMGB1 and RIP3 expression followed the same trend, confirming the occurrence of necroptosis. Finally, RIP3 was strongly expressed in the liver of patients with chronic liver disease, irrespective of etiology.
CONCLUSION: Overall, our results suggest that cell death induced by toxic bile acids, free fatty acids or TNF-alpha shifts from apoptosis to regulated necrosis when caspase activation is blocked in primary rat hepatocytes. In contrast, UDCA effectively prevented caspase-dependent and -independent cell death. Necroptosis may play a role in the pathogenesis and progression of inflammation-driven liver disease and should be regarded as a potential therapeutic target.

P044 DEOXYCHOLIC ACID INHIBITS NF-KB-MEDIATED ACTIVATION OF MIR-21 IN PRIMARY RAT HEPATOCYTES, PROMOTING APOPTOSIS IN A DOSE-DEPENDENT MANNER

P. M. Rodrigues[1], M. B. Afonso[1], A. L. Simão[1], D. M. S. Ferreira[1], P. M. Borralho[1,2], C. M. P. Rodrigues[1,2], R. E. Castro[1,2,*]. [1]*iMed.UL,* [2]*Department of Biochemistry and Human Biology, Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal*

INTRODUCTION: Cytotoxic bile acids, such as deoxycholic acid (DCA), are usually associated with several liver and gastrointestinal disorders. We have recently shown that bile acids modulate microRNA (miRNA/miR) expression in the liver and that DCA inhibits miR-21 expression in hepatocytes.
AIMS&METHODS: We aimed to clarify the mechanisms by which DCA modulates the miR-21 pathway and contributes to apoptosis in primary rat hepatocytes. Primary rat hepatocytes were incubated with 25-100 μM DCA for 4 to 48 h. Cell death, viability and caspase-3 activity were determined by the ApoTox-Glo™ Triplex Assay. miR-21 expression was evaluated by qRT-PCR. Programmed cell death 4 (PDCD4) and phosphatase and tensin homolog (PTEN), two miR-21 targets, as well as NF-κB, IκB and caspases were analysed by immunobloting. NF-κB activation was evaluated using a specific luciferase assay, and by analysing NF-κB subcellular localization. For functional studies, miR-21 and NF-κB were modulated using specific genetic and pharmacologic inhibitors/activators.
RESULTS: Our results show that the miR-21 pathway is modulated by DCA in a dose-dependent manner. 100 μM DCA significantly induced caspase-2/-3 activities and apoptosis, while reducing cellular viability ($p<0.05$). Moreover, miR-21 expression was inhibited ($p<0.01$) with a concomitant increase in PDCD4 and PTEN proteins ($p<0.05$). In addition, DCA inhibited NF-κB expression and activity ($p<0.05$), NF-κB/IκB ratio ($p<0.05$) and NF-κB nuclear localization ($p<0.05$), in a similar pattern to miR-21 inhibition. Importantly, miR-21 overexpression impaired the ability of DCA to induce PDCD4 and PTEN expression, as well as apoptosis ($p<0.05$), but had little effect on NF-κB activation. Finally, after ectopic activation of NF-κB, DCA was less capable of repressing miR-21, and its cytotoxicity was decreased ($p<0.05$). NF-κB inhibition by BAY 11-7085 had opposite effects ($p<0.05$).
CONCLUSION: Dose-dependent modulation of the miR-21 pathway by DCA correlates with its effects on apoptosis. DCA significantly inhibits miR-21 expression, resulting in increased PDCD4 and PTEN protein levels, as well as caspase activation and apoptosis. Importantly, DCA appears to modulate the miR-21-dependent pro-apoptotic pathway *via* inhibition of NF-κB activation. A better understanding of the mechanisms by which DCA impacts on cell death may allow for the development of new therapeutic tools to treat apoptosis-related pathologies.

P045 EFFECTS OF S-ADENOSYLMETHIONINE ON THE BIOLOGICAL BEHAVIOR OF ACTIVATED HUMAN HEPATIC STELLATE CELLS

F. Zhang[1], Y. Zhuge[1,*], Y. Li[1], J. Gu[1]. [1]*Department of Gastroenterology, Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

INTRODUCTION: Liver fibrosis is a common wound-healing event in response to a variety of chronic liver diseases, which characterizes the deposition of extracellular matrix (ECM) mainly originating from hepatic stellate cells (HSCs) that have transdifferentiated into myofibroblastlike cells (MFB). Previous studies have demonstrated that SAM could inhibit HSCs activation and reduce liver fibrosis.
AIMS&METHODS: To investigate the effects of S-Adenosylmethionine (SAM) on the proliferation, adhesion, migration, invasion and apoptosis of activated human hepatic stellate cells (HSCs) and to explore the relevant potential mechanisms.
Human HSCs LX-2 were cultured with SAM. The proliferation and adhesion were detected by CCK-8. Cell cycle distribution and apoptotic rate were analyzed by flow cytometry, and cell migration and invasion were tested by transwell assay. The expression of Rac1, MMP-2 and Cyclin D1 was identified by real-time PCR or western blotting, and activated Rac1 was detected by GST pull-down assay. The activity of MMP-2 and MMP-9 were analyzed by Substrate Zymography.
RESULTS: The proliferation of LX-2 cells was inhibited by SAM, exhibiting a dose-dependent manner. SAM retarded the LX-2 cells at the S stage and cell apoptotic rate induced by SAM was remarkably increased. SAM decreased the adhesion, migration and invasion of LX-2 cells. The mRNA of Cyclin D1 was up regulated and expression of α-SMA was inhibited by SAM. The expression and activation of Rac1 in LX-2 cells were significantly suppressed by SAM. In contrast, the activity of MMP-2 and MMP-9 was enhanced by SAM. SAM attenuated the up-regulated expression of Smad3/4 and Rac1 induced by TGF-β1.
CONCLUSION: SAM inhibits the proliferation, adhesion, migration and invasion of LX-2 cells in vitro probably via attenuating the expression and activation of Rac1 and up regulating MMP-2, MMP-9 and Cyclin D1 expression, which possibly provide a molecular basis for potential application of SAM in the therapy of liver fibrosis.

P046 PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR GAMMA INHIBITS MOUSE LIVER REGENERATION AFTER PARTIAL HEPATECTOMY VIA THE HGF/C-MET ERK1/2 PATHWAYS

D. Hartmann[1,*], Z. J. Cheng[1,2], L. Lu[1,2], V. Assfalg[1], J. Kleeff[1], H. Friess[1], M. Laschinger[1], N. Hüser[1]. [1]*Department of Surgery, Technische Universität München, Munich, Germany,* [2]*Department of General Surgery, Zhongda Hospital, Southeast University, Nanjing, China*

INTRODUCTION: Peroxisome Proliferator-Activated Receptor gamma (PPARγ) is a nuclear receptor demonstrated to play an important role in various biological processes. However, the role of PPARγ on liver regeneration remains unclear and controversial. Aim of this study was to determine the effect of PPARγ on liver regeneration upon partial hepatectomy in mice and to elucidate the underlying molecular mechanisms.
AIMS&METHODS: Eight- to ten-week-old female C57BL/6J mice were subjected to 2/3 partial hepatectomy by removal of the left and median lobe of the liver. Before surgery, mice were either treated with the PPARγ agonist rosiglitazone, the PPARγ antagonist GW9662 alone or in combination with the c-met inhibitor SGX523. Serum and tissue specimens were harvested and parameters, such as liver-to-body-weight ratio, serum transaminases, alkaline phosphatase, glucose, cholesterol, triglyceride levels, were assessed. To elucidate liver regeneration and hepatocyte proliferation, immunohistochemical analysis of PPARγ, Ki67 and PH3 was performed. Components of the PPARγ-specific signaling pathway during liver regeneration were identified by western blot (PPARγ, STAT3, CyclinD1, HGF, c-met, and ERK1/2) or RT-PCR (Tnfα and Il-6).
RESULTS: Our results indicate that liver regeneration after 2/3 partial hepatectomy is being inhibited by rosiglitazone and accelerated by PPARγ antagonist GW9662. Inhibition of c-met abrogates GW9662-induced liver regeneration and hepatocyte proliferation. In addition, STAT3 was found to be phosphorylated shortly after partial hepatectomy while hepatic cyclin D1 expression was delayed in rosiglitazone-treated mice. Similarly, HGF, phosphorylated c-met and phosphorylated ERK1/2 protein levels were significantly down-regulated after rosiglitazone treatment with oppositional tendency after GW9662 treatment.
CONCLUSION: These data support the concept that PPARγ does inhibit liver growth and hepatocellular proliferation by inhibition of the HGF/c-met ERK1/2 pathways. These pathways may represent potential targets during liver regeneration in response to liver disease and these findings could thus impact on the future development of molecular therapies in patients with liver disease.

P047 DO GLP-1 ANALOGUES AFFECT EARLY PHASE OF LIVER REGENERATION AFTER PARTIAL HEPATECTOMY IN RATS?

J. Fontana[1,*], O. Kucera[2], M. Andel[1], Z. Cervinkova[2]. [1]*Centre for Research of Diabetes, Metabolism and Nutrition, Third Faculty of Medicine, Charles University in Prague, Prague,* [2]*Department of Physiology, Faculty of Medicine in Hradec Králové, Charles University in Prague, Hradec Králové, Czech Republic*

INTRODUCTION: GLP-1 is an incretin hormone known for its proliferative and antiapoptotic effects on pancreatic β-cells. These effects are currently routinely used in the therapy of diabetes mellitus. From literature data, it is evident that GLP-1 affects liver functions and liver metabolism. But very little is known about its ability to modulate liver regeneration and proliferation of hepatocytes.
AIMS&METHODS: To determine the effect of GLP-1 analogues, exenatide (Ex4) and liraglutide, on liver regeneration and selected metabolic parameters in a model of 2/3 partial hepatectomy in male Wistar rats. Animals (264 ± 17 g) were divided into 6 groups ($n = 6$). On the first day, two doses of either GLP-1 analogues (Ex4 10 nmol/kg, liraglutide 0.75 mg/kg), or equivalent amount of saline (S) were injected intraperitoneally. On the second day, the animals were submitted to the 2/3 partial hepatectomy (PHx) (1) or sham laparotomy (LAP). The third dose of analogues or saline was injected immediately after the surgery. The animals were sacrificed 24 h after the surgery and the intensity of liver regeneration and selected metabolic parameters were evaluated.
RESULTS: In the rats with PHx, both analogues compared to saline controls decreased bromodeoxyuridine (BrdU) labeling ($p < 0.001$) - marker of S-phase activity. Liraglutide compared to Ex4 caused even lower BrdU labeling ($p < 0.001$). This effect was reflected in a decreased liver DNA content in the rats with PHx receiving liraglutide compared to both Ex4 ($p < 0.001$) and saline group ($p < 0.001$). Laparotomy groups had no significant difference in BrdU labeling and DNA content. Liraglutide treatment in contrast to both saline and Ex4 treatment led after any surgery (PHx, LAP) to an increase in serum urea (LAP-LIRA vs LAP-S: $p < 0.001$; LAP-LIRA vs LAP-Ex4: $p < 0.001$; PHx-LIRA vs PHx-S: $p < 0.05$; PHx-LIRA vs PHx-Ex4: $p < 0.01$). Ex4 did not exert any effect on serum urea. Liraglutide also reduced serum total biliribin ($p < 0.05$), serum triacylglycerols ($p < 0.001$) and liver cholesterol content ($p < 0.05$) in the rats with PHx. Analogues had no significant effect on body weight, liver weight, serum creatinine, serum total cholesterol, serum activities of AST, ALT and ALP, liver triacylglycerols content and mitochondrial respiration.
CONCLUSION: Our results suggest that GLP-1 analogues, exenatide and liraglutide, significantly affect (diminish) early phase of liver regeneration after 2/3 partial hepatectomy and that liraglutide effect is even more pronounced. Interesting finding is an effect of liraglutide on a serum urea level, without a concomitant effect on a serum creatinine.

P048 FGF SIGNALING PATHWAY IS PRINCIPAL REPRESENTATIVE FOR HEPATIC SPECIFICATION

P. keyhanvar[1], O. Mashinchian[1,2,*], S. Akbari Nakhjavani[3]. [1]*Medical Nanotechnology Dpt., The School of Advanced Technologies in Medicine, Tehran University of Medical Sciences, Tehran,* [2]*Nanomedicine Department, RESEARCH CENTER FOR PHARMACEUTICAL NANOTECHNOLOGY (RCPN), Tabriz University of Medical Sciences, Tabriz,* [3]*Molecular Medicine Dpt.,, The School of Advanced Technologies in Medicine, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of*

INTRODUCTION: Bmp and Fgf signaling pathways have remarkable role in regulation of hepatic specification based on the investigation from in vitro tissue explant and cell implantation, but additional research for demonstration of this hypothesis especially genetic research is indispensable. Consequently, utilization of zebrafish study model with overexpression of dominant-negative forms of Bmp or Fgf receptors can reveal the main mechanism. Additionally, genetic analysis demonstrated this point that, Foxa gene can regulate the competence of endodermal cells regarding to hepatic inductive signals [1]. Bmp and Fgf signaling have an additional role in the morphogenetic outgrowth of the hepatic endoderm regulation specially, FGF8 [2]. Altogether, this information suggests that, Bmp and Fgf signaling pathways are essential for hepatic specification/gastrulation and lacking of this pathways is observable in defects related to liver specification.
AIMS&METHODS: Embryos were heat shocked for 25 minutes at 40°C and 15 minutes at 37°C via transferring them into a prewarmed plate. Zebrafish line has utilized which overexpress dominant-negative *Bmpr1a*. In this experiment, hemizygous embryos were effortlessly distinguished and has tested for presence of the *hsp70:bmp2b* transgene by PCR technique. In situ hybridizations technics has performed through the *pdx1*, *prox1* and *foxa3* probes [3, 4].
RESULTS: Results reveal the important role of Bmp signaling in hepatoblast specification when was blocked at 30 hpf. In this period, *prox1* expression was reduced compared with wild-type. In embryos with blocked Bmp signaling, *gata6* expression was significantly decreased in the liver. In the heat-shocked hemizygous embryos, *hhex* expression was absent suggesting that Fgf signaling after 16 hpf is essential for hepatoblast specification.
CONCLUSION: Based on the in vitro tissue explant methodologies, Fgf signaling plays two main roles in early liver development. Genetic analysis have demonstrated that, Gdf6a and Alk8 is also expressed in the endoderm at the time of specification. This data have been confirmed the Fgf signaling role together with Bmp and TGF-β in the hepatoblast specification.

P049 GENE EXPRESSION PROFILING AND SECRETOME ANALYSIS DIFFERENTIATE ADULT-DERIVED HUMAN LIVER STEM/PROGENITOR CELLS AND HUMAN HEPATIC STELLATE CELLS

S. Berardis[1,*], C. Lombard[1], A. Taghdouini[2], P. Sancho-Bru[3], J. J. Lozano[3], L. Van Grunsven[2], E. Sokal[1], M. Najimi[1]. [1]*Laboratory of Pediatric Hepatology and Cell Therapy, Université Catholique de Louvain,* [2]*Liver Cell Biology Lab, Vrije Universiteit Brussels, Brussels, Belgium,* [3]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain*

INTRODUCTION: Adult-derived human liver stem/progenitor cells (ADHLSC) are isolated after primary culture of liver parenchymal fraction. The cells are currently developed as potential alternative to hepatocyte for liver cell based therapies. ADHLSC are of fibroblastic morphology and exhibit a hepatomesenchymal phenotype. Hepatic stellate cells (HSC) isolated from the liver non-parenchymal fraction present a comparable morphology as ADHLSC and are described as liver stem/progenitor cells.
AIMS&METHODS: In the current work, we strived to extensively compare both cell populations and to propose tools demonstrating their singularity.
ADHLSC and HSC were isolated from the liver of four different donors, expanded in vitro and followed from passage 5 until passage 11. Cell characterization was performed using immunocytochemistry, flow cytometry, and gene microarray analyses. The secretion profile of the cells was evaluated using Elisa and multiplex Luminex assays.
RESULTS: Both cell types expressed α-smooth muscle actin, vimentin, fibronectin, CD73 and CD90, in accordance with their mesenchymal origin. Microarray analysis revealed significant differences in gene expression profiles. HSC present high expression levels of neuronal markers as well as cytokeratins. Such differences were confirmed using immunocytochemistry. Both cell types also display distinct secretion profiles as ADHLSC highly secreted cytokines of therapeutic and immuno-modulatory importance, like HGF, interferon gamma and IL-10. Finally, ADHLSC and HSC behave differentially when incubated with specific growth factors involved in hepatogenic differentiation.
CONCLUSION: Our study demonstrates that, even sharing several phenotypic characteristics, ADHLSC and HSC are distinct liver fibroblastic cell populations as they exhibit significant different intrinsic gene expression and secretion profiles.
This study confirms the promising future of ADHLSC in liver regenerative medicine.

P050 IMPROVED OUTCOME OF HEPATOCYTE TRANSPLANTATION WITH PHARMACOLOGICAL ENHANCEMENT OF DONOR CELL ENGRAFTMENT

Y. Avsar[1,2,*], H. C. Zhou[3], X. Wang[2], J. Ding[2], I. Fox[4], N. Roy-Chowdhury[5], J. Roy-Chowdhury[2]. [1]*Deaprtment of Transplantation Medicine, University Hospital of Muenster, Muenster, Germany,* [2]*Department of Medicine and Genetics,* [3]*Department of Radiation Oncology, Albert Einstein College of Medicine, Bronx, New York,* [4]*Center for Innovative Pediatric Regenerative Therapies, University of Pittsburgh, Pittsburgh, Pennsylvania, United States,* [5]*Department of Medicine and Genetics, Albert Einstein College of Medicine, Bronx, New York, Germany*

INTRODUCTION: Hepatocyte transplantation is a safe and effective method to treat inherited metabolic liver diseases. However, it only partially corrects the underlying metabolic disorder and therefore limits its application. The number of hepatocytes that engraft during a single procedure is insufficient to fully correct the metabolic disorder, highlighting the importance to enhance donor cell engraftment. Potential barriers that prevent a sufficient engraftment include hepatic sinusoidal endothelial barrier, low sinusoidal blood flow, instant blood mediated immune response and Cyclooxygenase (COX)-mediated inflammation.
AIMS&METHODS: In the present study, we tested the hypothesis that pharmacological modulation ofthese barriers should enhance hepatocyte engraftment in mice and rats, and augment the metabolic benefit of hepatocyte transplantation in the UDP-UGT-1A1 deficient Gunn rat model of Crigler-Najjar syndrome type 1 (CN1). In a first series of experiments recipient C57/Bl6 mice were treated with Dextransulfate, Nitroglycerin, Naproxen, Cyclophosphamide or hepatic X-irradiation (HIR) prior transplantation of hepatocytes from (Rosa)26 C57BL/6 mice. Morphometric quantification of hepatocyte engraftment was performed three days after transplantation. For the second set of series, recipient Gunn rats were pretreated with Cyclophosphamide, Naproxen or Cyclophosphamide+Naproxen prior to transplantation of hepatocytes from

congeneic normal Wistar-RHA rats. Serial serum bilirubin levels were followed for six months.
RESULTS: Recipient mice: Cyclophosphamide, HIR, and Naproxen increased hepatocyte engraftment by 97%, 92% and 52%, respectively compared to control ($p<0.001$). No significant effect was observed with Dextransulfate or Nitroglycerin. Gunn rat recipients: Mean reduction of serum bilirubin levels four months after transplantation compared with sham-treated controls were: (a) no drug: 32.0%, (b) CPA: 54% (c) Naproxen: 44%, (d) CPA + Naproxen 68%.
CONCLUSION: Hepatocyte engraftment in mice was significantly increased by a single preparative dose of HIR, Cyclophosphamide or Naproxen. In recipient Gunn rats Cyclophosphamide or a combination of Cyclophosphamide and Naproxen doubled the hypobilirubinemic effect of hepatocyte transplantation. These findings may be relevant in hepatocyte transplantation-based therapies of CN1 and other liver-based inherited metabolic disorders.

P051 PREVALENCE OF METABOLIC SYNDROME IN A PROSPECTIVE STUDY OF PATIENTS REFERRED TO A SECONDARY HOSPITAL FOR HYPERFERRITINEMIA

A. Castiella[1,*], E. Zapata[1], L. Zubiaurre[1], A. Iribarren[1], P. Otazua[2], Burnia Group.. [1]*GASTROENTEROLOGY, MENDARO HOSPITAL, mendaro,* [2]*GASTROENTEROLOGY, mondragon hospital, mondragon, Spain*

INTRODUCTION: Nearly 25% of adult population in the western countries have the metabolic syndrome. Hyperferritinemia (HF) is frequently present in patients with this clinical entity.
AIMS&METHODS: To study the prevalence of the metabolic syndrome in patients referred for hyperferritinemia to a secondary hospital.
January to December 2010; prospective study; included 132 consecutive patients, aged 18 years or older, with HF ($> 200\mu g$ / L women,$> 300\mu g$ / L men); Laboratory: serum ferritin, transferrin saturation, serum iron, transaminases, glucose, cholesterol, triglycerides, HBV, HCV, HFE mutations. Blood pressure, weight, height, BMI, alcohol intake, hypertension and/or dyslipidemia treatment, were determined; Radiology: abdominal ultrasound, MRI to determine LIC (liver iron concentration);
The Metabolic syndrome was defined (1) by the presence of waist circumference $\geq$94cm men; $\geq$80 cm women (abdominal obesity). And two of the following factors: Triglycerids$\geq$150 mg/dL or treatment for this dislypemia; HDL $<$40 mg/dL women, $<$50 mg/dL men or treatment for this dislypemia; glucose$\geq$100 mg/dL or type 2 diabetes; hypertension: Blood Presure $\geq$130 mm Hg/ $\geq$85 mm Hg or treatment for elevated blood pressure.
RESULTS: 24 women, 108 men, mean age 54.42 SD 13.47 (range 23-83), Weight: 83.17 SD 15.86 (43-137); Height: 175.28 SD 55.20 (146-186), BMI: 28.80 SD 3.96 (17-39); Waist circumference: 80/97; 17/17 women $\geq$80 cm; 63/80$\geq$94 cm; blood pressure: systolic 139.26 mm Hg, SD 19,93 (100-190); dyastolic 81.19 mm Hg, SD 11,03 (50-105).
AST 41 IU/L, SD 35.33 (4-230); ALT 55.61 IU/L, SD 47.22 (12-371); GGTP 94.83 IU/L, SD 141.47 (8-806); AP 73.32 IU/L, SD 20.71 (34-160); Bilirrubin 0.74 mg/dL, SD 0.38 (0.15-2.71); albumin 4.60 g/L, SD 0.32 (3.50-5.50).
Glucose 106.95 mg/dL, SD 25.03 (73-272); triglycerids 151.75 mg/dL, SD 93.71 (40-477), cholesterol 201.71, SD 42.92 (96-338), HDL 54 mg/dL, SD 17.08 (28-162);
Ferritin 579.54 ng/mL SD 296.575 (206-1668), TRS 43.87% SD14.09 (12-95); Fe 134 µg/dL, SD 49.68 (55-322). Ferritin $>$ 1000, 12 patients (9%), overweight (BMI $\geq$ 25) 48.31%, obesity (BMI$\geq$ 30) 40.44%, 89% overweight or obese.
Hypertension treatment in 50 patients; dyslipidemia treatment in 35. Metabolic syndrome: 44/80 men (55%) and 10/17 women (59%) presented MS. Some of the results of the study were presented last year in UEGW 2012.
CONCLUSION: Metabolic syndrome is associated with more than 50% of patients with hyperferritinemia and is one of the main causes of a raised serum ferritin.

P052 HEPATIC STEATOSIS: PREVALENCE AND PREDICTIVE FACTORS IN A PORTUGUESE POPULATION

C. Fernandes[1,*], T. Pais[1], I. Ribeiro[1], S. Fernandes[1], A. P. Silva[1], J. Carvalho[1], J. Fraga[1]. [1]*Gastroenterology, C. HOSPITALAR VILA NOVA GAIA, Vila Nova Gaia, Portugal*

INTRODUCTION: Hepatic steatosis is a multifactorial condition extremely prevalent worldwide. Recently several predictive risk factors have been identified.
AIMS&METHODS: To evaluate hepatic steatosis prevalence and to determine predictive factors for its presence.
Prospective study of 288 assymptomatic individuals submitted to abdominal ultrasound for hepatic steatosis (according to the hepatorenal index), visceral and subcutaneous fat evaluation. Laboratorial evaluation, dietary questionnaires and alcohol consumption (cut-offs: men 30g/women 20g) were also evaluated in the same day. Hepatic steatosis divided in 2 groups: 1) without steatosis/mild steatosis; 2) moderate/severe.
After a descriptive analysis a comparative univariate analysis was performed. Data stratified by gender.
Tests: Chi-square and Man-Whitney Wilcoxon [$p < 0.05$].
RESULTS: Global hepatic steatosis prevalence was 57,6%. In our sample alcohol consumption was not statistically related to hepatic steatosis. After exclusion of the patients with alcohol consumption above the *cut-off* 195 individuals (64,4% male) were evaluated. From those, 37 had moderate/severe steatosis and 92 mild/no hepatic steatosis. Univariate analysis revealed that visceral obesity (RR=3.03; $p<0.001$), BMI$\geq$25 (RR=5.08;$p<0.001$), waist circumference $\geq$94 in men and $\geq$80 in women (RR=5.15; p=0.003) and fasting glucose$>$100 (RR=3.51; $p<0.001$) are risk factors for hepatic steatosis; Gamma-glutamyltransferase ($p<0.001$) and triglycerides (p=0.003) medians were significantly greater in patients with moderate/severe hepatic steatosis.
CONCLUSION: In our sample hepatic steatosis prevalence was 57,6%. Visceral obesity, BMI, waist circumference, fasting glucose, gamma-glutamyltransferase and triglycerides positively related to hepatic steatosis in individuals without excessive alcohol consumption.

P053 FATTY LIVER ÍNDEX – VALIDATION AND ITS APLICATION IN NON-ALCOHOLIC FATTY LIVER DISEASE AND VISCERAL OBESITY

C. Fernandes[1,*], T. Pais[1], I. Ribeiro[1], S. Fernandes[1], A. P. Silva[1], J. Carvalho[1], J. Fraga[1]. [1]*Gastroenterology, C. HOSPITALAR VILA NOVA GAIA, Vila Nova Gaia, Portugal*

INTRODUCTION: Although abdominal ultrasound is considered a valid option, liver biopsy is still the *gold-standard* to diagnose hepatic steatosis. Fatty Liver Index[1] (FLI) – a score calculated with triglycerides, body mass index, waist circunference and gamma-glutamyltransferase – revealed a adequate accuracy in the prediction of hepatic steatosis.
AIMS&METHODS: To validate FLI in our sample. Evaluate FLI applicability to predict visceral obesity and hepatic steatosis in individuals without excessive alcohol consumption.
Prospective analysis of assymptomatic individuals submitted to abdominal ultrasound with visceral fat measurement and hepatic steatosis classification according to the hepatorenal índex. Laboratorial evaluation, dietary questionnaires and alcohol consumption (cut-offs: men 30g/women 20g) were obtained. Original *cut-offs* for Fatty Liver Index. Visceral obesity cut-off according to Ribeiro et al. Hepatic steatosis divided in 2 groups: 1) without steatosis/mild steatosis; 2) moderate/severe.
Statistics: sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and area under receiving operator curve (AUROC).
RESULTS: 288 individuals (mean age 60.8 years, 53.8% male), from which 29.0% presented moderate/severe hepatic steatosis. FLI revealed good accuracy to predict hepatic steatosis (73%, specificity 77%, NPV 87%; PPV 57%, AUROC: 0.80); FLI also revealed adequate accuracy to predict visceral obesity (sensitivity 68%, specificity 77%, NPV 83%; PPV 60%; AUROC 0,81). Applying FLI to predict non-alcoholic fatty liver its accuracy is still adequate (sensitivity 68% specificity 81%; PPV 61%, NPV 86%; AUROC: 0,80.)
CONCLUSION: In our sample Fatty Liver Index revealed good accuracy to predict hepatic steatosis and visceral obesity.

P054 ENDOSCOPIC DUODENAL-JEJUNAL BYPASS LINER RAPIDLY IMPROVES NONALCOHOLIC FATTY LIVER DISEASE PLASMA PARAMETERS

C. De Jonge[1,2,*], S. S. Rensen[1], G. H. Koek[1], M. F. Joosten[1], W. A. Buurman[1], N. D. Bouvy[1], J. W. M. Greve[2]. [1]*maastricht university medical centre, Maastricht,* [2]*atrium medical center parkstad, Heerlen, Netherlands*

INTRODUCTION: Bariatric surgery reduces obesity, type 2 diabetes, and non-alcoholic fatty liver disease (NAFLD). Recently, the duodenal-jejunal bypass liner (DJBL) has been developed to mimic the bypass component of the gastric bypass in a minimally invasive way. Previous studies with this device have revealed improvement of obesity and type 2 diabetes. We investigated the effect of DJBL treatment on plasma parameters reflecting NAFLD.
AIMS&METHODS: Seventeen subjects with obesity and type 2 diabetes were prospectively included and received the DJBL for 24 weeks. Before, during, and after DJBL treatment, plasma aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyltransferase (γ-GT), albumin, caspase-

cleaved cytokeratin-18 (CK-18), and liver fatty acid-binding protein (L-FABP) were determined.
RESULTS: At baseline, patients had a BMI of 37.0±1.3kg/m^2. AST, ALT, and γ-GT were elevated (AST:35±4IU/L, ALT:54±5IU/L, and γ-GT:66±14IU/L). Caspase-cleaved CK-18 and L-FABP concentrations were 214.4±35.6U/L and 29.3±2.6ng/mL, respectively. Three months after initiation of DJBL treatment, BMI had decreased to 33.6±1.2kg/m^2 ($p<0.05$). Plasma levels of all NAFLD-related parameters had also decreased (AST:28±3IU/L, ALT:32±2IU/L, γ-GT:44±7IU/L, caspase-cleaved CK-18:140.6±16.3U/L, and L-FABP: 18.2±1.5ng/mL, all $p<0.05$). A further decrease of ALT and γ-GT was observed at month six (ALT:28±2IU/L and γ-GT:35±5IU/L) and BMI had decreased to 32.9±1.2kg/m^2 (all $p<0.05$). AST, caspase-cleaved CK-18, and L-FABP levels had stabilized (AST:23±2IU/L, caspase-cleaved CK-18:149.2±23.1U/L, L-FABP:20.2±1.6ng/mL, all p=ns). At month twelve, ALT, γ-GT, and caspase-cleaved CK-18 levels were still diminished (ALT:37±3IU/L, γ-GT:42±5IU/L, and caspase-cleaved CK-18:124.5±12.5U/L, all $p<0.05$). BMI was 34.3±1.5kg/m^2 ($p<0.05$). AST and L-FABP levels had returned to baseline levels (34±3IU/L and 29.5±3.1ng/mL respectively, both p=ns).
CONCLUSION: Weight loss induced by proximal small intestinal exclusion through DJBL positively affects NAFLD.

P055 ENERGY METABOLISM IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE IN COMBINATION WITH ARTERIAL HYPERTENSION

D. Janelidze[1,*], N. Kharchenko[1], G. Anokhina[1], V. Kharchenko[1]. [1]*National Medical Academy of Postgraduate Education named after P. L. Shupyk, Kiev, Ukraine*

INTRODUCTION: The increase cases of non-alcoholic fatty liver disease (NAFLD) due to the growth of patients with abdominal obesity. It belongs to the key factors in the development of metabolic syndrome, which is characterized by high rates of cardiovascular disease, particularly arterial hypertension (AH).
AIMS&METHODS: The aim of this study was to investigate violations of energy metabolism in patients with NAFLD/AH.
The study involved 182 patients with NAFLD/AH. For verification of diagnosis the following examinations were done: clinical-laboratory, instrumental, biochemical parameters of liver function, immune status assessment, Fibro-Max test. ATP, ADP and AMP were determined in erythrocytes of peripheral blood by thin-layer chromatography. Cell energy charge (EC) formula EC= ATP/(ADP+AMP) and key enzyme total activity of anaerobic glicolysis – serume lactatdehydrogenase (LDH), were calculated also.
RESULTS: Abdominal obesity was observed in all studied patients. Average BMI was 33,21±1,25 kg/m^2 . Changes of energy metabolism in examined patients consisted in ADP and ATP level reducing, which are the main indicators of energy supply for cells. ATP content in erythrocytes of the patients was 2,6 times lower than in normal group ($p<0,001$). AMP level was increased, which could indicate by ATP decay. It's known that ATP content takes a principal role in aerobic metabolism, while the LDH concentration, as LDH_{4-5}, is an indicator of anaerobic metabolism. LDH content increased in the blood of patients with NAFLD/AH. Exactly the LDH_{4-5} activity was increased, that characterizes anaerobic processes, while the activity of LDH_{1-2} was reduced ($p<0,05$). Coefficient LDH_{1-2}/LDH_{4-5} was reduced in patients with NAFLD/AH 3,8 times, which indicates on significant predominance of anaerobic glycolysis over oxidative phosphorylation ($p<0,001$). EC – 2,4 times lower in patients group than in normal one, which indicates on decreased energy supply of the body ($p<0,001$).
CONCLUSION: The results of the study showed that patients with NAFLD combined with AH had changes in energy metabolism, characterized by decreased ATP level, LDH activity increased and its spectrum shifted, which is caused by reducing the proportion of aerobic fraction – LDH_{1-2} and increasing proportion of anaerobic fraction – LDH_{4-5}. All of this indicates on less effective way of energy metabolism (anaerobic glycolysis) in patients with NAFLD/AH.

P056 CLINICAL APPROACH IN WILSON DISEASE USING LEIPZIG SCORING SYSTEM

D. Gancheva[1,*], M. Atanassova[1], M. Stamboliyska[1], I. Kotzev[1], M. Kaneva[2]. [1]*Hepatogastroenterology, University Hospital "St. Marina" - Varna,* [2]*Statistics, University of Economics, Varna, Bulgaria*

INTRODUCTION: Wilson disease (WD) is an autosomal recessively inherited disorder of the copper accumulation and toxicity. It's treatable, if diagnosed early. The recognition is clear in typical clinical presentations. Unexplained liver tests abnormalities are a diagnostic challenge and require more examinations.
AIMS&METHODS: *Aim:* To investigate the clinical features and diagnostic possibilities in WD.
Material and methods: Sixty three patients with WD were analysed (22 female, 41 male), from June 2010 to March 2013, aged at the end of evaluation between 18 and 64 years. Leipzig scoring system was used for diagnosis.
RESULTS: The patients were followed up from 3 months to 21 years from diagnosing. The diagnosis was based on clinical suspicion and findings, parameters of copper metabolism, ultrasonography, ophthalmological examination, liver biopsy, MRI, DNA analysis and assessment of the Leipzig scoring system at the final evaluation. Twenty seven patients (42,9%) were with liver disease alone, thirty one (49,2%) - with hepatic and neurological presentation, three with neurological features without signs of a liver injury and two asymptomatic patients. The hepatic presentation was as follows: steatosis (4/63), hepatitis 38,1% (24/63), cirrhosis in 47,6% (30/53), acute liver failure after a discontinuation of the treatment (2/63), hepatocellular carcinoma in one cirrhotic patient. The average level of the ceruloplasmin was 0,137 g/l. 24-hour urine copper was increased. D-penicillamine challenge test showed mean value 17,69 μmol/24 h of urine copper excretion. According to the Leipzig diagnostic criteria 55(87,3%) patients had a score ≥4 (max.12). Eight patients had score 3, but the exclusion of another etiology and the clinical course of the disease confirmed the diagnosis. 23(36,5%) patients had Kayser-Fleischer ring and 4 – sunflower cataract. Liver biopsy was performed in 23 patients, with rodamine positive staining in 9. DNA analysis was done in 54 patients and were found mutations in 26(48,1%).
CONCLUSION: WD is a treatable inherited disorder. It has to be considered in the liver diseases to prevent the delay of the recognition and the progression of the copper metabolic disorder. Our experience confirms that the Leipzig scoring system with a combination of clinical symptoms, laboratory parameters of copper metabolism, genetic testing and liver biopsy is useful for diagnosing of WD in the clinical practice.

P057 GLYCYRRHIZIN ALLEVIATES STEATOSIS AND INDUCES THE PRODUCTION OF REGULATORY T CELLS (TREGS) THAT ATTENUATES NONALCOHOLIC STEATOHEPATITIS (NASH) PROGRESSION

F. P. Wang[1,*], W. Jiang[1], J. Li[2]. [1]*Department of Gastroenterology, Zhongshan Hospital,* [2]*Department of Gastroenterology, Tongji Hospital, Shanghai, China*

INTRODUCTION: NASH has been confirmed as the rate-limiting step of non-alcoholic fatty liver disease (NAFLD) progressing to cirrhosis and becomes the main cause of obvious cirrhosis. Recently, high-fat diet (HFD)-induced steatosis was thought to be associated with the depletion of hepatic Tregs and the adoptive transfer of Tregs decreased inflammation in HFD-fed mice. Glycyrrhizin (GL), a natural triterpene in clinical treatment of patients with chronic liver disease, can significantly reduce free fatty acid (FFA)/ HFD induced hepatic lipotoxicity.
AIMS&METHODS: For induction of NASH, mice were fed with a methionin–choline-deficient (MCD) diet for 8 weeks. Control mice received a standard diet containing 10% fat. All diets were γ-irradiated. Development of liver injury was followed by intraperitoneal administration of GL or saline two times a week for the last 4 weeks. We evaluated the therapeutic effects of GL on the progression of NASH, and then the hepatic and splenic CD4+T cells phenotypes were analyzed by flow cytometry. Purified splenic CD4+CD25+T cells from MCD-fed mice or GL treated MCD-fed mice were collected and co-cultured with splenic CD4+CD25-T (Teffs) cells from control mice to explore whether GL can modulate the functions of splenic nTregs and the production of iTregs. Furthermore, specific inhibitor of PPAR-γ (GW9662) or agonist of PPAR-γ was also added along with GL treatment to observe whether the effects of GL were dependent on PPAR-γ signaling.
RESULTS: GL alleviated MCD-induced liver injury, by decreasing ALT and AST levels to normalization nearly in time and dose dependent manners, along with reduced hepatic inflammatory cell infiltrations and lipid overloading. Besides, GL altered the cytokines secretion and proportion of hepatic and splenic CD4+T cells showing the prevalence of Tregs in MCD-fed mice. GL promoted the apoptosis of hepatic and splenic Th1 and Th17 cells but inhibited which of Tregs. PPARγ was enhanced correlating with serum CD4+CD25+T cells positively by GL and in vitro experiment, PPARγ signaling participated in the GL-induced proliferation of splenic nTregs, as well as the enhanced inhibition functions on Teffs. Furthermore, GL promoted the production of iTregs and altered the apoptosis and cytokines secretion of iTregs.
CONCLUSION: GL, which has excellent anti-inflammatory characteristics, amelioration of hepatic injury and definite lipidlowering properties, may alleviate the progression of NASH. The therapeutic effects of GL partly contribute to the induction of Tregs and enhanced modulatory functions of Tregs, and furthermore, PPAR-γ signaling may be involved in the modulatory mechanism of GL.

P058 EFFECT OF GLP-1 ON DIET INDUCE NON-ALCOHOLIC FATTY LIVER DISEASE IN RATS

H. T. Gao[1,*], L. S. Xu[1], W. H. Sha[1], W. P. Deng[1], Z. G. Zeng[1]. [1]*Department of Gastroenterology, Guangdong General Hospital, Guangzhou, China*

INTRODUCTION: The aims of the study were to investigate the effect of glucagon-like peptide-1 (GLP-1) on diet induce non-alcoholic fatty liver disease (NAFLD) in rats.
AIMS&METHODS: A total of 30 male rats were randomly divided into three groups. Each group contained 10 rats, in which they were fed with normal diet (ND), high-fat diet (HFD), high-fat diet with intraperitoneal injection of liraglutide (HFD+GLP-1, first 12 weeks with HFD, later 4 weeks with liraglutide) for 16 weeks respectively. After 16 weeks' feeding, the rats were killed ethically and their blood samples and liver tissues were collected. The levels of

aminotransferase (ALT), aspartate-aminotransferase (AST), triglyceride (TG), total-cholesterol (TC) were detected by biochemistry automatic analyzer. The levels of superoxide dismutase (SOD) and malondial-dehyde (MAD), tumor necrosis factor-a (TNF-a), JNK-1 and P-JNK1 in liver homogenates were detected by RIA, ELISA and Western blot respectively.
RESULTS: The body weight, liver index, serum and liver homogenates levels of TG, TC, ALT and TG, TC, MAD, TNF-a in the HFD group were apparently higher than those in the normal group, while the level of SOD decreased significantly. When compared with the HFD group, the body weight, liver index, serum and liver homogenates levels of TG, TC, ALT and TG, TC, MAD, TNF-a in the HFD+GLP-1 group decreased apparently, while the level of SOD increased. ($P < 0.05$)
CONCLUSION: Liraglutide (GLP-1) has an anti-inflammatory effect on NAFLD rats, which is conducted by decreasing blood lipid and liver homogenate inflammation index level.
Disclosure of Interest: None Declared

P059 THE URSODEOXYCHOLIC ACID AS A MONOTHERAPY OF PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE COUPLED WITH METABOLIC SYNDROME

S. Ivanov[1], I. Lapinskii[1,*], E. Tkachenko[1], E. Avalueva[1], E. Skazyvaeva[1].
[1]*Introduction to internal diseases, North Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation*

INTRODUCTION: Non-alcoholic Fatty Liver Disease (NAFLD) is associated with Metabolic Syndrome (MS) frequently and has a tendency to increase in the last few years. NAFLD associated with MS is characterized by hepatic steatosis, inflammation with hepatocyte injury (ballooning) with or without fibrosis, lipid metabolism disorders, abdominal obesity, gastrointestinal dysfunctions and gastrointestinal microbiota lesions. It is need to optimize the therapy of NAFLD associated with MS in that hepatobiliary system is involved in pathological process in the majority of patients.
AIMS&METHODS: The aim was to assess efficacy of ursodeoxycholic acid in treatment of patients with NAFLD associated with MS. 21 patients with NAFLD associated with MS were observed (average age was 41±4,6 years). All patients were treated by ursodeoxycholic acid (UDHA) in dose 15 mg/kg twice a day during 2 months. The serum chemistry, analysis of body mass composition (determination of fat mass, water mass and dry body mass by bioimpedance analysis) and analysis of intestinal microbiota composition were performed before and after the treatment course. The intestinal microbiota composition was assessed by examination of stool culture and by using special microbial identification system based on studying of minor fatty acid profiles in blood samples (gas chromatography and mass spectrometry). Statistical analysis was performed with Wilcoxon test.
RESULTS: Alanine aminotransferase (ALT) rate was reduced by 32,3% (p=0,004), aspartate aminotransferase (AST) rate was reduced by 13,5% (p=0,080), γ glutamyl transpeptidase (γGT) rate was reduced by 5,6% (p=0,070) and lipids metabolism markers had uptrend to decrease after course of the UDHA treatment. Body mass was decreased after treatment in 62% of patients mainly due to fat mass reduction. The reduction of the mean body mass by 0,8 kg ($p = 0,008$) and reduction of the mean fat mass by 0,6 kg ($p = 0,005$) were observed in average in the patients after UDHA therapy. The quantity of *Lactobacterium spp*., *Bifidobacterium spp*. and *Enterococcus spp*. were significantly increased (p=0,006, p=0,005 and p=0,004 respectively) in examination of stool culture after course of UDHA treatment. Analysis of microbial identification by gas chromatography – mass spectrometry was demonstrated prominent elevation of endotoxins amount and total microbial quantity in blood samples before and significant decrease of these indexes after UDHA treatment.
CONCLUSION: The UDHA has beneficial effects on blood chemistry indicators, composition of body mass and intestinal microbiota in patients with NAFLD associated with MS.

P060 THE PREVALENCE OF NONALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

K. Aksentiychuk[1,*], V. Vdovychenko[1]. [1]*Therapy #1, Lviv National Medical University by Danylo Galytskyi, Lviv, Ukraine*

INTRODUCTION: According to several epidemiological studies in 24-88% of patients with diabetes exhibit nonalcoholic fatty liver disease (NAFLD). The problem of development and progression of NAFLD at the present time is one of the most important and urgent problems of internal medicine, a general medical and social importance for the leads to poor quality of life, disability and premature death. However, data on the prevalence referred to in the literature is not always true, because in order to diagnose nonalcoholic fatty liver disease, a liver biopsy is needed each of the examined patients, given the danger and pain of this procedure is not always available. Data on research-based on avtopsies was not found.
AIMS&METHODS: The aim of the study was to research the prevalence of NAFLD by histological examination of liver deaths, suffering from type 2 diabetes
The results of the liver histological in patients with type 2 diabetes mellitus who died from various causes in hospitals from 2000 to 2010 were examined. The age of patients ranged from 23 to 87, mean age 65,37 ± 0,66, the men were 93 women 183.For quality control protocols were processed autopsies in 2002 patients who died from various causes in hospital, but not suffering from diabetes. Among them were men 38, women 62. The average age of 69,84 ± 1,94. Standard wiring used drugs with staining sections with hematoxylin-eosin.
RESULTS: NAFLD frequency and its clinical forms in patients with type 2 diabetes often prevailed among the patients in the control group. According 65,6% in patients with type 2 diabetes, and 23% for the control group. Steatosis in patients of the main group was 24.6%, control,- only 14%. Steatohepatitis was diagnosed in 37,3% of patients with type 2 diabetes, while only 16% of patients without diabetes. Fibrosis, 3,6% in the main group and in 2% of the control group.
CONCLUSION: Since the study was based on prevalence avtopsies based protocols, indicating that diagnostic accuracy and eliminates the possibility of unreliable diagnosis, data on the prevalence NAFLDin patients with type 2 diabetes (65,6%) can be considered reliable and informative.

P061 MONITORING OF LIVER FUNCTION IN PATIENTS WITH FATTY LIVER DISEASE IN COMBINATION WITH CORONARY HEART DISEASE AND TYPE 2 DIABETES MELLITUS

K. Aksentiychuk[1,*], E. Sklyarov[1], N. Kurlyak[1], V. Vdovychenko[1]. [1]*Therapy #1, Lviv National Medical University by Danylo Galytskyi, Lviv, Ukraine*

INTRODUCTION: Nonalcoholic fatty liver disease (NAFLD) is diagnosed in a 72% of coronary artery disease and type 2 diabetes patients. However, more attention is paid to early diagnosis of NAFLD by using either special sets of designed formulas with biochemical parameters or respiratory tests with 13C-methacethine (C13-MBT)
AIMS&METHODS: The aim of the study was to examine the liver detoxification function by comparing a 13C- methacethine breath test, with a Forns formula and with liver transaminases in patients with coronary heart disease and type 2 diabetes mellitus in combination with nonalcoholic fatty disease. The study involved 52 patients with type 2 diabetes and coronary artery disease (male 24, female 28, mean age 60,94 ± 0,82 years). Biochemical tests were taken- total bilirubin, AST, ALT, AST/ALT and lipidogram. Studies for the presence of fibrotic changes were conducted by calculating a Forns formula: 7,811-3,131 × ln (platelets) + 0,781 × ln (GGTP) + 3,467 × ln (age) - 0,014 × (cholesterol, mg/dl). To determine the degree of liver injury all patients underwent a 13C-MBT.
RESULTS: Groups were formed based on the ultrasound information. Among them, 20 patients were found with steatosis, 22 - with steatohepatitis, 5 - with fibrosis and in 5 patients NAFLD was not found. Forns formula clearly showed presence of fibrotic changes at a value > 5.26 in patients with fibrosis. A strong negative relationship was marked between the Forns formula and ALT levels (r = -0,944) and bilirubin (r = -0,967) in fibrosis group. As a result of 13C-MBT, patients without NAFLD indexed antitoxic liver function beyond the norm (20,44 ± 0,66%), with steatosis and steatohepatitis- a moderate reduction in liver function, respectively, (10,94 ± 1,22%) and (11,69 ± 0,48%), with fibrosis meant a marked reduction in the liver antitoxic function(6,32 ± 1,47%). Analyse of liver transaminases and data-13C MBT showed a higher metabolic rate correlated with higher cumulative doses 40 and 120 minutes and normal ALT levels ($p < 0,05$). A reduction in the rate of metabolism and cumulative doses 40 and 120 minutes was observed with increasing levels of ALT ($p < 0.05$).
CONCLUSION: When monitoring the hepatic function in patients with coronary artery disease and type 2 diabetes it is desirable to include data from the ultrasound of the liver, the evaluation a 13C-methacetin test which shows a pathological changes in the early stages of NAFLD and positively correlated with the Forns formula which result more than 4.25 diagnose the fibrosis as clinical stage NAFLD. It is likely to find fibrosis of the liver when Forns formula is over 4.25, 13C-breath test at least 10%, lower levels of ALT and bilirubin.

P062 METABOLIC GENE POLYMORPHISMS, INTERACTION WITH ENVIRONMENTAL FACTORS AND NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)

L. Miele[1,2,*], C. Cefalo[1], V. Dell'Armi[3], G. Marrone[4], S. Racco[1], D. Arzani[5], B. Nedovic[5], W. Ricciardi[5], G. Rapaccini[4], A. Gasbarrini[1], S. Boccia[5], A. Grieco[1]. [1]*Internal Medicine, Catholic University of Sacred Hearth,* [2]*Association Columbus,* [3]*San Raffaele Pisana,* [4]*Catholic University of Sacred Hearth, Rome, Italy,* [5]*Hygiene, Catholic University of Sacred Hearth, Rome, Italy*

INTRODUCTION: Nonalcoholic fatty liver disease (NAFLD) is the most common cause of non-viral chronic liver disease. Even with the large prevalence, only few percentage of subjects with NAFLD develop nonalcoholic steatohepatitis (NASH), the most severe form. The oxidative stress and its interplay with genetic and environmental factors; seems to be the most important step for explaining the progression of liver disease.
AIMS&METHODS: Aim of our study was to evaluate the role of polymorphisms of metabolic genes (GSTT1, GSTM1, SULT1A1, CYP2E1 and 1A1) in NAFLD subjects and the effect of interactions of these genetic variants with environmental risk factors and clinical variables. 294 NAFLD cases and 359 controls were eligible for the statistical analysis. For each subject lifestyle and physical data through a structured questionnaire, venous blood sample for peripheral lymphocytes DNA extraction. A subgroup of NAFLD patients performed underwent liver biopsy. Multiplex-PCR for GSTM1 and GSTT1 null alleles and RFLP-PCR for SNPs analysis of SULT1A1, CYP2E1 and 1A1 were used respectively.

RESULTS: A statistically significant interactions were observed for: GSTM1 and fruit intake ($p<0.001$); GSTT1 and fruit intake ($p<0.001$); CYP1A1 and fruit intake ($p<0.001$); CYP2E1DraI and fruit intake ($p=0.001$); SULTI1A1 and fruit intake ($p<0.001$); GSTT1 and grilled meat or fish intake ($p=0.002$); CYP1A1 and grilled meat or fish intake ($p=0.011$); SULTI1A1 and grilled meat or fish intake ($p=0.002$). CYP1A1 and fruit consumption ($p<0.001$; CYP2E1DraI and fruit consumption ($p=0.001$). Statistical evidence of a difference between subjects with the wild-type form and those carrying a mutation (or with the null form) emerged with regards to: GSTT1 and obesity ($p=0.037$), CYP2E1PstI and diabetes ($p=0.028$); CYP2E1DraI and ALT ($p=0.021$); SULT1A1 and glycaemia ($p=0.025$), HOMA ($p=0.036$), total cholesterol ($p=0.047$), triglycerides ($p=0.027$). We also found a correlation between GSTM1 and inflammation at liver biopsy ($p=0.003$).
CONCLUSION: Some interaction between SNPs of metabolic genes and environmental factors may identify those subjects with potential evolutive NAFLD.

P063 MECHANISMS OF MYOCARDIAL STRESS DEPENDENT ON NON-ALCOHOLIC FATTY LIVER DISEASE: A ROLE FOR FGF21?

M. Vinciguerra[1,*], A. Planavila[2], F. Villarroya[2]. [1]*Institute for Liver and Digestive Health, University College London, London, United Kingdom,* [2]*Department of Biochemistry and Molecular Biology, University of Barcelona, Barcelona, Spain*

INTRODUCTION: Cardiac events are more common than liver events in causing morbidity and mortality in patients with non-alcoholic fatty liver disease (NAFLD). NAFLD is the hepatic component of the metabolic syndrome an umbrella of pathological conditions including insulin resistance and diabetes. NAFLD encompasses a spectrum of diseases ranging from simple hepatic steatosis to non-alcoholic steatohepatitis (NASH).
AIMS&METHODS: Increased risk of cardiovascular mortality in hepatic steatosis is found in absence of insulin resistance and diabetes in patients, and the mechanisms underlying the onset of left ventricular stress in this context are unknown. We studied these mechanisms in a model of NAFLD/NASH without insulin resistance/diabetes: the MCD mice fed a methionine choline deficient diet that lacks methionine and choline, essential factors for very low-density lipoprotein production.
RESULTS: We found that in the MCD mouse model of NAFLD an altered expression of anti-oxidant genes (SOD1/2, HIF1/2, catalase) was present in the myocardium. Circulating levels of fibroblast growth factor 21 (FGF21), an endocrine factor secreted by the liver that favour glucose metabolism, were increased in MCD mice. FGF21 role in heart is unknown. We found that FGF21-null mice had an increased heart weight and cardiomyocyte area and developed dilatation and cardiac dysfunction in response to isoproterenol infusion.
CONCLUSION: We propose that an increase in liver-generated FGF21 might be a compensatory mechanism of the body to protect against heart oxidative and hypertrophic stresses generated by NAFLD in absence of other metabolic risk factors.

P064 WILSON DISEASE: INDICATIONS FOR LIVER TRANSPLANTATION AND RESULTS

M. N. Costa[1,*], A. Morbey[1], J. Saiote[1], D. Carvalho[1], J. Esteves[1], L. Bento[1], H. Pinto Marques[1], E. Barroso[1], Centro Hepatobiliar e de Transplantação do Hospital Curry Cabral. [1]*Centro Hospitalar de Lisboa Central, Lisbon, Portugal*

INTRODUCTION: Wilson's disease (WD) is a hereditary disorder associated with decreased biliary excretion of copper, leading to its accumulation in various organs, particularly liver, brain and cornea. Patients often present with liver disease, varying from asymptomatic elevation of aminotransferases or serum bilirubin to acute liver failure (ALF) or liver cirrhosis. Liver transplantation (LT) is often necessary in the presence of ALF or end-stage liver disease (ESLD).
AIMS&METHODS: Between March 1995 and March 2013 1420 LT were carried out in 1233 patients at ''Centro Hepatobiliar e de Transplantação'' of the Curry Cabral Hospital. For this study, we only considered patients with WD. Overall survival was calculated using the Kaplan-Meier method.
RESULTS: Sixteen LT were performed in 12 patients with WD. The ALF was the indication for LT in 6 patients (3 men). One was being investigated for liver disease of unknown etiology and another had a diagnosis of WD for 13 years but had suspended the medication on her own. The mean age of patients transplanted for ALF was 22.8 years. Two patients died early after LT due to acute renal failure and cytomegalovirus infection. One patient was re-transplanted 3 times – due to hepatic artery thrombosis, chronic rejection and hepatic artery thrombosis with multiple liver abscesses. Another patient had to be re-transplanted because of ischemic cholangitis.
The ESLD was the indication for LT in 6 cases (4 men). The mean age at diagnosis was 19.3 years and at the time of transplantation was 30.3 years. The Child-Pugh score was B in 2 and C in 4 patients. Five of the six patients were under medical treatment until transplantation. The mean hospital stay after LT was 36 days.
In the 12 patients transplanted for WD there was no late mortality. The overall survival post-LT was 83.3% at 1, 5 and 10 years and these patients are clinically well and none developed any sign of recurrence.
CONCLUSION: Without treatment, the WD is progressive and invariably fatal. When diagnosed in a timely manner, patients often respond to medical therapy. However, the WD can manifest itself as ALF, observed in 5 patients in our series. In patients diagnosed with WD under medical therapy, there may be a rapid deterioration of liver function with ALF precipitated by discontinuation of therapy, which occurred in 1 patient in our hospital. In cases that do not respond to treatment and progress to ESLD, the LT has a prominent position. Overall survival after transplantation was similar to other series in the literature. WD is a rare indication for LT but when indicated this procedure allows for a good long-term survival.

P065 CHANGING TRENDS IN LOW-RANGE LIVER ENZYMES ELEVATION; IS NON-ALCOHOLIC FATTY LIVER DISEASE THE ELEPHANT IN THE ROOM?

R. A. Bendezu Garcia[1,*], M. Casado Martín[2], G. O. Patrón Román[2], M. González Sánchez[2], J. L. Vega Sáenz[2]. [1]*GASTROENTEROLOGY,* [2]*TORRECARDENAS HOSPITAL, ALMERIA, Spain*

INTRODUCTION: There is very little information regarding the most prevalent causes of elevation of liver enzymes in our population and usually is necessary to perform a number of tests and several visits to the specialist to reach a diagnosis. For these reasons, we designed a protocol to streamline the evaluation of patients presenting such elevations in a single-act office visit.
AIMS&METHODS: From March of 2008 until June of 2010 we performed a descriptive study of all patients presenting with an incidental elevation of liver enzymes who were referred by their primary care physicians. At the time of referral, all of these patients had a complete biochemistry analysis, and they got an abdominal ultrasound scan the same day of the office evaluation by the hepatologist.
RESULTS: A total of 427 patients were included. A definitive diagnosis was reached in the first referral visit in 322 (74%) of the cases. The most common cause of transaminase elevation (40%) was Non-Alcoholic Fatty Liver Disease (NAFLD), followed by alcohol intake (17%) and HCV infection (13%). Also NAFLD was the most common cause of isolated GGTP elevation (30%) and combined elevation with AP (21%). A self-limited elevation was seen in 9% and we could not identify a definite cause in 11% of cases.
CONCLUSION: NAFLD was the most common cause of elevated liver enzymes.
The single-act office visit has proven quite efficient, yielding a diagnosis in the majority of cases.
Transaminases elevation must be confirmed prior to initiating a more thorough work-up.

P066 WILSON'S DISEASE: LONG-TERM OUTCOME SEEMS TO BE INFLUENCED BY PRESENTATION FORM

S. Carvalhana[1,*], R. Marinho[1], H. Cortez-Pinto[1,2], J. Velosa[1]. [1]*Gastroenterology, Hospital de Santa Maria, CHLN,* [2]*Unidade de Nutrição e Metabolismo, FML, IMM, Lisbon, Portugal*

INTRODUCTION: Wilson's disease (WD) is a rare inborn disease related to copper storage, leading to liver cirrhosis and neuropsychological deterioration. Limited data are available on the long-term outcome of patients with WD.
AIMS&METHODS: A retrospective analysis of 35 consecutive patients with WD followed in our unit between 1980 and 2011 was performed, to determine clinical presentation and long-term outcome. Four patients were excluded due to absence of clinical data on admission or during follow-up.
RESULTS: Thirty-one patients were included, 58.1% females, mean age at diagnosis 18.4±8.2 years (22.1 in male, 15.5 in female, $p=0.025$), with mean follow-up

of 17.9±11.3 years. Clinical presentation: 32.3% hepatic (H) (mean age: 17.1 years), 25.8% asymptomatic (mean age: 13.6 years), 24.6% neuro-hepatic (NH) (mean age: 25.2 years) and 19.4% neurological (N) (mean age: 19 years). The patients with neurological symptoms were significantly older at the onset of symptoms than patients with hepatic symptoms. Kayser-Fleischer rings (KF rings) and mutations of the coding region of ATP7B were detected in 58.6% and 83% of patients, respectively. Liver biopsy was performed in 74.2% of patients. Histological analysis revealed: steatosis in 44.4%, fibrosis in 100% and cirrhosis in 47.8%.
During follow-up, 6 (19.4%) patients died, 4 (12.9%) required liver transplantation and 10 (32.3%) had clinical decompensation. No patient developed hepatocellular carcinoma.
Clinical presentation positively correlated with WD progression: NH with death (p=0.003), H with liver transplantation (p=0.007) and H+NH with clinical decompensation (52.9% vs. 7.1%, p=0.005). After initiating treatment, most patients (68%) experienced a stable or improved course of disease. Absence of response to treatment was associated with progression to clinical deterioration (p=0.030) and death (p=0.002). No association was found between the degree of fibrosis or steatosis and WD progression.
CONCLUSION: WD is a rare but important cause of chronic liver disease, with generally favourable outcomes for patients who respond to initial therapy. However, patients with hepatic symptoms (hepatic or neuro-hepatic presentation) were associated with a worst prognosis.

P067 EFFECT OF THE NAFLD LIFESTYLE EDUCATIONAL PROGRAM (NALEP) IN THE MANAGEMENT OF NON-ALCOHOLIC FATTY LIVER DISEASE IN CLINICAL PRACTICE

S. Traussnigg[1,*], C. Kienbacher[1], E. Halilbasic[1], K. Staufer[1], I. Weiß[1], P. Hillebrand[1], P. Munda[1], H. Hofer[1], M. Trauner[1]. [1]*Department of Internal Medicine III - Division of Gastroenterology and Hepatology, Medical University Vienna, Vienna, Austria*

INTRODUCTION: Non-alcoholic steatohepatitis (NASH) is a chronic and progressive liver disease strongly associated with the metabolic syndrome (MS). The only established therapies are life style intervention and treatment of concomitant metabolic disorders like dyslipidemia and diabetes.
AIMS&METHODS: Patients seen at the Vienna NAFLD outpatients clinic were offered the possibility to join a monthly NAFLD lifestyle educational program (NALEP) especially developed for patients with NAFLD including a detailed nutritional education. Patients were also advised to engage in physical training at least 3 times a week for 30-60 minutes. We prospectively analyzed the data available up to six months after the first intervention.
RESULTS: To date, 48 patients participated in NALEP. Follow-up data are available of 35 patients (17 female, 18 male). Median age was 51 years (26-75), median BMI 29 (21-40). Liver biopsy within 6 months before NALEP was performed in 21 patients (NASH n=19). In fifteen patients NAFLD was diagnosed by ultrasound, presence of MS and/or elevated transaminases after exclusion of other liver diseases.
Thirteen patients had previously or newly diagnosed type 2 diabetes and all patients dyslipidemia. If needed, patients were treated simultaneously with metformin (n=11, 6 de novo) or statins (n=21, 12 de novo).
Median follow-up (FU) was 4.3 months. 35 patients had a FU of 3 months (FU3), 18 also of 6 months (FU6). BMI significantly decreased at FU3 and FU6 (-5%/-3kg;p=0.001). Serum liver parameters decreased and normalized in 78% within the observation period from baseline to FU3 and FU6 (median AST 49/32/34 IU/L; ALT 75/45/45 IU/L; GGT 176/90/75 IU/L; p=0.01). Serum cholesterol and triglycerides also significantly declined from median 213 and 206 mg/dl, respectively at baseline, to 186 and 130 mg/dl at FU 6 (p=0.05).
CONCLUSION: Lifestyle intervention with close and continuous follow-ups effectively improved body weight, liver enzymes and metabolic parameters in patients with NAFLD. In clinical practice this could reduce the number of patients in need of drug interventions. Although a sustained effect has to be proven by longer follow up.

P068 DISCONTINUING TERLIPRESSIN POST BAND LIGATION: A FEASIBLE OPTION

A. Salim[1,*], A. Alam[1], A. K. Butt[1]. [1]*Gastroenterology, SHAIKH ZAYED HOSPITAL, Lahore, Pakistan*

INTRODUCTION: Terlipressin is recommended therapy for 3 to 5 days in the management of bleeding esophageal varices. This is an expensive drug with inherent side effects.
AIMS&METHODS: The aim of this study was to determine the feasibility of administering terlipressin therapy only prior to band ligation in managing bleeding esophageal varices.
61 patients presenting with esophageal variceal bleeding received terlipressin 2mg intravenous bolus followed by 1mg 6 hourly until undergoing endoscopic band ligation. The patients were monitored for the occurrence of re-bleeding for 5 days.
RESULTS: All patients received terlipressin until undergoing endoscopic band ligation. 12 (19.6%) patients underwent band ligation after a single 2mg dose of terlipressin, 15 (24.5%) patients after two doses (6 hours therapy), 10 (16.3%) patients after 3 doses (12 hours therapy), 5 (8%) patients after 4 doses (18 hours therapy), 5 (8%) patients after 5 doses (24 hours therapy) and 14 (22.9%) patients after more than 5 doses (more than 24 hours therapy). Band ligation was done within 12 hours in 37 (60.65%) patients and within 24 hours in 47 (77%) patients. Endoscopy was delayed beyond 24 hours in 14 (22.9%) patients. This delay was due to Sengstaken Blakemore tube placement, encephalopathy and blood transfusion requirements. Rebleeding was seen in 3 (4.9%) patients (p-value >0.05. No statistical significance). Repeat endoscopy on patients who rebled showed ulcers on sites of band ligation with no active ooze in 2 patients. These were managed conservatively. One patient had varices with red signs which required repeat band ligation. Two patients died. One secondary to hepatorenal syndrome and another due to persistent encephalopathy. No drug related adverse effects were noted.
CONCLUSION: Terlipressin is an important part of management of bleeding esophageal varices. Once definitive endoscopic therapy in the form of band ligation is performed, terlipressin may be safely discontinued. This can result in reduction in cost of treatment with no significant increase in morbidity and mortality.

P069 CIRRHOTIC CARDIOMYOPATHY?,INVESTIGATION OF LEFT VENTRICULAR DIASTOLIC DYSFUNCTION (LVDD) WITH ECHOCARDIYOGRAPHY AND QT PROLONGATION WITH ECG

A. Uyanikoglu[1,*], T. Aydogan[1], B. Cetin[1], H. Camlıbel[1], H. Nar[1], Y. Sezen[2], T. Ulas[3], N. Yenice[1]. [1]*Medıcal Faculty, Gastroenterology,* [2]*Medıcal Faculty, Cardiology,* [3]*Medıcal Faculty, Internal Medicine, HARRAN UNIVERSITY, Sanliurfa, Turkey*

INTRODUCTION: Cirrhosis is a controversial issue whether it is caused by cardiomyopathy. Echocardiography in patients with cirrhosis of left ventricular diastolic dysfunction (LVDD) and electrocardiogram (ECG) QT prolongation in cirrhotic cardiomyopathy looking to investigate.
AIMS&METHODS: A prospective cross-February-July 2012 period, the cirrhotic patients and the control group were investigated by echocardiography, left ventricular diastolic dysfunction. LVDD was assessed by echocardiography by experienced cardiologists.
RESULTS: In 34 of 60 patients with cirrhosis (56%) were male, mean age 51.78 $\pm$ 15.6 years (range 19-84), 26 serving as the control group, 14 (54%) were male, mean age 51.8 $\pm$ 8.4 years (range, 33 -67), respectively. 33 cirrhotic patients (55%) compensated, and 27 (45%) was decompensated. Patients, 31 of whom (52%) child A, 22 of them (36%) child B, 7 of them (12%) were C child. Etiology 24 (40%), hepatitis B, 14 (23%), cryptogenic, 12 (20%), hepatitis C, 4 (6%) Wilson cirrhosis, hepatitis delta 3, one each cardiogenic, chronic biliary, congenital hepatic fibrosis, respectively. Cirrhotic group, 22 (37%) patients in the control group 4 (15%) patients, QT prolongation ($p < 0.05$). 12 patients with compensated liver cirrhosis (36%) of QT prolongation, whereas patients with decompensated liver cirrhosis in 10 (37%) of QT prolongation ($p > 0.5$). Cirrhotic group, 27 (45%), higher than in the control group 16 (61%) patients had LVDD ($p < 0.05$). 13 patients with compensated liver cirrhosis (40%) of the cases LVDD, whereas 14 patients with decompensated liver cirrhosis (52%) patients had LVDD, the difference was not statistically significant ($p > 0.5$).
CONCLUSION: In cirrhotic patients, QT prolongation, more than 2 times higher than the control group, whereas no significant difference was observed among those with compensated and decompensated. In cirrhotic patients, left ventricular diastolic dysfunction in the control group were determined, to a lesser extent, compensated and decompensated There was no significant difference between those. Whether or not lead to cirrhosis, cardiomyopathy, the more different parameters, the more number of patients investigated.

P070 A PROSPECTIVE LONG TERM FOLLOW-UP OF IDIOPATHIC NON-CIRRHOTIC PORTAL HYPERTENSION: SLOW CIRRHOSIS OR NO CIRRHOSIS?

A. Krishnan[1,*], J. Venkataraman[1], None. [1]*Department of Gastroenterology and Liver Transplant, Stanley Medical College, Chennai, India*

INTRODUCTION: Idiopathic portal hypertension (IPH) is characterized by a long-standing non-cirrhotic portal hypertension(NCPH) because of the intrahepatic block of small portal vein branches. NCPH is due to various causes that generally are extrahepatic, involving the prehepatic or the post hepatic circulation. INCPH includes Extra Hepatic Portal Vein Obstruction (EHPVO) and Non-Cirrhotic Portal Fibrosis (NCPF). The natural history of INCPH is not clear
AIMS&METHODS: Aim: To determine prospectively the changes in the portal venous system in patients with NCPH.
Method: Patients with a diagnosis of NCPF and EHPVO registered since 2001 were serially followed at an yearly interval for changes in liver size, its echotexture, and in the intra and extrahepatic portal venous system. Baseline

demographic details, LFT, and co-morbid illness including virological profile were noted. Patients with co-morbid illness and those with known etiology of cirrhosis were excluded from the study.
RESULTS: There were 34 patients with NCPF (M: F 1:1.8) and 30 patients with EHPVO (M: F ratio 1.6:1). The mean age was 24.9 yrs and 41.2 yrs respectively. During follow up, 20 out of 34 and 16 out of 30 patients with NCPF and EHPVO respectively had no progression of disease. 14 patients with NCPF progressed to cirrhosis over a mean period of 5.21 years. Eight patients developed ascites and required diuretics. 14 patients with EHPVO progressed to NCPF over the mean period of 8.6 years, 12 patients further progressed to cirrhosis over a mean period of 5.1 years. Overall 40% of patients with EHPVO progressed to cirrhosis over a mean period of 13.7 years.
CONCLUSION: INCPH is a spectrum wherein EHPVO progresses to NCPF and further to cirrhosis over a period of 13.7 years at least in a proportion of patients. Conversely, identifying these changes may suggest to the clinicians the need to work-up a patient for portal hypertension.
Disclosure of Interest: None Declared
Keywords: EHPVO, INCPH, NCPF

P071 CAN TRANSIENT ELASTOGRAPHY,FIB-4, FORNS INDEX AND LOK SCORE PREDICT ESOPHAGEAL VARICES IN HCV RELATED CIRRHOTIC PATIENTS?

D. Omran[1], **E. Medhat**[1,*], M. El Beshlawey[1], M. abdo[1]. [1]*Endemic Medicine and Hepatology, Faculty of medicine, Cairo University, Cairo, Egypt*

INTRODUCTION: HCV is the most common cause of chronic liver disease in Egypt. Gastroesophageal varices are present in approximately 50% of patients with liver cirrhosis. The current guidelines recommend screening of all cirrhotic patients by endoscopy, but repeated endoscopic examinations are unpleasant for patients and cause significant burden to the endoscopy units and costs to the country.
AIMS&METHODS: The aim of this study is to evaluate liver stiffness measurement (LSM) using transient elastography (TE), Fib-4, Forns Index as potential noninvasive predictors of esophageal varices in patients with HCV related liver cirrhosis. This prospective study included fifty patients with HCV-related liver cirrhosis. All studied subjects underwent routine laboratory tests, TE and gastroduodenoscopy. Serum fibrosis scores were then calculated. The diagnostic performance of the methods were assessed using sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy, likelihood ratios and receiver operating characteristic curves.
RESULTS: The four predictors (LSM, FIB-4, Forns Index and Lok Score) demonstrated statistically significant correlation with the grade of esophageal varices (P values; 0.000, 0.000, 0.003 and 0.008 respectively). For prediction of large varices (grade2, 3), LSM showed the highest accuracy (80%) with a cutoff of 22.4KPa at an AUROC of 0.801. Its sensitivity was 84%, specificity 72%, PPV 84% and NPV 72%.The diagnostic accuracy of FIB-4, Forns Index and Lok Score were 70%,70% and76% respectively at cutoffs of 3.3, 6.9 and 0.7 respectively. The PPV of FIB-4, Forns Index and Lok Score were 79%, 75% and 77% respectively. Adding TE to each of the other diagnostic indices increased their sensitivities and specificities but LR+ or LR- did not show much improvement in combined results. Indeed, this combination decreased the LR- in all tests.
Table. Accuracy of diagnosis of large esophageal varices by serum fibrosis scores alone and after combining LSM with serum fibrosis scores.

Serum fibrosis scores alone						In combination with LSM			
	Best cutoff	sensitivity	specificity	LR+	LR-	sensitivity	specificity	LR+	LR-
Fib-4	≥3.3	72.9%	66.7%	2.2	0.42	100%	56%	2.2	0
Forns	≥6.9	78%	56%	1.8	0.39	97%	44%	1.76	0.07
Lok score	≥0.7	87.5%	55.5%	2	0.23	97%	44%	1.76	0.07

CONCLUSION: Noninvasive predictors can restrict endoscopic screening to patients presenting a high probability of having large esophageal varices. This is useful in clinical settings where resources are limited. Identifying patients at risk of having large esophageal varices may help in early management decisions and justifying health resource allocation.

P072 EARLY USE OF TIPS DECREASES REBEEDING AND IMPROVES THE SURVIVAL IN CIRRHOTIC PATIENTS OF EVL ULCER BLEEDING: A PROSPECTIVE STUDY

H. Garg[1,*], A. Chaudhary[1], A. Mukund[2], M. Kumar[1], R. Kumar[1], S. K. Sarin[1]. [1]*Hepatology,* [2]*Interventional Hepatology, Institute of Liver and Biliary Sciences, New Delhi, India*

INTRODUCTION: Endoscopic variceal ligation (EVL) is the recommended method to manage esophageal variceal bleeding with lower variceal ulceration and rebleeding rates compared to sclerotherapy. However, a proportion of patients do develop EVL induced ulcers and present with massive bleeding. In these cases, endoscopic therapy is difficult and often unsuccessful and definitive methods, such as TIPS need to be evaluated.
AIMS&METHODS: Aim: To determine the effectiveness of reduction in portal pressure by polytetrafluoroethylene-covered transjugular stenting (TIPS) for band-induced esophageal ulcer bleeding. **Method:** Following admission within 24 hours, consecutive patients with cirrhosis and EVL induced bleeding ulcers were prospectively treated using standard therapy (endoscopy and vasoactive drugs; Group 1, n=19) or standard therapy plus TIPS (Group 2, n=22). Primary end-point was survival at 6 wks. Secondary end-points were early and late rebleeding.
RESULTS: Results: Out of 488 cirrhotic patients who underwent EVL from 2010-11, 41 (8%) (Median age 42 (range 32-72), 90% males) developed bleeding EVL ulcer. These patients were enrolled and offered either of the two treatments. Baseline parameters including age, presence of ascites, HE, HRS, platelets, PT (INR), HVPG, Child and MELD score were similar in both the groups. After follow-up of 6 wks, 10 patients (62%) in group 1 and 5 (25%) in group 2 died ($p<0.05$). The incidence of failure to control bleed/early rebleed was seen in 9 patients (56%) in group1 and in 1(5%) in group 2 ($p<0.05$). Similarly, the incidence of late rebleeding was seen in 5 patients (45.4%) in group 1 while in 1(5%) in group2 ($p<0.05$). The median time to death was 2.5 (0.5-12) days and 13 (2-21) days in the two groups ($p<0.05$).
CONCLUSION: Conclusion: Around 8% patients develop life threatening EVL induced ulcer bleeding. Portal pressure reduction with the TIPS is significantly superior in the control of bleeding, preventing rebleeding and reduction in mortality.

P073 A RANDOMISED CONTROLLED TRIAL ON EFFICACY OF PROBIOTICS ON REVERSAL OF MINIMAL HEPATIC ENCEPHALOPATHY AND ITS CORRELATION WITH IMPROVEMENT IN SMALL INTESTINAL BACTERIAL OVERGROWTH AND OROCECAL TRANSIT TIME IN PATIENTS WITH CIRRHOSIS

M. Lunia[1,*], B. C. Sharma[1], S. Srivastava[1], S. Sachdeva[1]. [1]*G B Pant hospital, New Delhi, India, New Delhi, India*

INTRODUCTION: Hepatic encephalopathy (HE) is associated with poor prognosis. Small intestinal bacterial overgrowth (SIBO) and delayed orocecal transit time (OCTT) is associated with systemic endotoxemia and minimal hepatic encephalopathy (MHE). Abnormal intestinal motility may play an important role in increasing the growth of pathogenic bacteria and increased absorption of gut toxins. Probiotics alter gut flora with non urease producing organism with decrease ammonia production.
AIMS&METHODS: Present study assessed effects of probiotics on reversal of MHE and its correlation with improvement in SIBO and OCTT. In a prospective randomised controlled trial, patients with cirrhosis with MHE were divided into: group 1 (Probiotics, $n = 42$, one capsule TDS) (contatining *Bifidobacterium brev, Bifidobacterium longum, Bifidobacterium infantis, Lactobacillus acidophilus, Lactobacillus plantarum, Lactobacillus paracasei, Lactobacillus bulgaricus, Streptococcus thermophilus*, 110 billion CFU) and group 2 (control, $n = 39$). MHE was diagnosed when psychometric hepatic encephalopathy score (PHES) was ≤5. All patients underwent psychometric tests, critical flicker frequency (CFF), glucose hydrogen breath test (GHBT) for SIBO and lactulose hydrogen breath test (LHBT) for OCTT. Primary end point was reversal of MHE.
RESULTS: 81 patients (age 46.6±13.1 years, M:F 47:28) were included. 13 (16%), 24 (29.6%) and 44 (54.3%) were in CTP class A, B and C respectively. Mean CTP score was 9.72 ± 2.61 and MELD score was 19.22±6.91. Baseline laboratory parameters, CTP score, MELD score, CFF, PHES and OCTT were comparable.22 (48.8%) and 20 (51.2%%) patients in group 1 and 2 had SIBO respectively. OCTT was 135.13±13.95 min in Group 1 as compared to 137.59±14.80 min in group 2(p NS). Mean follow up of Group 1 patients was 38.6 ± 8.80 weeks and Group 2 patients was 34.3 ± 9.8 weeks (p=0.78). 7(8.6%) patients were lost during follow up. 4(9.5%) in Group 1 and 6 (15.3%) in Group 2 died (p=0.67). 5(11.9%) patients in Group 1 and 11(28.2%) patients in Group 2 developed overt HE ($p<0.05$, hazard ratio 2.6, 95% CI,1.30-6.43). 22 (52.3%) patients in Group 1 and 5 (12.8%) in Group 2 had reversal of MHE at 3 months ($p<0.05$). There was significant improvement in arterial ammonia levels, SIBO,

OCTT, PHES and CFF after 3 months of treatment with probiotics. Improvement in SIBO and OCTT were associated with improvement in PHES and reversal of MHE.

CONCLUSION: Probiotics are effective in reversal of MHE. This could be due to improvement in small intestinal bacterial overgrowth and orocecal transit time.

P074 ASSOCIATION OF SERUM ARYLESTERASE ACTIVITY WITH THE DEGREE OF SEVERITY OF LIVER CIRRHOSIS AMONG PATIENTS AT THE NATIONAL KIDNEY AND TRANSPLANT INSTITUTE

M. T. T. Panlilio[1,2,*], E. R. Que[1]. [1]*Department of Internal Medicine, National Kidney and Transplant Institute, Quezon City,* [2]*Section of Gastroenterology, University of the Philippines-Philippine General Hospital, Manila, Philippines*

INTRODUCTION: Cirrhosis is an important cause of morbidity and mortality in the world. The gold standard in its diagnosis is still liver biopsy. However, this carries substantial risk from complications and sampling error. Thus, assessment of one's liver function requires a battery of tests, such as total bilirubin, platelet count, prothrombin time, and albumin. The enzyme under study, Arylesterase, protects cell membranes from peroxidation, with subtype paraoxonase-1 (PON-1) being exclusively synthesized in the liver. It is then hypothesized that the enzyme activity would be useful as an index of liver function status.

AIMS&METHODS: This prospective study aims to investigate the relationship between serum arylesterase activity and the degree of severity of liver damage in patients with cirrhosis. Subjects consisted of healthy individuals and cirrhotics, the latter being further subdivided according to Child Pugh scoring. Blood extraction and subsequent spectroscopic determination of arylesterase activity were done. Absorbance at 270 nm was used to indirectly measure arylesterase activity.

RESULTS: Ninety-four patients, 47 controls and 47 cirrhotic patients (15 under Child Pugh A, 16 under Child Pugh B, and 16 under Child Pugh C) were matched and evaluated. More than half of the cases attributed their underlying chronic liver disease to Hepatitis (Chronic Hepatitis B/C or previous exposure to these viruses), and comprised 57.4% of the cases. The mean serum arylesterase activity was significantly lower (p-value < 0.01) for cases ($45.9 + 25.0$ kU/L), as compared to that of the control group ($123.4 + 19.6$ kU/L). Further comparing the enzyme activity among Child Pugh A, B, and C patients, we see a statistically significant decrease in activity (p-value < 0.01), with values of $74.6 + 10.4$ kU/L, $40.5 + 12.3$ kU/L, and $22.7 + 10.5$ kU/L, respectively. This is supported by a Pearson correlation of -0.84.

CONCLUSION: Serum Arylesterase levels were significantly reduced in patients with liver cirrhosis. Furthermore, the enzyme activities correlated with Child Pugh Class, and followed an inversely-linear pattern. The ease and reproducibility of the test, as shown in this study, may make it a good alternative for stratifying severity of liver cirrhosis.

P075 UTILITY OF LIVER STIFFNESS MEASUREMENT USING FIBROSCAN IN DIFFERENTIATING ACUTE SEVERE VIRAL HEPATITIS AND ACUTE ON CHRONIC LIVER FAILURE AT ADMISSION

R. K. Bansal[1,*], V. S. Shah[1], P. Sharma[1], P. Tyagi[1], A. Kumar[1], V. Singla[1], N. Bansal[1], A. Arora[1]. [1]*Gastroenterology & Hepatology, Sir GangaRam Hospital, delhi, India*

INTRODUCTION: Liver stiffness (LS) measurement using FibroScan is a reproducible and accurate technique for assessment of fibrosis and portal hypertension. Often it is difficult to differentiate severe acute viral hepatitis (AVH) from patients with acute on chronic liver failure (ACLF) at admission. Aim is to determine utility of LS measurement in differentiating patients from severe AVH and ACLF at admission.

AIMS&METHODS: A total of 90 patients with severe AVH (serum bilirubin > 5 and INR > 1.5) and ACLF as per APASL guidelines of varying aetiologies were recruited prospectively. LS and biochemical tests were performed at admission and liver biopsy was done if needed.

RESULTS: The mean age of the patients (78 men and 12 women) was 37.7 ± 14.9 years. The aetiology of acute hepatitis (n=45) included (HAV,n=12, HEV,n=18, drug induced, n= 3, HBV,n= 3 and unknown,n= 9).Similarly etiology of ACLF(n=45) were HBV with severe reactivation, n=10,Alcoholic with alcoholic hepatitis, n=24, acute viral hepatitis on cryptogenic cirrhosis, n=11. There was no significant difference at baseline between ACLF and AVH in body mass index(26.3 ± 4.3 vs $25.2 \pm 3.6 kg/m^2$,p=0.19) hemoglobulin (12.0 ± 1.9 vs 12.6 ± 1.7 gm%,p=0.13),platelet count(202 ± 88 vs 212 ± 78 thousand/cumm,p=0.22),serum bilirubin(15 ± 8 vs 13 ± 8.5 mg/dl,p=0.18) and INR(1.8 ± 0.4 s 1.8 ± 0.3).However there was significant difference in ACLF and AVH in median AST (123,33-1049 vs 230,54-3721 IU/L,p=0.01) and ALT(118,24-751 vs 246,66-6349 IU/L,p=0.001). Mean LS (53.3 ± 21.5 vs 16.1 ± 9 kPa,p=0.001) were significant more in ACLF compared to AVH. Multivariate analysis showed only LS at admission could differentiate severe AVH versus ACLF(p=0.0001).Taking a cutoff for LS as 28.2kPa sensitivity and specificity for diagnosing ACLF was 84% and 85% respectively.

CONCLUSION: Baseline liver stiffness measurement by fibroscan can differentiate severe acute viral hepatitis from acute on chronic liver failure at admission.

P076 ANTICOAGULATION FOR ACUTE PORTAL VEIN THROMBOSIS IN LIVER CIRRHOSIS IS SAFE AND DOES NOT INCREASE THE MORTALITY

K. Sliwa[1], N. Malek[1], R. R. Plentz[1,*]. [1]*Department of Internal Medicine I, Medical University Hospital Tuebingen, Tübingen, Germany*

INTRODUCTION: Portal vein thrombosis (PVT) is caused by liver cirrhosis, inflammatory diseases, cancer, myeloproliferative and coagulation disorders. Acute PVT can be distinguished from chronic PVT. Clinical presentation depends on the onset and the extent of the thrombosis and the development of collateral circulation / portal hypertension. For acute PVT early initiation of anticoagulation (AC) or thrombolytic therapy is recommended. The therapeutic approach in chronic PVT, especially in patients with liver cirrhosis, is controversial.

AIMS&METHODS: Our analysis was designed to validate retrospectively the managment of PVT in patients with different underlying illness. Therefore we reviewed all patients with diagnosed PVT (n=149) in a period of 2005 to 2012 at our Department of Medicine. Patient characteristics, including demographics, acute or chronic PVT, underlying disease, therapeutic managment and complications were analyzed.

RESULTS: PVT occurred in 102 men and 47 women. PVT was common in patients with gastrointestinal cancer, liver cirrhosis, inflammatory diseases, abdominal surgery, myeloproliferative and coagulation disorders. 76 patients had acute and 73 chronic PVT. 36 patients with acute PVT were treated by AC. AC (heparin, marcumar, thrombolytic therapy) could achieve in 20 patients recanalisation. In 7 patients AC caused impairment and 9 patients died. 20 patients with chronic PVT were treated by AC. AC could achieve in 3 patients recanalisation In 1 patient AC caused impairment, 16 patients showed no change and 5 patients died.

CONCLUSION: Patients with acute PVT benefit significantly from AC. AC is safe, especially in patients with liver cirrhosis (CHILD A & B) and had no significant impact on side effects and mortality. Patients with cancer (HCC, pancreatic cancer) and acute PVT have no advantage of AC.

P077 CLINICAL, BIOCHEMICAL PROFILE AND PREDICTORS OF EARLY MORTALITY IN PATIENTS WITH ACUTE ON CHRONIC LIVER FAILURE

V. S. Shah[1,*], R. K. Bansal[1], P. Sharma[1], P. Tyagi[1], A. Kumar[1], V. Singla[1], N. Bansal[1], A. Arora[1]. [1]*Gastroenterology and Hepatology, Sir Gangaram Hospital, New Delhi, India., New Delhi, India*

INTRODUCTION: Acute-on-chronic liver failure (ACLF) is defined as rapid deterioration occurring in a patient with known or unknown chronic liver disease due to acute insult. We describe the clinical, biochemical profile of ACLF and the effect of acute insult and associated complications on the natural course of patients.

AIMS&METHODS: Patients diagnosed to have ACLF as per APASL guidelines were prospectively enrolled. Patients were evaluated for the clinical presentation, etiology of acute decompensation and underlying chronic liver disease and in hospital mortality. Patients were further classified as ACLF-1 when they had no organ failure except liver, ACLF-2 when they had one organ failure along with liver, ACLF-3 when they had two organ failure along with liver and ACLF-4 with≥ 3 organ failure along with liver.
RESULTS: One thirty four patients with ACLF (mean age 44.2±10.3 years; M/F 128:8) were included. Median serum bilirubin 14.5 (5-45.9 mg%), mean CTP score (10.4±1.9), mean MELD score (25.6±7.7) and median hospital stay was (7,1-35 days). Alcoholic hepatitis (n=79,59%) followed by hepatitis B virus reactivation (n=23,17 %) were the commonest acute events. Underlying chronic liver disease was due to alcohol (n=92,69%),HBV(n=17,13%) and cryptogenic in 20(15%).Ascites was present in 118(88%),hepatic encephalopathy (50,37%),sepsis(11,8.2%),chest infection(22,16%),spontaneous bacterial peritonitis(17,13%),acute kidney injury in 52(39%). Overall mortality during hospitalization was (n=60, 45%).Mortality was 19% in ACLF-1, 45% in ACLF-2, 78% in ACLF-3 and 100% in ACLF-4. Patients who died had significantly lower age but higher CTP score, MELD score, sepsis, lower respiratory infections, acute kidney injury, HE and number of organ failure compared to survivors. On multivariate analysis only loss of >2 organ failure either at presentation or development during hospital stay was predictor of mortality.
CONCLUSION: Alcoholic hepatitis and hepatitis B virus were common acute insults in ACLF patients and loss of more than two organ function either at presentation or during hospital stay is an independent predictor of mortality in these patients. Measures to control sepsis and organ failure should be initiated early in the course of ACLF patients.

P078 DEVELOPMENT AND VALIDATION OF SINHALA VERSION OF THE CHRONIC LIVER DISEASE QUESTIONNAIRE (CLDQ)

C. K. Ranawaka[1,*], J. K. N. D. Miththinda[1], A. Pathmeswaran[2], A. Dassanayake[3], W. de Alwis[4], M. Mufeena[4], S. Senanayake[4], M. Niriella[4], A. de Silva[4], H. de Silva[4]. [1]*Professorial Medical Unit, Colombo North Teaching Hospital,* [2]*Department of Public Health,* [3]*Department of Pharmacology,* [4]*Department of Medicine, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka*

INTRODUCTION: The Chronic Liver Disease Questionnaire (CLDQ) is a validated tool measuring the Health Related Quality of Life among cirrhotics (1). It is designed to measure six domains of QOL; Abdominal symptoms, Fatigue, Systemic symptoms, Activity, Emotional functions and Worry. CLDQ has been translated and validated to different languages around the world and has shown good correlation with severity of liver disease (2,3)
AIMS&METHODS: Aim of this study was to develop and validate a Sinhala version of the CLDQ (sCLDQ) and to test its correlation with the degree of liver dysfunction in a cohort of Sri Lankan patients with cirrhosis.
A standard translation method was used to develop the sCLDQ. Pilot testing was done with relevant cultural and language adaptations. The final version was self-administered to stable CLD patients, together with the WHO Quality of Life-BREF (WHOQOL-BREF) validated Sinhala version, for comparison. sCLDQ was re-administered 4 weeks later to test internal consistency and reliability. The validation was assessed by Cronabach's alpha, intraclass correlation coefficient (ICC) and Pearson's correlation coefficient. ANOVA and Pearson's correlation were used to test correlation with the degree of liver dysfunction.
RESULTS: Validation was done with 214 subjects, mean age 55.6 (SD 10.4) years; male 77.6%. Overall Cronabach's alpha was 0.926. Itra-class correlations varied from 0.431 to 0.912 and all were significant (p 0.000). Retesting was done on a sub-sample of 18 subjects. Test-retest correlation was 0.695 (p 0.008). WHO-BREF was applied on a sub-sample of 48 subjects. There was a significant correlation (Pearson's r=0.391; p=0.004) between sCLDQ and WHOQOL BREF. sCLDQ was significantly associated with MELD (r=-0.13;p=0.038), MELD Sodium (r=-0.223;p=0.002), Bilirubin (r=-0.124;p=0.036), Serum Sodium (r=0.172;p=0.009), Serum Albumin (r=0.201;p=0.003) and Child grade (f=3.687;p=0.027).
CONCLUSION: sCLDQ is a reliable and valid tool to assess QoL of Sri Lankan cirrhotics and correlates well with known indices of disease severity.

P079 HIGHER EDUCATIONAL LEVEL PROTECTS AGAINST DRUG AND ALCOHOL ABUSE: A STUDY ON A YOUNG SATURDAY NIGHT DRIVERS POPULATION

E. Rosa-Rizzotto[1,*], D. Caroli[2], L. Peraro[1], S. Cocchio[3], V. Baldo[3], I. Simoncello[4], A. Vendramin[5], F. De Lazzari[1], S. Lobello[5]. [1]*Gastroenterology Unit, Padova,* [2]*Internal Medicine Unit, Chioggia,* [3]*Dpt of Molecular Medicine, Laboratory of Public Health and Population Studies, University of Padua,* [4]*Dpt of Hygene and Public Health, Prevention unit,* [5]*Dpt of Dependencies, Addiction Treatment Service Unit, Padova, Italy*

INTRODUCTION: Alcohol consumption is linked to social-cultural aspects in Northeast Italy. Precedently alcohol was consumed daily by all members of the family in North Italy (steady drinking). Young people now seem to prefer binge drinking. Drug use is also on the rise. It has been shown recently hepatic injury by Cocaine and Tetrahydrocannabinol (THC).
AIMS&METHODS: This study aimed to determine the prevalence of alcohol and drug consumption in drivers on weekend nights. As part of the government sponsored "Safe Roads" Program (November 2008 to September 2012) 3150 drivers were stopped in Padua (Italy) by law enforcement officials between midnight and 6. All underwent a preliminary alcohol test. Those who tested positive underwent the Breathalyzer test (710 MK III®) and also to urine test for drugs (RapiScan®, Cozart). Few anamnestic data were collected. Alcohol test >0.5 g/l was considered positive.
RESULTS: 1068 (909 M - 85% - and 159 F -15%; mean age 30.5 yr) drivers underwent the Breathalyzer test. 714 of 3150 (22.6%) were found positive (mean alcohol 0.77 g/l; range 0-2.67). 242 of 1068 (22.6%) were also positive for drugs. 114 drivers resulted positive for cocaine, 66 for THC, in other 26 those two drugs were associated. Drug use was more frequent in those resulting positive to alcohol (23,6% vs 15,4%; p=0.006209). The mean alcohol value was statistically higher (0.90±0.6 SD vs 0.62±0.5 SD, p<0,001) in the subjects positive to drugs as well as in the only cocaine users (1.00±0.6 SD vs 0.62±0.5 SD, p<0,001). The highest mean alcohol value (0.88 g/l) was found between 4 and 5 am (p=0.006509). Positivity rate for drugs and mean blood alcohol content resulted higher in subjects with lower educational levels (30,8% vs 18,0%, p< 0,001 and 0,689 g/l vs 1,027, p=0,00782). At the multivariate analysis drug use is correlated with age, sex, scholar level (OR 1,86 95% CI 1,27-2,73, p=0,001) and alcohol, instead positive test for alcohol is correlated only with scholar level (OR 1,50 95% CI 1,04-2,16, p=0,028) and use of drugs.
CONCLUSION: The prevalence of drugs and alcohol consumption on weekends is high. The most common drug used is cocaine, alone or in association. Drug use is associated to alcohol consumption. This type of behavior, in our opinion, may probably lead in the future to new types of chronic liver diseases. Is encouraging that high educational levels may be protective against the use of drugs and alcohol abuse.

P080 NON-ALCOHOLIC FATTY LIVER DISEASE: A SOMERSET SERVICE EVALUATION STUDY

J. Chalmers[1,*], S. Pugh[1], R. Matull[1]. [1]*Taunton and Somerset NHS Trust, Taunton, United Kingdom*

INTRODUCTION: Non-alcoholic fatty liver disease (NAFLD) is an increasing burden on the NHS. Prevalence is estimated at 20-30% in Western adults[1,2] and fatty liver has now overtaken alcohol as the leading cause of chronic liver disease in many developed countries[3]. This is being reflected in increasing referrals to secondary care. This survey aimed to review the process by which patients with NAFLD were evaluated and managed within West Somerset (350,000 population). It looked at primary care referrals, comparing it with the route outlined in the NHS Map of Medicine[4], the investigation and management of patients with NAFLD, including non-invasive fibrosis risk scoring, and the secondary care decisions made regarding discharge and follow-up.
AIMS&METHODS: We performed a retrospective case note review of all patients with a diagnosis of NAFLD seen in gastroenterology or hepatology clinics between 01/09/10 and 31/08/11. Patients were identified by using the search terms "Non-alcoholic fatty liver disease", "NAFLD", "NASH", "Non-alcoholic steatohepatitis" and "Fatty liver" within our clinic letter database. We excluded cases with additional liver pathology, except for alcohol intake (stratified into <20, 20-50, >50 units per week). We assessed our service against the American Association for the Study of Hepatology (AASLD) guideline on the management of NAFLD[5].
RESULTS: 158 patients were identified, 14 of which were excluded due to additional liver disease and 3 sets of notes were unobtainable, leaving 141 patients for analysis (71 new referral, 70 follow-up). 116 patients (82%) had pure NAFLD; alcohol was implicated in 25 cases (18%, >20 units per week). Non-invasive fibrosis risk stratification was done in 48% (68/141) of patients; 65% (44/68) of those had a low risk score. Liver biopsies were requested in 36 patients (25%), 20 (56%) of which had not been risk-stratified and 8 (20%) had a low fibrosis risk score. 71% (61/100) of patients referred in from primary care had an incomplete non-invasive liver screen (full Map of Medicine guidance was followed in only 2%). 24 (44%) of the 55 newly referred patients with full risk assessment had a low fibrosis score.
CONCLUSION: Non-invasive risk stratification was performed in less than half of secondary care patients with NAFLD and only 2% of primary care referrals. Almost half of newly referred patients with full NAFLD assessment were deemed dischargeable after the first visit; i.e. may not have required referral into secondary care. In the absence of a European guidance on the investigation and management of NAFLD, the Map of Medicine provides an evidence-based pathway for patients with abnormal liver function tests and can be utilised to form local referral pathways for patients with NAFLD.

P081 BINGE DRINKING, ALCOHOL ABUSE AND DEPENDENCE: SCREENING STUDY IN AN EMERGENCY DEPARTMENT

L. Peraro[1,*], S. Lobello[2], E. Rosa-Rizzotto[1], D. Caroli[3], F. Polato[1], F. De Lazzari[1]. [1]*Gastroenterology Unit,* [2]*Dpt of Dependencies, Addiction Treatment Service Unit, Padova,* [3]*Internal Medicine Unit, Chioggia, Italy*

INTRODUCTION: Alcohol is associated with many health problems and with 15.000-20.000 death/year in Italy. In Hospital Emergency Departments are examined alcohol related problems as consequence of short-term exposure to alcohol as well as consequences of long term alcohol use. The aims of this study are to investigate: the patterns of alcohol consumption among emergency room patients (risk or hazardous drinking, harmful drinking, alcohol abuse and dependence); the share and the characteristics of alcohol consumption subgroup; the feasibility of screening for alcohol problems in the emergency room.
AIMS&METHODS: The study was carried out at S. Anthony Hospital Department during a period from 8th January 2012 to 16th May 2012, 4 weeks were randomly selected. In three weeks screening was led from 8 am to 8 pm, in one week from 7 pm to 12 pm. Patients $>$ 18 years old were approached after they had been triaged, before or after being visited. AUDIT and CAGE tests were self-administered only to patients who accepted to perform the test in this way, the others were interviewed by the same interviewer. The statistical analysis was carried out with Pearson test.
RESULTS: 1520 patients were evaluated in emergency department during the period of the study. 1000 (65.8%) were examined. 874 (87.4%) were interviewed. 19.5% of interviewed patients had alcohol related problems on the basis of either CAGE or AUDIT. Higher rates were found for men ($p < 0.001$), young people aged 18-20 years ($p < 0.028$), divorced or single ($p < 0.003$), unemployed subjects ($p < 0.001$), homeless ($p = 0.005$), immigrants ($p < 0.001$). There was a lack of significant correlation between positive tests and day of presentation and need of admission.
CONCLUSION: Our data indicate that a large amount of emergency room patients have alcohol-related problems. Emergency Department may be the initial point of healthcare contact for patients with alcohol problems. Social outcast persons present higher risk of alcohol disorders. Screening can be useful to provide the first step of intervention in this group and is needed for early prevention and health care intervention.

P082 ETHNIC DIFFERENCES IN ALCOHOL-RELATED DISEASES IN SCOTLAND

N. Bhala[1,*], G. Brin[2], H. Ward[3], N. Bansal[2], R. Bhopal[2]. [1]*Queen Elizabeth Hospital, Birmingham,* [2]*University of Edinburgh,* [3]*Information Services Division, NHS Scotland, Edinburgh, United Kingdom*

INTRODUCTION: Alcohol-related harms, most commonly liver disease-related, are a public health priority in Scotland Previous research has identified variations in liver disease mortality endpoints using country of birth as a proxy for ethnicity in the UK. We report ethnic differences in the incidence of alcohol-related and liver disease using an adequate measure of ethnicity in Scotland.
AIMS&METHODS: Using the Scottish health and ethnicity linkage study (SHELS), linking NHS hospital admissions and mortality to the Scottish census 2001, we explored ethnic differences in incidence (2001-2010) of specific alcohol-related diseases (ARD) (NHS Information Services Division definition for ARD, all liver diseases, alcoholic liver disease) in Scotland. Risk ratios (RR) were calculated using Poisson regression with robust variance and multiplied by 100, by gender and adjusted for age. The White Scottish population was the standard reference population (100). 95% confidence intervals (CI) were calculated to enable comparison and exclude 100 in the results below.
RESULTS: For alcohol-related diseases, White Irish had about a 2 fold higher risk for both men (RR 225; 95% confidence interval [CI] 196 to 258) and women (182; 147 to 224); other British women also had a 25% higher risk (126; 107 to 148). Other White British men had a 10% lower risk (89; 80 to 98), with risks even lower in Pakistani men (66; 55 to 78) and women (49; 30 to 78), and Chinese men (47; 38 to 58).
For alcoholic liver disease, White Irish had about a 50% higher risk of ALD for both men (165; 130 to 209) and women (150; 117 to 193). Other White British men had about a third lower risk of ALD (61; 50 to 75), as did Pakistani men (62; 42 to 90) and a composite of South Asian women (73; 58 to 91).
For all liver diseases, some ethnic groups had about a third higher risk: Chinese men (144; 118 to 175) and women (133; 107 to 165) as well as Pakistani women (140; 112 to 176). Lower risks for all liver diseases occurred in other White British men (72; 62 to 83) and women (77; 69 to 87) and other White women (76; 64 to 90).
CONCLUSION: These findings show persistent differences in incidence by ethnicity for both alcohol-related and liver disease and have important clinical and public health implications. New policy, research and practical action are required to address these differences.

P083 FOSTERING EQUITY: LOCAL ACCESS TO LIVER TRANSPLANT SERVICE

R. Sinha[1,*], J. Hulley[1], S. White[2,3], S. Masson[2,3], A. Douglass[1]. [1]*Gastroenterology, South Tees NHS Foundation Trust, Middlesbrough,* [2]*Liver transplant Unit, Freeman Hospital,* [3]*Institute of Cellular Medicine, Newcastle University Medical School, Newcastle-Upon-Tyne, United Kingdom*

INTRODUCTION: In the UK, current landscape of service provision for patients with liver disease does not match that of disease burden[1]. Most hepatologists are based in the transplant centres and access to tertiary liver service is not geographically equitable[1]. In an attempt to improve access, we established a liver transplant outreach clinic from the regional liver unit within a large gastroenterology unit. Here, we describe the benefits of this clinic.
AIMS&METHODS: A dedicated monthly joint liver clinic was established in a large gastroenterology unit. Patients with complex liver disease, including pre- and post-transplant are seen by a consultant transplant hepatologist from the regional transplant unit and a local consultant gastroenterologist. Quantitative data was available from the transplant centre. A sample of patients (76) and specialists were asked to complete a written questionnaire on their opinions of the clinic service
RESULTS: Since August 2010, over 400 patients have been seen. In the 4 years prior to establishment of the clinic, there were a median of 3 (1-4) referrals annually for liver transplant assessment. This increased to 9.5 (9-10) in the subsequent 2 years. Patients were satisfied with the clinical service (Table 1) and the majority (95%) preferred local follow up, citing it as more convenient (99%) with easier travel arrangements (99%). Specialists (n=16) agreed unanimously that the clinic was more convenient for patients, easy to refer into and improved both accessibility to liver services and communication with the regional liver unit. Most (83%) felt that it reduced waiting times for specialist opinion.
Table1. Patient questions and mean score 1(low) – 5(high)

Patient Question	Mean Score
Overall quality of care and services	4.5
Access to specialty care, if needed	4.4
Skill, experience and training of doctors	4.5
Respect shown to you by doctors	4.7
Confidence in the doctor you saw	4.6

CONCLUSION: Establishing an outreach clinic has increased referrals for transplant assessment. Patients prefer to be seen locally and do not feel this affects their specialist care. They have confidence in the skill and experience of the clinicians they see and rate the quality of care, highly. Referring clinicians are also satisfied with the quality and accessibility of the outreach clinic. Overall, outreach clinics may serve to improve equity of access to transplant services.

P084 SPHINCTER OF ODDI DYSFUNCTION: BOTOX VS SPHINCTEROTOMY A LONDON TERTIARY CENTRE STUDY

J. Segal[1,*], P. Vlavianos[1], D. Westaby[1]. [1]*Gastroenterology, Hammersmith Hospital, London, United Kingdom*

INTRODUCTION: Sphincter of Oddi Dysfunction is rare and often difficult condition to treat. It is commonly seen in women post cholecystectomy[1]. The condition is felt to be secondary to sphincter dysmotility, distinct from papillary stenosis in which the obstruction is fixed [2-5]. Sphincter of Oddi Dysfunction is usually classified into three different types using the Milwaukee Criteria. Type 1 are defined as those with abnormal liver biochemistry and a dilated bile duct. Type 2 are classified as one of the above abnormalities and type 3 classified as typical biliary pain with none of the above features. It is therefore necessary to investigate potential Sphincter of Oddi Dysfunction using manometry and ercp.
AIMS&METHODS: Aims: To investigate optimum treatments for Sphincter of Oddi Dysfunction using pancreatic sphincterotomy, biliary sphincterotomy, botox or a combination of the three.

Methods: We followed up pain outcomes in 91 patients treated for Sphincter of Oddi Dysfucntion between January 2008 to March 2013. We recorded the interventions received be it either, botox injection, pancreatic sphincterotomy, biliary sphincterotomy or a combination of the three. Follow up was at 6 months post intervention. Pain outcome were recorded as worse, no difference, some improvement and complete resolution.

RESULTS: There were a total of 103 interventions with 9 patients having 2 interventions and one patient having 4 interventions. Of the 103 interventions 19 had botox only,18 had pancreatic sphincterotomy alone, 24 had biliary sphincterotomy alone, 5 had all three interventions, 23 had pancreatic sphincterotomy and botox, 4 had botox and biliary sphincterotomy and 10 had no intervention.

All patients receiving all 3 therapies recorded a decrease in pain at follow up. The next most successful treatment was biliary sphincterotomy and botox with 75% of patients recording improvement in pain. In the pancreatic sphincterotomy group 50% showed improvement in pain, this is similar to the biliary sphincterotomy group who showed 46% of patients had improvement of pain. In the botox only group 37% of patients showed some improvement in pain with 11% showing complete resolution. Of the patients who received both pancreatic and biliary sphincterotomies 35% demonstrated improvement in pain.

CONCLUSION: Treatment of Sphincter of Oddi Dysfunction remains very difficult with challenges and risks in both diagnosis and treatment. It is well documented that patients with Sphincter of Oddi Dysfunction often have overlapping functional disorders which can make treatment all the more difficult. Our study has shown that all three modalities of treatment have some success and that further larger scale studies may help determine which treatment is best.

P085 IS DOUBLE-GUIDEWIRE TECHNIQUE REALLY HELPFUL FOR DIFFICULT BILE DUCT CANNULATION ?

B. J. Song[1,*], D. H. Kang[1], H. W. Kim[1], S. J. Kim[1], J. B. Hong[1], C. W. Choi[1], S. B. Park[1]. [1]*Internal medicine, Pusan National University Yangsan Hospital, Yangsan, Korea, Republic Of*

INTRODUCTION: Needle-knife fistulotomy (NKF) is widely used in failed standard biliary cannulation (BC). But NKF requires experienced endoscopists, contains significant complication risks. Double-guidewire technique (DGT) has been reported to be useful for difficult biliary cannulation and to achieve a success rate of 47–93% in patients who fail BC.

AIMS&METHODS: The aim of this study was to compare the success rate and complications between the DGT and NKF in patients with difficult biliary cannulations. Patients who underwent endoscopic retrograde cholangiopancreatography (ERCP) between January 2009 and September 2012 were eligible for this study. DGT or NKF were performed if deep biliary cannulation was not achieved despite of five minutes of attempted cannulation or more than three attempted unintentional pancreatic cannulations. Patients with unsuccessful DGT underwent NKF as alternative procedure. The success rate of cannulation and the frequency of post-ERCP pancreatitis (PEP) were investigated.

RESULTS: A total 1550 ERCP cases were analyzed, the total success rate of selective biliary cannulation was 94.2% (1460/1550). Of the 302 patients with unsuccessful standard cannulation technique, DGT was performed in 70 patient and NKF was performed in 199. The success rate in the DGT and NKF groups were 41.4% (29/70) versus 81.4% (162/199) ($p < 0.01$). Thirty patients with unsuccessful DGT underwent NKF as alternative procedure, biliary cannulation was achieved in 70.0% (21/30). Three step protocol (traditional cannula with guidewire, DGT, and NKF is performed sequentially) was no signigicant benefit in success rate compared with NKF only group (84.7%, 50/59, $p = 0.453$). The incidence rate of PEP was significantly higher in DGT group (20.0%,14/70) than in NKF group (8.0%, 16/199) ($p < 0.01$). There was no significant difference in bleeding incidence.

CONCLUSION: DGT in patients with a difficult biliary cannulation resulted in a low success rate of biliary cannulation and a high incidence of PEP comparing with NKF. DGT before NKF had no statically additional benefit in cannnulation success. We suggest that NKF should be considered as a first approach in difficult cannulation situations.

P086 CHANGES IN CAUSATIVE PATHOGENS OF ACUTE CHOLANGITIS AND THEIR ANTIMICROBIAL SUSCEPTIBILITY OVER A PERIOD OF 6 YEARS

J. Han[1,*], D. Y. Yun[1], H. G. Kim[1], J. S. Kwon[1], H. H. Kwon[1], J. T. Jung[1], J. G. Kwon[1], E. Y. Kim[1]. [1]*Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of*

INTRODUCTION: For the most effective empirical antimicrobial therapy in acute cholangitis, knowledge of prevalence and antimicrobial susceptibility of the institution is essential.

AIMS&METHODS: We evaluated changes of bacteria cultured from bile and blood and their antimicrobial susceptibility over six years at our institution. From August 2006 to August 2012, medical records of patients with acute cholangitis who received biliary drainage were retrospectively reviewed. Acute cholangitis was diagnosed when one or more of the followings were present: 1) purulent bile in gross appearance, 2) leukocytes in bile≥ 50/HPF, 3) positive growth in bile culture. Total of 1589 cases were included. Cases were divided into community-acquired cholangitis (n=201, 12.6%) and hospital-acquired cholangitis (n=1388, 87.4%). Cases were also divided according to time period: Group A (August 2006-December 2008) and Group B (January 2009 - August 2012). Antimicrobial susceptibility were evaluated in each group.

RESULTS: Mean age of the patients was 68.3±13.8 years. There were 905 male patients (53.1%). Of 1589 cases with bile culture, growth was detected in 1513 cases (95.2%). Gram-negative bacteria were isolated in 1422 cases (94%). Most frequently isolated Gram-negative bacteria were extended beta-lactamase (ESBL)-producing *Escherichia coli* (*E. coli*) (n=482, 33.9%), *E. coli* (n=211, 14.8%), *Citrobacter freundii* (n=110, 7.7%), *Klebsiella pneumoniae* (*K. pneumoniae*) (n=99, 7.0%), and ESBL-producing *K. pneumoniae* (n=90, 6.3%). In hospital-acquired cholangitis group, prevalence of ESBL-producing *E. coli* and *Citrobacter freundii* was higher (52.1 vs. 31.4%, p=0.00; 13.5 vs. 6.9%, p=0.002). In Group B, prevalence of E. coli has decreased significantly (p=0.017). Antimicrobial agents with high susceptibility were as follows: amikacin (85.3%), piperacillin-tazobactam (70.3%), cefotetan (77.7%), and imipenem (95.7%). In Group B, susceptibility to piperacillin-tazobactam has decreased significantly (67.9 vs. 73.7%, p=0.027).

CONCLUSION: Prevalence of ESBL-producing *E. coli* and *K. pneumoniae* in cholangitis has increased over six years. In hospital-acquired cholangitis, prevalence of ESBL-producing *E. coli* and *Citrobacter freundii* is higher. Susceptibility to piperacillin-tazobactam has decreased over recent years.

P088 MARKED HYPERTRANSAMINEMIA: A NEW PARADIGM?

S. Campos[1,*], A. Oliveira[1], D. Branquinho[1], N. Silva[2], A. Carvalho[2]. [1]*Gastroenterology department,* [2]*Internal Medicine Department, Centro Hospitalar Universitário Coimbra, Coimbra, Portugal*

INTRODUCTION: In general practice, it is estimated that severe transaminases elevations correspond to ischemic hepatitis, viral or toxic. However, cases of biliary obstruction, increasingly common, have been associated with marked hypertransaminemia. With this study we thus intend to determine the true etiology of increased transaminases in the context of hospital emergency.

AIMS&METHODS: We identified retrospectively all patients going to the emergency unit of Centro Hospitalar Universitário de Coimbra (CHUC) between 1 January 2010 and 31 December 2010 with at least one of transaminases increased more than 15 times. All patient records were analyzed to determine a diagnosis of hypertransaminemia.

RESULTS: A cohort of 273 patients was analyzed. The most frequently etiology found for marked hypertransaminemia was pancreatobiliary acute disease (39.3%), mostly lithiasic, followed by malignancy (20.5%), ischemic hepatitis (17.2%), acute primary hepatocellular disease (13.9%) and muscle damage (6.4%). We could not find a diagnosis in 10 cases (2.7%) after study. There were 27 cases of recurrence in the group of pancreatic-biliary pathology lithiasic, 24 of which had not undergone cholecystectomy ($p = 0.014$). The etiology of hypertransaminemia was influenced by age ($p < 0.001$), by sex ($p = 0.052$), by cholestasis ($p < 0.001$) and by GPT average ($p = 0.022$).

CONCLUSION: The pancreatobiliary lithiasis, often treatable, has been underestimated in the differential diagnosis of hypertransaminemia, and its possibility should always be considered in such situations, in order to improve prognosis. Not performing cholecystectomy early after the first episode predisposes to recurrent biliary obstruction.

P089 THE CLINICAL USEFULNESS OF ENDOSCOPIC ULTRASONOGRAPHY ACCORDING TO ASGE PROBABILITY OF CHOLEDOCHOLITHIASIS IN PATIENTS WITH SUSPECTED CHOLEDOCHOLITHIASIS BUT A NEGATIVE CT SCAN

J. H. Cho[1,*], W. S. Kang[1], T. J. Jeon[2], S. W. Chun[1], J. S. Choi[1], E. T. Hwang[1], H. M. Kim[1]. [1]*Division of Gastroenterology, Department of Internal Medicine, Myongji Hospital, Kwandong University College of Medicine, Goyang,* [2]*Division of Gastroenterology, Department of Internal Medicine, Inje University College of Medicine, Sanggye Paik Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Endoscopic ultrasonography (EUS) is a minimally invasive technique with low morbidity and proven efficacy in the diagnosis of choledocholithiasis.

AIMS&METHODS: We aimed to investigate the usefulness of EUS in patients with clinically suspected choledocholithiasis but a negative CT scan. Between March 2008 and January 2013, 108 patients with clinically suspected choledocholithiasis and no evidence of CBD stones according to MDCT underwent EUS. Common bile duct stones were confirmed by endoscopic retrograde cholangiography (ERCP) and clinical data were retrospectively collected. The risk of choledocholithiasis was assessed by applying the ASGE guidelines, which provide recommendations for categorizing patients into low, intermediate, and high probability.
RESULTS: The accuracy of EUS findings were confirmed according to ASGE probability of choledocholithiasis. EUS accuracy for common bile duct stones were 88.9% (sensitivity 96%, specificity 72%, positive predictive value 89%, negative predictive value 89%). In patients with high and intermediate probability of choledocholithiasis, the detection rate for CBD stones were 83.9% and 70%. CBD stone in patient with low probability was not detected. On multivariate logistic analysis using significant factors after univariate analysis, EUS finding of CBD stone was the only significant predictive factor associated with the presence of choledocholithiasis (OR, 43.2 CI, 9.3-201.4 $P<0.01$). However, EUS finding (stone, dilation), CBD dilation on CT, fever, abnormal liver biochemical test, and ASGE choledocholithiasis probability classification were not associated with the presence of choledocholithiasis.
CONCLUSION: EUS is recommended for further CBD evaluation in patients with suspected choledocholithiasis despite recent improvements in the accuracy of MDCT. CBD Stone on EUS is useful predictor of diagnosis for choledocholithiasis with negative CT scan, regardless of ASGE probability of choledocholithiasis. But EUS is not necessary in patients of the low probability of ASGE guideline and negative CT scan due to very low stone detection rate.

P090 BASIC AMINO ACIDS CAUSE MITOCHONDRIAL DAMAGE IN RAT PANCREATIC ACINAR CELLS

E. Végh[1,*], G. Kovács[1], B. Iványi[2], T. Wittmann[1], P. Hegyi[1], Z. Rakonczay Jr[1]. [1]*First Department of Medicine,* [2]*Department of Pathology, University of Szeged, Szeged, Hungary*

INTRODUCTION: Acute pancreatitis (AP) is the sudden inflammation of the pancreas. Large *i.p.* doses of basic amino acids induce AP in rodents, but the mechanisms mediating pancreatic toxicity remain unknown. Mitochondrial injury is thought to play a role in the pathomechanism.
AIMS&METHODS: Our aim was to get insight into the mechanisms through which basic amino acids damage the exocrine pancreas. Pancreatic acinar cells were isolated from rat pancreas with enzymatic digestion. Isolated cells were treated with different concentrations (20-60 mM) of L-arginine, L-lysine or L-ornithine. The morphology of acinar mitochondria was monitored with electron microscopy. We measured intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) by microspectrofluorometry using the Ca^{2+}-sensitive fluorescent dye FURA-2-AM. The effect of basic amino acids on basal and cerulein-stimulated amylase secretion was tested.
RESULTS: We observed the swelling of mitochondria after incubating the cells for 2 hours with 20-60 mM basic amino acids. However, we did not detect any change in the $[Ca^{2+}]_i$ of cells in response to administration of basic amino acids, whereas marked Ca^{2+} signaling was found in response to 100 μM carbachol. Basal and cerulein stimulated amylase secretion was not influenced by basic amino acids vs the control group.
CONCLUSION: Our data suggest that basic amino acids are unlikely to cause pancreatitis via calcium signaling, they do not alter amylase secretion, but they injure mitochondria. Further experiments are needed to investigate the exact pathomechanism.

P091 MOLECULAR IDENTIFICATION AND REGULATION OF GHRELIN SYSTEM IN THE AR42J CELLS

J. Bonior[1,*], J. Jaworek[1], M. Kot[2], P. Pierzchalski[2], S. J. Konturek[3]. [1]*Department of Medical Physiology, Faculty of Health Sciences, School of Medicine Jagiellonian University, Krakow,* [2]*Zakład Fizjologii Medycznej, Wydział Nauk o Zdrowiu, Wydział Medyczny Uniwersytetu Jagiellońskiego,* [3]*Chair of Physiology Medical Faculty, School of Medicine Jagiellonian University, Kraków, Poland*

INTRODUCTION: Ghrelin (GHRL), is 28-amino acid polypeptide, originally isolated from the stomach and it has also been identified in the pancreas. This peptide is an endogenous ligand for the growth hormone (GH) secretagogue receptor (GHS-R). In animal experiments GHRL protects the gastric mucosa and the pancreas from the acute damage, but the involvement of GHS-R and/or endogenous polypeptide in acute pancreatitis (AP) is still unclear.
AIMS&METHODS: To determine the effect of GHRL and caerulein stimulation of AR42J cells on protein levels of GHS-R1a subtype and of acylated GHRL.
AR42J cells were incubated in standard medium at 37^0C for 48 h, under basal conditions and stimulated with caerulein (10^{-8}M), GHRL (10^{-7}M), or combination of above. Protein expression was assessed employing Western-blot.
RESULTS: GHS-R1a subtype and acylated GHRL have been detected in the pancreatic AR42J cells under basal conditions. Incubation of these cells in presence of GHRL alone resulted in the significant upregulation of both detected proteins. On the contrary, application of caerulein to the cell culture significantly downregulated GHS-R1a, but failed to affect the signal for GHRL. Addition of GHRL reversed caerulein-induced suppression of this protein.
CONCLUSION: Caerulein is able to modify the GHS-R1a subtype in the pancreatic AR42J cells. This effect could be prevented by pretreatment with GHRL and perhaps might be implicated in the mechanism of pancreatic damage induced by caerulein overstimulation.

P092 EFFECT OF TRYPTOPHAN METABOLITE ON PANCREATIC AMYLASE SECRETION IN THE RATS

K. Nawrot-Porabka[1,*], A. Leja-Szpak[1], J. Szklarczyk[1], M. Kosiba[1], J. Jaworek[1]. [1]*Department of Medical Physiology, Jagiellonian University School of Medicine, Krakow, Poland*

INTRODUCTION: The kynurenines, products of tryptophan metabolism, are involved in many physiological processes as well as in regulation of the immune response of the organism. These products have been detected within gastrointestinal system, but their effects on pancreatic amylase secretion have not been investigated yet.
AIMS&METHODS: To assess the effects of intraduodenal (i.d.) infusion of L-kynurenine on pancreatic amylase outputs under basal conditions and following the stimulation of pancreatic secretion with diversion of pancreatobiliary juice (DPBJ) and the role of CCK in that process.
The study was performed on Wistar rats weighing 350g. Under pentobarbitane anesthesia the animals were surgically equipped with silicone catheters, inserted into pancreato-biliary duct, and into duodenum. L-kynurenine (50 or 250 mg/kg i.d.) was given under basal conditions or following stimulation of pancreatic secretion with DPBJ. In the part of the study the lorglumide, the CCK_1 receptor antagonist (1 mg/kg i.d.) was administered 15 minutes prior to application of L-kynurenine. Samples of pancreato-biliary juice were collected to measure the amylase outputs. The blood specimens were taken for determination of CCK employing ELISA.
RESULTS: Intraduodenal administration of L-kynurenine resulted in dose-dependent increase of pancreatic amylase secretion alike under basal conditions as well as during stimulation with DPBJ. These changes in amylase outputs were accompanied by significant increase of CCK plasma levels. Administration of CCK_1 receptor blocker completely abolished the secretory effects of L-kynurenine on pancreatic exocrine function.
CONCLUSION: CCK is involved in the stimulatory effects of tryptophan metabolite, L-kynurenine, on exocrine pancreatic secretion in the rats.

P093 OPEN-LABEL, MULTICENTER, RANDOMIZED CROSSOVER STUDY COMPARING SAFETY AND EFFICACY OF PANZYTRAT 25000 TO KREON 25000 FOR CONTROL OF STEATORRHEA IN CYSTIC FIBROSIS AND EXOCRINE PANCREATIC INSUFFICIENCY PATIENTS >7 YEARS

M. Stern[1,*], M. Woynarowski[2]. [1]*University Children's Hospital, Tuebingen, Germany,* [2]*Children's Health Memorial Institute, Warsaw, Poland*

INTRODUCTION: Introduction & Objectives: Exocrine pancreatic insufficiency (EPI) affects the majority of cystic fibrosis (CF) patients causing significant morbidity and mortality. Panzytrat®, an enteric-coated pancreatic enzyme product (PEP), has been widely available in Europe and South America for over 20 years for the treatment of EPI; however, its efficacy was not studied in patients with EPI due to CF previously. This study compared the efficacy and safety of Panzytrat® 25 000 Ph Eur Units and Kreon® (an enteric-coated PEP) 25 000 Ph Eur Units for the control of steatorrhea in CF patients with EPI.
AIMS&METHODS: Methods: This open-label, randomized study enrolled patients aged ≥7 years with CF and EPI who were receiving Panzytrat® or Kreon® as their main PEP for ≥30 days. The study employed a crossover design with two 14-day treatment periods. Stools were collected over the last 3 days of each treatment period, and dietary intake was recorded over the last 4 days of each treatment period. The primary end point was the coefficient of fat absorption (CFA%). Stool characteristics and presence/frequency of abdominal symptoms were secondary efficacy end points.
RESULTS: Results: Eighty-seven patients (53 male, 34 female; median age, 12y [range, 7-36y]) were randomized to Panzytrat® then Kreon® (n=42) or Kreon® then Panzytrat® (n=45), with 39 and 42 patients, respectively, completing the study (per protocol population). Both groups had similar baseline nutritional status. Mean study drug compliance was 93-98% during each period. Mean CFA% for patients while taking Panzytrat® was 78.3% (95% confidence interval [CI], 73.2-83.7) and 80.4% (75.2-85.9) for patients on Kreon® (P=0.46, 95% CI, –7.2-4.0 for treatment difference; PP analysis). Thus, Panzytrat® was noninferior to Kreon®.
There were no clinically significant differences in stool characteristics, pain, flatulence or abdominal distention reported between groups. The percentage of patients reporting adverse events (AEs), drug-related AEs (abdominal pain, flatulence or diarrhea) and severe AEs was modestly higher with Panzytrat® than Kreon® (37.2% vs 23.5%, 12.8% vs 4.7% and 18.6% vs 10.6%, respectively). No serious AEs or deaths occurred.
CONCLUSION: Conclusions: Panzytrat® demonstrated noninferiority to Kreon® using CFA% as the primary efficacy parameter in a population of

patients with EPI due to CF. Stool characteristics, abdominal symptoms (pain, flatulence or distention) and AEs did not differ significantly during treatment with Panzytrat® vs Kreon®. Panzytrat® thus provides an efficacious treatment option for CF patients with EPI.

P094 URSODEOXYCHOLATE AMELIORATES THE TOXIC EFFECT OF CHENODEOXYCHOLATE ON PANCREATIC DUCTAL CELLS

M. Katona[1,*], P. Hegyi[1], Z. Rakonczay Jr[1], J. Maléth[1], Z. Rázga[2], V. Venglovecz[3]. [1]*First Department of Medicine,* [2]*Department of Pathology,* [3]*Department of Pharmacology and Pharmacotherapy, University of Szeged, Szeged, Hungary*

INTRODUCTION: Recent work by our group has shown that chenodeoxycholate (CDC) at high concentration (1mM) strongly inhibited ion transporters and induced irreversible mitochondrial injury in intact guinea pig pancreatic ducts (*Venglovecz et al. Gut, 2008)*. Previous studies demonstrated that ursodeoxycholate (UDC) and its conjugated forms have antiapoptotic and cell protective effects.
AIMS&METHODS: The AIM of this study was to investigate the effect of UDC on cell damage induced by high concentration of CDC. METHODS: Inta-interlobular ducts were isolated from guinea pig pancreas by enzymatic digestion. Ducts were then pretreated with different concentration of UDC (0.1 and 0.5 mM) for 5 and 24-hours and changes in intracellular Ca^{2+} concentration $[Ca^{2+}]_i$, ATP level $[ATP]_i$ and pH $[pH]_i$ were measured by microfluorometry. Morphological changes of mitochondria were studied by transmission electron microscopy.
RESULTS: 5-hour pretreatment with 0.1 or 0.5 mM UDC and 24-hour pretreatment with 0.1 mM UDC did not significantly influence the effect of 1 mM CDC on duct cells. In contrast, 24-hour pretreatment with 0.5 mM UDC significantly decreased the rate of ATP depletion and mitochondrial injury caused by 1 mM CDC. In addition, 0.5 mM UDC prevented the inhibitory effect of CDC on acid-base transporters.
CONCLUSION: Our results indicate that UDC may represent a novel option against bile acid-induced ductal injury.

P095 CATIONIC ELASTASE AND TRYPSIN ISOFORMS ARE PREMATURELY ACTIVATED UPON DYSBIOSIS IN RATS WITH CHRONICALLY SUPPRESSED GASTRIC ACID SECRETION

S. E. Vakal[1], K. O. Dvorshchenko[1], M. K. Ashpin[1], TV. Borodina[1], L.I. Ostapchenko[1,*]. [1]*ESC "Institute of Biology", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine*

INTRODUCTION: Long-term suppression of gastric acid secretion (LTS-GAS) is associated with a range of negative consequences for the gastrointestinal tract (GIT). One of them is dysbiosis development that leads to colonization of GIT by opportunistic microbiota, thus favouring inflammatory processes both in GIT and associated glands, such as pancreas (Zavros et al., 2002). Premature activation of pancreatic enzymes and self-digestion of the gland are potential consequences. Levels of different pancreatic enzymes in pancreatic tissue, serum and feces are markers of these processes. Cure of dysbiosis with probiotics can help us to elucidate the role of pathogenic microbiota in pancreatic physiology dysregulation.
AIMS&METHODS: The purpose of work was to assess the activity of different pancreatic enzymes and level of α-1-antitrypsin (A1AT) in gland tissue, blood serum and feces, as well as to establish the involvement of dysbiosis in its dysregulation upon LTS-GAS.
The study was performed with white non-strain male rats. Chronical suppression of GAS (second group) was reached by 28-day long abdominal injection of omeprazole (14 mg/kg once a day). Multistrain probiotic "Symbiter" was administrated daily *per os* (third group). Control animals were treated with water.
A1AT level was determined by immunoturbidimetric assay. Trypsin, lipase and pancreatic amylase activities were measured in blood serum and pancreatic tissue with standard spectrophotometric assays. Faecal and pancreatic juice proteolytic profiles were assessed with contact zymography.
RESULTS: Substantial dysbiotic changes in the stomach upon this experimental model were proved by our colleagues (Abdulahad et al., 2012). Significant elevation of serum A1AT (main inhibitor of trypsin and elastase) level and lipase activity was observed; however, serum amylase and trypsin activities weren't changed upon LTS-GAS. Low cationic trypsin activity, as well as slight activation of lipase and amylase were found in rat pancreatic tissue upon LTS-GAS. Subtle activity of cationic (but not anionic) proteases were indicated in few pancreatic juice samples. Enzymography of faecal samples showed increased activity of cationic proteases, which were identified as cationic elastases-1/2 and trypsin-3 starting from 21st day of low gastric acidity. Most of abovementioned parameters weren't deviated form control values upon cure of dysbiosis with multistrain probiotics.
CONCLUSION: Thus, there is evidence of preliminary activation of cationic elastase and trypsin isoforms, as well as important role of GIT dysbiotic changes as causative factor upon long-term suppression of gastric acid secretion.

P096 ATPI IS A KEY MOLECULE IN THE TOXICITY OF ETHANOL AND ITS NON-OXIDATIVE METABOLITES ON CFTR FUNCTION

V. Venglovecz[1,*], L. Judák[2], Z. Rakonczay Jr[2], J. Maléth[2], M. A. Gray[3], P. Hegyi[2]. [1] *Department of Pharmacology and Pharmacotherapy,* [2]*First Deparment of Medicine, University of Szeged, Szeged, Hungary,* [3]*Institute for Cell and Molecular Biosciences, University Medical School, Newcastle upon Tyne, United Kingdom*

INTRODUCTION: Excessive alcohol consumption causes acute pancreatitis but the mechanism involved is not well understood. Recent investigations suggest that pancreatic ductal epithelial cells (PDECs) are involved in the pathogenesis of pancreatitis. Because the cystic fibrosis transmembrane conductance regulator (CFTR) Cl^- channel plays a major role in PDEC anion and fluid secretion, and that dysfunction of CFTR is often associated with pancreatitis, we therefore tested the hypothesis that ethanol exerts a direct effect on CFTR to impair ductal function.
AIMS&METHODS: The dose- and time-dependent effects of ethanol, its oxidative and nonoxidative metabolites (acetaldehyde (Ac) and palmitoleic acid ethyl ester (POAEE), respectively) and palmitoleic acid (POA) were investigated on CFTR activity on freshly isolated guinea pig PDECs and Capan-1 cell line, using the whole cell configuration of the patch clamp technique. Changes in intracellular ATP (ATP_i) were measured by spectrofluorometry.
RESULTS: Ethanol (10 and 100 mM) significantly increased the basal, but reversibly blocked forskolin-stimulated CFTR currents. The inhibitory effect of ethanol was mimicked by POAEE and POA, the latter being produced by fatty acid ethyl esterase hydrolase. Ethanol, POAEE and POA caused depletion of intracellular ATP (ATP_i) linked to CFTR inhibition, since their inhibitory effects were almost completely abolished if ATP_i depletion was prevented.
CONCLUSION: We propose that ethanol causes functional damage of CFTR through an ATP_i-dependent mechanism. Furthermore, we suggest that the maintenance of ductal ATP_i may represent a therapeutic option in the treatment of the disease.

P097 THE STRAIN DEPENDENCY OF L-ARGININE-INDUCED ACUTE PANCREATITIS IN MICE

B. Kui[1,*], Z. Balla[1], B. Iványi[2], T. Wittmann[1], P. Hegyi[1], Z. Rakonczay[1]. [1]*First Department of Medicine,* [2]*Department of Pathology, University of Szeged, Szeged, Hungary*

INTRODUCTION: Acute pancreatitis (AP) is a sudden inflammation of the pancreas. The pathogenesis of AP is not well understood and the disease has no specific therapy. To investigate the pathomechanism of AP, we mainly rely on animal models such as L-arginine-induced AP. The use of L-arginine to induce AP in mice is becoming increasingly popular. However, we found high mortality with the originally published dose (2x4 g/kg) of L-arginine in mice. Thus, we aimed to establish a basic amino acid-induced AP model with a lower mortality rate.
AIMS&METHODS: AP was induced with various intraperitoneal (ip.) doses of L-arginine in FVB/n or C57Bl/6 mice. Control mice were injected with physiological saline. Laboratory (serum amylase and pancreatic myeloperoxidase activities) and histological (necrosis and inflammatory infiltration) parameters were measured to determine AP severity.
RESULTS: Ip. injection of mice with 2x4 g/kg L-arginine resulted in a 82 % mortality rate in FVB/n and 55 % in C57Bl/6 mice, which was independent of AP. Using 4 hourly injections of 2.5 g/kg L-arginine, we found significantly lower mortality (33 % in FVB/n and 10 % in C57Bl/6 mice), and similar degree of AP morbidity compared to 2x4 g/kg L-arginine dose. The pancreatic myeloperoxidase and serum amylase activities and histological parameters were significantly elevated in all L-arginine treated groups compared to control mice.
CONCLUSION: Different mouse strains show various sensitivities to L-arginine and there is a fine borderline between the effective and lethal dose of L-arginine. All laboratories have to precisely determine the effective dose of L-arginine used for the induction of AP.

P098 MANIFESTATIONS OF ENDOGENOUS INTOXICATION IN ACUTE PANCREATITIS-ASSOCIATED LUNG DAMAGE IN EXPERIMENTAL CYTOFLAVIN CORRECTING

G. Shabat[1,*], M. Fedorkiv[2]. [1]*Surgery 2 and Cardiosurgery,* [2]*General Surgery, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*

INTRODUCTION: Despite some progress in the diagnosis and treatment of acute pancreatitis, some aspects of its pathogenesis remain poorly understood, which, along with other determining factors impact on fatality rates, which vary between 5-22% [1, 3], when the disease is complicated development of the syndrome of acute lung injury mortality reaches 48-86% [2] without a significant trend towards improvement in recent decades.

AIMS&METHODS: The aim of the study was to examine the effectiveness of multiantihypoxants and antioxidant "Cytoflavin" at different stages of acute pancreatitis-associated lung injury in rats.

The experiment simulated acute pancreatitis in rats by two intraperitoneal injections of 20% L-arginine (total dose of 5 g/kg, with an interval of one hour) by the method of L. Czako. In the comparison group animals within 5 min after simulation acute pancreatitis injected drug "Cytoflavin" in a dose of 0.21 ml/kg body weight. Determined amylase, Medium Molecule MM_{254} and MM_{280} content, the level of malonic aldehyde, diene conjugates in blood, lung and pancreas tissue examined histologically.

RESULTS: In experimental acute pancreatitis indicators of endogenous intoxication significantly increases of over 12-48 h, which is directly dependent on the severity of membrane destruction processes in the tissues of the pancreas against the growing activity of lipid peroxidation. Determined a significant increase in lipid peroxidation, which triggers a similar increase in the content of its products in the blood. However, the medical correction within the first 72 hours, there was reduction of malonic aldehyde and diene conjugates by 3.54 % and 31.25 % compared to similar indicators in the control group ($p < 0,05$).

CONCLUSION: Use of the drug "Cytoflavin" reduces the severity of endotoxemia: reducing MM - 24 h and 72 h, malonic aldehyde and diene conjugates - after 24 hours. He also has a positive impact on the protective components of aero-hematic barriers and reducing their damage in acute pancreatitis-associated lung damage in the experiment by reducing swelling interalveolar barriers and improve microcirculation.

P099 TRYPTOPHAN METABOLITE; KYNURAMINE ATTENUATES ACUTE PANCREATITIS IN THE RATS AND INCREASES PRODUCTION OF HEAT SHOCK PROTEIN

J. Jaworek[1,*], J. Szklarczyk[1], M. Kot[1], K. Nawrot-Porabka[1], R. Tomaszewska[2]. [1]*Department of Medical Physiology Faculty of Health Sciences,* [2]*Chair of Cell Morphology Medical Faculty, Jagiellonian University School of Medicine, Krakow, Poland*

INTRODUCTION: Melatonin precursor: L-tryptophan protects the pancreas against acute pancreatitis. The effect of L-kynuremine (KYN), the product of L-tryptophan metabolism, on acute pancreatitis has not been investigated. Heat shock protein (HSP) are intracellular chaperons, guarding the other proteins.

AIMS&METHODS: To assess the effects of KYN on caerulein-induced pancreatitis (AP) in the rats and on HSP60 production in AR42J pancreatic acinar cell line.

AP was induced by subcutaneous caerulein infusion (25 microgr/kg). KYN (25, 50 or 100 mg/k) was given intraperitoneally to the rats 30 min prior to the induction of AP. Lipid peroxidation products (MDA+4HNE) and the activity of an antioxidant enzyme; glutation peroxydase (GPx) were measured in pancreatic tissue. Blood samples were taken for evaluation of amylase and TNF alpha concentrations. HSP60 was determined by Western blot in AR42J cells subjected to KYN (10^{-12}, 10^{-10}, 10^{-8}) without or with addition of caerulein (10^{-8}M).

RESULTS: AP was confirmed with histological examination and by the increases of amylase and TNF alpha blood levels (by 800% and 300%, respectively). In the pancreas of AP rats contents of MDA+4HNE was increased by 300%, whereas GPx activity was reduced by 50%. KYN significantly diminished histological manifestations of AP, dose-dependently decreased amylase and TNF alpha blood levels, significantly reduced MDA+4HNE and augmented GPx in the pancreas of AP rats. In AR42J cells KYN (10^{-10} 10^{-8}) alone or combined with caerulein markedly increased HSP60 protein signal.

CONCLUSION: L-kynuremine significantly attenuated acute pancreatitis. This beneficial effect could be related to the antioxidative effect of: L-kynuremine and, possibly, to the increase of HSP60 in the acinar cells.

P100 ETHANOL AND FATTY ACIDS STRONGLY INHIBIT PANCREATIC DUCTAL BICARBONATE SECRETION AND DECREASE THE EXPRESSION OF CFTR CHLORID CHANNEL IN PANCREATIC DUCTAL EPITHELIAL CELLS

J. Maléth[1,*], L. Judak[1], L. Kemeny[1], Z. Balla[1], B. Kui[1], P. Pallagi[1], V. Venglovecz[2], A. Somoracz[3], K. Borka[3], A. Balazs[1], I. Nemeth[4], Z. Rakonczay[1], M. Gray[5], P. Hegyi[1]. [1]*First Dept. of Medicine,* [2]*Department of Pharmacology and Pharmacotherapy, UNIVERSITY OF SZEGED, Szeged,* [3]*2nd Department of Pathology, Semmelweis University, Budapest,* [4]*Department of Dermatology and Allergology, UNIVERSITY OF SZEGED, Szeged, Hungary,* [5]*Institute for Cell & Molecular Biosciences, Newcastle University, Newcastle upon Tyne, United Kingdom*

INTRODUCTION: Excessive ethanol (EtOH) consumption is one of the most common causes of acute pancreatitis, which has no specific treatment. Pancreatic ductal epithelial cells (PDEC) secrete HCO_3^- rich fluid via Cl^-/HCO_3^- exchanger (CBE) and cystic fibrosis Cl^- channel (CFTR), which prevents acinar damage. However, no information is available about the effects of EtOH and EtOH metabolites ((fatty acid ethyl esters (FAEE) and fatty acids (FA)) on PDEC.

AIMS&METHODS: In our experiments human pancreatic epithelial cell line (Capan-1), guinea pig and human pancreatic tissue were used. The effects of EtOH, FAEE and FA on intracellular pH (pH_i), Ca^{2+} concentration ($[Ca^{2+}]_i$), ATP [$(ATP)_i$], mitochondrial membrane potential ($\Delta\Psi$) and CFTR Cl^- current were measured. The effect of EtOH and FA on the expression and localization of CFTR were analysed in PDEC, in guinea pig and human pancreatic tissue samples.

RESULTS: High concentration of EtOH (100mM) and palmitoleic acid (POA) (200μM) strongly decreased the activities of the apical CBE and CFTR and inhibited the HCO_3^- secretion of PDEC *in vitro* after 10 min. The administration of 100mM EtOH and 200μM POA induced sustained $[Ca^{2+}]_i$ elevation by releasing Ca^{2+} from the endoplasmic reticulum via IP_3 and ryanodin receptor activation and extracellular Ca^{2+} influx. Moreover 100mM EtOH and 200μM POA depleted the $(ATP)_i$ and decreased $\Delta\Psi$. The prevention of the sustained $[Ca^{2+}]_i$ elevation abolished the inhibitory effect of EtOH and POA. The expression of CFTR was significantly decreased by EtOH and POA after 48h in PDEC. Moreover *ip* injection of EtOH and FA decreased the luminal expression of CFTR in guinea pig pancreas. Importantly, we observed the same decrease in the pancreatic tissue of acute and chronic alcoholic pancreatitis patients.

CONCLUSION: These results suggest that EtOH and FA inhibit pancreatic ductal HCO_3^- secretion via sustained $[Ca^{2+}]_i$ elevation and decrease the expression of CFTR, which can contribute to the development of acute pancreatitis. The restoration of the HCO_3^- secretion may be a potential therapeutic target in alcohol induced acute and chronic pancreatitis.

P101 INFLAMMATORY AND OXIDATIVE STRESS MARKERS IN RAT PANCREAS UPON LONG-TERM GASTRIC HYPOCHLORHYDRIA AND ITS CORRECTION WITH MULTIPROBIOTIC "SYMBITER"

K. Dvorshchenko[1,1], S. Vakal[1], A. Dranitsina[1], O. Bernyk[1], L. Ostapchenko[1,*]. [1]*Educational and Scientific Centre "Institute of Biology", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine*

INTRODUCTION: Long-term usage of medications suppressing gastric acid secretion upon treatment of acid-related disorders is a risk factor for acute pancreatitis development or even pancreatic malignization [1, 2]. But common factors and mechanisms of pancreatic structural and functional reorganization upon long-term gastric hypochlorhydria are still poorly understood. Probiotics are widely used for restoration of gastrointestinal tract homeostasis, since they have a broad spectrum of biological activity.

AIMS&METHODS: The purpose of study was to assess the cytokine profile and intensity of free-radical processes in rat pancreas upon long-term gastric hypochlorhydria and administration of multiprobiotic "Symbiter".

All experiments were carried out on white non-strain male rats. Hypochlorhydria was induced by 28-day long abdominal omeprazole injection (14 mg/kg once a day). The second group of rats simultaneously with omeprazole was treated with "Symbiter" (0.14 ml/kg *per os*). Control animals were treated with water: 0.2 ml abdominally + 0.5 ml orally during 28 days. Studied parameters were determined in pancreatic homogenates with standard assays.

RESULTS: The increased levels of reactive oxygen species in rat pancreas upon long-term gastric hypochlorhydria were observed: superoxide anion and hydrogen peroxide levels were 1.5 and 1.8 times higher than control, respectively. Upon the same conditions, thioredoxin reductase activity, total NO-synthase activity, nitric oxide content and iNOS gene expression were 1.8, 4, 2.3 and 3 times higher than control, correspondingly. Upregulation of IL-1α, IL-6, IL-8, TNF-α and IFN-γ upon these conditions was also observed: their levels were 2.8, 1.5, 4.5, 3 and 1.8 times higher in comparison with the control, respectively. At the same time IL-4 and IL-10 concentrations were decreased in 1.5 and 1.8 times. Joint administration of multiprobiotic «Symbiter» with omeprazole was associated with normalization of studied parameters in rat pancreatic tissue.

CONCLUSION: The intensification of free-radical processes and inflammation development in rat pancreas upon long-term gastric hypochlorhydria were established. Multiprobiotic «Symbiter» exerted antioxidative and immunomodulatory properties upon correction of hypochlorhydria-associated consequences in pancreas.

P102 ATAXIA TELANGIECTASIA MUTATED LOSS DRIVES PANCREATIC CANCER FORMATION VIA EMT INDUCTION

A. Kleger[1,*], R. Russell[1], L. Perkhofer[1], T. Seufferlein[1], M. Wagner[1].
[1]*Department of Internal Medicine 1, Ulm University Hospital, Ulm, Germany*

INTRODUCTION: Pancreatic ductal adenocarcinoma (PDAC) is one of the leading causes of cancer deaths in the developed world, with a 5 year survival rate as low as 5%. In recent years, genetically engineered animal models of pancreatic cancer which recapitulate the human disease have provided a useful means of studying both the morphological and molecular features associated with PDAC.
AIMS&METHODS: The most commonly studied model to date has been the expression of active Kras under the control of an endogenous, pancreas specific promoter which leads to a spectrum of changes in the pancreas recapitulating development of human PDAC. Interestingly, PDAC develops much more rapidly when further oncogenes such as *SMAD4* or p53 are deleted.
RESULTS: In the current study, we address the role of Ataxia Telagiectasia Mutated (Atm) gene in PDAC and describe a loss of ATM protein with advanced UICC stage in primary human tumor specimens. We also found that mutations in the ATM gene are more abundant in large collectives of human pancreatic cancer. Subsequently, we show that loss of Atm enhanced the metastatic potential of the Kras mouse model and decreased survival of mice to 36 and 38 weeks for homozygous and heterozygous Atm deletion, respectively. These mice developed a greater number of pre-malignant pancreatic intraepithelial neoplasias (mPanINs) with a significant increase in proliferation and α-smooth muscle actin positive cells, indicative of activated pancreatic stellate cells (PSCs). This was followed by an increase in large, dysplastic papillary lesions and a significant amount of surrounding fibrosis compared to controls. Our results furthermore establish that the loss of Atm in this mouse model promoted early EMT and a dedifferentiated PDAC phenotype. Moreover, early EMT upon ATM loss was associated with increased invasive properties.
CONCLUSION: Taken together, our data suggests that there may be an intimate link between Atm activity and pancreatic cancer formation, one of the major signalling pathways altered in PDAC and targeting this axis may provide therapeutic potential in the future.

P103 OVEREXPRESSION OF P-HSP27, HSP70 AND HSP90A/B IN PANC-1 CELLS IN RESPONSE TO KYNURAMINES. INVOLVEMENT OF 5-HT AND MEL A/B-1 RECEPTORS.

A. Leja-Szpak[1,*], J. Jaworek[1], K. Nawrot-Porabka[1], M. Jastrzebska[1], P. Pierzchalski[1]. [1]*Department of Medical Physiology Faculty of Health Sciences, Jagiellonian University School of Medicine, Krakow, Poland*

INTRODUCTION: Kynuramines, metabolites of L-tryptophan and melatonin, are synthetized endogenously by oxygenases or by interaction with free radicals. Previously we have reported that melatonin stimulated expression and phosporylation of HSP27, production of HSP70 and HSP90a/b in PANC-1 cells. Based on above results, we hypothetized that above process could be involved in the mechanism of intrinsic proapoptotic pathway interruption.
AIMS&METHODS: Here in, we would like to present that L-kynurenine (L-KYN) and N^1-acetyl-N^2-formyl-5-methoksykynuramine (AFMK) lead to the overexpresion of HSPs synthesis and that this process is partially abolished by 5-HT_3 or Mel A/B-1 receptors antagonists. PANC-1 cells in culture were treated with L-kynurenine or AFMK, Mel A/B-1 receptors antagonist; luzindole, 5-$HT2_{,3}$ receptor antagonists; ketanserin, MDL72222, or combination of above. After incubation, cells had been harvested, the cytoplasmic and nuclear proteins fractions were isolated for immunoblotting or/and immunoprecipitation analysis of HSP27, HSP70 and HSP90$\alpha\beta$.
RESULTS: Our studies have shown that both L-kynurenine and AFMK significantly decreased cytoplasmic HSP27 content, presumably due to increase of its phosphorylation and consequent translocation, confirmed by immunoprecipitation of phosphorylated HSP27. These changes were accompanied by slight augmentation of HSP70 and HSP90 abundance in cytosolic fraction. Pretreatment of the cell cultures with luzindole or MDL72222 followed by the addition of kynuramines reversed the stimulatory effects of L-KYN or AFMK on HSPs expression in PANC-1 cells, whereas ketanserin failed to affect analyzed protein signal.
CONCLUSION: We conclude that L-kynurenine or AFMK could stimulate phosphorylated HSP27, HSP70 and HSP90$\alpha\beta$ production in PANC-1 cells through interaction with the Mel A/B-1 or/and 5-HT_3 receptors.

P104 LYMPHOTOXIN-ASSOCIATED INFLAMMATION AS AN ETIOLOGICAL FACTOR OF PANCREATIC CARCINOGENESIS

S. Sonda[1], G. M. Seleznik[1,*], T. Reding[1], M. Heikenwälder[2], R. Graf[1]. [1]*Swiss HPB Center, University Hospital Zurich, Zurich, Switzerland,* [2]*Helmholtz-Zentrum, Institute for Virology, München, Germany*

INTRODUCTION: Pancreatic inflammation is a well-known risk factor for pancreatic ductal adenocarcinoma (PDAC) development in humans, and its initiation is linked to activating mutations in KRAS oncogene. Recent studies propose a stepwise process starting from acinar cells undergoing ductal reprogramming (acinar to ductal metaplasia, ADM) throughout premalignant PanIN (pancreatic intraepithelial neoplasia) lesions leading to tumor formation. However little is known about the mechanisms how inflammatory damage promotes ADM and PanIN progression.
AIMS&METHODS: Here we establish a new genetic model by intercrossing the commonly used $p48^{+/Cre}$;$Kras^{+/G12D}$ (KP) model for pancreatic tumorigenesis, to a novel transgenic mouse developing spontaneous pancreatic inflammation, due to overexpression of Lymphotoxin (LT). Immunohistochemistry along with RT-PCR were used to obtain an inflammatory signature.
RESULTS: Overexpression of Lymphotoxin in mice harbouring a constitutively active form of Kras mutation in the pancreas (LTKP) dramatically accelerates the development of premalignant PanIN lesions compared to KP animals. Already at the age of 6 weeks we observed highly proliferating cells, development of ADM and PanIN in LTKP mice. This coincided with a significant upregulation of pro-inflammatory cytokines and cell-cycle inhibitors. This type of molecular and phenotypic change was only observed around 16 weeks of age in Kras animals. Similarly, earlier activation of downstream targets of Kras was observed in LTKP mice. Furthermore, in the KP model we detected a significant elevation of ligands and receptors of the LTβR-signalling pathway during PanIN progression.
CONCLUSION: Our data point towards the involvement of LTβR-signalling in the initiation of pancreatic cancer, revealing Lymphotoxin as a critical component of spontaneous and pancreatitis-accelerated PDAC precursor formation.

P105 NEURAL INVASION IN PANCREATIC CANCER IS CHARACTERIZED BY BETA-1-INTEGRIN- AND L1-CAM-DEPENDENT HETEROTYPIC CELL ADHESION BETWEEN PANCREATIC CANCER CELLS AND NEURAL SCHWANN CELLS

I. E. Demir[1,*], N. Klose[1], E. Brunner[1], H. Friess[1], G. O. Ceyhan[1]. [1]*Department of Surgery, Klinikum rechts der Isar, TU München, München, Germany*

INTRODUCTION: Neural invasion is one of the most frequent modes of tumor spread in pancreatic cancer (PCa). However, how PCa cells can attach to and migrate along Schwann-cell-covered axons in nerves remains unclear.
AIMS&METHODS: The aim of this study was to investigate the potential heterotypic cell adhesion between PCa cells and Schwann cells (SC) and to identify the surface molecules that enable this interaction. Human SC, PCa cells, human PCa tissue, normal human pancreas and intrapancreatic nerves were investigated for the expression of the cell adhesion molecules beta-1-Integrin, NCAM, L1-CAM and NrCAM via immunoblotting, QRT-PCR and immunohistochemistry. Heterotypic cell adhesion and mutual migration between SC and PCa cells were quantified via a recently established adhesion assay and 3D migration assay by applying neutralizing antibodies against these adhesion molecules.
RESULTS: Expression of beta1-Integrin and L1-CAM were more prevalent in PCa tissues, human SC, intrapancreatic nerves and PCa cells than NCAM and NrCAM. Confrontation of SC with PCa cells led to rapid heterotypic cell adhesion, which could be inhibited by neutralizing antibodies against beta-1-Integrin and L1-CAM, but not against NCAM and NrCAM on PCa cells. Similarly, blockade of beta-1-Integrin on PCa cells diminished the carcinotropic migration of SC. Interestingly, inhibition of these molecues on SC did not influence the adhesion or carcinotropic migration of SC.
CONCLUSION: Neural invasion harbors heterotypic cell adhesion and mutual migration between SC and PCa cells. Therefore, cell-cell-adhesion represents a key pathophysiological mechanism in neural invasion and for the associated local tumor recurrence and neuropathic pain in PCa.

P106 PHOTOACOUSTIC ULTRASOUND IMAGING TO DETECT HYPOXIC AREAS IN A SYNGENEIC, PRECLINICAL MODEL OF PANCREATIC DUCTAL ADENOCARCINOMA

M. Gerling[1,*], S. Nania[2], Y. Zhao[2], J. Norberg[2], B. Englert[1], A. Neese[3], R. Toftgård[1], J. M. Löhr[2], R. L. Heuchel[2]. [1]*Center for Biosciences,* [2]*CLINTEC, Karolinska Institutet, Stockholm, Huddinge, Sweden,* [3]*Gastroenterologie, Phillips Universität zu Marburg, Marbug, Germany*

INTRODUCTION: Preclinical testing of novel therapeutics in mouse models relies on reproducible read-outs to assess treatment efficacy. Non-invasive imaging techniques are thus pivotal to assess orthotopic tumor growth in internal organs, which defy conventional caliper measurements.
To this end, high frequency ultrasound for rodents has been introduced, which allows for conventional B-mode scans, as well as color-coded Doppler imaging of internal organs. As an emerging technology, photoacoustic scanners provide additional functional information such as tissue oxygenation, which can be combined with conventional ultrasound. Here, we applied 3D-photoacoustics to

assess tumor growth and intraparenchymal oxygen saturation longitudinally in a syngeneic, orthotopic model of pancreatic carcinoma in mice.
AIMS&METHODS: Murine pancreatic ductal adenocarcinoma cells (C57BL/6 background) were injected intrapancreatically and subcutaneously using high-frequency ultrasound guidance (Visualsonics Vevo®-LAZR integrated micro-ultrasound/photoacoustic system, VisualSonics, Canada). Tumor development was monitored by trimodal imaging (3D-ultrasound, 3D-photoacoustics, IVIS-Spectrum-bioluminescence). In particular, relative tissue oxygen saturation was determined with a photoacoustic probe (20Hz tunable laser 680-970nm) in 3D and overlaid with B-mode ultrasound data. Specific labeling of hypoxic areas on tissue specimens was achieving using immunohistochemic detection of pimonidazol (hypoxyprobe), which was injected prior to sacrifice when tumors reached the size of 0.8 cm^3.
RESULTS: Conventional ultrasound, photoacoustics and bioluminescence imaging allow monitoring tumor growth at different resolution and accuracy. Photoacoustic imaging can be utilized to monitor the development of hypoxic and necrotic regions in subcutaneous and orthotopic pancreatic tumors. Photoacoustic signatures of tissue hypoxia can be correlated to hypoxic regions as detected in post-mortem analysis.
CONCLUSION: Photoacoustic imaging can be utilized to detect hypoxic and necrotic tumor regions in pancreatic carcinoma mouse models and is a putative novel tool to assess early treatment response in preclinical studies.

P107 HEAT TREATMENT INHIBITS EPITHELIAL-MESENCHYMAL TRANSITION (EMT) IN HUMAN PANCREATIC ADENOCARCINOMA CELL LINE.

R. Kimura[1,*], S. Kokura[1], T. Ishikawa[1], T. Okayama[1], S. Adachi[1], K. Mizushima[1], K. Katada[1], K. Kamada[1], K. Uchiyama[1], N. Sakamoto[1], O. Handa[1], T. Takagi[1], N. Yagi[1], Y. Naito[1], Y. Ito[1]. [1]*Department of Gastroenterology and Hepatology, Kyoto Prefectural Univ. of Medicine, kyoto, Japan*

INTRODUCTION: Pancreatic cancer (PC) is an aggressive malignancy that has a proclivity to lead to early metastasis and relatively poor outcome. Although gemcitabine (GEM) is the standard therapy for PC, survival benefit is insufficient. Recently, it has been reported that epithelial-to-mesenchymal transition (EMT) plays a crucial role in cancer metastasis and is associated with a poor prognosis in patients with PC. And GEM-resistant pancreatic cancer cells have shown to be associated with EMT. We have reported that heat treatment inhibited NF-kB activation, which mediates EMT and resistance to chemotherapy. In this study, we evaluated the effect of heat treatment on TGF-β or GEM-induced EMT in pancreatic cancer cells. Moreover, we evaluated the efficacy of regional hyperthermia (HT) combined with GEM in patients with unresectable locally advanced PC.
AIMS&METHODS: Human pancreatic cell lines (PANC-1, MIAPaCa-2 and BxPC-3) were stimulated by TGF-β or GEM, and evaluated for morphological changes using immunofluorescence and EMT-related factors (i.e. E-cadherin, Vimentin, Snail and Zeb-1) using RT-PCR. To examine the effect of heat on EMT, the cells were treated with heat (43°C) for 1h followed by the stimulation of TGF-β (10ng/ml). Moreover, we retrospectively analyzed 10 patients with unresectable locally advanced PC, who received combination therapy with GEM and HT at our hospital between November 2008 and December 2011. The patients received GEM (1000mg/m2) intravenously on day 1, 8 and 15, and HT (40min/once) weekly.
RESULTS: After treatment with TGF-β or GEM, pancreatic cancer cells changed their morphology from a typical epithelium to mesenchymal spindle-shaped. The expression of vimentin and snail was up-regulated by TGF-β or GEM, and the expression of E-cadherin was down-regulated. These TGF-β-induced changes in morphology and expression of EMT-related factors were attenuated by the heat treatment. As for clinical efficacy of HT, the objective response rate and disease control rate were 20% and 100%, respectively. Median overall survival was 17.3 months. No severe HT-related toxicities were observed.
CONCLUSION: Our results suggest that the heat treatment could suppress TGF-β- and GEM-induced EMT, and HT could improve prognosis of locally advanced PC. These results support the potential of HT as a treatment for cancer metastasis.

P108 COMBINED SUPPRESSION OF NOTCH AND JAK/STAT IMPAIRS PANCREATIC CANCER PROGRESSION IN VITRO AND IN VIVO AND IS SUPERIOR TO MONOTHERAPIES

V. Palagani[1], P. Bozko[1], M. El Khatib[1], H. Belahmer[1], B. Sipos[2], N. Malek[1], R. R. Plentz[1,*]. [1]*Department of Internal Medicine I,* [2]*Department of Pathology, Medical University Hospital Tuebingen, Tübingen, Germany*

INTRODUCTION: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive disease with a high rate of metastasis. Recent studies have indicated that Notch and JAK2/STAT3 signaling pathways are both important for the initiation and progression of PDAC.
AIMS&METHODS: The purpose of this study was to determine the outcome of targeting these two tumor signaling pathways simultaneously both *in vitro* and *in vivo*. We assessed the combinational effects of the gamma-secretase inhibitor IX (GSI IX) and JAK2 inhibitor (AG-490) on growth and epithelial plasticity of human pancreatic cancer cell lines, and in a genetically engineered mouse model (Pdx1- Cre; LSL-KrasG12D; p53 $^{lox/+}$) of PDAC.
RESULTS: Dual treatment with GSI IX and AG-490 significantly impaired cell proliferation, migration, invasion, soft agar growth and apoptosis when compared to monotherapies. Most importantly, combinational treatment significantly attenuates tumor progression *in vivo* and suppresses conversion from acinar-ductal-metaplasia (ADM) to PDAC.
CONCLUSION: Our results suggest that targeting Notch and JAK2/STAT3 signaling pathways simultaneously is superior to single inhibitions, supporting combined treatment by GSI X and AG-490 as a potential therapeutic approach for PDAC.

P109 IDENTIFICATION OF A SUBPOPULATION OF PANCREATIC CANCER PATIENTS WITH MTOR DEREGULATION: NEW CHANCES FOR RAPAMYCIN TREATMENT

W. K. Utomo[1,*], V. Narayanan[1], K. Biermann[2], C. van Eijck[3], M. Bruno[1], M. Peppelenbosch[1], H. Braat[1]. [1]*Gastroenterology and Hepatology,* [2]*Pathology,* [3]*Surgery, Erasmus Medical Center, Rotterdam, Netherlands*

INTRODUCTION: Pancreatic cancer (PC) remains one of the most lethal common malignancies worldwide. Deregulation of several core signaling pathways have been identified in PC and distinct pathways are affected between different patients. Hence, personalized based medicine is an attractive approach in the treatment of PC.
AIMS&METHODS: We aim to identify a subpopulation of PC patients with activation of the Mammalian Target Of Rapamycin (mTOR) pathway by measuring phosphorylated S6 (pS6), a downstream protein of the mTOR pathway, in Endoscopic Ultrasound–Fine Needle Aspiration (EUS-FNA) obtained tissue.
Methods: Immunohistochemical (IHC) staining of pS6 on Formalin Fixed Paraffin Embedded (FFPE) specimens from PC resection was performed. To study mTOR activation and inhibition by rapamycin, PC cell lines were analyzed by means of western blot (cleaved caspase 3, pS6, LC3A/B), cell viability assays and flow cytometry (pS6). Single cell suspensions obtained through EUS-FNA of pancreatic tumors were stained for cytokeratin 8/18 (CK8/18) and pS6 expression and subsequently analyzed using flow cytometry.
RESULTS: The proportion of tissue (n=66) expressing pS6 is 50% in healthy ducts, 67% in PanIN lesions, and 82% in tumor regions. In PC cell lines, rapamycin decreased cell viability in a dose dependent manner and decreased pS6 expression by 30 to 665-fold.
On flow cytometry analysis of cell lines, two hours of incubation with 0.1 μM rapamycin reduced the Mean Fluorescence Intensity (MFI) in CK8/18 positive cells of pS6 by more than 50%. Similarly, in ex vivo analysis of fresh EUS-FNA tissue, rapamycin inhibited pS6 expression in CK8/18+ cells in two out of nine samples (22%). In these potential responders, rapamycin reduced the amount of pS6 expressing cells by more than 90%. Potential responders showed a mean reduction in MFI of 81.3% (±2.7%), while the average MFI change in non-responders was 8.8% (±6.1%) ($p<0.01$).
CONCLUSION: As hypothesized, great variation exists in the expression of pS6 between PC patients. In PC cell lines, rapamycin markedly reduced cell viability and pS6 expression. Validation in ex vivo EUS-FNA biopsies showed a subpopulation of PC patients sensitive for rapamycin. The result of this study shows that in PC patients, the identification of a subpopulation eligible for mTOR inhibition is possible which is a first step towards personalized based medicine in PC.

P110 THE ASSOCIATIONS BETWEEN THE COAGULATION/IMMUNE MOLECULES AND SYSTEMIC TRAFFICKING OF BONE MARROW-DERIVED STEM CELLS IN PATIENTS WITH PANCREATIC NEOPLASMS.

T. Starzynska[1], W. Blogowski[1,*], D. Salata[2], M. Budkowska[2], K. Dabkowski[1], B. Dolegowska[2], M. Z. Ratajczak[3,4]. [1]*Department of Gastroenterology,* [2]*Department of Medical Analytics,* [3]*Department of Physiology, Pomeranian Medical University in Szczecin, Szczecin, Poland,* [4]*Stem Cell Institute at the James Graham Brown Cancer Center, University of Louisville, Louisville, United States*

INTRODUCTION: Recently we have reported that in patients with pancreatic malignancies intensified peripheral trafficking of bone marrow (BM)-derived stem cells (SCs) occurs (*Starzynska et al. JCMM 2013*), and this was associated with activity of the complement cascade. Nevertheless, the mechanisms responsible for selective SCs mobilization in patients with malignancy are not known, and immune system together with coagulation cascade are hypothesized to contribute to this phenomenon.
AIMS&METHODS: In this study we examined a panel of immune-derived chemokines (IL-1, IL-6, IL-8, IL-10, IL-12, IL-17 and IL-23), coagulation molecules (kalikrein 2 and 10, TAT) together with inflammatory molecules (tumor necrosis factor-alpha-TNFα and granulocyte-colony stimulating factor-G-CSF), and verified whether activity of these molecules was associated with abnormal peripheral trafficking of BMSCs in patients with pancreatic neoplasms. 26 patients with pancreatic neoplasms (22 *adenocarcinoma*, 4 neuroendocrine tumors) and 32 control individuals were recruited. Plasma levels of these molecules were measured using ELISA.

RESULTS: Significantly higher levels of IL-6, IL-8, IL-10, TAT, TNFα, and lower of IL-23 were observed in patient with pancreatic neoplasms (in all cases at least $P<0.02$). IL-6, IL-8, TNFα and TAT levels negatively correlated with absolute numbers of circulating hematopoietic and endothelial stem/progenitor cells (in all cases $P<0.05$), and IL-10 was positively correlating with numbers of very small embryonic/epiblast-like stem cells ($P<0.05$). Furthermore, analysis using receiver operating characteristics (ROC) curves demonstrated area under ROC curve values ranging between 0.70-0.83 for IL-6, IL-8, IL-10, TAT and TNFα.
CONCLUSION: Selected coagulation and immune-derived molecules seem to be involved into the orchestration of abnormal peripheral trafficking of BMSCs in patients with pancreatic neoplasms. Clinical significance and predictive value of examined molecules require furthers investigations. Study supported by Ministry of Science and Higher Education grant (402 423038) assigned to TS.

P111 CLOBENPROPIT ENHANCES ANTI-TUMOUR EFFECT OF GEMCITABINE IN PANCREATIC CANCER

W. H. Paik[1,*], J. K. Ryu[2], K.-S. Jeong[2], J. M. Park[2], B. J. Song[2], S. H. Lee[2], Y.-T. Kim[2]. [1]*Internal Medicine, Asan Medical Center,* [2]*Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Histamine is associated with carcinogenesis through activation of its 4 membrane-specific receptors. We evaluated the anti-tumour effect of clobenpropit, which is the specific H_3 antagonist and H_4 agonist, with gemcitabine combination in pancreatic cancer cell line.
AIMS&METHODS: Three kinds of human pancreatic cancer cell lines (Panc-1, MiaPaCa-2, and AsPC-1) were used in this study. Expression of H_3 and H_4 receptor in pancreatic cancer cell was identified with Western blotting. Effects of clobenpropit on cell proliferation, migration and apoptosis were evaluated. Alteration of epithelial and mesenchymal markers after administration of clobenpropit was analyzed. *In vivo* study with Panc-1 xenograft mouse model was also performed.
RESULTS: H_4 receptors were present as 2 subunits in human pancreatic cancer cells, while there was no expression of H_3 receptor. Clobenpropit inhibited cell migration and increased apoptosis of pancreatic cancer cells in combination with gemcitabine. Clobenpropit up-regulated E-cadherin, whereas down-regulated vimentin and matrix metalloproteinase 9 in real-time PCR. Also, clobenpropit inhibited tumor growth and enhanced apoptosis in combination with gemcitabine by up-regulation of E-cadherin and down-regulation of Zeb1 in Panc-1 xenograft mouse.
CONCLUSION: Clobenpropit enhanced anti-tumour effect of gemcitabine in pancreatic cancer cells through inhibition of epithelial-mesenchymal transition process.

P112 INSULIN-LIKE GROWTH FACTOR-I RECEPTOR AS A CANDIDATE FOR A TARGETING MOLECULE IN HUMAN PANCREATIC ADENOCARCINOMA HAVING A MUTATED K-RAS

Y. Adachi[1,*], Y. Matsunaga[1], H. Yamamoto[1], K. Nosho[1], K. Akino[2], H. Suzuki[1], Y. Arimura[1], T. Endo[2], Y. Kato[2], Y. Shinomura[1]. [1]*First Department of Internal Medicine, Sapporo Medical University,* [2]*Department of Internal Medicine, Sapporo Shirakaba-dai Hospital, Sapporo, Japan*

INTRODUCTION: Insulin-like growth factor-I receptor (IGF-IR) signaling is required for tumorigenicity and progression of human malignancies, including human pancreatic adenocarcinoma. We have previously reported successful therapy for several gastrointestinal carcinomas using recombinant adenoviruses expressing dominant negative IGF-IR (IGF-IR/dn, Ad-IGF-IR/dn). Mutation (MT) in k-ras plays important roles in both the progression and the resistance for anti-EGFR therapy in gastrointestinal cancers and is detected in around 80% of pancreatic cancer.
AIMS&METHODS: In this study, we sought to evaluate the effect of IGF-IR targeting therapy for human pancreatic adenocarcinoma with k-ras MT. We assessed the effect of IGF-IR blockade on proliferation, survival, and signal transduction in several pancreatic cancer cell lines with or without k-ras MT. Combination effects of anti-IGF-IR and chemotherapy were studied. Then IGF-IR blockades were evaluated in the treatment for pancreatic cancer xenografts in nude mice. To block IGF-IR signals, we used an Ad-IGF-IR/dn and a monoclonal antibody for IGF-IR.
RESULTS: IGF-IR blockades suppressed proliferation and tumorigenicity. Targeting for IGF-IR inhibited survival by itself and up-regulated chemotherapy (5-FU and gemcitabine) induced apoptosis. Anti-IGF-IR blocked autophosphorylation of the receptor and the downstream signals. Moreover, the combination of anti-IGF-IR and chemotherapy was effective against tumors on mice. The effect of IGF-IR blockade was not influenced by the MT stasis of k-ras. IGF-IR targeting reduced peritoneal dissemination and prolonged survival of k-ras mutated tumor bearing mice. The drug did not affect on neither murine body weight nor blood concentrations of glucose, insulin, and IGFBP-3.
CONCLUSION: IGF-IR might be a good molecular therapeutic target for human pancreatic adenocarcinomas even if k-ras is mutated.

P113 ASSESSMENT OF GLUCOSE TOLERANCE, INFLAMMATORY CYTOKINES AND ENDOTHELIAL DYSFUNCTION IN PATIENTS WITH CHRONIC PANCREATITIS AND NEWLY DIAGNOSED PANCREATIC CANCER

A. Gasiorowska[1,*], R. Talar-Wojnarowska[1], A. Kaczka[1], A. Borkowska[2], L. Czupryniak[2], E. Małecka-Panas[1]. [1]*Department of Digestive Tract Diseases,* [2]*Diabetology and Metabolic Diseases Department, Medical University of Lodz, Lodz, Poland*

INTRODUCTION: Patients with chronic pancreatitis (CP) and pancreatic cancer (PC) often demonstrate abnormal glucose metabolism. The mechanism of the association between diabetes and these diseases is elusive but is known to results in metabolic, hormonal and immunological alterations that influence tumor growth.
AIMS&METHODS: The aim of the study was to identify the differences in cytokines and parameters of endothelial dysfunction and observe their correlations with the glycemic status in patients with CP and PC. A total of 45 patients were included in the present investigation, 27 with CP and 18 with PC. In addition, the study included 13 age- and body weight-matched healthy subjects served as controls. All subjects underwent oral glucose tolerance test (OGTT) with plasma glucose and insulin measurements. HOMA index and fasting plasma adiponectin, TNF-alfa, interleukin-6 (IL-6), interleukin-1beta (IL-1b), E-selectin, thrombomodulin, adhesion molecules ICAM and VCAM, and endothelin-1 were assessed.
RESULTS: PC and CP patients as compared with controls had significantly greater plasma adiponectin (13292 and 12227 vs 5408 ng/ml; $p<0.0003$), TNF-alfa (22.1 and 23.1 vs 13 pg/ml; $p<0.0002$) and IL-6 (6.6 and 7.3 vs 3.3 pg/ml; $p<0.0001$). Moreover there was significantly higher concentration of ICAM (931 and 492 vs 290 ng/ml; $p<0.005$) and VCAM (1511 and 1080 vs 840 ng/ml; $p<0.01$) in PC and CP patients. The concentration of endothelin-1 was lower in pancreatic diseases compare with healthy (1.81 and 1.7 vs 3.2 pg/ml; $p<0.03$). According to OGTT we diagnosed diabetes or impaired glucose tolerance in 12 patients (44%) from CP group and 5 (28%) from PC group. In the PC and CP patients insulin resistance, as assessed with HOMA was similar with the control group. When PC and CP patients with and without diabetes were considered separately, there was no difference in adiponectin, cytokines and parameters of endothelial dysfunction. No significant differences between serum cytokines and age, gender, BMI, smoking status, and clinical data of patients with pancreatic diseases have been found.
CONCLUSION: These data demonstrate that endothelial dysfunction is present in patients with PC and CP. Moreover, despite absence of insulin resistance, CP and also PC subjects present with clinical markers of subclinical inflammation. Changes in adiponectin, inflammatory cytokines and endothelial dysfunction in patients with CP and PC are not likely related to endocrine disorders.

P114 A CELL AUTONOMOUS EGFR-NFATC1 LOOP PROMOTES ACINAR TO DUCTAL METAPLASIA IN PANCREATIC CARCINOGENESIS

G. Singh[1,*], N. Chen[2], L. Regul[2], E. Glesel[2], S. Baumgart[2], S. K. Singh[2], A. König[2], K. Reutlinger[2], B. Gissel[2], T. M. Gress[2], V. Ellenrieder[2]. [1]*Gasteroentrology, Philipps University of Marburg,* [2]*Gastroenterology, Philipps university of Marburg, Marburg, Germany*

INTRODUCTION: Recent evidence has shown a crucial role for EGFR activation in $Kras^{G12D}$ -driven pancreatic carcinogenesis. However, the key transcription pathways conferring EGFR signaling in early tumorigenesis are enigmatic.
AIMS&METHODS: To define signaling networks in EGFR driven ADM formation *in vitro* and *in vivo*. $Kras^{G12D}$ mice strains with pancreas specific differential NFATc1 activation ($Kras^{G12D}$-c.n.NFATc1 and $Kras^{G12D}$-NFATc1$^{fl/fl}$) were challenged by chronic pancreatitis. Acinar cells were isolated from $Kras^{G12D}$ or $Kras^{G12D}$-NFATc1$^{fl/fl}$ mice and treated with EGF (20ng/ml). Pancreata and acinar cell explants were analysed by IHC, RT-PCR and immunoblot. ChIP-seq and microarray analysis were performed to identify NFATc1 target genes and co-immunoprecipitation was carried out to identify NFATc1 transcription partners.
RESULTS: We identified a cell-autonomous EGFR-NFATc1 loop in ADM formation. Furthermore, genetic depletion of NFATc1 reduced EGFR expression and signaling and thwarted ADM formation in $Kras^{G12D}$ mice, even in context of chronic inflammation. Mechanistically, EGFR induces NFATc1 and c-Jun transcription complex formation and subsequent Sox9 promoter induction, a key step in ADM formation.
CONCLUSION: Our study uncovers a cell-autonomous EGFR-NFATc1 signaling loop which is required for pancreatic cancer initiation.
Disclosure of Interest: None Declared
Keywords: ADM, EGFR, NFATc1

P115 COMPARISON OF THERAPEUTIC EFFICACY BETWEEN FULL-DOSE GEMCITABINE-BASED CONCURRENT CHEMORADIOTHERAPY (CCRT) AND 5-FLUOROURACIL-BASED CCRT IN LOCALLY ADVANCED PANCREATIC CANCER

H. Kang[1,*], T. G. Oh[1], M. J. Chung[1], J. Y. Park[1], S. W. Park[1], S. Y. Song[1], J. B. Chung[1], S. Bang[1]. [1]*Division of Gastroenterology, Department of Internal Medicine and Yonsei Institute of Gastroenterology, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Concurrent chemoradiotherapy (CCRT) is a standard therapeutic option for managing locally advanced pancreatic cancer (LAPC). Although 5-fluorouracil (5-FU) or gemcitabine are recommended as the reference chemotherapeutic agent for CCRT, the optimal dosage for CCRT is still controversial.
AIMS&METHODS: The aim of this study was to compare the therapeutic efficacy and tolerability of full-dose gemcitabine based CCRT (GEM-CCRT) and low dose 5-FU based CCRT (5FU-CCRT) for LAPC. From January 2006 to March 2013, 110 patients with LAPC who received GEM-CCRT (n=90) or 5FU-CCRT (n=20) were included for retrospective analysis. GEM-CCRT included full-dose weekly gemcitabine monotherapy (1000mg/m^2) or combination therapy with cisplatin (70mg/m^2). 5FU-CCRT treated with radiosensitizing low dose of bolus 5-FU (500mg/m^2, weekly) plus leucovorin (20mg/m^2). Concurrent radiotherapy targeted the primary tumor with 5 to 10 mm margin without regional lymph node irradiation. One month after completion of CCRT, response evaluation was conducted by computed tomography scan.
RESULTS: GEM-CCRT had more advanced T-stage at the time of diagnosis (T4 - 86.7% versus 60.0%; $p = 0.005$). Objective response rate (ORR) and disease control rate (DCR) was significantly higher for GEM-CCRT than 5FU-CCRT (ORR – 32.6% versus 5%; $p = 0.013$; DCR – 79.8% versus 50.0%; $p = 0.006$). Both groups showed similar loco-regional control rate (92.2% versus 85.0%; $p = 0.362$) but distant metastasis rate was higher in 5FU-CCRT (17.8% versus 45.0%; $p = 0.017$). Grade 3 or higher neutropenia (34.4% versus 10%; $p = 0.031$) and thrombocytopenia (21.1% versus 0%; $p = 0.021$) was more frequent in GEM-CCRT. The subgroup of GEM-CCRT patients who received gemcitabine monotherapy showed no significant differences in toxicity rate compared with 5FU-CCRT (all $p > 0.05$).
CONCLUSION: Full-dose gemcitabine based CCRT seems more effective on initial local and distant control of LAPC than bolus 5-FU based CCRT. With cautious monitoring on hematologic toxicities, GEM-CCRT can be tolerably conducted. Considering that distant metastasis is one of treatment failure pattern in CCRT of LAPC, full-dose gemcitabine CCRT should be regarded as the first line treatment.

P116 RECURRENCE AFTER SURGERY FOR IPMN WITH LOW (LGD) TO HIGH-GRADE DYSPLASIA (HGD)

J. Perinel[1,*], ADHAM M.[2]. [1]*hospices civils de lyon,* [2]*edouard herriot hospital, LYON, France*

INTRODUCTION: Background: IPMN offers a chance to cure when surgery is performed at an early stage. Nonetheless this may lead to over treating patients with benign lesion.
Objective: To evaluate the long-term outcome of pancreatic resection for IPMN with LGD to HGD.
AIMS&METHODS: Retrospective review of prospectively collected data on all patients operated for IPMN. All 147 patients who had pancreatic surgery between 1994 - 2011 were reviewed. Among them 87 had IPMN with LGD to HGD. All patients had frozen section of pancreatic cut surface and extension of resection was done when needed. There were 41 men and 48 women with a mean age of 60.2±13.1. Surgery included 38 PP-pancreaticoduodenectomies, 21 distal pancreatectomie, 11 PP-total pancreatectomie, 4 duodenum preserving pancreatic head resection, 7 duodenum preserving total pancreatectomies and 6 central pancreatectomies. Postoperative course was uneventful in 41%. Severe complications occurred in 24% including 1% mortality at 90-day. Pathological examination showed LGD in 39 cases, and HGD in 48 cases. All had R0 resections except 3 with LGD on pancreatic margin. 5 patients had incidental NET and 28 had associated chronic pancreatitis. In one case, Pan-In IA was also present. IPMN was a main duct type in 9 cases, a branch duct in 26 cases and a combined duct type in 52 cases. All patients had yearly MRI follow-up (CT-scan before 1998). During follow-up 8 patients died from causes other than pancreatic neoplasms one from PPH, 2 from colorectal cancer, 4 from cardiovascular causes and 1 from cerebrovascular accident.
RESULTS: During follow-up 9 (10.3%) patients had radiological recurrence. Initial pathologies were: Duct types = 3 BD, 1 MD & 5 CD; histology = 2 LGD & 7 HGD. At recurrence duct types were 2 BD, 2 MD, 4 CD and 1 patient died from infiltrating unresectable carcinoma. 2 patients with IPMN recurrence are currently under surveillance. 6 patients had surgery, 5 were confirmed on pathological examination (1 LGD, 3 HGD, 1 Adenocarcinoma pT3) and one was Pan-In IA. DFS was 60±107 months.
CONCLUSION: In our experience, 10% of patients who had pancreatectomy for IPMN with LGD to HGD will present recurrence. Our data suggests that long-term close follow-up is mandatory. Despite initial benign lesion, patient may also develop pancreatic carcinoma.

P117 VISCERAL ABDOMINAL OBESITY AND PANCREATIC CANCER RISK: A CASE CONTROL STUDY

K. Hosono[1,*], Y. Kato[1], Y. Fujita[1], Y. Sekino[1], K. Kubota[1], A. Nakajima[1]. [1]*Gastroenterology, YOKOHAMA CITY UNIVERSITY SCHOOL OF MEDICINE, Yokohama, Japan*

INTRODUCTION: Recent evidence indicates that obesity and related metabolic abnormalities are associated with increased incidence for a number of cancers including pancreas. However, there are few studies addressing the association between measured values of visceral fat accumulation and pancreatic cancer.
AIMS&METHODS: We assessed the relation between visceral abdominal obesity and pancreatic cancer risk in a Japanese case-control study. Following ethical approval, 149 patients with pancreatic cancer (84 men and 65 women) who had undergone staging computed tomography (CT) between 2006 and 2012 were identified from our database. Abdominal adipose tissue distribution for these 149 patients was compared with that of 547 healthy control subjects (312 men and 235 women), standardized for age, sex, and body mass index. Visceral and subcutaneous adipose tissue volumes were calculated from a single axial CT slice at the level of the umbilicus. A two-sample t test for the difference in volume between the two groups was used. The associations between visceral adipose tissue and pancreatic cancer were estimated with adjusted odds ratio and 95% confidence intervals (CI).
RESULTS: The visceral fat areas (VFA) of pancreatic cancer group were significantly larger than that of controls (104.3 ± 33.8 cm^2 and 75.7 ± 49.4 cm^2, P = 0.012). Compared with participants who had VFA of less than 100 cm^2, the odds ratio for pancreatic cancer was 1.18 (95% CI, 1.00-1.39) for VFA of more than 100 cm^2. There were no statistically significant difference in subcutaneous fat areas (136.8 ± 70.3 cm^2 and 111.3 ± 59.3 cm^2, P = 0.08).
CONCLUSION: Patients with pancreatic cancer have a relatively greater proportion of abdominal visceral adipose tissue compared with controls. Our study adds further evidence to a positive link between visceral abdominal obesity and risk of pancreatic cancer.

P118 JASPAC 03: A PHASE II STUDY OF S-1 PLUS LEUCOVORIN AS FIRST-LINE TREATMENT FOR METASTATIC PANCREATIC CANCER

M. Matsuyama[1,*], A. Todaka[2], S. Nakamori[3], M. Ikeda[4], J. Furuse[5], H. Hara[6], T. Okuno[7], T. Okusaka[8], H. Ishii[1], T. Yamanaka[4], N. Boku[9], A. Fukutomi[2]. [1]*Cancer Institute Hospital of JFCR, Tokyo,* [2]*Shizuoka Cancer Center, Shizuoka,* [3]*Osaka National Hospital, Osaka,* [4]*National Cancer Center Hospital East, Kashiwa,* [5]*Kyorin University School of Medicine, Tokyo,* [6]*Saitama Cancer Center, Saitama,* [7]*Kobe University School of Medicine, Kobe,* [8]*National Cancer Center Hospital, Tokyo,* [9]*St. Marianna University School of Medicine, Kawasaki, Japan*

INTRODUCTION: S-1 is an oral fluoropyrimidine and one of the current standards for metastatic pancreatic cancer (mPC) in Japan. Leucoborin (LV) is a calcium folinate and enhances cytotoxicity of fluorouracil. Combination of S-1 plus leucovorin showed promising activity for metastatic colorectal cancer.[1]
AIMS&METHODS: We designed a single-arm phase II study to evaluate the efficacy and toxicity of S-1 plus LV as first-line therapy in patients with mPC. Patients with an age of 20-75 years, ECOG PS of 0-1, measurable lesion, and adequate organ function were eligible. S-1 (40 to 60mg based on body-surface area) and LV (25mg) were administered orally twice a day for one week, repeated every 2 weeks until disease progression or unacceptable toxicity. The primary endpoint was response rate (RR) according to the RECIST ver.1.1. Secondary endpoints were progression free survival (PFS), overall survival (OS), and toxicity (CTCAE ver.4.0). Planned sample size of 30 provided 85% power to reject the RR of 20% under the expectation of 40% with one-sided alpha of 0.1.
RESULTS: Between August 2011 and May 2012, 32 patients were enrolled from 8 centers in Japan. Of 31 eligible patients, the median age was 69 years (range, 42-75); male/female 21/10; advanced/recurrence 23/8; ECOG PS 0/1 17/14. Six patients achieved partial response and 11 patients showed stable disease. RR was 19.4% (80%CI, 10.5-31.5%) and disease control rate was 54.8% (41.8-67.3%). With a median follow-up time of 14.2 months, the median PFS and OS were 2.8 and 9.0 months, respectively. The most common grade 3 or 4 adverse events were anorexia (6.5%), fatigue (6.5%), diarrhea (6.5%), mucositis oral (6.5%) and leukopenia (6.5%).
CONCLUSION: The combination of S-1 and LV was well-tolerated but showed modest activity for mPC in the first-line setting. Clinical trial information: UMIN000004958

P119 IDENTIFICATION OF RISK FACTORS THAT LEAD TO MALIGNANT TRANSFORMATION OF INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS: A COHORT ANALYSIS OF 91 PATIENTS

N. Bochon[1], S. Clasen[2], N. Malek[1], R. R. Plentz[1,*]. [1]*Department of Internal Medicine I,* [2]*Department of Radiology, Medical University Hospital Tuebingen, Tübingen, Germany*

INTRODUCTION: Intraductal papillary mucinous neoplasms (IPMN) are common cystic lesions of the pancreas. IPMNs are considered as premalignant precursors of pancreatic ductal adenocarcinoma (PC). The management of IPMNs is still under debate.
AIMS&METHODS: Our analysis was designed to determine new predictive risk factors for malignant IPMNs. We retrospectively reviewed all patients with radiologically diagnosed IPMNs in a period of November 2005 to August 2012. Comparisons were made between IPMNs with and without malignancy.
RESULTS: A total of 91 patients were analyzed with IPMN during a 7-year period. 15% of the patients developed malignant tumor of the pancreas. The proportion of women was significantly higher in the IPMN group (41.6%) compared to the IPMN+PC group (21.4%). In both groups, the mean age at diagnosis was about 67 years. The mean size of the neoplastic IPMN was 29.6mm. Body mass index (BMI) was higher in the IPMN group (25.1) compared to the IPMN+PC group (22.9). Patients with IPMN+PC were significantly more likely to have diabetes (50%), pain, jaundice and diarrhea (35.7%). The tumor localization was 64.3% in the pancreatic head. Main duct type IPMN was present in 21.4% and a branch duct type IPMN in 28.6%.
CONCLUSION: IPMNs are being diagnosed with increasing frequency. Identification of IPMNs with malignant transformation is challenging and a general resection controversial. Our data analysis revealed the following potential risk factors: Male sex, IPMN lesions> 20mm, low BMI and diabetes.

P120 THE MANAGEMENT OF PATIENTS WITH BRANCH-DUCT TYPE INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS BASED ON INITIAL EUS FINDINGS.

T. Osoegawa[1,*], H. Kubo[2], K. Nakamura[1], A. Aso[1], Y. Niina[1], T. Oono[1], N. Sawamura[1], E. Ihara[1], H. Igarashi[1], T. Ito[1], M. Osada[3], S. Aishima[3], M. Tanaka[4], R. Takayanagi[1]. [1]*Medicine and Bioregulatory Science, Graduate School of Medical Sciences, Kyushu University,* [2]*Gastroenterology, Social Insurance Nakabaru Hospital,* [3]*Anatomic Pathology, Pathological Sciences,,* [4]*Surgery and Oncology, Graduate School of Medical Sciences,Kyushu University, Fukuoka, Japan*

INTRODUCTION: Accumulated evidence has been shown that branch-duct type intraductal papillary mucinous neoplasm (BD-IPMN) usually has a benign clinical behavior unlike main-duct type IPMN (MD-IPMN). However, there are still some cases of BD-IPMN, which has morphological changes afterward and results in having a malignant clinical behavior. It is very important to differentiate malignant BD-IPMN from benign BD-IPMN, while it has yet to be determined. The objectives of the present study were to determine what initial EUS findings were related to a malignant behavior in the future.
AIMS&METHODS: A total of 43 patients with BD-IPMN were enrolled in this study. The EUS findings including tumor location, tumor size, main pancreatic duct (MPD) size, presence of mural nodule (MN) and chronic pancreatitis were initially evaluated and those EUS features were evaluated again over a year later. The significant morphological changes of BD-IPMN could be useful as indicator of developing a malignant behavior in the future. The morphological changes were defined as follows; increased tumor size by more than 2 mm/year, increased size of MPD, appearance of newly MN or increased size of MN. The patients were categorized into two groups; morphologically changed group (CG) and non-changed group (NCG). By comparing two groups, we investigated the initial EUS findings that were associated with morphological changes of BD-IPMN.
RESULTS: Tumor growth more than 2 mm/year was seen in 14 patients. Increase in MPD was observed in 10 patients. Appearance of newly MN or increased size of MN was observed in 10 patients. Some patients overlapped the morphological changes above. As a result, 25 patients were in CG, while the remaining 18 patients were in NCG. In statistical analysis, the initial EUS findings including MPD dilation (P=0.029) and existence of MN (P=0.031) are significantly associated with morphological changes of BD-IPMN later. However, other EUS findings such as tumor location, tumor size and chronic pancreatitis were not related.
CONCLUSION: The initial EUS findings of MPD dilation and presence of MN might be related to developing a malignant clinical behavior in the future. EUS could be a useful modality of choice to differentiate malignant BD-IPMN from benign BD-IPMN. BD-IPMN with MPD dilation or MN should be followed up carefully by EUS.

P121 EUS IS MANDATORY FOR DETERMINATION OF PANCREATIC CANCER UNRESECTABILITY

V.I. Egorov[1,*], R. Petrov[1], E. Solodinina[2], G. Karmazanovsky[3], N. Starostina[3], N. Kuruschkina[2]. [1]*Surgical Oncology,, Ostroumov 14th City Hospital, Sechenov First State Medical University,* [2]*Endoscopy,* [3]*Radiology, Vishnevsky Institute of Surgery, Moscow, Russian Federation*

INTRODUCTION: The salient indication of pancreatic cancer (PC) unresectability is superior mesenteric artery (SMA) and celiac artery (CA) encasement, indicating arterial invasion. Computed tomography (CT) is the gold standard for the evaluation of PC resectability.
AIMS&METHODS: Radiology data were compared with the findings from 51 standard, 58 extended and 17 total pancreaticoduodenectomies; 9 distal resections with CA excision; and 28 palliations for PC. The survival of 11 patients with controversial CT and EUS data with regard to arterial invasion, after R0/R1 procedures (false-positive CT results, Group A), was compared to survival after eight R2 resections (false-negative CT results, Group B) and after 12 bypass procedures for locally advanced cancer (true-positive CT results, Group C)
RESULTS: In all of the cases in group A, operative exploration revealed no arterial invasion, as predicted by CT. The one-year survival in Group A was 88.9%, and the two-year survival was 26.7%, with a median follow-up of 22 months. One-year survival was not attained in groups B and C, with a significant difference in survival (Pa-b = 0.0029, Pb-c = 0.003).
CONCLUSION: Arterial encasement on CT does not necessarily indicate arterial invasion. Whenever PC is considered unresectable, endoUS should be used. In patients with controversial CT and EUS data for peripancreatic arteries involvement radical resection might be possible, providing survival benefit as compared to R2–resections or palliative surgery
Disclosure of Interest: None Declared

ENDOSCOPY AND IMAGING I – Poster Area

P122 L-MENTHOL SPRAYED ON THE GASTRIC MUCOSA AFFECTS ENDOSCOPIC FINDINGS.

A. Mori[1,*], M. Nozaki[1], S. Hayashi[1], A. Yoshida[1], N. Oohashi[1]. [1]*Ichinomiya Nishi Hospital Gastroenterology, Ichinomiya, Japan*

INTRODUCTION: L-menthol (LM) is useful as a safe antiperistaltic drug for esophagogastroduodenoscopy (EGD) to identify small gastric lesions. However, we realized that LM sprayed on the gastric mucosa frequently caused the specific change, annular and/or reticular edematous thickening, of the distal gastric mucosa.
AIMS&METHODS: Our aims were to evaluate whether LM causes the specific change and whether the atrophic gastritis affects it, and to investigate the impact on the diagnosis of gastric lesions. To enhance the minimal change of the gastric mucosa, indigocarmine (IC) was added to LM. A total of 96 patients scheduled to undergo EGD were randomly assigned to receive LM solution (160mg of 0.8% LM added 2.5ml IC) (n=48; LM group) or decuple diluted IC solution without LM (n=48; nonLM group). Each solution was sprayed into the distal gastric mucosa. We compared the incidence of the specific change on the gastric mucosa, the prevalence of the atrophic gastritis and the difference in endoscopic findings of several gastric lesions between the groups. Additionally, in some gastric lesions that were detected in non LM group, we resprayed LM solution after the study and observed the change induced in them.
RESULTS: The annular-reticular-like mucosal change appeared immediately after administration of LM solution. The change was observed in 71% (34/48 subjects) of LM group compared with 13% (6/48 subjects) of non LM group ($P < 0.01$). The prevalence of the atrophic gastritis did not differ significantly difference between the groups. In the non LM group, the change was observed in 15% (5/33 subjects) of subjects with atrophic gastritis compared with 7% (1/15 subjects) of subjects without atrophic gastritis (P=0.72), whereas in the LM group, the change was observed in 84% (27/32 subjects) of subjects with atrophic gastritis compared with 44% (7/16 subjects) of subjects without atrophic gastritis ($P < 0.01$). The incidence of gastric lesions (hyperplastic polyps, adenomas, cancers, erosions / ulcers) detected in the study did not differ significantly difference between the groups. Most of early gastric cancers, erosions and ulcers became well-demarcated after administration of LM in non LM group. Gastric peristalsis was significantly suppressed in LM group ($P < 0.01$).
CONCLUSION: LM changes a superficial gastric mucosa into an edematous mucosa and the change was more exposed in the atrophic gastric mucosa and less in the pathological lesions. LM may be useful not only to suppress the peristalsis but also to detect easily the demarcation of pathological gastric lesions.

P123 ENDOSCOPIC OBSERVATION USING MONOCHROME MODE IS USEFUL FOR OBSERVING VASCULAR LESIONS COMPARED WITH THE CURRENT NBI SYSTEM WITH A DISTANT VIEW

A. Imagawa[1,*], H. Terasawa[1], Y. Yoshida[1], K. Takeuchi[1], H. Sakae[1], H. Endo[1], H. Yasuhara[1], H. Jinno[1], E. Kaji[1], H. Hata[1], A. Moriya[1], M. Nakatsu[1], M. Ando[1]. [1]*Gastroenterology, MITOYO GENERAL HOSPITAL, Kan-onji, Japan*

INTRODUCTION: Magnified observation of detailed mucosal structure and blood vessels using the narrowband imaging (NBI) system has become very common in recent years. Implementing the NBI system requires time and cost,

however. On the other hand, a clear image can be obtained of vascular lesions using monochrome mode, which is an endoscopic observation function originally featured in the LUCERA system (CV-260, Olympus co., Tokyo).
AIMS&METHODS: The aim of this study was to evaluate the usefulness of endoscopic observation methods using monochrome mode for vascular lesions compared with the current NBI system. From May 2009 to September 2012, 14 cases (VE: vascular ectasia, 8 cases; GAVE: gastric antral vascular ectasia, 2 cases; RC: radiation colitis, 4 cases) were enrolled in this study. For these cases, 28 images were taken (close view: 14 images, distant view: 14 images) in the same situation using each of normal mode, NBI mode and monochrome mode (MONO mode). Normal mode observation was defined at 5 points. A total of 84 images (28 images for each of three modes) were evaluated by 15 trainee doctors with little experience of endoscopy, on a scale of one to ten, for each of a: Recognition of the lesion, b: Observation of the vessel and c: Observation of the background mucosa.
RESULTS: The scores for NBI mode (a: 5.37, b: 5.50, c: 5.06) and MONO mode (a: 5.33, b: 5.44, c: 5.02) showed almost the same evaluation results, and they were better than in normal mode. In the close view, the scores for NBI mode were better than with MONO mode for recognition of the lesion (a: 5.72 vs. 5.43, $p < 0.05$) and observation of the background mucosa (c: 5.51 vs. 5.17, $p < 0.05$). However, although there was no significant difference in the distant view, better results were obtained for all factors with MONO mode (a: 5.23, b: 5.17, c: 4.86) compared with NBI mode (a: 5.03, b: 5.01, c: 4.62). The brightness of the field of view obtained using MONO mode, even in the distant view, was considered to be a reason for the results. Moreover, MONO mode was effective for observation of remaining blood vessels after APC ablation for GAVE and RC, as an evaluation of endoscopic treatment.
CONCLUSION: Monochrome mode is convenient and useful in endoscopy for observation of vascular lesions.

P124 PROB-BASED CONFOCAL LASER MICROSCOPY (PCLE) FOR THE DIAGNOSIS OF DYSPLASTIC BARRETT'S ESOPHAGUS AND IMMEDIATE RADIOFREQUENCY (RF) TREATMENT

B. Hotayt[1,2,*], G. Rahmi[1], E. Samaha[1], B. Filoche[3], J. M. Canard[1], C. Cellier[1]. [1]*Hopital Euopeen Georges Pompidou, Paris, France,* [2]*MH Hospital- Lebanon, Beirut, Lebanon,* [3]*CHU LILLES, Lilles, France*

INTRODUCTION: The miniprobe confocal endomicroscopy (MCE Cellvizio, Mauna Kea Technologies, France) diagnoses in vivo Barret's Esophagus (BE) dysplasia that allows immediate treatment by radiofrequency (RF) with BAARx system (Covidien, U.S.).
AIMS&METHODS: Monocentric retrospective study has been realised from March 2011 to July 2012. About 23 pCLE examinations for 14 patients with known BE has been done. 11 of these examinations,in whom pCLE was followed by RF treatment in the same session, were selected for the final analysis. The probe was passed in the operating channel and placed in contact to the area to be analyzed. This area was previously analyzed with the white light and NBI (Narrow Band Imaging, Olympus GIF 180). For pCLE, glandular architecture, the appearance of cells and vascularization were studied after injection of 2.5 ml of fluorescein IV. Target biopsies on suspected areas for dysplasia allowed a retrospective analysis of concordance.
RESULTS: BE was not nodular in all cases. The average classification of C5M6, follow up to 3.6 years (1-9 years). and age was 58 years. All patients (19H) were under proton pomp inhibitor. 8 patients had been already treated by circumferential RF (HALO 360) and pCLE was performed as a control 2 months before any additional focal treatment. The pCLE exam showed normal cardiac mucosa in 1 patient, intestinal metaplasia IM in 1 patient, LGD in 2 patients, HGD in 4 patients and non-classified dysplasia in 3 patients. No complication related to pCLE was reported. Only the ''normal'' classified exam has not been treated. One RF related complication was reported, retro-sternal pain that developped in one patient but resolved within 48 hours. Assessment of concordance with histology has not been possible in 2 cases (biopsy not performed). The first corresponded to an aspect of intestinal metaplasia and the second to a known HGD. Histological analysis showed a concordance with the MCE in 8 of 9 cases. The discordant case corresponded to a suspicion of non-classified dysplasia pCLE but was not confirmed by histology (which showed intestinal metaplasia). The case of normal mucosa at the gastroesophageal junction cardia was confirmed by histology.
CONCLUSION: The pCLE allows in vivo diagnosis of Barrett's esophagus; And the good concordance with the histology provide an argument for the possibility of the treatment during the same procedure, thus avoiding multiple biopsies and complications from repeated general anesthesia for the patient.

P125 PILOT STUDY OF TRANSESOPHAGEAL ENDOSCOPIC PERICARDIAL RESECTION BY SUBMUCOSAL ENDOSCOPY

B. Liu[1,*], J. Song[1], L. Kong[1]. [1]*Department of Gastroenterology and Hepatology, THE SECOND HOSPITAL OF HARBIN MEDICAL UNIVERSITY, Harbin, China*

INTRODUCTION: The mediastinal space could be safely accessed by submucosal endoscopy with the mucosal flap safety valve (SEMF) technique. The NOTES approach provides potential access to central structures for minimally invasive surgery.
AIMS&METHODS: Aim of the study is to evaluate the technical feasibility of transesophageal endoscopic pericardial resection by using submucosal endoscopy technique. Acute animal experiment was performed with 3 Beagle dogs. A longitudinal mucosal incision was made on esophageal right wall approximately 25 cm from the incisors. A submucosal tunnel was created at least 5 cm distal to the mucosal incision. Then a myotomy was performed inside the submucosal space, enlarging the incision for insertion of a cap-fitted endoscope and establishing the mediastinum access with IT knife. The mediastinum was endoscopically accessed through the myotomy site along the trachea. After crossing the bifurcation of trachea, pericardium was exposed and pericardial window was created with a hook knife. Then pericardial resection was performed with an IT knife by circumference incision. After the operation, resected pericardium was removed, the myotomy site of the esophageal was covered by the tunnel mucosal flap and the mucosal entry site was closed with clips. A necropsy was performed to study the esophagus, mediastinum, pericardial space and resected locations on the pericardium after the procedure immediately.
RESULTS: Transesophageal access to mediastinum and heart by submucosal endoscopy was achieved in all 3 dogs. Pericardial resection was successfully performed in 2/3 dogs. One dog died during the procedure because of inadvertent injury of pulmonary veins, the other 2 dogs were euthanized immediately after the procedure. The esophageal incision was closed tightly by clips, the trace of endoscopic access could be observed, pericardial space and resected locations on the pericardium were normal in appearance.
CONCLUSION: Transesophageal endoscopic pericardial resection by submucosal endoscopy is feasible technically. It gives us a new choice to the minimally invasive surgery of central structures in mediastinal space. The further survival study and familiarity with local anatomy are required.

P126 TUMOR LOCALIZATION USING MAGNETIC MARKING CLIP DURING LAPAROSCOPIC SURGERY FOR GASTRIC SUBMUCOSAL TUMOR : A PILOT STUDY

C. D. Kim[1,*], J. S. Lee[1], H. J. Chun[1], H. S. Choi[1], E. S. Kim[1], B. Keum[1], Y. T. Jeen[1], H. S. Lee[1], S. H. Kim[1], J. M. Lee[1]. [1]*Division of Gastroenterology and Hepatology, Korea University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: It is difficult to locate a tumor simply and correctly during laparoscopic surgery for submucosal tumor (SMT). Various methods such as intraoperative sonography, intraoperative endoscopy, etc, are performed in localization gastrointestinal tumor for laparoscopic surgery. However there are limitations of methods, such as discomfort for surgeon, complexity. To overcome these limitation, we devised a simple marking clip with magnet to locate a tumor.
AIMS&METHODS: This study enrolled 11 patients undergoing laparoscopic wedge resection for SMT. Enrolled criterias were intraluminal growing and suspicious of malignancy. We devised 10mm sized ring type magnet (**outdiameter:D10mm, indiameter:4mm, thickness:3mm**, **maximal magnetic force:2660G**), which was coated with silicon and fixed to endoclip using 3-0 nylon. A magnetic marking clip was applied on the center of lesion during preoperative esophagogastroduodenoscopy. During surgery, magnetic body hanged with long thread which was inserted through laparoscopic trocar, was used to find intragastric lesion which marked by magnetic clip. We analized tumor detection rate, detection time, proximal & distal margin from lesion and complication.
RESULTS: In 7 patients, tumors located on the anterior wall of stomach, and 4 located on the posterior wall of stomach. Tumor size ranged from 12.0mm to 18.0 mm. Magnetic marking clips were successfully detected in all 11 patients. The time required for detection ranged from 20 to 85 sec. The resected margin from lesion ranged from 5 to 30 mm. 8/12 of pathology was confirmed GIST, 3/12 was leiomyoma, 1/12 was schwanoma. None of our patients experienced complication s from this marking technique.
CONCLUSION: Magnetic marking clip method was simple and convenient for surgeon, and showed good results for accuracy of tumor localization, and detection rate. Also complication associated with method was not shown. Therefore the magnetic marking clip method may be useful for tumor site detection during laparoscopic SMT wedge resection.

P127 CHARACTERISTICS OF GASTRODUODENAL EROSIVE AND ULCERATIVE LESIONS IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

E. Kostiakova[1,*]. [1]*University of Medicine, Smolensk, Russian Federation*

INTRODUCTION: Chronic obstructive pulmonary disease (COPD) as a systemic disease has an impact on various systems and organs including gastrointestinal tract. Erosive and ulcerative lesions are accompanied by serious complications with a prognostic significance.
AIMS&METHODS: To identify clinical and endoscopic features of erosive and ulcerative lesions 75 moderate and severe COPD patients were included in the study. 50 individuals were treated with inhaled corticosteroids, 25 participants did not receive these medications. The control group covered 65 patients without COPD. Esophagogastroduodenoscopy (EGDS) was performed with endoscope Pentax EG 2990 i (Japan); biopsy was taken from the location of erosive and ulcerative lesions. Helicobacter pylori was detected morphologically and with rapid urease test.
RESULTS: 10 (13,3%) patients from the main group and 27 (41,5%) individuals from the control group complained of the epigastric discomfort, pain and nausea

(χ^2=14,25; p<0,001). Erosions were revealed in 35 (46,7%) patients from the main group (χ^2=4,16; p=0,041 compared to the control group). In 24 individuals with COPD erosions were localized in the stomach (68,6%), in 11 patients (31,4%) they were found in the stomach and duodenum (χ^2=4,66; p=0,031 compared to the control group). Ulcers were detected in 25 (33,3%) participants from the main group and in 10 (15,4%) patients from the control group (χ^2=5,98; p=0,015). In the main group stomach ulcers were observed in 9 (36%) patients, duodenal ulcers were revealed in 16 (64%) individuals (p=0,029 compared to the control group). Patients from the control group had only duodenal ulcers. Multiple ulcerative lesions (2 and more) were seen only in patients from the main group (14,7%, p=0,011 compared to the control group). Erosions (62%, p<0,001) and ulcers (44%, p=0,005) were significantly more often found in COPD patients treated with inhaled corticosteroids. Combination of the atrophic features, detected during EGDS with the i-scan SE function, erosive and ulcerative stomach lesions was disclosed in 23 (30,7%) participants from the main group and in 4 (6,2%) individuals from the control group (p<0,001). A direct correlation was revealed between inhaled corticosteroids intake and development of gastroduodenal erosions (r=+0,75, p<0,001) and ulcers (r=+0,70, p<0,001). There wasn't any confirmed link between Helicobacter pylori contamination degree and development of erosions and ulcers in COPD patients.

CONCLUSION: Erosive and ulcerative lesions in COPD patients are not accompanied by marked clinical picture and can more frequently be seen in those treated with inhaled corticosteroids.

P128 SYSTEMATIC NOTES MEDIASTINOSCOPY VS CONVENTIONAL MEDIASTINOSCOPY: A RANDOMIZED LONG-TERM SURVIVAL STUDY IN SWINE.

H. Córdova[1,*], M. Boada[2], E. Cladellas[2], A. Rodríguez-D'Jesús[1], G. Cubas[3], M. Beltrán[1], C. Rodríguez de Miguel[1], J. M. Perdomo[3], H. Uchima[1], J. LLach[1], G. Martínez-Pallí[3], J. M. Gimferrer[2], G. Fernández-Esparrach[1]. *[1]IMDiM, [2]Institut del Tórax, [3]Anestesiology Department, Hospital Clínic, Barcelona, Spain*

INTRODUCTION: Natural Orifice Transluminal Endoscopic Surgery (NOTES) mediastinoscopy through the esophagus has proven to be feasible in the animal model. However, pneumotorax is a frequent complication that could affect the outcome of the surgery. Inflammatory impact of transesophageal mediastinoscopy has never been assessed.

AIMS&METHODS: Aim: to compare the efficacy, inflammatory impact and safety of systematic transesophageal NOTES mediastinoscopy and conventional video-assisted mediastinoscopy (VAM). Methods: 24 pigs were randomly assigned to NOTES or VAM. Animals were kept NPO for 24 hours prior to procedure and pre -op antibiotics were administered. Anti-septic technique was utilized in NOTES whereas VAM was performed in sterile conditions. In NOTES group, the mediastinum was accessed through a 10 cm-submucosal tunnel in the esophageal wall. In VAM group, a transverse cervical incision was made. 30-minute mediastinoscopies were performed with identification of 7 structures (carina, right pulmonary artery, right atrium, vena cava, porcine bronchium, brachiocephalic vein, right vagus nerve). Blood samples were drawn pre and post-operatively for IL-6, IL-1beta, alfaTNF, blood cell count and RCP (1h, 8h, 24h, and 48h). Animals were survived for 7 days. Upon necropsy animals were weighted, adequacy of closure and degree of adhesions were evaluated and interleukin analysis was performed.

RESULTS: Results: 24 animals weighting 31.3+1.9 kg were included in this study (12 NOTES and 12 VAM). Mediastinoscopy was not possible in two animals (1 NOTES and 1 VAM). The mean number of identified organs and total time of surgery was not different in NOTES (6.8+2.2 and 42+7 min) vs VAM (7.7+0.5 and 45+3 min; p=ns). Intrasurgical complications were more frequent in NOTES than in VAM (7 vs 1, p=0.013) being hemorrhage the most frequent (4 and 1, respectively) (see table). 22 animals completed follow-up and 2 in NOTES group had a poor recovery. At necropsy, pathological findings were seen in 11 animals (7 NOTES and 4 VAM; p=ns) (see table). Interleukin levels, blood cell count and RCP were not related with complications.

CONCLUSION: Systematic NOTES mediastinoscopy is possible and comparable to VAM in terms of number of organs identified and inflammatory impact. However, the higher number of complications in NOTES mediastinoscopy raises concern about its potential role as a safe alternative to VAM.

P129 DETECTION RATE OF PHARYNGEAL CANCER DURING ROUTINE UPPER GASTROINTESTINAL ENDOSCOPY USING NARROW BAND IMAGING OBSERVATION: A SINGLE-CENTER EXPERIENCE

H. Nakanishi[1,*], H. Doyama[1], K. Takemura[1], Y. Takeda[1], Y. Asahina[1], Y. Kito[1], R. Ito[1], T. Hayashi[1], K. Tsuji[1], K. Tominaga[1], S. Inagaki[1], N. Yoshida[1], Y. Waseda[1], S. Tsuji[1], K. Miwa[1], Y. Kaneko[1], S. Yamada[1], T. Okada[2]. *[1]Gastroenterology, [2]General Medicine, Ishikawa Prefectural Central Hospital, Kanazawa, Japan*

INTRODUCTION: Narrow band imaging (NBI) with non-magnifying observation is useful for detecting abnormal pharyngeal lesions with quite high sensitivity. NBI with magnifying observation enables us to make a precise diagnosis, such as in distinguishing between cancerous and non-cancerous lesions. Thus, NBI including magnifying observation is very useful in detecting pharyngeal cancer at an early stage. Early detection allows for minimally invasive treatment. When NBI is used with the pharyngeal cancer high risk group, it is detected at high frequency. However it is not known how many cancerous lesions can be detected in a routine examination.

AIMS&METHODS: The aim of this study was to evaluate the detection rate of pharyngeal cancer during routine upper gastrointestinal (UGI) endoscopy using NBI. Between January 2009 and December 2012, a total of 11,050 consecutive patients underwent their first UGI endoscopy using NBI at our hospital. Primary endpoint was detection rate of the pharyngeal cancer among all patients, and the detection rate based on patients' initial purpose for the endoscopy. The purposes were divided into 5 groups as follows: screening, pharynx discomfort, surveillance after treatment of head and neck cancer (HNC), pretreatment or after treatment of esophageal cancer (EC), pretreatment or after treatment of gastric cancer (GC). Secondary endpoint was frequency of superficial cancer, in which depth of invasion was defined until subepithelial layer, and treatment procedure.

RESULTS: Detection rate of pharyngeal cancer was 0.26% (29/11,050) among all patients. The detection rate in the HNC group (9.7%, 3/31) and EC group (3.5%, 10/282) were significantly high. The rate in the screening, pharynx discomfort and GC group were 0.11% (10/8,872), 1.1% (3/265) and 0.19% (3/1,600), respectively. Overall, 38 lesions were detected, of which 25 (65.8%) in 20 patients (69.0%) were removed by endoscopic resection or surgical local resection. Pathological examination revealed that the 25 lesions were all superficial. The remaining lesions were treated with chemo and/or radiotherapy. The invasion depths of these lesions were pathologically unclear.

CONCLUSION: Pharyngeal cancers were found in not only the pharyngeal cancer high risk group, but also the screening group although the rate was low. Accordingly, we should consider the use of NBI in a routine UGI endoscopy for the early detection of pharyngeal cancer.

P130 ASSESSMENT OF STILL AND MOVING IMAGES IN THE DIAGNOSIS OF GASTRIC LESIONS USING MAGNIFYING NARROW-BAND IMAGING: MULTICENTER TRIAL, NBI-SM STUDY

H. Nakanishi[1,*], H. Doyama[1], T. Hayashi[1], Y. Shirota[2], H. Ohta[3], K. Miwa[4], H. Tsuji[5], T. Masunaga[6], S. Terasaki[7], Y. Matano[8], K. Tsuji[9], Y. Kaneko[10], S. Kaneko[11]. *[1]Gastroenterology, Ishikawa Prefectural Central Hospital, [2]Gastroenterology, Saiseikai Kanazawa Hospital, [3]Gastroenterology, Kanazawa Medical Center, [4]Gastroenterology, Kanazawa Social Insurance Hospital, [5]Gastroenterology, Kanazawa Municipal Hospital, [6]Gastroenterology, KKR Hokuriku Hospital, [7]Gastroenterology, Kanazawa Redcross Hospital, Kanazawa, [8]Gastroenterology, Komatsu Municipal Hospital, Komatsu, [9]Gastroenterology, Suzu General Hospital, Suzu, [10]Sangane Clinic, Kouta, [11]Gastroenterology, Kanazawa University Hospital, Kanazawa, Japan*

INTRODUCTION: Magnifying narrow-band imaging (M-NBI) is very useful for the accurate diagnosis of gastric cancer. In a recent trial, M-NBI including moving images was shown to be more accurate than white-light imaging for diagnosing depressed small gastric cancer [1]. However, it is uncertain whether moving M-NBI images have additional effects compared with still images.

AIMS&METHODS: To identify the additional benefits of moving M-NBI images by comparing the diagnostic accuracy of still images only with that of both still and moving images. Thirty-four endoscopists from 10 institutions participated. Still and moving M-NBI images of 40 undiagnosed gastric lesions were recorded by an expert endoscopist. Pathological examination diagnosed 21 cancerous and 19 non-cancerous. Each participant was first tested using the still images only (still test), and then tested a month later using both the still and moving images (moving test). The primary endpoint was to compare the diagnostic accuracy between the still test and the moving test. The secondary endpoint was a subgroup analysis of the characteristics of the participants, including whether or not they were board-certified by the Japan Gastroenterological Endoscopy Society, and their M-NBI experience.

RESULTS: There was no significant difference in the diagnostic accuracy between the still and the moving test (60% vs 61%). However, it was significantly lower in the still test than the moving test in the subgroup of board-certified (63% vs 67%, p=.04), and that of endoscopists who had experienced more than 200 M-NBI procedures (66% vs 69%, p<.05).

CONCLUSION: The addition of moving images to still M-NBI images did not improve the diagnostic accuracy of gastric lesions. However, moving images may have some additional diagnostic benefit for experienced endoscopists.

P131 ENDOSCOPIC DIAGNOSIS OF EARLY ORAL CAVITY AND LARYNGOPHARYNGEAL CARCINOMA IN PATIENTS WITH ESOPHAGEAL SQUAMOUS CELL CARCINOMA USING A TRANSNASAL ULTRATHIN ENDOSCOPE (EG-580NW).

H. Fujiwara[1,*], K. K. Kawada[1], K. Saito[1], N. Fujiwara[1], S. Ohta[1], T. Okada[1], Y. Miyawaki[1], Y. Tokairin[1], Y. Nakajima[1], Y. Kumagai[1], K. Nagai[1], T. Kawano[1]. [1]*Esophageal and General Surgery, Tokyo Medical And Dental University, Yushima1-5-45, Bunkyo-ku, Japan*

INTRODUCTION: New diagnostic techniques have dramatically increased the detection of superficial pharyngeal cancer. However, some patients cannot be examined using transoral esophagogastroduodenoscopy (EGD) at otorhinolaryngeal sites due to their gag reflex. On the other hand, Transnasal EGD can be performed comfortably because of its attenuation of the gag reflex. It has some disadvantages compared with conventional endoscopy such as brightness, image solution, and suction ability, so its diagnostic abilities have not been sufficiently evaluated. The procedure has been tremendous progress, and a new endoscope (model EG-580NW, FUJI film, Tokyo, Japan) has been manufactured beginning in September, 2011. The endoscope is a transnasal endoscope that provides of 140°with FICE system.
AIMS&METHODS: We retrospectively assessed the diagnostic value of transnasal EGD in detecting another primary head and neck cancers in patients with esophageal cancer(EC). One hundred twenty one EC patients(male 106/female 15 mean age 68.3 years old) underwent transnasal EGD screening with both a white light and an FICE system between September 2011 and September 2012. The Valsalva maneuver and screening of the oral cavity was also performed.
RESULTS: A total of 23 superficial cancers were found in 18 patients (14.8%) by transnasal EGD. In particular, 15 hypopharyngeal cancers were detected in this study. In addition, six cases of mesopharyngeal cancer, floor of the mouth and larynx in one case were found. Seventeen of those cases were determined to have intraepithelial neoplasia. 5 hypopharyngeal cancers which located at nearby the orifice of the esophagus were detected during the Valsalva maneuver. It hadn't been found among the standard screening. The FICE system enables easily observation of the presense of scattered brown dots to diagnose superficial cancers.
CONCLUSION: Therefore, transnasal endoscopy using the Valsalva maneuver may become the standard examination modality for the screening of the oral cavity, pharynx and larynx.

P132 RISK FACTORS OF BLEEDING EVALUATED BY FORREST CLASSIFICATION AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR EARLY GASTRIC NEOPLASMS IN JAPANESE POPULATION

H. Noda[1,*], N. Ogasawara[1], Y. Hijikata[1], R. Masui[1], S. Izawa[1], Y. Kondo[1], Y. Ito[1], M. Sasaki[1], K. Kasugai[1]. [1]*Gastroenterology, Aichi Medical University School of Medicine, Nagakute, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been now standard therapy for early gastric neoplasms in Japan. Although safety of the ESD procedure has been substantiated, complications such as perforation and bleeding are still serious problems.Post-ESD bleeding was considered one of the most major complications related with gastric ESD. Endoscopic hemostasis is effective for stopping post-ESD bleeding in mostly cases, if an emergency endoscopy is properly performed. Therefore, for the presuming appropriate management, it is necessary to beforehand determine the nature and risk factors of the post- ESD bleeding. In our study, we investigated the relationship among backgrounds of patients, characteristics of tumors, and exposed vessel on artificial post-ESD ulcers evaluated by Forrest classification on emergency or scheduled second-look endoscopy.
AIMS&METHODS: Subjects were 200 consecutive patients (145 males and 55 females; mean age, 71.0 years) who underwent ESD for gastric epithelial neoplasms (42 adenomas and 158 adenocarcinomas) between January 2006 and April 2012. Properly preventative coagulation for all exposed vessels on the artificial ulcer with hemostatic forceps was performed routinely at the end of ESD procedure. The vessel types on artificial post-ESD ulcers were evaluated by Forrest classification at the next day after ESD and were divided into two groups, high risk group including Ia, Ib and IIa which are essentially required with endoscopic hemostasis; low risk group including IIb and III which are not required with endoscopic hemostasis. To identify risk factors for possible bleeding after ESD, We analyzed patients and tumor related various factors between the two groups.
RESULTS: Patients with dialysis in the high risk group was significantly higher than those in the low risk group (p=0.03). However, there were no significant differences in patient-related factors (age, gender, comorbidities, use of anticoagulants and antiplatelet drugs) and tumor related factors [tumor location, histological type (adenoma *vs* adenocarcinoma), depth (intramucosal invasion *vs* submucosal invasion), size of the resected specimen, operation time].
CONCLUSION: Patients undergoing dialysis were considered to harbor high risk factor for post-ESD bleeding in gastric epithelial neoplasm, and these patients require carefully observation and optimal management after ESD for avoiding massive bleeding which may consecutively induce unexpected mortality. It is important to prepare to perform emergency or prophylactic endoscopic hemostasis for these patients.

P133 PILOT TRIAL ON EFFICACY OF SINGLE DOSE PERIOPERATIVE INTRAVENOUS DEXAMETHASONE FOR PAIN RELIEF AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION

H. W. Lee[1,*], H. Chung[1,2], J. C. Park[1,2], S. K. Shin[1,2], S. K. Lee[1,2], Y. C. Lee[1,2], H. Lee[1,2]. [1]*Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea,* [2]*Institute of Gastroenterology, Seoul, Korea, Republic Of*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is the gold standard technique for performing en bloc resection of large superficial tumors in the upper and lower gastrointestinal tract. Very little is known about the management of epigastric pain after ESD for gastric neoplasm.
AIMS&METHODS: This study aimed to investigate the utility and safety of single dose perioperative intravenous dexamethasone for pain relief after the operation. This was a double-blind, placebo-controlled trial of intravenous dexamethasone 0.15 mg/kg after ESD for early gastric neoplasm (DM group), comparing with a control group receiving placebo saline only (PL group). Patients completed a questionnaire comprising the present pain intensity and short-form McGill pain (SF-MP) score at immediate postoperative period, 6, 12, 24 hours after ESD. The primary outcomes variable was present pain intensity (PPI) measured at 6 hour after ESD. The secondary outcomes variables included pain medication, McGill pain score, complications, second-look endoscopic finding, and length of stay.
RESULTS: Thirty-six patients receiving ESD for early gastric neoplasm participated. The mean value of 6-hour PPI in DM was lower than that of PL group (1.67±1.21 vs. 2.28±1.56, P=0.003). The total 6-hour SF-MP score, especially in sensory domain, was higher in PL group than in DM group (12.05±4.13 and 9.314±2.12, P=0.026). Tramadol for pain relief was more frequently injected in PL group than DM group (42 % vs. 24%, P=0.041). No difference of length of stay was noted. The distribution of artificial ulcer patterns on second-look endoscopy performed 48 hours following ESD was similar between the groups. There was no difference in complication including acute or delayed bleeding between two groups.
CONCLUSION: Single dose perioperative intravenous dexamethasone after ESD was effective for epigastric pain relief at 6-hour postoperatively.

P134 PROSPECTIVE STUDY ON ACUTE COMPLICATION RATES AND ASSOCIATED RISK FACTORS IN ENDOSOPIC THERAPY OF DUODENAL ADENOMAS

I. Messer[1,*], J. Richl[1], J. König[1], J. Pohl[1], H. Manner[1], C. Ell[1], A. May[1]. [1]*HSK WIESBADEN, Wiesbaden, Germany*

INTRODUCTION: Endoscopic therapy of duodenal adenomas has gained importance. However, there are only a few and mainly retrospective studies regarding complications and identificiation of controllable risk factors.
AIMS&METHODS: Determination of complication rates during and after endoscopic therapy of duodenal adenomas and identification of factors that influence the complication rate.
From May 2011 to October 2012, 61 duodenal adenomas of 50 patients have been resected endoscopically. Complications (bleeding, pain, fever, pancreatitis, perforation) have been recorded. Thereafter, the dependence of a bleeding from other factors (gender, age, anticoagulation, adenom location and size, primary internistic disease, lesion type, resection type and performance of a bleeding prophylaxis with APC therapy) has been investigated.
RESULTS: Bleeding was the main complication. Major bleedings appeared in 4 cases (6.5%), minor bleedings in 11 (18%). Furthermore, one occult perforation occured. The dependence of the bleeding probability on the adenoma size was statistically significant (increased size, increased bleeding probability p=0.012). Moreover, the promising trend of APC therapy for bleeding prophylaxis was identified with an odds ratio of 0.31. Because of this measure, the bleeding risk was reduced by two thirds in this study. However, due to the small number of six patients that received bleeding prophylaxis with APC therapy, this result was not statistically significant (p=0.31).
CONCLUSION: Bleeding is the main complication of endoscopic therapy of duodenal adenomas. The bleeding risk increases with adenoma size significantly. The achieved results regarding a prophylactic APC therapy for lowering the bleeding risk are promising. However, the other above mentioned factors seem to play no major role. Due to the relevant rate of complications, endoscopic resection of duodenal adenomas is only recommended under inpatient conditions.
Disclosure of Interest: None Declared
Keywords: duodenal adenoma, endoscopic resection

P135 IS PORCINE STOMACH SUITABLE AS AN ANIMAL TRAINING MODEL FOR GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD)?

J. Horii[1,*], U. Toshio[1], M. Shimoda[2], A. Fujimoto[1], O. Goto[1], Y. Okada[2], N. Yahagi[1]. [1]*Research and Development for Minimally Invasive Treatment, Cancer Center,* [2]*Department of pathology, Keio University School of Medicine, shinjuku-ku, Japan*

INTRODUCTION: Training using animal model is generally recommended before starting endoscopic submucosal dissection (ESD) in human because of the high-level of its technically difficulty. However, we often experienced discrepancy of maneuverability between a porcine and a human stomach. In fact, few reports have demonstrated these ESD differences using training model.

AIMS&METHODS: To clarify the suitability of isolated porcine stomach as an animal training model for ESD. *Study1*; Six experienced endoscopists who continually practice in gastric ESDs in the human were enrolled to perform ESD for 6 hypothetical lesions located in 6 sites of an isolated porcine stomach (1.Lower third (L)/greater curvature (Gre);2.L/anterior wall (Ant);3.L/posterior wall (Post);4.Upper third (U)/Gre;5.U/Ant;6.U/Post). The size of each lesions were 2cm in diameter. A single-channel endoscope (GIF Q260J; Olympus Co., Tokyo, Japan) with a distal attachment was used. Procedure time for each ESD (sec / cm2) was compared among each site. After the procedure, we asked to the endoscopists the maneuverability of endoscope in three steps of ESD (injection, incision and dissection). A score questionnaire (scoring 1-5) was used to assess the similarity to the L of human stomach. *Study2*; The comparison of histology were investigated between an isolated porcine stomach and resected human gastric specimen of donated body. Thicknesses of mucosal layer were evaluated between above-mentioned 6 sites in porcine (n=3) and human stomachs (n=3).
RESULTS: *Study1*; Procedure times were statistically long in L/Gre and U/Gre of porcine stomach (p=0.016). The survey revealed similarity of maneuverability between human and porcine stomach in L/Ant, L/Post, U/Ant and U/Post during the dissection step (p=0.024). In contrast, discrepancies of maneuverability were showed in L/Gre during the step of injection (p=0.001) and incision (p=0.004). *Study2*; A mucosal layer of porcine stomach was significantly thicker than human stomach in L, especially in L/Gre (L/Gre;2541±363/1029±175μm(p=0.0029), L/Ant;1178±129/768±157μm(p=0.025), L/Post 1164±134/807±80μm(p=0.017), U/Gre;758±240/933±134μm(p=0.34), U/Ant;435±67/932±74μm(p=0.001), U/Post;570±198/836±281μm(p=0.25)). However, the mucosal layer of porcine stomach was thinner than human in U/Gre, U/Ant and U/Post, but the statistical difference revealed only in U/Ant.
CONCLUSION: The maneuverability of ESD and the histological feature were different between a porcine and a human stomach. The porcine stomach may be suitable as animal training model for gastric ESD in L/Ant, L/Post, U/Ant and U/Post.

P136 UTILITY OF ENDOSCOPIC RESECTION FOR THE TREATMENT OF DUODENAL CARCINOID TUMORS

J.-H. Choi[1,*], D.-W. Seo[1], D. H. Park[1], S. S. Lee[1], S.-K. Lee[1], M.-H. Kim[1].
[1]*Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Few studies have been reported on the safety and efficacy of endoscopic resection in duodenal carcinoid tumors. The aim of this study was to evaluate the utility of endoscopic resection in duodenal carcinoid tumors.
AIMS&METHODS: Between February 2004 and February 2012, 35 patients with sporadic duodenal carcinoids managed by endoscopic resection were enrolled. The endoscopic resection was performed for patients with duodenal carcinoids but no node or distant metastasis. The rate of endoscopic complete resection, histologically complete resection, procedure related complications, and tumor recurrence were retrospectively analyzed.
RESULTS: Twenty-five duodenal carcinoid tumors were resected by endoscopic mucosal resection, four duodenal carcinoids were resected by endoscopic submucosal dissection (ESD), and six ampullary carcinoids were treated by snare papillectomy. The mean patient age was 60.9 years (range 43-82 years). The mean (± standard deviation) tumor sizes were 7.8 ± 2.4 mm (range, 3-12 mm) in nonampullary carcinoids, and 13.6 ± 5.4 mm (range, 5-20 mm) in ampullary carcinoids. The endoscopic complete resection rate was 97.1%: one patient with tumor invading the muscularis propria experienced incomplete resection during ESD. The histologically complete resection was accomplished in 31 of 35 patients (88.6%) on the initial attempt. One patient required 2 sessions for complete resection. With regard to the procedure-related complications, perforation during the endoscopic resection occurred in 3 patients with nonampullary carcinoid (8.6%): two patients were treated by endoscopic closure, and in the other one patient was performed by local excision. After a median follow-up period of 39 months (range 10 to 96 months), local recurrences developed in 1 patients (2.8%) with nonampullary carcinoids, including one from tumor larger than 10 mm. Neither local recurrence nor distant metastasis was detected in patients with ampullary carcinoid after endoscopic papillectomy during a median follow-up period of 40 months (range 18 to 100 months).
CONCLUSION: Endoscopic resection is considered as the safe and effective therapeutic option for small (≤10mm), nonampullary carcinoids without any sign of infiltration to the muscularis propria. For ampullary carcinoids smaller than 20mm and confined to submucosa, minimally invasive endoscopic papillectomy could be considered in particular in patients with a high risk of postoperative complications due to old age or advanced comorbidity.

P137 NEW TECHNIQUES TO IMPROVE THE ENDOSCOPIC VIEW FOR THE HYPOPHARYNGEAL CANCER USING TRANSNASAL ESOPHAGOGASTRODUODENOSCOPY

K. K. Kawada[1,*], T. Kawano[1], Y. Nakajima[1]. [1]*Esophageal and General Surgery, Tokyo Medical And Dental University, Yushima1-5-45, Bunkyo-ku, Japan*

INTRODUCTION: Narrow band imaging (NBI) and magnifying endoscopy is thought to be a usefull for hypopharyngeal screening. However circumferential observation of hypopharyngeal mucosa is difficult during conventional endoscopy because of its anatomically closed nature, pharyngeal reflex. Thus it is important to develop procedures for widening and improving the endoscopic field of view of the pharynx. Recently, we applied new transnasal esophagogastroduodenoscopy and modifications of endoscopic techniques for observing hypopharyngeal cancers.
AIMS&METHODS: A total of 69 lesions in 66 patients with hypopharyngeal cancer between January 2011 and October 2012, were retrospectively analyzed. Patient characteristics were as follows: median age, 68 years; range, 51 to 85 years; male:female, 63:3; cStage 0/I/II/III/IV23/15/17/5/9; cTis/T1/T2/T3/T4=23/17/19/7/3. We applied procedures for wide visualization of pharynx to the patients. We employed a transnasal endoscope''EG-580NW'' and ''EG-530NW''(FUJI FILM, Tokyo,Japan). First, after endoscopic inspection of the oral cavity, the patients were asked to bow their head deeply in the left lateral position, and then we put our hand on back of patients' head and pushed it forward by one span of our hand. Then they were asked to lift up the chin as far as possible (lateral sniffing position). Only topical anesthesia was used,the endoscope is passed through the nose with no sedation, and the laryngopharynx is observed. The tip of the endoscope is positioned above the inlet of the larynx, and the patient is asked to blow hard and puff the cheeks with the mouth closed. The endoscopist pulled the patient's chin with the right hand forward. Images were recorded with a digital video cassette recorder during the procedures. Four endoscopists retrospectively observed the recorded video, and the extent of the view of hypopharyngeal opening was classified into 3 caregories (excellent, good, poor) by mutual consensus.
RESULTS: The wide endoscopic view of the pharynx was obtained in a series of the procedures(Excellent, 87.9%; good, 4.5%; and poor 7.6%) This new method is effective for the observation of the postcricoid and posterior wall of the hypoparynx region. We successfully identified 13 small lesions, especially in the hypopharynx, that are usually not detected with the conventional method. Among them, the SCCs were intraepithelial cancer in 6 lesions, had invaded up to the submucosa in 5. Moreover, the excellent visualization of the hypopharynx was demonstrated in 80 per cent (8/10)of the advanced cases(T3+T4).
CONCLUSION: The new procedure for wide visualization of the hypopharynx provided an excellent endoscopic field of view of pharynx.

P138 UPPER GASTROINTESTINAL MUCOSAL CHANGES IN PATIENTS WITH CONGESTIVE HEART FAILURE

Z. E.-A. A. Syed[1], M. Abdel-Ghany[2], L. Abdel-Wahid[1], K. M. Attallah[3,*].
[1]*Internal Medicine,* [2]*Cardiology, Assiut University, Assiut,* [3]*Hepatology and Gastroenterology, National Liver Institute, Menoufiya, Egypt*

INTRODUCTION: Congestive heart failure increases systemic venous pressure which is transmitted to the inferior vena cava and the hepatic veins, this may induce gastro-intestinal changes. This research aimed to study gastro-intestinal tract changes in patients with congestive heart failure.
AIMS&METHODS: 120 patients with congestive heart failure (CHF) presenting with gastro-intestinal symptoms underwent upper endoscopy. All patients underwent echocardiography to determine the ejection fraction and the degree of tricuspid regurgitation and pulmonary hypertension. Abdominal ultrasound was done to measure the diameters of the hepatic veins, the inferior vena cava, and the portal vein for which pulsatility index was assessed.
RESULTS: Gastric mucosal changes were present in 106 (88.4%), duodenal mucosal changes in 71 (59.2%), and esophageal mucosal changes in 3 (0.3%) patients.
Gastric mucosal changes were the following: mosaic-like pattern (n = 92, 76.7 %), punctate spots (n = 73, 60 %), thickened folds (n = 20, 16.7 %), watermelon stomach (n = 8, 6.7%), and telangiectasia (n = 35, 29.2%). Duodenal mucosal changes were the following: mosaic-like pattern (n = 58, 48.4 %), thickened folds (n = 17, 14.2 %), and telangiectasia (n = 7, 5.9 %). Gastrointestinal symptoms were significantly associated with gastropathy and duodenopathy (p = 0.000). There was a positive correlation between the degree of gastro-intestinal symptoms and gastropathy and duodenopathy (r value, 0.6 and 0.5 respectively). Patients with gastropathy and duodenopathy had higher mean inferior vena cava (IVC) and hepatic vein diameters than those without gastropathy and duodenopathy. Low EF was associated with increased portal vein, IVC and hepatic vein diameters, (P values = 0.02, 0.008, 0.002) respectively. Moreover it was associated with gastro-intestinal symptoms, gastropathy and duodenopathy (P value = 0.000). There was a positive correlation between the ejection fraction and severity of gastro-intestinal symptoms (r =0.6, P = 0.00). Tricuspid regurgitation was associated with gastro-intestinal symptoms, stomach gastropathy, diameter of hepatic vein and IVC (P value 0.007, 0.019, 0.000, 0.000). Mean pulsatility index in patients in the present study was 0.7 ± 0.53 and there was positive correlation between pulsatility index and Pulmonary Artery Systolic Pressure (PASP) (P = 0.02, r = 0.61). Patients with low ejection fraction have a higher pulsatility index than patients with higher ejection fraction (0.7 ± 0.67, 0.6 ± 0.18, p value, 0.26).

CONCLUSION: CHF is associated with gastro-intestinal changes which are significantly associated with the severity of congestive heart failure.

P139 DURABILITY COMPARISON OF MUCOSAL APPOSITIONS AND INVERTED SEROSA TO SEROSA CLOSURES FOR REPAIRING LARGE GI WALL DEFECTS USING AN ENDOSCOPIC SUTURING DEVICE.

M. Kobayashi[1,*], K. Sumiyama[2], Y. Ban[1], A. Dobashi[2], T. R. Ohya[2], K. Nakajima[3], H. Tajiri[1,2]. [1]*Division of gastroenterology & hepatology, Department of Internal Medicine,* [2]*Department of Endoscopy, The Jikei University School of Medicine, Tokyo,* [3]*Division of Next Generation Endoscopic Intervention, Osaka University, Osaka, Japan*

INTRODUCTION: Reliable closure of large GI wall defects after endoscopic tissue removal is technically challenging with traditional endoclips. Endoscopic suturing devices have been developed as alternatives to achieve more secure tissue approximation. However, it has yet to be proven that the robust mucosal tissue apposition is durable enough to prevent adverse events.
AIMS&METHODS: Aims of this study were to investigate durability of endoscopic suturing of large GI wall defects after endoscopic submucosal dissection (ESD) and endoscopic full-thickness resection (EFTR) in *in vivo* porcine models. A total of 10 pigs were studied under general anesthesia. In 7 pigs, 2 ESD ulcers over 3 cm in size were made in the lower half of the stomach for each animal. In one of the seven pigs, an additional third ESD ulcer left open without closure was created in the upper corpus as a control. In 3 pigs, 1 full-thickness defect approximately 3 cm in size was made with an assistance of percutaneous anterior gastric wall lifting using tissue anchors. After the endoscopic tissue removals, the both mucosal and full-thickness defects were completely approximated with interrupted stitches placed every 5 to 10 mm with an endoscopic suturing device (Overstitch, Apollo Endosurgery, Austin, USA) mounted on a 2-channel gastroscope (GIF-2T240, Olympus Medical systems, Tokyo, Japan). The post EFTR defects were closed while inverting the serosal edges into the lumenal side. Pigs were survived for one week with an oral administration of proton pump inhibitors and sacrificed following an endoscopic observation of studied sites. A necropsy was performed and the studied sites were sampled for histologic evaluation.
RESULTS: The mean size of sampled ESD specimens in the maximum diameter was 4.27 cm. The defect closure was achieved in 12 of 14 attempts (86%) for the post ESD repair, and in all attempts (100%) for the post EFTR repair. The average number of stitches required to close the defects were 2.41 stitches for post ESD ulcers and 4 stitches for post EFTR defects. All pigs survived for one week without significant complications. At the necropsy, all repaired post ESD ulcers were loosened, although minor deformity of the ulcer edge was observed. Meanwhile, all post EFTR defect closures sustained for one week.
CONCLUSION: The immediate closure of large post ESD ulcers and post EFTR defects could be accomplished using the Overstitch device. The serosa to serosa approximation provides more durable and reliable repair compared with the simple mucosal apposition.

P140 ONE HUNDRED CASES OF PERCUTANEOUS TRANS ESOPHAGEAL GASTRO TUBING BY ENDOSCOPIC ASSISTANCE

M. Murakami[1,2,*], K. Nishino[1], S. Murakami[1], Y. Takaoka[1], K. Mori[1], B. Murakami[1], M. Azuma[2], S. Tanabe[2], M. Kida[2], W. Koizumi[2]. [1]*Internal medicine, MURAKAMI MEMORIAL HOSPITAL, saijo,* [2]*Gastroenterology, Kitasato University East Hospital, Sagamihara, Japan*

INTRODUCTION: Percutaneous transesophageal gastrotubing (PTEG) was developed as an alternative route to access the gastrointestinal tract for the patients that Percutaneous Endoscopic Gastrostomy was contraindicated with conditions such as prior gastrectomy, gastric anterior wall malignancies, or massive ascites. PTEG was originally developed to be performed without endoscopy. However, endoscopy may enhance the safety of the procedure.
AIMS&METHODS: The aim of this study is to evaluate the clinical usefulness of PTEG supported by endoscopy. A rupture-free balloon (RFB) catheter is inserted into the lower esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient's neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed. We performed PTEG under endoscopiy in a total of 100 patients (65 men and 35 women, mean age 71.0 years) in whom PEG was not feasible. PTEG was performed for nutrition in 56 patients and for decompression in 44.
RESULTS: Satisfactory results were achieved in all 100 patients. Median follow-up was 60.5 days in patients who received decompression because of the obstruction due to malignancies and 301.0 days in those who received nutrition. Nine patients who were started in the fluoroscopically assisted according to the original method needed endoscopic assistance to complete the procedure. None of the 91 patients in the endoscopic assistance required fluoroscopy. There were no major complications, but one patient had tracheal penetration, which was managed conservatively. Other complications were minor oozing bleeding in five patients that did not require blood transfusion, subcutaneous emphysema in two patients, which were managed conservatively. Eight accidental (four self) tube removals occurred more than 2 weeks after the procedure, without any problem in reinsertion. The overall complication rate associated with PTEG was 12.0%. No patient required surgical treatment or died after PTEG.
CONCLUSION: PTEG supported by endoscopy is as feasible, safe, and useful as PTEG supported by fluoroscopy, the original procedure. The use of endoscopy enhances the safety of the procedure and allows better confirmation of each step involved.

P141 DIGESTIVE ENDOSCOPIC SUB-MUCOSAL DISSECTION WITH A NEW WATER JET SYSTEM (NESTIS® ENKI II®) USING A BI-FONCTIONAL CATHETER, FIRST PROSPECTIVE TRIAL IN 17 HUMANS INJECTING SALINE SERUM IN SUPERFICIAL TUMORS OF THE ESOPHAGUS, THE STOMACH AND THE RECTUM.

M. Pioche[1,2,*], V. Lépilliez[1], M. Ciocirlan[3], C. Pinset[4], N. Gonon[4], T. Ponchon[1]. [1]*Hôpital Edouard Herriot,* [2]*Inserm U 1032, Labtau, Lyon, France,* [3]*Institut Carol Davila, Bucarest, Romania,* [4]*Nestis, Lyon, France*

INTRODUCTION: ESD is the first-intent method to treat superficial neoplasms of the digestive tract at it allows an en-bloc resection. Several tools are necessary to perform ESD with the standard technique. Development of water jet with bi functional catheter allows significant reduction of perforation risk. For this purpose, Nestis introduced the Enki 2 pulsed jet technology with high pressure system to inject efficiently and at any time viscous solutions in direct viewing and retroflexion. In addition, preclinical studies on living pig colon have demonstrated that perforation rates and operating times are significantly reduced compared to a standard electrosurgical knife. The present study was performed to confirm this system capability to perform ESD in humans safely.
AIMS&METHODS: We planed to perform 18 ESD with saline serum injection using Nestis® system. Patients had superficial lesions corresponding to Japanese indications of ESD.
RESULTS: Currently, 18 ESD procedures had been performed in 17 patients (one patient with two LST of the rectum). There were 6 lesions of the esophagus (2 adenocarcinoma on Barrett's, one high grade dysplasia (HGD) on Barrett's, and 3 epidermoid carcinoma), 3 gastric adenocarcinoma and 9 lesions of the rectum (5 granular lateral spreading tumors (LST-G) in HGD and one with sm1 adenocarcinoma, one in Low grade dysplasia (LGD), one LST in histology analysis at the moment, and one polypoid lesions with in situ carcinoma). The mean maximal diameter was 42.2 mm (17-106 mm) with a mean time of procedure of 62.5 min (20-155 min). During the procedures, no case of perforation or delayed bleeding occurred. However, one patient needed clipping of an incomplete muscle dehiscence. All resections were en bloc macroscopically. Currently, histology is available in only seventeen first patients including 15 with microscopically complete resections (R0), one with complete macroscopically resection but with vascular embols (epidermoid esophageal cancer), one with R1 resection in lateral margins and one with indeterminate residual tissue (Rx). 3 months endoscopic control is planed. There were no technical issues during the procedures.
CONCLUSION: Nestis Enki II® system appears to be a safe and effective ESD high pressure water jet system that can be used in clinical practice for superficial lesions of the digestive tract. Moreover, The Enki 2 capability to inject various viscous macromolecular solutions is promising.

P142 ENDOSCOCOPIC TRAINING IN UPPER GASTROINTESTINAL BLEEDING (UGIB): A UK REGIONAL AND NATIONAL AUDIT

M. Kurien[1,*], E. F. Wong[1], E. Ejinavi[1], M. Lau[1], F. Gohar[1], B. Hoeroldt[2], K. L. Dear[3], A. J. Lobo[1], D. S. Sanders[1]. [1]*Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield,* [2]*Department of Gastroenterology, Rotherham Hospital, Rotherham,* [3]*Department of Gastroenterology, Chesterfield Hospital, Chesterfield, United Kingdom*

INTRODUCTION: UGIB frequently requires endoscopic intervention. Training in therapeutic endoscopy for UGIB is not mandatory in the UK. Furthermore UGIB endoscopic experience may be diminished by the European Working Time Directive and a Consultant delivered service. There has been no published data on trainees' opportunities for UGIB endoscopic experience. This study evaluates GI trainee experience in the South Yorkshire (SY) region and nationally.
AIMS&METHODS: Rockall scores for patients requiring an endoscopy for an UGIB (n=622, 5 hospitals) was prospectively collected in SY between Sept-Dec 2011. Trainee experience from this cohort was then compared with a historical SY UGIB cohort (n=274) from 1996. Nationally, all BSG trainees (n=478) were invited to respond to a custom designed web based questionnaire (Nov-Dec. 2012). Information was collected about OGD competency (both diagnostic and

therapeutic) and trainees' confidence of acquiring sufficient endoscopic skills in UGIB prior to completing specialty training.
RESULTS: Regionally, comparison between the 2011 and 1996 SY UGIB cohorts demonstrated comparable 30-day mortality rates (8.5% vs 8.1%, p=0.78), with similar median post-endoscopy Rockall scores (6 v 5). When comparisons were made between trainee and non-trainee performed procedures, no mortality difference was identified (p=0.286). However, when comparing trainee undertaken procedures between the two cohorts, a significant decline was observed with 76% (208/274) of endoscopic procedures for UGIB being performed by trainees in 1996 compared with only 16% (97/622) in 2011 ($p < 0.0001$). Nationally, questionnaires were returned by 51% (245/478) of BSG trainees (median = 4 years registrar training, range 1-9 years). Of these, 42% (104/245) had completed a basic upper GI endoscopy training course and 40% a therapeutic course. Median number of OGD's performed by trainees was 500, with therapeutic exposure <10% in 76% of cases. 23% (57/245) of trainees felt their endoscopic skills in UGIB will be insufficient at the time of specialty training completion.
CONCLUSION: This study objectively demonstrates a decline in regional training for gastroenterology trainees in UGIB endoscopic procedures. Furthermore our regional audit is supported by the National audit, which suggests that trainees across the UK are both limited in their opportunities and concerned that a level of competency may not be attained during registrar training. We advocate reviewing UK endoscopic training provision for UGIB ensuring qualified and confident endoscopists are produced to meet future service needs.

P143 MANAGEMENT OF BURIED BUMPER SYNDROME – EXPERIENCE FROM ROCHDALE, UNITED KINGDOM

N. Radhakrishnan[1,*], R. K. Sharma[1], R. George[1], L. Quest[1]. [1]*Gastroenterology, The Pennine Acute Hospitals NHS Trust, Rochdale, United Kingdom*

INTRODUCTION: Buried Bumper Syndrome (BBS) is a rare but major complication of percutaneous endoscopic gastrostomy/jejunostomy (PEG/J) with an incidence of 1.5-1.9%. It is caused by the internal migration of the rigid flange of the gastrostomy tube into the gastrostomy track
AIMS&METHODS: To ascertain the incidence of BBS and to review the methods used in our hospital in the management. Details of all patients (pts.)who had a new PEG/J placed between April 1998 to March 2013 and who developed BBS during this period were obtained from the PEG Register kept in the Endoscopy Unit, Rochdale
RESULTS: Number of new PEG/J- 918. Number of pts. 32 with 33 episodes of BBS. Male 23, Age 22-80 mean age (MA) 51, Female 9 Age 34-87 MA 64. Of the 32 pts. with BBS 20 had their PEG/J placed at Rochdale giving an incidence of 2.17%. Indications for PEG/J : traumatic brain injury 6, CVA 9, Multiple Sclerosis 4, Huntington Chorea 2, Achalasia 1, dementia 1, hydrocephalus 1, syringobulbia 1, benign oesophageal stricture 1, Parkinson's disease 1, Meningioma 1, Anoxic brain injury 1, brain injury following removal of brain tumour 1, unknown 2. Types of PEG: Fresenius 15 Fr -25, Fresenius 9 Fr -3. Types of PEJ: Wilson Cook 20 Fr- 2, Freka -3. After excluding 8 patients in whom we could not get the date of insertion of their PEG/J the mean duration between PEG/J insertion and diagnosis of BBS was 28.4 months (3-65 months). BBS successfully removed at index gastroscopy by: Balloon traction /push technique -in 10 cases (in 9 pts.) out of 33, Forceps pull- 1, Quill technique -1. In 13 pts. 9 Fr and in 1 pt. a 15 Fr Fresenius gastrostomy tube through the bumper track was placed with continuation of feeding. Of the above 14 pts., 8 (57%) had their buried flanges gradually resurfaced and were easily removed endoscopically after a mean period of 4.7 months (1- 20 months). In the remaining 7 pts. - 1 removed by minilap, 4 had side by side PEG placed, 1 jejunal tube placement, 1 died from abdominal wall abscess.
CONCLUSION: Incidence of BBS in our series was 2.17%. 31 out of 33 BBS cases were associated with Fresenius make. Buried flange was successfully removed endoscopically in 20 out of 33 cases (61%). Balloon method has been successful in removing the buried flange at first attempt in 30% of cases. Our experience suggests that in difficult patients, placing a 9Fr or 15 Fr Fresenius gastrostomy tube via the opening of buried bumper may enable the release of the buried bumper and facilitate its easy removal at a later stage.

P144 THE FEASIBILITY OF TRANS-UMBILICAL ROUTE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF UPPER GASTRIC LESION AND SINGLE PORT LAPAROSCOPIC LYMPH NODE DISSECTIONS; PORCINE EXPERIMENTAL MODEL

C. Y. Ha[1], O. J. Lee[1,*], H. Kim[1]. [1]*Gyeongsang National University, Jinju, Korea, Republic Of*

INTRODUCTION: The complete endoscopic resection of upper gastric lesion is very difficult. The aim of this study was to verify the feasibility of trans-umbilical (TU) route for the endoscopic submucosal dissection (ESD) of upper gastric body lesion compared to trans-oral (TO) route, and to compare the performances of single port laparoscopic lymph node dissections (SPLLND) and conventional multiport laparoscopic lymph node dissections (MPLLND).
AIMS&METHODS: Ten healthy pigs were allocated to two groups: TO/MPLLND (n=5) and TU/SPLLND (n=5) groups. We performed ESD on the anterior wall of gastric high body (HBAW) and fundus via TO or TU route in each group. After ESD, lymph nodes (LN 1, 2, 3, 4sa, 4sb) were resected laparoscopically using multiport in TO/MPLLND and single port in TU/SPLLND group. The complete resection rate, operating time, tissue weight and size, and perforation rate for ESD, and completion rate and operating time for LN dissection were compared between groups.
RESULTS: The operating time for ESD was shorter in TU group than TU group for both HBAW (9.2 ± 0.6 vs 16.2 ± 0.8 min, $p < 0.01$) and fundus (19.4 ± 6.3 vs. 27.0 ± 3.6 min, p=0.04). There was no significant difference in the complete resection rates, tissue weight and size between two groups. The overall perforation rate was 80% (4/5, 2 during procedure and 2 postoperative) in TO/MPLLND group and 20% (1/5, postoperative) in TU/SPLLND group. There was no significant difference in the complete resection rate of overall LN and operating time for LN dissection between 2 groups. MPLLND group had a higher complete resection rate for LN 2 (80%) than SPLLND group (60%).
CONCLUSION: TU ESD had comparable performance to TO route, and showed a shorter operating time and lower perforation rate compared to TO route procedure. TU route could be feasible for safe ESD in the patients with the upper gastric body lesion. SPLLND was also comparable to MPLLND.

P145 CLINICAL APPLICATION OF OVERSTITCH FOR TISSUE APPROXIMATION IN GASTROINTESTINAL TRACT – A PILOT STUDY

P. Chiu[1,*], A. Teoh[1], M. Chan[2], E. Ng[1], F. Chan[3], J. Lau[1]. [1]*Department of Surgery,* [2]*Department of Anesthesia and Intensive Care,* [3]*Dept of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: Previously we had conducted preclinical studies on Eagle Claw suturing for massively bleeding ulcer and closure of gastrotomy in animal models. This study aimed to investigate clinical application of Overstitch endoscopic suturing for management of complicated gastrointestinal luminal defects.
AIMS&METHODS: We recruited patients with large bleeding ulcers, perforations and luminal defects after POEM and ESD. All procedures were performed under MAC or general anesthesia and CO2 insufflation. The Overstitch device was mounted onto a double channel endoscope and pass to luminal defect through an overtube. Tissue approximation was performed using continuous suturing. The perioperative and technical outcomes were recorded.

Table: P145

Age / gender	Indication Closure of rectal ESD perforation	Technical success	Operative time	Size of luminal defect	No of stitches	Mortality	Complication	Additional procedure
M/73		Yes	30 mins	10mm	2	Nil	Nil	Nil
F/59	Closure of bronchoesophageal fistula	Yes	20 mins	30mm	1	Nil	Nil	1. Thoracotomy for abscess drainage 2. OTSC clip
F/78	Fixation of stent for perforated duodenal ulcer	Yes	30 mins	30mm	2	Yes	Sepsis and wound infection	Nil
M/66	Bleeding duodenal ulcer	Yes	40 mins	20mm	3	Nil	Nil	Nil
M/61	Closure of gastric perforation after failed EUS drainage	Yes	20 mins	10mm	1	Nil	Nil	Nil
F/66	Esophageal perforation	Yes	45 mins	40mm	3	Yes	Mediastinal abscess	1. Thoracoscopic drainage of abscess 2. Stenting
M/78	Bleeding gastric ulcer	Yes	25 mins	30mm	1	Nil	Nil	Transarterial embolization
F/33	Post-POEM closure	Yes	13 mins	30mm	1	Nil	Nil	Nil
F/56	Post-POEM closure	Yes	15 mins	30mm	1	Nil	Nil	Nil
F/73	Post gastric ESD closure	Yes	20 mins	35mm	1	Nil	Nil	Nil

RESULTS: From June 2012 to April 2013, 10 patients received endoscopic tissue approximation using Overstitch (Table 1). Majority of these procedures were indicated as emergency, with 5 patients having perforation of the gastrointestinal tract, 2 had bleeding peptic ulcers and 3 had large mucosal tissue defect. Technical success of endoscopic suturing was achieved in all patients, while two patients succumbed due to severe sepsis. The mean operative time for the procedures was 25.8 minutes, while the mean size of mucosal defect was 26.5mm. All the endoscopic sutures were performed without complication, and most of the tissue approximation required only one overstitch with continuous suturing.
CONCLUSION: Endoscopic tissue approximation using Overstitch is a safe and technically feasible for management of large size gastrointestinal luminal defect. Endoscopic suturing for management of gastrointestinal perforation is limited by difficulty in achieving drainage and debridement of abscess collection.

Lovat[1,2]. *[1]UCLH, [2]UCL, [3]GSTT, London, [4]RLUH, Liverpool, [5]PAH, Portsmouth, [6]BTHFT, Bradford, [7]CMUH, Manchester, [8]GRI, Glasgow, [9]CUH, Cambridge, [10]RBCH, Bournemouth, [11]RIE, Edinburgh, [12]GHUT, Gloucs, [13]SUH, Southampton, [14]AUH, Liverpool, [15]QEH, Birmingham, [16]SMH, London, United Kingdom, [17]SJH, Dublin, Ireland, [18]NNUH, Norwich, [19]FPH, London, [20]SRHFT, Manchester, United Kingdom*

INTRODUCTION: Barrett's esophagus (BE) is the pre-cursor to oesophageal adenocarcinoma (OAC). Endoscopic mucosal resection (EMR) & Radiofrequency ablation (RFA) are alternative treatments to surgery for these patients.
AIMS&METHODS: Aims - Prospective data from 19 centres in United Kingdom (UK) registry
Methods - Before RFA, superficial lesions were removed by EMR. Patients then underwent RFA 3 monthly until all BE was ablated or cancer developed (endpoints). Biopsies were taken at 12 months. Primary outcomes for clearance dysplasia (CR-D) & BE (CR-BE) at 12 months were assessed over two time periods, between 2008-2010 & from 2011 till present day.
RESULTS: 400 patients have completed treatment with 12 month histology over 5 years. CR-D & CR-BE have improved significantly between the former & later time periods from 75% & 56% to 88% & 79% respectively ($p=0.0005$, $p<0.0001$, Chi^2). EMR prior to RFA treatment has also increased significantly from 46% to 59% ($p=0.0163$, Chi^2). Rescue EMR during RFA is used less over the last 2 years compared to the initial time period ($p=0.0011$, chi^2). Progression to OAC although lower in the later time period is not significantly different (2.2% in 2011-2013 versus 5% 2008-2010, $p=0.28$, chi^2).
CONCLUSION: Outcomes have improved over time with improved lesion recognition, & more aggressive EMR of visible lesions before initiating RFA. As a result the requirement for rescue EMR during RFA has reduced. Although the rate of progression is lower in the later part of the registry experience, this is not statistically significant & implies that despite advances in technique with minimally invasive endothepry the rate of progression remains in the region of 2-5% in these high risk patients.

P147 DISCRIMINATION BETWEEN SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA AND INTRAEPITHELIAL NEOPLASIA USING NARROW BAND IMAGING WITH MAGNIFICATION

T. Miike[1,*], Y. Miyata[1], S. Yamamoto[1], S. Suzuki[1], N. Uehara[1], S. Takeda[1], S. Natsuda[1], K. Hashimoto[1], T. Yamaji[1], M. Nagayama[1], H. Abe[1], K. Shimoda[1], K. Yorita[2], H. Kataoka[2]. *[1]Gastroenterology and Hematology, [2]Oncopathology and Regenerative Biology, University of Miyazaki, Miyazaki, Japan*

INTRODUCTION: Superficial esophageal tumors were recategorized in 2011 according to a new Japanese esophagus tumor' classification system. This system is based in part on background coloration, a color change in the area between intrapapillary capillary loops (IPCLs) in superficial esophageal tumors, using narrow band imaging (NBI) with magnification.
AIMS&METHODS: Here, we retrospectively examined superficial esophageal squamous cell carcinoma (SCC) and intraepithelial neoplasia (IN) to determine whether they could be distinguished on the basis of this new classification system. Between June 2009 and July 2012, a total of 24 lesions were diagnosed as SCC or IN on the basis of endoscopic submucosal dissection performed at the Miyazaki University Hospital. These cases were assessed in the current study. Five endoscopic images with white light and NBI were randomly selected. These were then reviewed by 13 specialist or non- specialist endoscopists in a blinded manner to determine whether these lesions were SCC or IN according to the new Japanese esophagus tumor' classification system using NBI with magnification. If the lesion was diagnosed as SCC, the basis for this diagnosis was recorded with respect to 4 characteristic IPCL patterns (dilatation, winding, caliber variation, and non-uniformity).
RESULTS: The overall accuracy with which SCC was distinguished from IN was 60.9%, and the accuracy for diagnosing SCC was 67.0%. The total accuracy achieved by specialists (84.3% ± 14.0%) was significantly higher than that achieved by non-specialists (61.8% ± 15.7%, $P < 0.05$). The accuracy of SCC diagnosis achieved by specialists (71.0% ± 4.0%) was also significantly higher than that achieved by non-specialists (57.9% ± 13.8%, $P < 0.05$). The basis for SCC diagnosis was additional dilatation in 16.9% of casas, winding in 36.9%, caliber variation in 13.8%, and non-uniformity in 32.3%.
CONCLUSION: Specialist' endoscopists could discriminate between SCC and IN according to the new Japanese esophagus tumor' classification system using NBI with magnification with greater accuracy than non-specialist endoscopists. Winding and non-uniformity were the particularly important specific IPCL patterns for diagnosing SCC.

P148 SPARSE APPEARANCE OF CRYPT OPENINGS IS A HIGHLY SPECIFIC SIGN FOR DIFFERENTIATED TYPE EARLY GASTRIC CANCER: MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING

T. Kanesaka[1,*], A. Sekikawa[1], T. Tsumura[1], T. Maruo[1], Y. Osaki[1]. *[1]Gastroenterology and Hepatology, Osaka Red Cross Hospital, Osaka, Japan*

INTRODUCTION: Discrimination between differentiated and undifferentiated types (according to Lauren's classification, intestinal and diffuse types) of early gastric cancer (EGC) is an indispensable factor for the indication of endoscopic resection. However, this is difficult by an endoscopic examination using conventional white light imaging alone. Recently, we reported that dense-type crypt openings (CO) seen on magnifying endoscopy with narrow-band imaging (ME-NBI) is characteristic for low-grade adenoma.[1]
AIMS&METHODS: In the present study, we aimed to clarify whether the density of CO is a useful finding for discrimination between differentiated-type early gastric cancer (D-EGC) and undifferentiated-type early gastric cancer (UD-EGC). We included patients with EGC (D-EGC, UD-EGC, and mixed type) who had undergone an endoscopic examination in Osaka Red Cross Hospital from January 2010 to October 2011. We evaluated the presence of CO in magnified endoscopic photographs obtained by ME-NBI for each lesion. We then counted the number of CO in a quarter of the area of high power endoscopic field. These lesions were classified as dense-type CO (number of CO $\geq$20), sparse-type CO (number of CO $\geq$1 and $<$20), or absent-type (number of CO=0). We also evaluated the presence of these types of CO and calculated the sensitivity and specificity of the sparse-type CO to discriminate between D-EGC and UD-EGC.
RESULTS: In the present study, 98 consecutive patients with 104 lesions (D-EGC, 83; UD-EGC, 16; and mixed type, 5) were included. CO were observed in 46 (44%) of 104 EGCs. Moreover, CO were detected in 45 (54.2%) of 83 D-EGCs. In contrast, CO were detected in one (6.2%) of 16 UD-EGCs. Thus, the detection rate of CO in D-EGC was significantly higher than that in UD-EGC ($P < 0.001$). The number of CO was significantly larger in the D-EGC group than in the UD-EGC group (3.9 ± 6.9, 95% CI 0.5-7.3 *vs.* 0.1 ± 0.3, 95% CI 2.4-5.4, $P = 0.027$). The sensitivity, specificity, and accuracy of detecting CO for discriminating D-EGC from UD-EGC were 54.2%, 93.8%, and 60.6%, respectively ($P < 0.001$). Dense-type CO were detected in only six (7.3%) of 83 D-EGC. In contrast, sparse-type CO were detected in 39 (47.0%) of 83 D-EGC. The sensitivity, specificity, and accuracy of sparse-type CO for discriminating D-EGC from UD-EGC were 47.0%, 93.7%, and 54.5%, respectively ($P = 0.002$).
CONCLUSION: Sparse-type CO is a highly specific sign for D-EGC. Our data suggest that observation of CO in EGC by ME-NBI contributes to discrimination between D-EGC and UD-EGC.

P149 THE NEW VALSALVA MANEUVER METHOD (MOUTHPIECE AND MOUTH-HOLDING METHOD) IN UPPER-GASTROINTESTINAL ENDOSCOPY EXAMINATION

T. Matsuda[1,*], T. Omori[1], R. Nakamura[1], H. Kawakubo[1], T. Takahashi[1], N. Wada[1], Y. Saikawa[1], H. Takeuchi[1], A. Yokoyama[2], T. Mizukami[2], K. Koyanagi[3], K. Aiura[3], Y. Kitagawa[1]. *[1]Keio University School of Medicine, tokyo, [2]National Hospital Organization Kurihama Medical and Addiction Center, [3]Kawasaki Municipal Hospital, Kanagawa, Japan*

INTRODUCTION: Valsalva maneuver has been known as a method to observe the piriform sinus and postcricoid area for the nasal endoscope used by ENT doctors. But Valsalva maneuver wasn't possible because patients couldn't be pooled air in the oral cavity in oral endoscope examination. To solve this problem and observe the endoscope observation difficult part of a larynx and pharynx, we developed the new Valsalva maneuver method (Mouthpiece and Mouth-holding method) for oral endoscope.
AIMS&METHODS: Objects are 434 patients who received oral endoscope with Valsalva maneuver method experienced from March to October in 2011. The mouthpiece method: The Valsalva maneuver method was performed using the mouthpiece with a valve which set up the entrance of mouthpiece to prevent flowing out the breath-air from oral cavity (Sumitomo Bakelite Co., LTD).

After the endoscope insertion to the hypopharynx, patient exhales strongly and breath accumulated in the oral cavity, which was closed with a valve. The mouth-holding method: At the end of the examination, the mouthpiece was removed from the mouth and patient mouthed the endoscope by his lips and performed the Valsalva method. The view of a laryngopharynx was evaluated in four steps. (A: The larynx is completely elevated. The piriform sinus, postcricoid area, and palisade vessels can be clearly observed. B: A larynx is elevated. The piriform sinus can be clearly observed, but only a part of postcricoid area and palisade vessels can be observed. C: The piriform sinus can be clearly observed, but postcricoid area and palisade vessels is unobservable at all. D: Almost the same view without the Valsalva maneuver method.)
RESULTS: The evaluation about the view of a laryngopharynx in 434 patients was as being shown below. The mouthpiece method: A 55.3% B 21.5%. The mouth-holding method: A 49.1%, 29.3%. The whole hypopharynx was observed by about 77% of the patients. There was no adverse event by this method, and it was able to carry out again and again safely and easily. The causes of the evaluations C and D were profound sedation, posttreatment scar, pharyngeal reflex and failed Valsalva maneuver method. By using this method, we found the 6 hypopharygeal superficial type cancers during this study.
CONCLUSION: The Valsalva maneuver method (Mouthpiece and Mouth-holding method) can be performed safely and easily in UGI endoscopy. The method is new technique for improving the view of the laryngopharynx and may lead to the early detection of laryngopharyngeal cancer.

P150 ENDOSCOPIC ULTRASOUND IN STAGING ESOPHAGEAL CANCER AFTER NEOADJUVANT CHEMOTHERAPY – RESULTS OF A MULTICENTER COHORT ANALYSIS

H. Heinzow[1], H. Seifert[2], H. Wolters[3], T. Kucharzik[4], W. Domschke[1], D. Domagk[1], T. Meister[1,5,*]. [1]*Department of Medicine B, University Hospital Muenster, Muenster,* [2]*Department of Gastroenterology, University of Oldenburg, Oldenburg,* [3]*Department of General and Visceral Surgery, University Hospital Muenster, Muenster,* [4]*Department of Gastroenterology, University Teching Hospital Lueneburg, Lueneburg,* [5]*Department of Medicine II, HELIOS ALBERT-SCHWEITZER KLINIK NORTHEIM, Northeim, Germany*

INTRODUCTION: Endoscopic ultrasound (EUS) is considered a gold standard in the initial staging of esophageal cancer. There is an ongoing debate whether EUS is useful for tumor staging after neoadjuvant chemotherapy (NAC).
AIMS&METHODS: Forty-five patients with esophageal cancer who had undergone NAC were retrospectively analyzed. In all patients EUS was performed after NAC and histological correlation through surgery was available. uT/uN classifications were compared to pT/pN stages. Statistical analysis included calculation of sensitivity, specificity and accuracy rates. Agreement between endosonography and T staging was assessed with Cohen's kappa statistics.
RESULTS: Overall accuracy of uT and uN classification was 29% and 62%, respectively. Sensitivity, specificity and accuracy rates for local tumor extension after NAC were as follows (%): T1: –/97/84; T2: 13/76/53; T3:86/29/46; T4:20/100/91; T1/2: 27/83/56; T3/4: 89/31/56. Cohen's kappa indicated poor agreement (kappa=0.129) between uT classification and pT stage. Relating to positive lymph node detection sensitivity and specificity were 100% and 6%, respectively (kappa=0.06). T stage was overstaged in 23 (51%) and understaged in 7 (16%) of the patients.
CONCLUSION: In routine clinical practice, the initial endosonographic staging results of esophageal cancer may be revised by informations from other diagnostic procedures, such as radiographic imaging (MRI, CT, PET-CT). Nevertheless, our previously published data with analysis of a large patient cohort of esophageal cancer shows convincing results of initial EUS for accurate staging of esophageal tumors thus allowing for adequate further clinical management. In contrast, however, EUS after NAC does not allow for reliable T, N and UICC classification of esophageal cancer and should, therefore, not be used for staging purposes

P151 THE MANAGEMENT OF GASTIC LESIONS DIAGNOSED AS ADENOMAS BY ENDOSCOPIC BIOPSY.

T. Yamaguchi[1,*], T. Kuwai[1], A. Tsuboi[1], K. Boda[1], K. Yamashita[1], T. Mizumoto[1], Y. Hiyama[1], A. Yamaguchi[1], H. Kouno[1], H. Kohno[1]. [1]*Gastroenterology, KURE MEDICAL CENTER AND CHUGOKU CANCER CENTER, Kure, Japan*

INTRODUCTION: There are no definite clinical criteria for the management of gastric adenomas (Vienna classification category 3) diagnosed by endoscopic biopsy.
AIMS&METHODS: The aim of this study was to evaluate the clinical and endoscopic characterizations of gastric lesions that are preoperatively diagnosed as adenomas using endoscopic biopsy to elucidate how to manage them. We studied 208 consecutive gastric lesions from 171 patients (127 men and 44 women; mean age: 71.6 y.o) that were preoperatively diagnosed as adenomas using endoscopic biopsy during the period from September 2007 to September 2012 at our hospital. All biopsy samples were diagnosed histologically according to the Vienna Classification. All 208 lesions were treated with endoscopic submucosal dissection (ESD) and divided into two groups; adenomas (150 lesions) and carcinomas (58 lesions) with post-resection final pathological diagnoses. We investigated the association between the final diagnoses (adenoma or carcinoma) and the following clinical features and endoscopic findings: age, gender, lesion location, size, color, and macroscopic type.
RESULTS: Age and gender were not different between the two groups. Additionally, there were no significant differences between the two groups in terms of lesion location or macroscopic type. However, lesion size was significantly larger in carcinomas than in adenomas ($p < 0.05$). Carcinomas were significantly more frequently found in 20mm or larger lesions than in 1-9mm and 10-19mm lesions ($p < 0.01$ for 1-9mm; $p < 0.05$ for 10-19mm). Additionally, carcinomas were significantly more frequently found in reddish lesions than in discolored lesions ($p < 0.05$). All lesions that yielded both findings, discolored and a size of 1-9mm in diameter, were adenomas.
CONCLUSION: ESD can be recommended if a gastric lesion that is preoperatively diagnosed as adenoma by endoscopic biopsy has at least one of following factors: a size of 10mm or larger in diameter, or a reddish color.
Disclosure of Interest: None Declared
Keywords: Adenoma, ESD (endoscopic submucosal dossection)

P152 DYSPHAGIA WITH NORMAL ENDOSCOPIC APPEARANCES – COULD WE DO BETTER?

V. Sehgal[1,*], M. Abayalingam[1], H. Alexander[1], A. Mitra[1], I. Ahmed[1], B. Krishnan[1], N. van Someren[1], K. Besherdas[1]. [1]*Gastroenterology, Barnet & Chase Farm Hospitals NHS Trust, London, United Kingdom*

INTRODUCTION: Dysphagia is an 'alarm symptom' that merits prompt investigation by gastroscopy to exclude cancer. Cases in whom cancer is diagnosed at endoscopy in the UK are 'fast tracked' for multidisciplinary team discussion to plan future management. If endoscopy shows no cancer or intrinsic lesion (peptic stricture, oesophageal ring or web), the cause is usually secondary to oesophageal dysmotility. It is recommended that this group of patients should receive a trial of anti-reflux therapy to exclude reflux-related dysmotility. If no improvement in symptoms is seen patients should be referred for oesophageal physiology studies.
AIMS&METHODS: To assess the number of patients who underwent a gastroscopy for dysphagia that had no intrinsic cause found and to evaluate if these patients were managed in line with recommendations.
A retrospective analysis of all patients who underwent a gastroscopy for an indication that included dysphagia at Chase Farm Hospital over a 3-month period (April-June 2012) was performed. Data was obtained from endoscopy reports via the Unisoft GI Reporting Tool (Middlesex) and clinic outcome letters. Intrinsic oesophageal causes for dysphagia were said to be cancer, benign oesophageal stricture and eosinophillic oesophagitis (EE).
RESULTS: 106 patients (37 male, 69 female), median age 66 years, were investigated. 26 (24.5%) had an intrinsic cause for dysphagia - benign oesophageal stricture 18 (17%), cancer 8 (7.5%) and EE 2 (1.9%). 80 (75.5%) patients had no intrinsic cause – reflux oesophagitis 26 (32.5%), Barrett's oesophagus 2 (2.5%), hiatus hernia 28 (35%), gastritis/duodenitis 39 (48.8%), normal 22 (27.5%) and other 13 (16.3%). 55 (68.7%) of these patients had no follow-up organised after endoscopy. The remaining had clinic review 20 (25%), repeat endoscopy 4 (5%) or referral for oesophageal physiology studies 1 (1.3%). 30 (37.5%) patients with no intrinsic cause were prescribed anti-reflux medication after endoscopy. 19 (63.3%) of these patients had no further follow-up. The remaining had clinic review 9 (30%) or a repeat endoscopy 2 (6.7%); none were sent for oesophageal physiology studies.
CONCLUSION: In this study, 75% of patients with dysphagia had no intrinsic cause identified. The majority of patients are discharged from the service without an accurate diagnosis or management recommendation. Our study highlights important shortcomings in the management of patients with a benign cause of dysphagia. We recommend that patients presenting with dysphagia who at endoscopy have no intrinsic cause, be prescribed acid suppression therapy followed by clinical review, and if symptoms persist be considered for oesophageal physiological studies.

P153 THE ENDOSCOPIC SUBMUCOSAL DISSECTION(ESD), THE FINDINGS OF THE TRAINEES IN OUR HOSPITAL

Y. Sato[1,*], T. Maehata[1], K. Hosoya[1], M. Suzuki[1], S. Ishigouoka[1], S. Nakatsu[1], S.-I. Ozawa[1], Y. Watanabe[1], H. Yasuda[1], F. Itoh[1]. [1]*gastroenterolory, St Marianna University, kawasaki miyamae, Japan*

INTRODUCTION: In our hospital, the gastric ESD was introduced from 2004. In addition, from 2011, we also started gastric ESD done by trainees who have reached the level ESD enforcement in our hospital. At the present time, there are 4 ESD trainees. We started from the antrum lesion, because it reportedly has fewer complications. And then, we gradually moved on to the body of the stomach lesion, fibrosis lesion, esophageal lesion, and colonic lesion. We evaluated the ESD training system, and the gastric ESD findings of the trainees in our hospital.
AIMS&METHODS: We targeted 120 patients (124 lesions), who underwent gastric ESD done by trainees among the 285 patients(294 lesions) who underwent gastric ESD in our hospital from March 2011 to December 2012. We evaluated how to use devices, guidelines, locations, en block resection rate, and complication rate retrospectively. In addition, we also compared with the result of 165 patients (170 lesions) who underwent gastric ESD done by an expert at during the same period.
RESULTS: Male79, Female41, average age72.9. We used flush knife BT2.0 on all patients. 101 lesions(81.4%) were guideline criteria, 6 lesions(4.8%) were expand criteria, 4 lesions(3.2%) were intra criteria, and 13 lesions(10.4%) were gastric adenoma.

Guideline criteria were the most frequent cases. About location, 8 lesions(6.4%) were in the upper part of the stomach, 27 lesions(21.7%) were in the middle part of the stomach, and 89 lesions(71.4%) were in the lower part of the stomach. Lower part of the stomach lesions were the most frequent cases. En block resection rates were 100%. Perforation was 1 lesion(0.8%), and post bleeding were 2 lesions(1.6%). The device used was the same as used by Expert ESD. 92 lesions(54.1%) were guideline criteria, 50 lesions(29.4%) were expand criteria, 18 lesions(10.5%) were intra criteria. 34 lesions(20%) were in the upper part of the stomach, 86 lesions(50.5%) were in the middle part of the stomach, 50 lesions(29.4%) were in the lower part of the stomach. En block resection rates were 99.4%. Perforation was 1 lesion(0.5%), and post bleeding were 3 lesions(1.7%). When ESD was carried out by the trainees, there were more lower part of the stomach lesions and guideline criteria lesions than when the ESD was carried out by the expert ; however, the result of the trainees for en block resection and complication were equivalent to the expert.
CONCLUSION: The ESD result of the trainees was equivalent to the result of the expert. The result show that the training system in our hospital is effective.

P154 DOSE CARBON DIOXIDE INSUFFLATION REDUCE MEDIASTINAL EMPHYSEMA AFTER ESOPHAGEAL ENDOSCOPIC SUBMUCOSAL DISSECTION? A PROSPECTIVE, RANDOMIZED, DOUBLE-BLIND, CONTROLLED TRIAL.

Y. Maeda[1,*], D. Hirasawa[1], N. fujita[1], Y. harada[1], T. ohira[1], T. yamagata[1], K. suzuki[1], Y. koike[1], M. tanaka[1], R. yamada[1]. [1]*Department of Gastroenterology, SENDAI CITY MEDICAL CENTER, sendai, Japan*

INTRODUCTION: Mediastinal emphysema sometimes develops following esophageal endoscopic submucosal dissection (ESD) without perforation because the esophagus has no serosa. Carbon dioxide (CO_2) insufflation during esophageal ESD is expected to reduce the incidence of mediastinal emphysema.
AIMS&METHODS: The aim of this study was to assess the efficacy of CO_2 insufflation for reduction of mediastinal emphysema after esophageal ESD. A total of 46 patients who were to undergo esophageal ESD were randomly assigned to CO_2 insufflation (CO_2 group, n = 24) or air insufflation (Air group, n = 22). The patients and the endoscopists were all blind with regard to the type of gas used. Low-dose computed tomography (CT) was carried out immediately after ESD and the next morning. Abdominal pain and distention were chronologically recorded on a 100-mm visual analogue scale (VAS). The volume of residual gas in the digestive tract was measured on CT images. The amount of sedative drugs, end-tidal CO_2 pressure ($EtCO_2$), oxygen saturation (SpO_2) levels during procedure, and clinical courses were recorded. All participants provided written informed consent prior to study enrollment.
RESULTS: The incidence of mediastinal emphysema immediately after ESD in the CO_2 group was significantly lower than that in the Air group (17% vs. 55%, $p = 0.012$). Mediastinal emphysema on the day after the procedure was 8.3% vs. 32% ($p = 0.066$). The mean severity of pain on a 100-mm VAS was 9.6 mm vs. 11.1 mm immediately after ESD, 22.4 vs. 13.9 one hour after the procedure, 16.7 vs. 14.3 three hours after the procedure, and 10.9 vs. 18.8 the next morning, showing no difference between the groups. Abdominal distention scores on VAS at any post-procedure time points did not differ by group either. The volume of residual gas in the digestive tract immediately after ESD was significantly smaller in the CO_2 group than that in the Air group (808 ml vs. 1173 ml, $p = 0.013$). The dosage of sedative drugs used during the procedure did not differ between the groups. Neither the maximum $EtCO_2$ levels nor the minimum SpO_2 levels during ESD differed by group. The incidence of fever of over 38°C was infrequent and similar in both groups (8.3% vs. 9.1%, n.s.). No serious cardiopulmonary complications occurred.
CONCLUSION: Insufflation of CO_2 during esophageal ESD, as compared with that of air, significantly reduced postprocedural mediastinal emphysema. CO_2 insufflation also reduced the volume of residual gas in the digestive tract, but not the VAS scores of pain and distention.

P155 PROPOFOL SEDATION USING A TARGET CONTROLLED INFUSION PUMP DURING COLONSCOPY: A PROPOSAL OF STANDARD OPERATING PROCEDURE

A. Scatto[1,*], E. Rosa-Rizzotto[2], P. Tresin[3], A. Della Rocca[2], E. Guido[2], L. Peraro[2], D. Caroli[2], F. De Lazzari[2]. [1]*Intensive Care Unit, Azienda Ospedaliera,* [2]*Gastroenterology Unit, St Anthony Hospital,* [3]*Anesthesiology Unit, St Anthony Hospital, Padova, Italy*

INTRODUCTION: Many drugs have been proposed for sedation during colonoscopy.For its short onset time and quick recovery propofol is widely used.A safe and standardized protocol of administration is still lacking.
AIMS&METHODS: To demonstrate that propofol infusion using a Target Control Infusion(TCI) pump is safe and well tolerated.From February to April 2013 two endoscopic units enrolled 200 consecutive patients going for colonoscopy.Endoscopies were performed by 6 skilled gastroenterologists(>400 colonsopies/year);anesthesiologists were on call.Standard monitoring(ECG, pulsossimetry, NIBP) and capnography were used.Propofol infusion was controlled by a TCI pump(Syramed®µSp6000,Arcomed AG) set on Schnider protocol. Initial Effect Site Target Concentration(ESTC) was 2,5 µg/ml. After 1 minute from the beginning of infusion, endoscopy began.If the patient felt pain, increments of 0,5 µg/ml were allowed to a maximum of 4 µg/ml.At cecum,ESTC was lowered to 0 µg/ml.Propofol administration and monitoring was performed by a trained nurse.Patients were discharged when Aldrete criteria were met and after a Numeric Visual Scale(NVS) test. Patients underwent telephone interview 24h after endoscopy.
RESULTS: 107(53%) males, 93(47%) females,age 22-84 years,ASA 3-4 18(9%),Mallampati 3-4 62(31%), cardiovascular diseases 99(46%),compromised ventilation 5(2,5%),difficult airway related diseases 1(0,5%).Cecal intubation rate was 98,5% and mean cecal intubation time was 7 minutes.ESTC was 2,5 µg in 26(13%), 3 µg in 75(37,5%), 3,5 µg in 94(47%), 4 µg in 5(2,5%);NVS scale was 1,76±2,62, 0,56±1,60, 0,37±1,13, 0±0, respectively(2,5 µg vs 3,0 µg and vs 3,5 µg,p<0,001;3,0 µg vs 3,5 µg and vs 4,0 µg,p=ns). Hypotension <90 mmHg occurred in 20 pt(10%). Nor treatments or the intervention of the anesthesiologist were needed.199 patients were satisfied and would repeat the exam with the same technique.Discharge criteria were fully met 16,5±12,3 minutes after the end of the procedure.
CONCLUSION: The TCI technique allows a propofol infusion to achieve and to maintain the level of sedation required;this standardized technique is less "operator-dependent" than the titration technique. Furthermore,TCI algorythms decrease the risks of side effects due to initial bolus and guarantee a constant and safe level of sedation.We performed this technique on elderly patients, with severe comorbities and with features of risk of ventilation problems; despite of this, we didn't have any severe complications.We suggest an initial ESTC of 3 µg/ml that can be increased to a maximum of 4 µg/ml.
Disclosure of Interest: None Declared

P156 SAME-DAY BIDIRECTIONAL ENDOSCOPY WITH PROPOFOL ADMINISTED BY NON-ANESTHESIOLOGISTS: A PROSPECTIVE OBSERVATIONAL STUDY ON ITS ADVANTAGES AND SAFETY

A. J. Lucendo[1,*], Á. Arias[2], S. González-Castillo[1], T. Angueira[1], D. Guagnozzi[1], M. Fernández-Fuente[1], M. Serrano Valverde[1], M. Sánchez-Cazalilla[1], O. Chumillas[1], M. Fernández-Ordoñez[2], J. M. Tenías[2]. [1]*Gastroenterology, Hospital General de Tomelloso, Tomelloso,* [2]*Rearch Support Unit, Complejo Hospitalario Mancha Centro, Alcázar de San Juan, Spain*

INTRODUCTION: Same-day bidirectional endoscopy (BDE), including esophagogastroduodenoscopy (EGD) and colonoscopy, have not been evaluated in terms of safety, efficiency and reduction of expenses when carried out with nurse-administered propofol sedation (NAPS) under the supervision of the endoscopist.
AIMS&METHODS: A single-centre prospective registry of consecutive American Society of Anesthetics (ASA) class I-III outpatients undergoing EGD, colonoscopy and BDE was carried out. Propofol was the sole sedative agent used. Adverse events, recovery time and procedure-related expenses were analysed.
RESULTS: Of the 1,500 outpatients (51.5% women) included in the study, EGD, colonoscopy and BDE were carried out in 449, 702 and 349 patients, respectively. All patients were discharged directly from the endoscopy room. Age (mean 54.4, range 18–96 years), body mass index and type of procedure showed no differences among genders or type of procedure. Propofol doses for BDE were 25.9% lesser to both EGD and colonoscopy carried out separately ($p<0.001$). Five different endoscopists assisted by six nurses carried out all the exams; no differences were observed in the results between different explorers. Statistically significant relationships existed among propofol doses, patient' age, weight/BMI and ASA class: the amount of propofol administered directly correlated with patient weight (Spearman's rho=0.135; $p<0.001$) and BMI (rho=0.077; p=0.014) and inversely correlated with age (rho=-0.397; $p<0.001$) and ASA class (rho =-0.336; $p<0.001$). Overall adverse events, including transient O_2 saturation less than 90%, systolic blood pressure <90 mmHg and bradicardia (<50 beats/minute) respectively appeared in 10.7% of single EGD and 8.6% of EGD within BDE. Regarding to colonoscopy, adverse events were documented in 8.6% as single procedures and 9.5% within a BDE (p=ns). However, recovery time to discharge after BDE was 47.9% shorter for BDE than the hypothetical case of EGD and colonoscopy had been carrying our separately ($p<0.001$). Expenses of same-day BDE reduced in 28.1% of that of EGD and colonoscopy as separated procedures ($p<0.001$).
CONCLUSION: If required, same-day BDE with NAPS is resulted in reductions of 25.9% in propofol doses, 47.9% in recovery time, and 28.1% in procedure-related expenses, compared to the case both EGD and colonoscopy would had carried out separately. Adverse events during BDE did not increase regarding EGD and colonoscopy as single procedures.

P157 PROPOFOL SEDATION IN OUTPATIENT COLONOSCOPY BY TRAINED PRACTICE NURSES SUPERVISED BY THE GASTROENTEROLOGIST: IS A FORECAST OF ASPIRATION PNEUMONIA POSSIBLE?

A. Sieg[1,2,*], S. Beck[3], D. Rex[4], W. Stremmel[5], K. Friedrich[5], BNG-Working Group. [1]*Practice of Gastroenterology,* [2]*University Hospital,* [3]*Gastroenterology, Unifersity Hospital, Heidelberg, Germany,* [4]*Gastroenterology, University of Indiana, Indiana, United States,* [5]*Gastroenterology, University Hospital, Heidelberg, Germany*

INTRODUCTION: Propofol has several advantages for sedation of endoscopic procedures. Sedation administered by anaesthesiologists is associated with high

costs. In this study the safety of propofol sedation administered by trained practice nurses under supervision of the gastroenterologist in a cohort of outpatients of an ambulatory practice of gastroenterology in Germany is evaluated.
AIMS&METHODS: METHODS: During 21 months all patients referred to colonoscopy were eligible for this prospective observational study. The familiar CRC risk of the individuals, indication, completeness and results of the colonoscopy were registered together with the dose of propofol. Propofol was administered by intermittent intravenous bolus titration by trained practice nurses under supervision of the gastroenterologist. Oxygen saturation, heart rate and blood pressure were recorded constantly during the procedure and adverse cardiopulmonary events were monitored by the endoscopy team. All patients received a questionnaire to be answered at 24 hours following the endoscopy, provide information about the change compared to the day of examination, and send it back via addressed envelope. Aspiration pneumonia was defined as a sum of cough and fever and/or shortness of breath 1 day following the endoscopy.
RESULTS: A total of 24.441 endoscopies were recorded and sedated with propofol (52% mono-sedation, 48% combination with midazolam). Major events (mask ventilation or laryngospasm) occurred in 4 patients. Minor adverse events occurred in 110 patients (hypoxemia, bradycardia, hypotension, bleeding, coughing or vomiting) and correlated to age and propofol dosage. 64% of the patients sent back the questionnaire. Aspiration pneumonia occurred at 130 (0.8%). Special minor events (coughing and vomiting) correlated significantly with aspiration pneumonia ($p < 0.001$). The relative risk of getting aspiration pneumonia in patients with special minor events was 26,2 (95% CI 12.5-54.9).
CONCLUSION: Propofol can be administered safely for ambulatory colonoscopy by trained practice nurses, with careful monitoring under the supervision of the gastroenterologist. Patients with coughing or vomiting during the propofol sedation have a high risk of aspiration pneumonia, which may be prevented by giving antibiotics before symptoms occur.

P158 DOES THE TOPICAL TREATMENT CAN SHORTEN THE DURATION OF TREATMENT WITH APC IN RADIATION PROCTITIS?

B. Merino Rodríguez[1,*], C. González Asanza[1], Ó. Nogales Rincón[1], K. Klimova[1], L. Ibáñez[1], F. Díaz Fontenla[1], C. P. De Gracia[1], P. Menchén Fernández Pacheco[1]. [1]*Endoscopy, Gregorio Marañón Hospital, Madrid, Spain*

INTRODUCTION: Chronic radiation proctitis is a long-term complication of radiation therapy for pelvic malignancy. This complication requires prolonged and expensive treatment.
AIMS&METHODS: The aim of this study was to compare the efficacy and safety of two treatment regimens, local agents following argon plasma coagulation (APC) vs. APC alone for chronic haemorrhagic radiation proctitis. A single-centre, randomized study was performed on patients with haemorrhagic chronic radiation proctitis after irradiation for prostate (60 patients) and cervical cancer (2 patients). Patients were randomized to 5-aminosalicylic acid compounds/sucralfate /budesonide for 4 weeks plus APC and APC alone. APC was repeated every 8 weeks if necessary after the first session. Using an established scoring system, patients were classified into three groups, with none, mild or severe disease before and at 16 weeks after initial APC treatment (1.5-2 l/min, 25-40 W) and after 48 weeks. Success was defined either as cessation of bleeding or a significant reduction so that further treatment was not required.
RESULTS: 62 patients (mean age 68.4 years). All presented with rectal bleeding, occurring a median 26.8 months (range 7-100 months) after radiotherapy. At baseline there were no significant differences between the local agents plus APC (30 patients) and APC alone (32 patients) groups. At 1 year, a significant improvement in the clinical scale in both groups occurred compared with baseline without statistically significant difference. There were marked differences in the number of sessions (2, 15 vs. 4, 2) and duration of treatment (1, 2 vs. 4, 45) in the group with local agents plus APC (not significant statistically significant). There were no complications related to the procedure
CONCLUSION: APC is safe and effective for the management of chronic radiation proctitis. Additional local agent treatment did not influence the clinical or endoscopic outcome, but could reduce the duration of the treatment. Studies with larger numbers of patients are needed to confirm this.

P159 ENDOSCOPIC MAGNETIC MARKING TECHNIQUE FOR LAPAROSCOPIC COLON TUMOR OPERATION : A PILOT STUDY

B. Keum[1,*], J. S. Lee[1], H. J. Chun[1], H. S. Choi[1], E. S. Kim[1], Y. T. Jeen[1], H. S. Lee[1], C. D. Kim[1], S. H. Kim[1], S. J. Nam[1]. [1]*Division of Gastroenterology and Hepatology, Korea University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: It is difficult to locate correctly and safely a colorectal tumor for laparoscopic surgery. Tattooing is simple, so generally used for localization of colorectal tumor during laparoscopic surgery. However there are limitations, such as incorrect tumor localization due to spread of ink, risk of bowel perforation. To overcome these limitations, we devised a simple magnetic marking technique. We conducted pilot study.
AIMS&METHODS: This study enrolled 12 patients undergoing laparoscopic surgery for early colorectal cancer. We devised 10mm sized ring type magnet (**outdiameter:10mm, indiameter:4mm, thickness:3mm**, **maximal magnetic force:2660G**) which was coated with silicon, and we tied loop using 3-0 nylon. We inserted the marking magnet near lesion with biopsy forcep, and then clipped magnet on target through loop of magnet. A magnetic marking clip was applied on the distal side of lesion during preoperative colonoscopy. During surgery, another magnetic body hanged with long thread which was inserted through laparoscopic trocar, was used to find out the lesion that was marked by magnetic clipping. We analyzed detection rate, detection time, resection margin length from lesion and complication.
RESULTS: 7 of 12 patients' tumor locations were on the rectum, 5 were on sigmoid colon. Tumor size ranged from 10 to 18 mm. Magnetic marking clips were successfully detected in all 12 patients. The time required for detection ranged from 10 to 35 sec. The resection margin from lesion ranged from 40 to 50mm. None of our patients experienced complication s from this marking technique.
CONCLUSION: Magnetic marking technique was simple and convenient for surgeon, and showed good result for accuracy of tumor localization without complication. Therefore, the magnetic marking clip method may be useful for colorectal tumor detection during laparoscopic surgery. And we expect that correct and simple method results in minimizing extent of colon resection.

P160 THE MANAGEMENT OF COMPLICATIONS FOR COLORECTAL ESD ~ THE USEFULNESS OF CLOSURE OF THE MUCOSAL DEFECTS WITH ENDOCLIPS~

C. Hideyuki[1,*], S. Takuma[1], K. Naoya[1], A. Keiichi[1], S. Shihoko[1], T. Akihiro[1], T. Shinsuke[1], I. Tomonori[1], M. Taiki[1], T. Goto[1]. [1]*gastroenterology, Omori Red Cross Hospital, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been applied to the treatment of large colorectal tumors in Japan. However, the rate of complications, such as perforation or bleeding, for colorectal ESD is higher than conventional endoscopic resection. Closure of the mucosal defect may reduce the risk of complications.
AIMS&METHODS: To analyze the usefulness of closure of the mucosal defect with endoclips after colorectal ESD, we retrospective analyzed consecutive 44 patients who underwent ESD for large tumor (≧20mm) in Omori Red Cross Hospital from 2012 April to 2013 March. We closed it by following main three conditions: a muscle layer exposed on the surface (①), thick fibrosis or ulceration (②), or a difficulty with stopping bleed during a treatment (③). There were two groups: patients with closing the mucosal defect (A) and patients without closing it (B). The two groups were compared with respect to their clinical background and the clinical courses.
RESULTS: Median age was 66.6 years. Tumor location was Rt20/Lt12/Rectum12. Tumor size, sample size, median operation time, rate of complete en bloc resection and recurrence were 30.5±16.0mm (15-95), 39.3±17.9mm (20-110), 42.5min, 100%, 0%, respectively. Pathological findings were adenoma26/intramucosal cancer17/submucosal invaded cancer1. The overall rate of perforation and bleeding were 0% and 0%, respectively. 28 of all 44 mucosal defects were closed by endoclips. The reasons of closure (there was some overlapping) were ①8cases, ②6cases, and ③2cases. Average closure time was 8.7min (3-20). Average sample size, operation time, WBC(/μl), CRP(mg/dl), a number of having a high fever(≧38°C), using antibiotic agents and taking a painkiller after ESD were similar: 43.5mm, 48.7min, 7636, 0.85, 1, 5 and 1 in group A, and 35.4mm, 39.0min, 7013, 0.79, 1, 3 and 1 in group B.
CONCLUSION: Reasons for closing the mucosal defect demanded on endoscopic findings during ESD. These selected cases which were needed to close it might be thought to be a higher risk lesions of any complications. As a result of the measures, there was no significant difference between with or without closure and sample size, operation time, clinical data or having any agents. Closure by endoclips does not take much time and will enable to be more safety against complications for colorectal ESD.

P161 SPLIT-DOSE POLYETHYLENE GLYCOL PREPARATION IMPROVED POLYP DETECTION RATE: A BACK-TO-BACK STUDY

I. S. Papanikolaou[1,*], A. D. Sioulas[1], N. Magdalinos[2], L.-D. Lazaridis[1], I. Beintaris[1], I. Stasinos[1], D. Polymeros[1], G. Dimitriadis[1], K. Triantafyllou[1]. [1]*Hepatogastroenterology Unit, 2nd Department of Internal Medicine and Research Unit, Attikon University General Hospital, Haidari,* [2]*Salamina General Private Cinic, Salamina, Greece*

INTRODUCTION: Colonoscopy is the current standard method for colon evaluation. Adequate bowel cleanliness is critical for colonoscopy to be safe and effective.
AIMS&METHODS: We assessed the impact of previous day polyethylene glycol (PEG) preparation vs. split-dose PEG preparation on polyp detection rate among patients referred for polypectomy in an academic endoscopic facility. 20 patients (10 male) were included. Median age was 62 years (52-79). All patients underwent two colonoscopies: an index in a private clinic and a second for polypectomy in the endoscopy unit of a University hospital. Median interval period was 5 weeks (1-25). Examinations were performed by two experienced specialist endoscopists, different in each facility. Indications for the index colonoscopies were: 8 screening, 3 blood in stool, 6 abdominal pain and 3 follow-up after resection for colorectal cancer. PEG was administered for bowel preparation in both procedures. Previous day preparation was utilized initially, while split-dose was preferred for the second intervention. Preparation

was characterized as adequate (excellent or good) and inadequate (fair or poor). Based on size, polyps were divided to diminutive (≤ 5 mm), small (6 to 9 mm) and large (≥ 10 mm). We retrospectively compare the polyp detection rate between these procedures and correlate it with the quality of preparation.
RESULTS: Cecal intubation was achieved in all examinations. Adequate bowel preparation was reported in 12 cases with previous day preparation (60%) vs. 15 with split-dose (75%). Respectively, inadequate cleansing was observed in 8 (40%) vs. 5 (25%) patients. A total of 47 polyps were detected during index colonoscopies, while 68 polyps were identified during the subsequent procedures ($p<0,01$). Regarding size, 36 vs. 50 were diminutive ($p<0,05$), 10 vs. 13 small and 1 vs. 5 large. Pathology revealed 23 tubular adenomas with low grade intraepithelial neoplasia (LGIN), 4 tubulovillous with LGIN, 3 serrated, 1 tubular with high grade intraepithelial neoplasia (HGIN), 1 malignant and 36 hyperplastic polyps.
CONCLUSION: Split-dosing resulted in improved colon cleansing compared with preparation taken the day prior to the examination and significantly enhanced total and diminutive polyp detection rate.

P162 DOES SUFFICIENT OBSERVATION PRIOR TO TRAINING INFLUENCE COLONOSCOPY PROFICIENCY?

D. H. Kim[1], **S. J. Park**[1,*], J. H. Cheon[1], T.I. Kim[1], W. H. Kim[1], S. P. Hong[1]. [1]*Yonsei University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Little is known of the proper prerequisites for colonoscopy training. The objective of this study was to determine whether the experience of upper endoscopy or the number of cases for colonoscopy observation influence the whole learning process and overall proficiency.
AIMS&METHODS: Starting from March 2011, twenty eight of first-year gastrointestinal fellows were trained in colonoscopy at a single tertiary center up to February 2013. As baseline training, all fellows were board certified in Internal Medicine, but with no experience of full colonoscopy before entering their fellowship training. Endoscopic quality indices like adenoma detection rate (ADR), success rate or withdrawal times prospectively measured throughout the first training year and were compared between two groups, A (14 fellows) with more than 100 cases of upper endoscopy experiences and colonoscopy observations, while B (14 fellows) with less.
RESULTS: A total of 18,263 colonoscopy cases were evaluated and 5,413 of them were screening colonoscopies. Success rate and adequate bowel preparation rate were 97.63% and 84.35%, respectively. There were no significant differences of overall quality index between two groups except for the insertion time (619.2 ± 109.0 vs. 766.4 ± 204.7 seconds, respectively, P=0.012). But the improvement of ADR from the first half year into the latter half was significantly higher for group A when compared to group B (28.8% to 35.5% vs. 31.8% to 28.9%, respectively, P=0.007). However, multivariate analysis showed that withdrawal time was the only significant factor for ADR in the second half year (0.061 ± 0.027 [β±SE], P=0.033).
CONCLUSION: Sufficient observation of colonoscopy before training might facilitate the colonoscopy training for fellows according to this study. However, definite high ADR was related to longer withdrawal times.

P163 SPLIT DOSE BOWEL PREPARATION IN DETECTING HIGH RISK PATIENTS FOR COLON NEOPLASIA: A PROSPECTIVE STUDY (PRELIMINARY RESULTS)

E. Voudoukis[1], **A. Tavernaraki**[1,*], A. Theodoropoulou[1], K. Karmiris[1], E. Vardas[1], K. Giannakopoulou[1], G. A. Paspatis[1]. [1]*Gastroenterology, Venizeleion Hospital, Heraklion, Crete, Heraklion, Greece*

INTRODUCTION: Polyethylene glycol (PEG) solutions are considered the optimal bowel preparation as they achieve better patients' compliance, improve bowel cleansing and have less side effects than other purgatives.
AIMS&METHODS: Our aim in this prospective designed study was to evaluate the number and characteristics of missed polyps due to unsuccessful bowel preparation in routine colonoscopies. Outpatients with unsuccessful bowel cleansing (at least inadequate in Aronchick scale) that received 4 LT of PEG solution the previous day of examination were enrolled in the study. In those patients we advised a split dose of 2 LT the previous and 2 LT on the day of examination and a new colonoscopy within 4 months was scheduled. Moreover, patients were pointed out to perform a 7 day low-fiber diet prior to the repeat examination with only liquid consumption the previous day. Patients with inflammatory bowel disease, familiar polyposis coli and colon surgery were excluded. Complete colonoscopy was considered when cecal intubation was achieved. All detected polyps were removed and recorded. Ottawa and Aronchick score were used for the estimation of the bowel cleansing. Exam indication, comorbidities, drug therapy and bowel habits were also recorded.
RESULTS: Forty-five outpatients were enrolled, 32 (71%) underwent a second endoscopy and 13 were lost from the follow up. Patients' characteristics were: male (65.6%), age (mean value±SD) (61.8±10.3), smokers (30.3%). Parameters compared between exams were: polyp detection rate (PDR) 68.8% vs 78.1%, adenoma detection rate (ADR) 59% vs 48.4%, high risk (HR) patients (≥3 adenomas, 1 adenoma≥1cm, adenoma with villous features or high grade dysplasia) 45.2% vs 29%, withdrawal time 7.25±2.1 vs 9.5±2.64, Ottawa bowel preparation score 0.76±0.17 vs 0.32±0.171, and Aronchick score for endoscopy no 2 was 1.66±0.7. A total of 49 vs 38 adenomas were found with mean size of 6.12 vs 3.9 mm. Among the other measured parameters none was statistically significant except for Ottawa bowel cleansing scale ($p<0.001$) and withdrawal time (p=0.001). Notable is that in 2nd colonoscopy 13 out of 15 patients had at least 1 adenoma in their right colon and that in 3 out of 4 HR patients with villous components, adenomas were located right. Per adenoma miss rate (adenomas 2nd colonoscopy/adenomas 1st +2nd colonoscopy) was 42.7%.
CONCLUSION: Our data enforce the views that consider 4L PEG split dose as the optimal preparation for bowel cleansing in routine base. Split dose has proven its efficacy in right colon cleansing where most exams fall short and dysplasia can be more aggressive.
Disclosure of Interest: None Declared

P164 INVESTIGATION OF RECTAL BLEEDING: IS FLEXIBLE SIGMOIDOSCOPY FAR ENOUGH?

F. J. Chedgy[1,*], R. J. Leicester[2], G. J. Sadler[1]. [1]*Gastroenterology,* [2]*Endoscopy, St George's Hospital, London, United Kingdom*

INTRODUCTION: Current UK guidelines recommend patients with persistent rectal bleeding are referred for further assessment. Choice of investigation is at the discretion of the clinician and is not guideline based. The aim of this study was to ascertain whether a significant proportion of right sided colon cancer might be missed if flexible sigmoidoscopy was undertaken in preference to colonoscopy.
AIMS&METHODS: The St George's endoscopy database was interrogated for all procedures performed in patients presenting with rectal bleeding. Colonoscopies that identified lesions suspicious for cancer were then stratified by age and location of pathology. Lesions confirmed histologically to be adenocarcinoma, or adenomas with high-grade dysplasia (advanced adenomas), were grouped as colorectal cancer (CRC) and included in the analysis. Flexible sigmoidoscopy data over the same period was also analysed.
RESULTS: 6,734 colonoscopies and 5,868 flexible sigmoidoscopies were performed between 1992 and 2012.
At colonoscopy, left-sided CRC was found in 6.24%, but right-sided CRC in only 0.8% of cases overall. The yield of left-sided CRC at colonoscopy increased significantly with each decade of patient age, reaching a maximum of 18.4% in the 71-80 year age group. This rising trend was mirrored in the flexible sigmoidoscopy data, with a maximal yield of 11.4% in the 81+ years age group.
In contrast, the yield of CRC in the right colon did not increase significantly with advancing age, and remained low in patients under age 70 0.45%, those aged 71-80 1.7%, and in those aged 81+ 2.4%. In patients with right-sided CRC, 33.9% had a left-sided adenoma (42.1% of these were over 1cm in size), and 20.2% were found to have an indication in addition to rectal bleeding necessitating subsequent colonoscopy.
CONCLUSION: It has recently been suggested1 that 3% of right-sided CRC would potentially be missed if flexible sigmoidoscopy were undertaken in patients presenting with a history of change in bowel habit, with or without rectal bleeding. Our data provides an estimate of age-specific risk of right-sided CRC in patients presenting with rectal bleeding, and suggests the overall yield of right sided CRC in these patients is low (0.8%). In over half of these patients, left-sided (flexible sigmoidscopy) colonic findings or additional clinical indications would have prompted further colonoscopic evaluation.
REFERENCES:
1. Colorectal Diseases 2012 Oct; 14 (10): 1197-200
We would therefore advocate flexible sigmoidoscopy as the first line investigation in patients presenting with rectal bleeding, particularly in those aged under 70 years. If applied in clinical practice, this might have significant cost saving and beneficial waiting list implications, without fear of missing significant numbers of CRC.

P165 COMPARISON OF SPLIT-DOSING VERSUS MORNING REGIMEN FOR BOWEL PREPARATION FOR COLONOSCOPY

H. S. SHAH[1,*], D. DESAI[1], A. JOSHI[1], T. Gupta[1], P. ABRAHAM[1]. [1]*GASTROENTEROLOGY, P.D. HINDUJA HOSPITAL AND MRC, MUMBAI, INDIA, MUMBAI, India*

INTRODUCTION: For effective bowel cleansing, the timing of bowel preparation is important. Split-dose preparation is reported better than previous-evening preparation.
AIMS&METHODS: 1. To compare using the Ottawa Bowel Preparation Scale, the efficacy of split versus morning administration of polyethylene glycol (PEG) solution for colon cleansing in patients undergoing colonoscopy. 2. To assess the optimal preparation-to-colonoscopy (PC) interval.
Prospective, randomized, investigator-blind study of 200 outpatient and hospitalized patients requiring elective colonoscopies (mean age 51.5 years, 121 men) between December 2010 and November 2011, assigned to receive one of the two bowel regimens. Exclusion criteria included patients under 18 years of age, creatinine clearance <30 mL/min, pregnant or lactating women, NYHA III or IV heart failure, history of bowel obstruction or resection, known allergies to PEG, refusal to consent or inconvenience to the timing of scopy
RESULTS: Split preparation resulted in better bowel preparation compared to morning preparation (Ottawa score [SD] 5.52 [1.23] vs. 6.02 [1.34]; p=0.017). However, as a result of longer PC interval, afternoon (1-4 PM) colonoscopies had poor bowel preparation compared to morning (11 AM-1 PM) colonoscopies with both regimens. Ottawa score was 4.50 (0.70) vs 7.39 (0.69) in the morning

and afternoon procedures with morning preparation and 4.67 (0.84) vs 7.58 (0.64) with the split preparation, respectively. There was no difference in the tolerability and compliance between the two regimens

CONCLUSION: A PM/AM split-dosing regimen results in better bowel cleansing compared to morning preparation. Preparation-to-colonoscopy interval longer than 6 hours resulted in suboptimal preparation.

P166 COMPARISON OF CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION AND ENDOSCOPIC MUCOSAL RESECTION FOR LARGE COLORECTAL TUMORS AT TWO ASIA-PACIFIC EXPERT CENTERS: A PROSPECTIVE COHORT STUDY

H. Tanaka[1,*], Y. Saito[1], F. Nakamura[1], S. Kuribayashi[1], T. Sakamoto[1], Y. Ohtake[1], T. Nakajima[1], T. Matsuda[1], M. Bassan[2], B. Holt[2], S. Williams[2], R. Sonson[2], M. Bourke[2]. [1]*Endoscopy Division, National Cancer Center Hospital, Tokyo, Japan,* [2]*Department of Gastroenterology, Westmead Hospital, Sydney, Australia*

INTRODUCTION: We previously reported short-term outcomes to compare ESD and EMR at two expert centers in DDW 2012. We additionally enrolled cases prospectively and analyzed a one-year follow up data.

AIMS&METHODS: There is few data about the clinical outcomes and cost effectiveness between colorectal ESD and EMR in a multi-country study. The aim of our study is, therefore, to compare the one-year follow-up outcomes and total costs of ESD and EMR at the two Asia-Pacific high volume centers. Prospectively collected data for all attempted resections on colorectal tumors ≧20mm from one with expertise in ESD and the other in EMR was analyzed from September 2010 to March 2012. Data collected included patient and polyp characteristics, en bloc resection rates, complication rates, length of hospital stay, follow up rates, follow up colonoscopy and local recurrence rates.

RESULTS: ESD was performed on 177 lesions and EMR was performed on 273. There was no significant difference between ESD and EMR in patient's age (67.2±9.9 /67.8±11.5; p= 0.575) and mean tumor size (38.2±16.5mm/ 39.3±17.3mm; p= 0.516). Lesions undergoing ESD had significantly higher submucosal invasion rates compared to EMR (18.1% vs. 4.8%; $p<0.001$) but complication rates between two groups were similar and higher en bloc resection rates in ESD compared to EMR (92.7% vs.15.7%; $p<0.001$). Follow up rates was 90.3% (160/177) in ESD and 34.8 % (95/273) in EMR. There was no local recurrence in the ESD group during a mean endoscopic follow up period of 12.6±4.0 months (range: 2-27 months). In comparison, local recurrence occurred in 5.26 % (5/95) in EMR group during a mean endoscopic follow up period of 5.77±3.18months (range: 3-18 months). All recurrences were, however, treated endoscopically without surgery. Limitation of this study was lower follow-up rate in the EMR group, so cost analysis was not carried out.

CONCLUSION: ESD was associated with higher technical success rates than EMR. There were 5% local recurrences in the EMR group, however, all recurrences were managed successfully by repeated endoscopic treatment. Ongoing follow up is being undertaken to assess longer-term outcomes and costs of these two techniques.

P167 DIAGNOSTIC PERFORMANCE OF MAGNIFYING CHROMOENDOSCOPY COMPARED WITH NBI MAGNIFICATION FOR DEPTH OF INVASION IN EARLY COLORECTAL TUMORS.

H. Takamaru[1,*], T. Sakamoto[1], M. Makazu[1], M. Yamada[1], Y. Otake[1], T. Nakajima[1], T. Matsuda[1], Y. Saito[1]. [1]*Endoscopy Division, National Cancer Center Hospital, Tokyo, Japan*

INTRODUCTION: High-grade dysplasia (HGD) and superficial submucosal colorectal cancers can be managed by endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR). Therefore, endoscopic diagnosis for depth of invasion plays an important role in treatment for early colorectal cancer (ECC).

AIMS&METHODS: The aim of this study is to evaluate diagnostic value for submucosal invasion in ECC, using crystal violet (CV) magnifying chromoendoscopy compared with narrow band imaging (NBI) magnifying endoscopy.

Two thousand eight hundred three colorectal tumors were resected endoscopically or surgically between October 2011 and December 2012 at the National Cancer Center Hospital in Tokyo. In these tumors, 314 tumors were retrospectively analyzed: those which were diagnosed by both CV chromoendoscopy and NBI endoscopy before treatment, and those histopathologically revealed as HGD or submucosal invasive cancer. In diagnostic processes, we first observed the lesion with NBI magnifying endoscopy, and after that CV staining with magnifying chromoendoscopy was performed. Endoscopic findings of NBI magnification were graded into Capillary Pattern (CP) type II, IIIA and IIIB as described by Sano. Type V pits were classified into invasive or non-invasive pattern as described by Matsuda. Lesions were diagnosed as deep submucosal invasion when CP type IIIB or type V pits of invasive pattern were observed. We evaluated the accuracy of each endoscopic diagnosis method compared with histopathological results. We assessed the confidence level of diagnosis in each method. Confidence level was defined as a diagnosis with more than 90% certainty.

RESULTS: Among a total of 314 lesions, overall accuracy with NBI endoscopy and CV chromoendoscopy was 85.6% and 87.2%, respectively. In the lesions of HGD or superficial submucosal invasive cancer, the accuracy with NBI endoscopy and CV chromoendoscopy was 90.4% and 92.0%, respectively. In lesions diagnosed with high-confidence, the accuracy with NBI endoscopy and CV chromoendoscopy was 75.8% and 81.4%, respectively.

CONCLUSION: NBI endoscopy and CV chromoendoscopy both showed sufficient diagnostic performance for ECC, especially in HGD or superficial submucosal invasive cancer. In the lesions diagnosed with high-confidence, the accuracy of CV chromoendoscopy seems higher compared with NBI endoscopy. These results suggest that additional observation of CV endoscopy after NBI endoscopy improves diagnostic accuracy in ECC.

P168 COMPARISON OF COMPLICATION RATES OF POST-EMR OF LARGE SESSILE POLYPS BETWEEN BOWEL CANCER SCREENING COLONOSCOPIST VERSUS NON-BOWEL CANCER SCREENING COLONOSCOPISTS IN A DISTRICT GENERAL HOSPITAL

J. Ishtiaq[1,*], J. Gasem[1]. [1]*gastroenterology, Ysbyty Gwynedd, Bangor, North Wales, UK, Bangor, United Kingdom*

INTRODUCTION: Introduction: EMR for large polyps is a complex procedure and carries significant complication rate. Therefore, experienced endoscopists with special training and interest in EMR should carry out such procedures.

AIMS&METHODS: Methods: 37 patients (25 men and 12 women) undergone EMR for large (≥ 20mm) sessile polyps, over a 2 year period between January 2011 and December 2012 were retrospectively analysed.

RESULTS: Results: Of the 37 polyps removed (one polyp per patient) were either tubulovillous (n=23), or villous (n=14) adenomas.

Mean polyp size was 31.6 mm (range: 20 – 60).

Polypectomy sites were caecum (n=7), ascending colon (n=4), hepatic flexure (n=3), transverse colon (n= 1), sigmoid (n= 11), and rectal (n=11).

Bowel screening Wales (BSW) colonoscopist (n=1) performed 14 (37%) EMRs. Non-BSW colonoscopists (n=4) performed the remaining 23 EMRs.

Comparison between BSW colonoscopist and Non-BSW colonoscopists

	BSW Colonoscopist (n=1)	**Non-BSW Colonoscopists (n=4)**
Mean age of patients	71.5 years	73.7 years
Number of polypectomies	14 (38%)	23 (62%)
Mean polyp size	37.5mm (largest = 60mm)	28mm (largest = 40mm)
Patients awaiting surveillance endoscopy for more than 3 months	1 (7%)	7 (30%)
Recurrence of polyps	None	3 (caecal = 2, rectal = 1)
Peroration	None	1 (requiring surgery)
Major bleeding	None	None
Other major complications	None	None

CONCLUSION: Conclusion: Our data concludes that our post-EMR major complication rates for high risk, large sessile polyps in a district general hospital are very low, and are in keeping with the international standards.

Moreover, in age- and health-matched two groups of patients, there were no complications reported in the BSW colonoscopist group as compared to non-BSW colonoscopist group. This highlights the need for specialising in this field.

P169 CLINICAL PROFIL AND NATURAL HISTORY OF SYMPTOMATIC ILEO-CECAL ULCERS

J. Toshniwal[1,*], R. Chawlani[1], M. Kumar[1], A. Arora[1], S. Bhalla[2], M. Sachdeva[1], K. MÖNKEMÜLLER[3]. [1]*Gastroenterology and Hepatology,* [2]*Pathology, Sir Ganga Ram Hospital,New Delhi 110060 INDIA, New Delhi, India,* [3]*Division of Gastroenterology and Hepatology, University of Alabama at Birmingham, Birmingham, AL 35249, United States*

INTRODUCTION: Ileo-cecal (IC) ulcers represent 15-50% of the total ulcers diagnosed during colonoscopy.Ulcerations in the IC region have a plethora of etiologies and outcomes with a variable natural history.

AIMS&METHODS: Aim of this prospective study was to evaluate the etiology, clinical presentations and natural history of IC ulcers. Patients diagnosed to have ulcerations in the IC region during colonoscopy were enrolled.Their clinical presentation and outcome at first visit were recorded.These patients were followed at every three month interval for presence of symptoms for atleast one year;and colonoscopy was repeated in symptomatic patients.

RESULTS: Out of 1632 colonoscopies performed in a tertiary care hospital from May 2010 to October 2011, 104 patients had ulcerations in the IC region. This population represents the study group. The median age was 44.5 years (range 18-85) and 59% were male. The predominant presentation was lower GI bleed

(55.5%), pain abdomen +/-diarrhea (36.3%)or diarrhea alone (9.9%). Associated fever was present in 32 (31%) patients. The etiology of ulcers was classified into infective causes (43%), non-infective causes (29%), and non-specific ulcers (28%) at first visit. Three patients (3%) died (all had presented with bleed and had non-specific ulcers).These remaining 101 patients were followed at every 3 months for atleast one year.All patients with infective etiology were asymptomatic at one year follow-up.Of the 14 patients with crohn's disease 3 were symptomatic at 1 year follow-up;all were on treatment with steroids.Of the 6 patients with malignant IC ulcers 3 expired;while 3 were asymptomatic.Of the 29 patients with non-specific ulcers;3 were diagnosed as tubercular IC ulcers at follow-up and responded to anti-tubercular treatment ;while 1 was diagnosed as Non-Hodgkins lymphoma and responded well to chemotherpy ;while 2 were diagnosed as Crohn's disease during follow-up and were asymptomatic at end of 1 year on medications.

CONCLUSION: Infection was the most common (>40%) cause of ulcerations of the IC region in the study. Cecal involvement and fever were important clues to infective cause.Majority of the patients(95/101)were asymptomatic at the end of one year;while 3 patients with Crohn's disease were symptomatic at the end of one year. 50% of patient with malignant IC ulcers expirenced mortality at end of one year.While 20%(6/29)patients with non -specific ulcers were reclassified in terms of etiology during the follow-up period of one year.

P171 NATURAL HISTORY OF DIMINUTIVE COLORECTAL POLYPS: PROSPECTIVE OBSERVATION BY COLONOSCOPY

K.-I. Mizuno[1,*], Y. Suzuki[2], M. Kobayashi[1], M. Takeuchi[3], S. Hashimoto[1], Y. Aoyagi[3]. [1]*Department of Endoscopy, Niigata University Medical and Dental Hospital,* [2]*Department of Gastroenterology, Niigata Rinko Hospital,* [3]*Division of Gastroenterology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*

INTRODUCTION: Endoscopic removal of colorectal adenomatous polyps effectively prevents cancer. New developments in biomedical optics have enabled the detection of smaller polyps. However, it remains unclear whether the resection of smaller polyps contributes to cancer prevention. To determine whether small polyps should be resected, the natural history of polyps has to be understood.

AIMS&METHODS: The aim of this study was to clarify the natural history of diminutive polyps (≤5 mm) by prospective colonoscopic examinations. A total of 207 diminutive polyps (≤5 mm) detected in 112 patients (73 men, median age 61.9 years) were randomly selected and studied from December 1991 through March 2002 at Niigata University Medical and Dental Hospital, Niigata, Japan. All patients received a detailed explanation of the study protocol and provided informed consent. All polyps were sessile and superficially elevated type with no depressed component and were diagnosed colonoscopically as mucosal low-grade neoplasia (without biopsy). The polyp size was measured by comparison with the diameter of a biopsy forceps placed next to the polyp. To ensure that the same polyp was followed, a site near the polyp was marked with India ink. All patients underwent periodic colonoscopy. If the followed polyp showed clinically significant enlargement (≥10 mm) or the patient desired removal of the polyp, it was resected endoscopically.

RESULTS: During a median follow-up of 86.4 months (range 12.4–223), the mean polyp diameter increased from 3.2 ± 1.0 mm (range 1.3–5.0) to 3.8 ± 1.6 mm (range 1.3-10.0) (p=0.002). Among polyps followed for at least 5 years (134 of 207), 1 polyp (0.7%) grew to more than 10 mm, 28 (20.9%) grew to 6–9 mm, and 105 (78.4%) remained within ≤5 mm at the end of follow-up. Among the polyps followed for less than 5 years, no polyp grew to more than 10 mm. Twenty-four of the 207 polyps were resected endoscopically at the end of follow-up. The histopathological diagnosis was mucosal high-grade neoplasia (Category 4) for 1 polyp, and mucosal low-grade neoplasia (Category 3) for 23 polyps. There was no submucosal invasive carcinoma (Category 5) according to the revised Vienna classification system.

CONCLUSION: Our prospective observations suggest that diminutive polyps grow very slowly. It may not be necessary to resect diminutive polyps for at least 5 years.

P172 CLINICAL SIGNIFICANCE OF SMALL AND DIMINUTIVE COLORECTAL POLYPS

K. O. Kim[1,*], B. I. Jang[1], H. H. Chung[1], S. H. Lee[1], K. H. Kim[1], T. N. Kim[1]. [1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, YEUNGNAM UNIVERSITY COLLEGE OF MEDICINE, Daegu, Korea, Republic Of*

INTRODUCTION: The management of small and diminutive colorectal polyps is not definite. Our aims were to review the clinicopathologic characteristics of diminutive and small polyp and evaluate the risk factors of advanced adenomas.

AIMS&METHODS: The medical records of total 4711 patients who were diagnosed as colon polyp were reviewed retrospectively. Polyp below 0.5 cm defined as diminutive polyp and 0.6≤size≤0.9 as small polyp. The baseline characteristics of the patients, size, location, morphology and histology were assessed. We analyzed the risk factors of advanced adenomas which defined as villous or tubulovillous polyps and/or dysplasia or intramucosal carcinoma histologically.

RESULTS: Male to female ratio was 60.3 : 39.7 and mean age was 56.2±13.0years. Of the 4711 patients, 5058 polyps were detected and polyps below 1cm were noted in 93.0%(4704/5058) and adenoma less than 1cm in size was noted in 54.6%(2761/5058). Diminutive polyp was noted in 75.4%(3549/4704) and small polyp was noted in 24.6%(1155/4704). Diminutive adenoma was noted in 58.2%(1607/2761) and small adenoma was noted in 41.8%(1154/2761). Mean size of polyps was 0.40±0.15. 47.4% of polyp less than 1cm in size was located in right colon. The incidence was most common in sigmoid colon(24.9%). The most common shape was sessile type(56.3%). Advanced adenomas below 1 cm were noted in 0.7%, with villous component(in 19 cases), high grade dysplasia in(3 cases) and adenocarcinoma(in 6 cases). Mean size of advanced adenoma was 0.62 cm, sessile type was most common type and they were most commonly detected in the rectum(28.6%). There were significant differences in age, gender and size of the polyp between advanced and non-advanced adenoma. By multivariate analysis, old age, male gender and size above 0.5cm were risk factors of advanced adenoma of polyps below 1.0cm.

CONCLUSION: The incidence of advanced adenomas below 1 cm was 0.7%. Polyp size, male sex and old age were identified as risk factors of advanced adenoma. Although the size is small, we need more meticulous examination not to miss and active complete removal of the lesion especially with these risk factors.

P173 CLINICOPATHOLOGICAL FEATURES OF COLORECTAL POLYPS: COMPARISON WITH 10 YEARS AGO

K. O. Kim[1,*], B. I. Jang[1], H. H. Chung[1], S. H. Lee[1], K. H. Kim[1], T. N. Kim[1]. [1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, YEUNGNAM UNIVERSITY COLLEGE OF MEDICINE, Daegu, Korea, Republic Of*

INTRODUCTION: As endoscopic examination of colorectum increase in number, detection rate of colorectal polyp is also on the increase. However, comparative studies about the clinicopathologic feature of the colorectal polyps between past and present in Korea are limited. The aim of the present study was to compare the clinicopathologic characteristics of colorectal polyps with 10 years ago.

AIMS&METHODS: The medical records of 4007 patients who underwent colonofibroscope were reviewed retrospectively. The patients were classified into 2002 group and 2012 group. The patients' characteristics, size, gross morphology, location and pathology of all polyps were analyzed.

RESULTS: Mean age of 2002 group was older than that of 2012 group(63.09±13.3 *vs* 52.27±11.9, *p=0.000*). Colorectal polyps were diagnosed in 1816 patients. The numbers of colorectal polyps were 3723 and mean polyp number per one patient was 2.05. Mean polyp size was 0.49 cm and it was larger in polyp 2002 group than that of 2012 (0.60±0.39*vs*0.43±0.32). Sessile type was the most common morphology in both groups. The most common histology was tubular adenoma and more common in right colon in both groups. Although there is no meaningful difference in morphology, distribution and histology between groups, the location of advanced adenoma including villous, tubulovillous adenoma, high grade dysplasia and adenocarcinoma was significantly different between groups(*p=0.010*). Unlike in 2002 group, advanced adenoma was detected more commonly in right side in 2012 group(30.4% *vs*63.6%,*p=0.012*).

CONCLUSION: There was no significant change in distribution of polyp between recent and last decade. However, advanced adenoma was more common in right side recently. Our results suggested that there might be a shift in location of advanced adenomas from left side to right side of the colon. We need to pay more attention not to miss and more active treatment of right side colon polyps.

P174 STUDY COMPARING POLYETHYLENE GLYCOL (PEG) 3350 + SPORTS DRINK + BISACODYL REGIMEN TO PEG-ASCORBIC ACID ON EFFICACY, PATIENT SATISFACTION, TOLERABILITY, EFFECTS ON SERUM ELECTROLYTES & POLYP DETECTION RATE

K. Patel[1], M. A. Khan[2,*], G. Swanson[2], J. Losurdo[2], A. Keshavarzian[2], M. D. Brown[2]. [1]*Internal Medicine,* [2]*Gastroenterology and Hepatology, Rush University Medical Center, Chicago, United States*

INTRODUCTION: Electrolyte-free PEG 3350 (Miralax®), which is only FDA-approved for constipation, combined with 1.9 L of sports drink (SD,Gatorade®) and 2 tablets of Biscodyl (B) (PEG 3350+SD+B) has been increasingly used for bowel preparation (BP) citing patient satisfaction and tolerability. There are no data comparing this regimen to FDA-approved standard split-dose PEG-ascorbic acid (PEG-AA) (MoviPrep®) on bowel prep efficacy in cleansing the colon, patient satisfaction, tolerability and their effect on the electrolytes. Our aim was to assess the efficacy, patient satisfaction, tolerability, polyp detection rate and effect on electrolytes safety of these two PEG-based preparations
AIMS&METHODS: This was a prospective, single-blind, block randomization trial. Patients were randomized to single dose 238 g PEG 3350 + 1.9 L SD + 2 tablets of Bisacodyl(PEG 3350+SD+B) or 2L PEG-AA. The primary outcome was preparation quality using the validated Boston Bowel Prep Scoring (BBPS) system by the endoscopist performing the procedure (E1), nurse assisting the procedure (N) and by a blinded endoscopist (E2) using photos from the procedure. Basic metabolic panels were checked on the day of the randomization and on the day of the procedure. Patients completed a survey on the day of the procedure to assess their experience with the bowel preparation. (NCT 01695863)
RESULTS: We randomized 150 patients (74 PEG 3350 +SD+B, 76 PEG-AA). Patients receiving PEG AA had statistically significantly better BBPS scores for the right side of the colon as rated by E1, N & E2 ($p=0.005$, $p<0.001$, $p=0.001$, respectively) and for the left side and transverse colon as rated by the N ($p=0.004$ and $p=0.026$, respectively) & E2($p=0.000$ and $p=0.006$, respectively) compared to patients receiving PEG 3350+SD+B. After dividing the quality of BP into poor/fair and good/excellent, a significantly higher percentage of patients receiving PEG-AA had good/excellent preparations compared to PEG3350+SD+B ($p=0.03$) group for the right side of the colon (see table below). There was no statistical difference in patient satisfaction, tolerability, polyp detection rate and change in serum electrolytes preceding and following the BP.
Table 1 comparing Movi Prep vs Miralax

Bowel Preparation	Poor/Fair	Good/Excellent	P value
Movi Prep (R)	7.9%	43.3%	0.003
Miralax +SD+B	18.9%	29.9%	

CONCLUSION: Use of single-dose, non-FDA approved PEG 3350+SD+B was inferior in bowel preparation for colonoscopy compared to a split-dose PEG-AA, and thus cannot be recommended for bowel preparation for screening colonoscopy

P175 FEASIBILITY OF NARROW BAND IMAGING MAGNIFICATION FOR THE INVASION DEPTH DIAGNOSIS OF EARLY COLORECTAL CANCERS

M. Takahashi[1,*], R. Chinzei[1], K. Sasajima[1]. [1]*Gastroenterology, SAITAMA RED CROSS HOSPITAL, Saitama, Japan*

INTRODUCTION: Narrow Band Imaging (NBI) magnification is convenient and time-saving method for the endoscopic diagnosis of early colorectal lesions. However, it remains controversial whether NBI magnification is useful for the diagnosis of invasion depth of early colorectal cancers, compared to chromoendoscopic magnification.
AIMS&METHODS: The aim of this study was to clarify the clinical efficacy of NBI magnification for the diagnosis of submucosal massively invasive cancer (SM-M) in the assessment of our modified criteria. The subjects of this retrospective study were 615 early colorectal cancers resected endoscopically or surgically from May 2007 to March 2013. After observation with a conventional image, NBI magnification diagnosis was performed from the standpoint of the shape and arrangement of microvessels according to Sano's classification. Type IIIB, an indicator of massively submucosal invasion with NBI magnification, was determined only by the presence of the following specific irregular findings of microvessels: "caliber change of microvessels", "long irregular vessel" or "decline of microvessel density". Subsequently, chromoendoscopic magnification diagnosis after crystal-violet dye-stain was based on Kudo's classification. VI high-grade and VN pit pattern were defined as indicators of massively submucosal invasion. Histological diagnosis was assessed on the basis of Vienna classification and massively submucosal invasion was defined as an invasion depth $\geqq 1000\mu$m.
RESULTS: 615 colorectal cancers consisted of 449 intramucosal cancers, 69 submucosal slightly invasive cancers and 97 SM-M. Sensitivity, specificity and accuracy of type IIIB for SM-M were 66.0%, 98.8% and 93.7%, whereas those of VI high-grade and VN pit pattern were 76.3%, 98.3% and 94.8%, respectively. There was no significant difference between NBI and chromoendoscopic magnification. The frequency of type IIIB was significantly lower in flat type lesions (39.1%, 9/23) than that in protruded (66.7%, 24/36) and depressed type lesions (81.6%, 31/38, $p=0.0010$). All specific findings of type IIIB had high specificity for SM-M (99.1%, 99.8% and 99.5%, respectively). The "decline of microvessel density" finding was significantly more frequent in depressed type (71.4%) than in protruded (28.1%) and flat type (9.5%, $p<0.0001$).
CONCLUSION: NBI magnification would have the clinical advantage in the diagnosis of submucosal massively invasive cancers. Although diagnostic ability in flat type lesions was not satisfactory, our modified criteria and specific irregular findings of microvessels would be useful for the diagnosis of submucosal massively invasive cancers.

P176 IMPROVEMENT OF THE FLAT ADENOMA DETECTION RATE WITH PANCOLONIC CHROMOENDOSCOPY WITH INDIGO CARMINE

O. Toyoshima[1,*], S. Yoshida[2], N. Fujiwara[2], K. Hata[1], Y. Yamaji[2]. [1]*gastroenterology, Toyoshima clinic,* [2]*gastroenterology, The University of Tokyo, Tokyo, Japan*

INTRODUCTION: The adenoma detection rate (ADR) is one of the independent predictors used to reduce the risk of interval colorectal cancer in screening colonoscopy. Colonoscopic removal of adenomatous polyps decreases the incidence and mortality rate of colorectal cancer. Given that, it is important to improve the ADR in colonoscopy. Several studies have suggested that interval cancer is more likely to be found at the proximal colon than the distal colorectum. Therefore, a bigger emphasis should be placed on detecting precancerous lesions at the proximal colon in advance. Pohl et. al. reported that pancolonic chromoendoscopy (PCC) with indigo carmine markedly improved the ADR and was practicable enough for routine application. The aim of this study is to clarify whether PCC is effective at achieving higher ADR than the conventional method in screening colonoscopy.
AIMS&METHODS: Retrospectively, PCC (with 0.3% indigo carmine spraying during continuous extubation) was compared with conventional colonoscopy (control group) in consecutive patients attending for a routine colonoscopy performed by either of the two endoscopists (T and Y). A total of 7251 examinees received a colonoscopy at our clinic from August 2008 to December 2012. After reviewing their clinical features and endoscopic data, we chose a control population matched for age, gender, and endoscopist by the statistical program R (http://cran.r-project.org). The patients' characteristics, procedure findings including withdrawal time, size, location, morphology and histopathology of the lesions detected were reviewed from medical records and pathological reports of the endoscopic resection or biopsy specimens.
RESULTS: A total of 794 patients were included (397 in the PCC group, 397 in the non-PCC control group) after matching. The patients' demographic characteristics and indications for colonoscopy were similar between the two groups. The proportion of patients with at least one adenoma detected wasn't statistically different between the PCC and the non-PCC group (46.6% vs 43.3%; $p=0.35$). Chromoendoscopy increased the overall detection rate for flat adenomas (23.7% vs 15.4%; $p=0.003$), not for those located at the distal flat adenomas (10.6% vs 10.3%; $p=1.00$) but for those at the proximal colon (19.1% vs 12.8%; $p=0.02$). Mean withdrawal time was slightly but not significantly shorter in the PCC group than the non-PCC group (17.47 min vs 18.73 min; $p=0.40$).
CONCLUSION: Pancolonic chromoendoscopy markedly enhances flat adenoma detection rates, especially at the proximal colon. This procedure may be effective for screening colonoscopy to improve the ADR at the proximal colon and mortality rate of colorectal cancer.

P177 ALLOCATION OF TECHNICAL AND HUMAN RESOURCES IN COLO-RECTAL SCREENING PROGRAMS IN NORTHEASTERN ITALY

R. Fasoli[1,*], G. de Pretis[1], On behalf of Italian Society of Digestive Endoscopy. Veneto and Trentino-Alto Adige Section. [1]*Department of Gastroenterology and Difestive Endoscopy, OSPEDALE SANTA CHIARA TRENTO, Trento, Italy*

INTRODUCTION: Colonoscopic screening for colo-rectal cancer necessitates an important engagement of economic, technical and human resources.
In Italy the main screening protocol consists of the performance of a total colonoscopy in faecal occult blood-test (FOBT)-positive subjects of both sexes - 50-69 or 50-74 years of age - with few scattered centres performing flexible sigmoidoscopy.
Northern and central Italy show a satisfactory coverage of the involved population, whereas Southern Italy is still trailing, with many areas still to be covered by screening campaigns. Preliminary results of a recent and wide survey conducted in northern and central Italy have shown satisfactory data as regards quality in screening colonoscopy, mainly measured through completion of the examination and polyp and adenoma detection rate.
AIMS&METHODS: We hereby report the results of a survey conducted in 2012 and involving 39 secondary level endoscopic centres in North-eastern Italy, all performing second level colonoscopies in FOBT-positive subjects. Reported data relate to the execution of first colonoscopy in first or second round (follow-up colonoscopies are excluded).

RESULTS: 51% of centres reported a standard time slot dedicated to screening colonoscopies, 49% a longer time slot, as compared to colonoscopies done in symptomatic patients.
In 33% dedicated time was 30 minutes; in 15% 40 minutes; in 18% 45 minutes; in 21% 50 minutes; in 13% 60 minutes.
In 15% of centres screening medical staff has been reported to be selected in advance; in 85% no selection has been made.
As regards technical appliances, only 3% of centres declared to care for a selection of instruments and devices for screening colonoscopies; 97 % of centres employed currently used equipment in a random fashion.
CONCLUSION: These data suggest that in Northern Italy management of colonoscopic lists in FOBT-positive subjects recognizes special care in selecting human and technical resources only in a minority of cases.
Time dedicated to screening colonoscopies is longer than in examinations performed in symptomatic subjects in about 50% of cases.
In the absence of recognized standards concerning these issues and considering that these choices do not seem to influence quality of screening colonoscopy, we believe that our data should be taken into consideration for further evaluation both at national and international level.

P178 ENDOTICS SYSTEM, A NEW WAY TO UNDERGO THE ENDOSCOPIC VALUATION OF LOWER GI TRACT : OUR INITIAL EXPERIENCE.

R. Bozzi[1,*], A. inzirillo[1], E. d'avenia[2], M. inzirillo[1], C. dewerra[3], D. cattaneo[1].
[1]uoc chir ed endoscopia digestiva, azienda ospedaliera dei colli, [2]uoc chir ed endoscopia digestiva, UOC CHIRURGIA ED ENDOSCOPIA DGESTIVA "V.MONALDI", [3]Departimento di Chirurgia, Università degli Studi di Napoli Federico II, napoli, Italy

INTRODUCTION: Video-colonoscopy is considered the gold-standard for the diagnosis of colonic diseases, but this diagnostic technique shows some technical limitations, such as invasiveness and patient discomfort, which limit the adherence to the procedure.The *Endotics System* is composed of a disposable probe and a workstation. The probe has a steerable tip, a flexible body and a thin tail.The workstation allows the endoscopist to fully control the disposable probe by means of a hand-held console and to visualize on a screen real time images. This technology thanks its extremely flexible and disposable probe is highly safe and painless.
AIMS&METHODS: This study assessed both the acceptability and efficacy and diagnostic capabilities of this new endoscope. The key primary endpoint was to evaluate diagnostic capabilities in a cohort of patients who wouldn't to undergo conventional colonoscopy without sedation; secondary endpoints were to evaluate the painless capabilities scoring a pain index in a scale ranging from 0 to 10, the cecal intubation rate and the cecum reaching time. A total of twenty patients participated to the study (9 men, 11 women; mean age 55 years). Three patients were excluded: one because of panic syndrome before procedure occurs and two because of inadequate bowel preparation where procedures were stopped on rectum colon. The cecum was reached in 15 patients (cecal intubation rate 100%).
RESULTS: The mean time to reach the cecum was 55 min (range 48-75) and mean pain score was 2. Endoscopic findings were: 4 polyps lesions (mean size x 110 mm), whereof one Ca *in situ*, in 3 people; 7 diverticular disease in 7 people. All findings was confirmed by following conventional colonoscopy procedure with sedation and no additional findings were notice (Sensitivity=100%, Sensibility= 100%). No device-related complications were encountered.Limits of the Endotics System consist on the absence of an instrument channel and procedure time longer than conventional colonoscopy.
CONCLUSION: The Endotics System represents a new painless method to undergo the endoscopic inspection of the lower GI tract, specially, in patients who are not willing to have a conventional colonoscopy procedure without sedation. Endotics System could be useful also for CCR prevention, but the absence of the instrument channel and the longer procedure time represent a limitation for this purpose. Further clinical and comparative studies are warranted.No financial disclosure.

P179 THE WATER IMMERSION METHOD MIGHT CONTRIBUTE TO COMFORTABLE TOTAL COLONOSCOPY: RANDOMIZED TRIAL

R. Shiraishi[1,*], T. Yukimoto[1], E. Takeshita[1], S. Mine[1], H. Isoda[1], M. Kitayama[1], K. Ario[1], Y. Kadokawa[1], S. Tsunada[1], R. Iwakiri[2], K. Fujimoto[2]. *[1]Ureshino Medical Center, Ureshino, [2]SAGA MEDICAL SCHOOL, Saga, Japan*

INTRODUCTION: It is well known that in total colonoscopy (TCS) straightening of the sigmoid colon is important and a basic skill for a comfortable examination. Recently, the water immersion method (WIM) was reported to be better for relieving abdominal discomfort caused by colonoscopy than the traditional air insufflation method (AIM). Additionally, WIM efficiently supports trainees to master TCS skills.
AIMS&METHODS: The aims of this study were 1) to compare insertion times and achievement rates of straight insertion by the WIM with the AIM by TCS experts and to evaluate the efficacy of the WIM in the progress of TCS skills in trainees. 1) A total of 220 patients undergoing TCS were randomized to the WIM or AIM (males, 119; females, 101; mean age, 63.7 years). We used a universal colonoscope with variable hardness, a clear hood, lukewarm water, and normal air, and did not administer sedatives. Cecal insertion time and achievement rates of straight insertion were evaluated in both groups. 2) A total of 113 patients underwent TCS by trainees who had experienced less than 30 cases. These patients were separated into the first 57 patients who underwent TCS (preceding period) and the latter 56 patients (latter period), and were evaluated as in 1).
RESULTS: 1) Nineteen patients were excluded for reasons such as cancerous stenosis of the colon and poor bowel preparation. The overall success rate of cecal insertion was 98.0% (197/201). The success rate was not significantly different between the WIM and AIM (91/93, 97.8% vs. 102/104, 98.0%). Cecal insertion time with the WIM was significantly shorter than the AIM (420±39 s vs. 540±30 s; P=0.0001), and the achievement rate of straight insertion was higher in the WIM than the AIM (64/93, 68.8% vs. 55/104, 52.9%; P=0.022). In the WIM group, there was no difference in cecal insertion time between sexes. However, in the AIM group, TCS in men was faster than that in women (P=0.023). 2) The success rate of TCS was significantly higher in the latter period than in the preceding period (50/56, 89.3% vs. 37/57, 64.9%; P=0.0019). In the latter period, rapid TCS with straight insertion was achieved in many cases.
CONCLUSION: The WIM might support painless and smooth TCS, even in experts. Additionally, the WIM encourages TCS skills in trainees. Popularization of the WIM could contribute to comfortable TCS and lead to early detection of colorectal cancer.

P180 COLONOSCOPIC POLYPECTOMY PRACTICES IN AUSTRALIA.

S. A. O'connor[1], **S. Gupta**[1,*], L. Hourigan[1], D. Burger[1], G. Holtmann[1].
[1]Gastroenterology and Hepatology, Princess Alexandra, Woolloongabba, Australia

INTRODUCTION: Polypectomy is the mainstay of colorectal cancer prevention [1], however there is little consensus on optimal techniques. This study explores the link between training, experience and case volume on polypectomy practice within Australia.
AIMS&METHODS: A questionnaire to capture relevant demographic, practice history and methods of polyp resection was developed and pre tested. Polyps were categorised as left or right sided and pedunculated or sessile. They were further broken down into 5 different size groups (<5mm, 5-9mm, 10-15mm, 16-20mm and >20mm). Polyp management techniques included cold biopsy, hot biopsy, cold snare, hot snare, submucosal injection with hot snare or referral to tertiary centre. The questionnaire was sent to 140 colonoscopists across Australia. Distribution of surveys commenced in June, 2012 and the final completed survey was collected in November 2012 with the majority of surveys distributed via mail. Data was collected anonymously and analysed using SPSS.
RESULTS: 65 questionnaires were returned. 45 responders were Gastroenterologists, 14 Interventional Endoscopists, 5 Advanced Trainees and one Surgeon. 40 responders had greater than 10 years experience and 28 had trained in ERCP or advanced endoscopy. 36 performed > 500 colonoscopies per year. 44 were from a capital city. Cold snare technique dominated other polypectomy techniques for sessile polyps <10mm (53.8%; p=0.02) and submucosal pre injection and hot snare for sessile polyps ≥10mm (73.3%; p<0.0001). Hot snare was the preferred technique for pedunculated polyps (65.5%; p<0.0001). The chosen technique was not linked to experience (p>0.5), location of practice (p>0.5) or annual volume of procedures (p>0.5). Preparedness to resect sessile right sided polyps >20mm was associated with training in interventional endoscopy (p<0.02). Hot biopsy remains a popular choice for diminutive polyp resection especially in colonoscopists with greater than 10 years experience. 11 (27.5%) of colonoscopists in this group used hot biopsy as their preferred technique for left sided sessile polyps <10mm. This compares to 3 (12%) of those with less than 10 years experience (p=0.2).
CONCLUSION: Polypectomy technique among colonoscopists is highly variable. Location, size and morphology of polyp significantly influence choice of technique. There was no link between experience, location of practice or annual volume of procedures and choice of technique. Despite known safety and inefficacy, [2-3] hot biopsy is still frequently used especially for diminutive polyps. Scope of practice is aligned with previous training as those trained in interventional endoscopy are more likely to attempt removal of large right sided sessile polyps.

P181 COLONOSCOPY IN THE OVER NINETIES: HOW USEFUL AND SAFE IS IT?

S. Butt[1,*], A. Chitembwe[1], K. Besherdas[1]. [1]*CHASE FARM HOSPITAL, enfield, United Kingdom*

INTRODUCTION: Colonoscopy is accepted as the gold standard imaging modality of the colon for investigation of colonic symptoms including altered bowel habit, anaemia, rectal bleeding and for the detection of colorectal cancer. The incidence of pathological findings within the colon in particular colorectal cancer increases with age, and the detection of these cancers comprise a major role of colonoscopy in the elderly population. However, colonoscopy in the elderly may be more difficult, as elderly patients are more likely than younger patients to have poor bowel preparations. Furthermore, complications of colonoscopy, in particular cardiovascular, maybe higher in this age group. To date no data exist in colonoscopies performed in those over 90 years of age.
AIMS&METHODS: The aim of the study was to assess the diagnostic yield and safety of colonoscopy in the very elderly patients over 90 years of age. A single centre, retrospective analysis of patients over 90 years of age in a district general hospital from north London was performed. The patients were identified using the Unisoft Endoscopy reporting software over a period between June 2006 to March 2013. Data obtained during the study period was scrutinised for indication, sedation administered, quality of bowel prep, findings of procedure, and complications.
RESULTS: During the study period, 66 colonoscopies were performed out of a total 666 endoscopic procedures in patients over 90. The indications for colonoscopy included : abnormal CT scan 5/66, altered bowel habit in 17/66, anaemia 24/66, rectal bleeding 15/66, colonic obstruction 3/66, previous polyp/colon cancer 4/66, abdominal mass 1/66. 18/66 patients had poor bowel prep. Findings included normal in 18/66, colo-rectal cancer in 13/66 patients, colonic polyps in 5/66, ischaemic colitis 1/66, angiodysplasia 2/66, diverticulosis in 31/66. Sedation administered varied from none in 4/66, to midazolam 5mg + pethidine 50mg in 2/66. There were no complications from the colonoscopy in 66 patients within the study.
CONCLUSION: The data from this study demonstrates that colonoscopies can be performed safely in patients over 90years of age with no increase in procedure related mortality. Despite poor bowel preparation encountered in 28%, the diagnostic yield of pathology in patients over 90 having colonoscopy was very high with an abnormality in 48/66 (72% in this study). Colonoscopy in the very elderly is very safe and worthwhile and clinicians should not be reluctant in referring those over 90 years of age for colonoscopic examination.

P182 DIAGNOSTIC FEATURES OF DEPRESSED-TYPE COLORECTAL NEOPLASMS WITH MAGNIFYING ENDOSCOPY AND ENDOCYTOSCOPY

S.-E. Kudo[1,*], S. Matsudaira[1], H. Miyachi[1], K. Ichimasa[1], H. Oikawa[1], T. Hisayuki[1], Y. Mori[1], M. Misawa[1], T. Kudo[1], T. Hayashi[1], K. Wakamura[1], E. Hidaka[1], S. Okoshi[1], F. Ishida[1], S. Hamatani[1]. [1]*Digestive Disease Center, Northern Yokohama Hospital, Yokohama city, Japan*

INTRODUCTION: Colorectal cancers are generally recognized to develop from protruded-type "polyps". This "adenoma-carcinoma sequence" theory has been in the mainstream of development of colorectal cancers. But recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenoma stage. This theory is called "*de novo*" pathway. It is now available to estimate the histology of colorectal lesions using magnifying endoscopy (Pit pattern classification). And endocytoscopy (EC), using an ultra-high magnification system, can observe not only the structural atypia but also the cellular atypia in living colorectal lesions.
AIMS&METHODS: The aim is to clarify diagnostic features of depressed-type colorectal neoplasms, demonstrating the validity of EC classification together with pit pattern diagnosis.

A total of 19186 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our unit from April 2001 to December 2012. Of these, 15925 lesions were low-grade dysplasia, 2345 were high-grade dysplasia and 829 were submucosal (SM)-invasive carcinomas. According to morphological/development classification, they were divided into 3 types: flat, protruded and depressed type. We evaluated the rate of SM invasion, and investigated characteristic findings of depressed-type neoplasms concerning pit pattern and EC classification.
RESULTS: The SM invasion rate of depressed-type lesions reached to 62.8% (170/272), meanwhile that of flat-type and protruded-type lesions was 3.7% (272/7368) and 3.3% (381/11546) respectively. Within under 5mm in diameter, that was 10.7%, 0.00% and 0.02% respectively. Most (90.7% and 88.5%) of the flat-type and protruded-type lesions showed type IIIL or IV pit patterns corresponding to adenomas, whereas 94.2% of the depressed-type lesions were characterized by type IIIs, VI or VN pit pattern corresponding to carcinomas. As for endocytoscopy, the flat-type and protruded-type lesions showed various EC images. In contrast, the depressed-type lesions were presented with EC3a (19/84;22.6%) and EC3b (61/84;72.6%) corresponding to SM invasion.
CONCLUSION: This study revealed the diagnostic features of depressed-type lesions: they present typically type IIIs, VI or VN pit patterns and type EC3a or EC3b in endocytoscopy. These lesions tend to invade the SM layer even when they are small. Therefore, it is important to give a careful consideration to the development and progression of colorectal neoplasms.

P183 RISK FACTORS FOR DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL NEOPLASMS

S. Suzuki[1,*], T. Suganuma[1], A. Chino[1], T. Kishihara[1], N. Uragami[1], Y. Tamegai[1], M. Igarashi[1]. [1]*Department of Gastroenterology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is a safe and effective treatment for superficial colorectal neoplasms, and is becoming a common procedure. The most common serious complication is delayed bleeding; however, the risk factors of delayed post-ESD bleeding are unknown.
AIMS&METHODS: This study aimed to identify the factors associated with the risk of delayed post-ESD bleeding. This retrospective study included 304 lesions in 297 consecutive patients undergoing ESD for superficial colorectal neoplasms at our hospital from January 2009 to April 2013. We analyzed the risk factors for delayed post-ESD bleeding in relation with various clinical factors related patients, lesions, and procedure characteristics.
RESULTS: Delayed post-ESD bleeding was evident in all 13 lesions from 13 patients (4.27% of all specimens, 4.38% of patients). All hemorrhagic episodes were successfully treated using endoscopic hemostatic clips, and none required surgery. Only 1 patient needed blood transfusion (0.33% of all specimens, 0.34% of patients). There were no deaths related to the colorectal ESD procedure. Lesions located in the cecum (odds ratio [OR] 14.13; 95% confidence interval [CI], 3.22-62.08; $p = 0.0005$) and significant bleeding during ESD (OR 19.43; 95% CI, 2.53-149.37; $p = 0.0044$) were significant factors associated with delayed post-ESD bleeding on univariate and multivariate analyses. Lesion size and histology were not risk factors. Submucosal invasive carcinoma was associated with significant bleeding during ESD on univariate and multivariate analysis (OR 9.30; 95% CI, 1.48-58.46; $p = 0.0174$).
CONCLUSION: Lesions located in the cecum and significant bleeding during ESD were highly significant risks for delayed post-ESD bleeding, and submucosal invasive carcinoma was found to be associated with significant bleeding during ESD. ESD for colorectal neoplasms should be done with caution, and it is also desirable to modify the management after ESD under these conditions.

P184 TELE-ENDOSCOPY ASSISTED DIAGNOSIS OF COLO-RECTAL NEOPLASIA: BRINGING THE PATHOLOGIST CLOSER TO THE ENDOSCOPIC PROCEDURE ROOM – A PILOT STUDY.

S. Meisner[1,*], A. J. Glenthøj[2]. [1]*Endoscopy Unit, Bispebjerg Hospital,* [2]*Pathology, Rigshospitalet, Copenhagen, Denmark*

INTRODUCTION: Tissue send to the pathology department for microscopic examination, is accompanied by a short clinical history. Adding information, such as images is rarely done despite the fact that the exchange of information is done electronically. Endoscopic procedures are often documented using images and video. The value for the pathologist of adding footage to the clinical history might be beneficial but cost-effective issues has to be addressed as well.
AIMS&METHODS: Primary aim was evaluate the impact on the histopathologic diagnosis by a-synchronous tele-endoscopy where the pathologist can view video and/or images from the procedure. Secondary aim was to test the possibility of uploading selected macro and microscopic images of the specimen alongside the stored endoscopic images and/or video.
Before performing endoscopic mucosa resection (EMR) of colo-rectal adenomas, video and still images was recorded. Olympus HD/NBI 180 EXERA II or HD/NBI 190 EXERA III endoscopes was used on the EXERA III system with Olympus EndoAlpha Video Management. The recorded footage was stored on the Endoalpha Endobase server on the hospitals network. The resected specimen was send to one senior GI pathologist. An Endobase client was installed on the pathologist desktop PC, making it possible to view the recorded footage (a-synchronous tele-endoscopy). The pathologist either viewed the footage before or after performing the microscopic examination of the specimen. Time used, IT related problems and clinical/diagnostic impact was recorded.
RESULTS: A total of 17 EMR cases were recorded. In 9 cases the footage was viewed *before* microscopic examination with a mean viewing time 10.11 minutes (range 5 to 22). In 7 out these 9 cases, no added value was gained. In 1 case the footage could not be found (spent 22 minutes) and in 1 case the video was to long and skipped. In 8 cases the footage was viewed *after* the microscopic examination with a mean viewing time 9.5 minutes (range 5 to 23). In 7 out these 9 cases, no added value was gained. In 1 case the footage could not be found (spent 8 minutes) and in 1 case problem with file size during viewing (spent 23 minutes). In 5 cases of the 8 viewed after microscopy, a mean of 8 images was uploaded to the server (range 1 to 24). Uploading was found time consuming – up to 18 minutes.
CONCLUSION: Adding a-synchronous tele-endoscopy service to the pathologist, in an un-selected set of clinical cases, did not add value to the final diagnosis.

Average time spent per case was 10 minutes. It was durable to upload and add microscopic images to the endoscopic footage. The value of this feature still needs to be evaluated.

P185 USEFULNESS OF CHROMOENDOSCOPY WITH INDIGO CARMINE DYE SPRAYING FOR DETECTION OF CECAL ADENOMA

T. Fujii[1,*]. [1]*Gastroenterology, TF CLINIC, Tokyo, Japan*

INTRODUCTION: Background: Chromoendoscopy with indigo carmine dye spraying has been shown to be a useful technique for detection of colorectal adenoma. However, application of the staining agent over the entire colorectal mucosa during chromoendoscopy has been reported to be associated with diagnostic difficulties in patients with poor bowel preparation or in areas of the mucosa whose view is obstructed by spray fluid residue. Thus, chromoendoscopy combined with narrow-band imaging (NBI) is currently drawing attention in numerous reports as a useful modality for detection of colorectal adenoma. In this study, we focused attention on the cecum to examine the ability of chromoendoscopy with indigo carmine spraying to detect adenoma.
AIMS&METHODS: Objective: To evaluate the usefulness of chromoendoscopy with indigo carmine dye spraying for detection of adenoma in the cecum.
Methods: Indigo carmine staining was applied to the cecum in a total of 547 patients who underwent chromoendoscopy between March 2012 and March 2013 (indigo group), and routine colonoscopy was conducted in a total of 9,918 patients (routine group) to compare the frequency of detection of adenomas and serrated polyps (SSA/Ps, and TSAs) between the two groups.
RESULTS: Results: Cecal adenoma detection rate was significantly higher at 16.1% (88/547) in the indigo group compared to 5.4% (538/9918) in the routine group, while the detection rate of serrated polyps was not significantly different at 6.8% (6/88) (6 SSA/Ps) in the indigo group compared to 7.2% (42/548) (38 SSA/Ps and 4 TSAs) in the routine group. The mean adenoma size was 6.5 mm in diameter (range, 1-30 mm) in the routine group vs. 4.2 mm (range, 1-18 mm) in the indigo group, with smaller adenomas tending to be detected in the indigo group. By macroscopic appearance, the number of Polypoid type/Non-polypoid type adenomas detected in the routine and indigo groups was 156/389 (0.40) and 5/76 (0.06), respectively, with more Non-polypoid type adenomas tending to be detected in the indigo group.
CONCLUSION: Conclusions: Chromoendoscopy with indigo carmine spraying to the cecum was shown to be more effective than routine colonoscopy in detecting adenomas, which tended to be smaller, non-polypoid type adenomas, while it was not found more effective than routine colonoscopy in detecting serrated polyps.

P187 TRAINING IN COLONOSCOPY: THE VALUE OF A STANDARDIZED ASSESSMENT PROGRAM

V. E. Ekkelenkamp[1,*], A. D. Koch[1], W. Lesterhuis[1], E. J. Kuipers[1], R. A. De Man[1]. [1]*Gastroenterology and Hepatology, Erasmus MC University Medical Center, Rotterdam, Netherlands*

INTRODUCTION: Colonoscopy is a practical skill requiring extensive training. There has been little attempt to comprehensively assess both generic and specific technical skills in colonoscopy. Standardized self-assessment during colonoscopy training may provide insight in performance and enable specific intervention to improve skills. On top of that, implementation of an intensified assessment program, where trainees are closely observed during live colonoscopies on regular points in training, provides the opportunity for such interventions. The aim of this study was to assess the value of a standardized assessment program on top of self-assessment of performance.
AIMS&METHODS: We developed a standardized skills training and assessment program for colonoscopy. All procedures were self-assessed. Trainees were systematically evaluated during two colonoscopies after every 50 colonoscopies performed during their formal colonoscopy training. A single expert closely observed the trainee and gave feedback on the trainees' performance. In order to assess the value of this assessment program on top of the self-assessment program, we used a historical control group of trainees as a reference. The historical group only participated in the self-assessment program. The primary outcome parameter was the incremental change in cecal intubation rate (CIR) expressed in a learning curve.
RESULTS: The study group consisted of twelve trainees from different centers. All were included in the standardized skills training and assessment program. The intensified assessment program was additional. The reference group consisted of 18 trainees, all from one center. A total number of 1960 colonoscopies were performed in the study group against 2887 in the historical control group. 55 trainee assessments (range 1-4 per trainee) were carried out by an expert endoscopist. Baseline CIR after 30 procedures was 53.4% versus 65.3% in the reference group ($p=0.004$). The slopes of the two learning curves differed significantly between the study and control group (β 0.18 vs. 0.10, $p<0.001$). Evaluation of the program showed that trainees experienced the assessment program as positive and useful (score of 4.6 on a Likert scale of 1-5).
CONCLUSION: The addition of a standardized assessment program on top of self-assessment in colonoscopy training proves to be useful and results in a steeper learning curve, especially in the early training stage. Trainees experienced this program as very valuable.

P188 A RANDOMIZED PROSPECTIVE TRIAL COMPARING DIFFERENT REGIMENS OF ORAL PICOSULPHATE AND POLYETHYLENE GLYCOL-BASED LAVAGE IN THE PREPARATION OF PATIENTS FOR COLONOSCOPY

Y. T. Jeen[1,*], S.-J. Nam[1], J. S. Lee[1], E. S. Kim[1], B. Keum[1], H. J. Chun[1], H. S. Lee[1], S. H. Um[1], C. D. Kim[1], H. S. Ryu[1]. [1]*Internal Medicine, Korea University Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Adequate bowel cleansing is essential for a high-quality, effective, and safe colonoscopy. There are rare reports that compare directly conventional polyethylene glycol (PEG) intake and picosulphate.
AIMS&METHODS: The aim of this study is to compare the efficacy, safety, and tolerability of different regimens of oral picosulphate and PEG. This study involved 200 adult patients undergoing elective colonoscopy and was single-blinded prospective randomized design in tertiary-care institutions of South Korea. Patients were randomized into four groups with endoscopist was blinded to the regimen. Group A: PEG 4L at 4-6 hours before procedure on the day of the colonoscopy. Group B: PEG 2L at 6:00 PM the day before and 4-6 hours before procedure. Group C: One of 2 sachets of sodium picosulphate at 6:00 PM the day before and 4 hours before procedure. Group D: One of 3 sachets of sodium picosulphate given at 6:00 and 09:00 PM the day before and at 4 hours before procedure.
RESULTS: PEG 4L group (both split and non-split dosage) and 3 sachets of picosulphate produced better mucosal cleansing than 2 sachets of picosulphate. Side effects were more frequent in PEG 4L than picosulphate. Patients' preferences were most high in picosulphate than other goups.
CONCLUSION: Picosulphate is as effective as high-volume PEG-electrolyte solution but has superior tolerance. It has fewer adverse events and is preferred by patients.

P189 ENDOSCOPIC BALLOON SPHINCTEROPLASTY AS AN ADJUNCT TO ENDOSCOPIC SPHINCTEROTOMY IN REMOVING LARGE AND DIFFICULT BILE DUCT STONES IN THE ELDERLY

B. Merino Rodríguez[1,*], C. González Asanza[1], Ó. Nogales Rincón[1], L. Pérez Carazo[1], J. García Lledó[1], M. Romero[1], J. Miranda[1], L. Holguera[1], P. Menchén Fernández Pacheco[1]. [1]*Endoscopy, Gregorio Marañón Hospital, Madrid, Spain*

INTRODUCTION: Extraction of common bile duct stones at endoscopic retrograde cholangiopancreatography can be technically challenging when the size of the stone exceeds that of an endoscopic sphincterotomy. These stones are more common in the elderly, with higher risks involved invasive procedures in this population.
AIMS&METHODS: The aim of this study was to evaluate the efficacy and safety of papillary balloon dilation after sphincterotomy for extraction of these difficult-to-remove bile duct stones in the elderly
This was a retrospective study in patients older than 65 years with large common bile duct stones that could not be extracted using a stone retrieval balloon and basket after endoscopic sphincterotomy. Endoscopic balloon dilatation was performed by using standard 12-20 mm Controlled Radial Expansion balloons. The success rate and the complication rate for the papillary balloon dilation technique were assessed
RESULTS: A total of 154 patients (71 men, 83 women; mean age 79, range 65 - 93) were enrolled in this study from January 2008 to march 2013. The mean stone size was 16 mm (range 12 - 20 mm). Stones were removed with sphincteroplasty in first session in 148/154 (96.1%) patients, 6/154 (3.9%) patients in the second session. Six patients (3.9%) required adjunctive mechanical lithotripsy for stone extraction. Surgery was advised for 4 (2.6%) patients because of failure to remove stones by sphincteroplasty. Overall success of endoscopic sphincterotomy and large balloon dilatation in our study was 93.5%
Complications were seen in 24 patients (16.2%). Bleeding was encountered in 5 (3.3%) patients which was controlled by adrenaline injection in 2 patients and all other conservatively. Moderate pancreatitis necessitating admission was seen in 15 patients (9.7%). None of the patients had severe pancreatitis. There were two (1.3) perforation secondary to the procedure, managed with conservative treatment. No patient died as a result of the procedure
CONCLUSION: Papillary balloon dilation after endoscopic sphincterotomy is an effective technique for retrieval of difficult common bile duct stones. The procedure obviates the need for mechanical lithotripsy or surgery in a majority of patients. Although it is a safe procedure, the number of complications in the elderly is higher than those described in the general population.

P190 NEW CLASSIFICATION OF BILIARY OBSTRUCTION AFTER LIVER TRANSPLANTATION

E. Linghu[1,*], Z. Qin[2]. [1]*Department of Gastroenterology and Hepatology,* [2]*the chinese PLA General Hospital, Beijing, China*

INTRODUCTION: To propose a new classification of biliary obstruction after liver transplantation for selecting appropriate endoscopic treatment.
AIMS&METHODS: we screened out the data of patients after liver transplantation with endoscopic pictures clear enough to reveal biliary imaging, who underwent endoscopic therapy from May 2006 to September 2011 at our Digestive Endoscopic Center. After analyzing the correlation between intrahepatic biliary and anastomotic structure we proposed a new endoscopic classification(Ling classification) of biliary obstruction after liver transplantation. There were four types based on the criteria of Ling classification: type A, normal biliary structure; type B, anastomotic stricture and normal intrahepatic biliary structure; type C, narrow and stiff intrahepatic biliary structure or beaded intrahepatic biliary structure or intrahepatic biliary cast without anastomotic stricture ; type D, narrow and stiff intrahepatic biliary structure or beaded intrahepatic biliary structure or intrahepatic biliary cast with anastomotic stricture. Two endoscopists made a final decision upon mutual agreement through discussion if their separately recorded characteristics were different.
RESULTS: Among the 112 screened patients with jaundice after liver transplantation, 93 qualified patients were selected for the analysis, including 76 males and 17 females. The average age was 50.3years, ranging from 12 to 69 years. type B was the most commonly observed type of biliary obstruction after liver transplantation, accounting for 47.3%(44/93), and type A was the least commonly observed type of biliary obstruction after liver transplantation, accounting for 9.7%(9/93). And type C accounted for 23.7%(22/93)and type D accounted for 19.3%(18/93)
CONCLUSION: A new endoscopic classification of biliary obstruction after liver transplantation is proposed that might help in determining the proper candidates for treatment.

P191 ENDOSCOPIC MANAGEMENT OF LARGE BILE DUCT STONES AND COMMON BILE DUCT ROCK PAVING : SUCCESS RATE, COMPLICATIONS, AND ASSOCIATED FACTORS

H. Seddik[1,*], Y. Hnach[1], T. A. Addioui[1], F.-Z. El Hamdi[1], A. Benkirane[1]. [1]*gastro-enterology II, military hospital of rabat, RABAT, Morocco*

INTRODUCTION: Residual lithiasis of the common bile duct is an indication of choice for endoscopic sphincterotomy. Endoscopic treatment provides a clearance of the common bile duct in 90% of cases. However, the presence of a rock paving or a large stone may limit its results. The aim of this study is to evaluate the success rate, associated factors and complications of endoscopic treatment of the rock paving and large stones of the commun bile duct.
AIMS&METHODS: All patients (542) who had undergone endoscopic retrograde cholangiopancreatography for commun bile duct stones from January 2007 to March 2013 were reviewed. We compared the results and complications of ERCP in patients with choledochal rock paving and / or a large stone (group I) versus patients with simple commun bile duct stones: $\leq$ 3 stones, without obstruction (group II). The rock paving was defined by the presence of multiple stones (more than 3) and the large stone by the obstruction of the commun bile duct by a stone that measure more than 15 mm. The success of endoscopic treatment was defined as a complete removal of stones of the common bile duct at the end of procedure
RESULTS: The rock paving and/or large cholelithiasis (group I) represented 32.8% of CBD stones (178 patients). Group II included 364 patients (67.1%). The Success rate was achieved after a single catheterization in 64% of the cases in group I versus 90,2% in group II ($p<0{,}001$). The overall success rate after additional maneuvers and / or recovery the patient was 95.3% in group II versus 89% in group I ($p = 0.006$). The overall rate of early complications was 4.8% in group II versus 7,5% in group I ($p = 0.37$). In multivariate analysis including the factors : age, sex, history of surgery (cholecystectomy, choledochotomy, gastroduodenal surgery), severe acute pancreatitis, cholangitis, stenosis of the common bile duct, diverticulum peri-ampullary, diameter of the bile duct), only the presence of cholangitis, a periampullary diverticulum and / or stenosis of the common bile duct were factors associated with decreased of overall success of endoscopic treatment.
CONCLUSION: Though representing a limit to the endoscopic treatment, in our serial the clearance of the CBD in case of rock paving and / or large stone was obtained after additional maneuvers in 89% of cases without significant increase in early complications. The presence of cholangitis, a periampullary diverticulum and / or stenosis of the CBD appear to be factors associated with decreased overall success of endoscopic treatment.

P192 PERI-DIVERTICULAR PAPILLA: CLINICAL SIGNIFICANCE IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY CANNULATION

M. A. Alburquerque[1,2,*], M. Figa[1,3], M. Pérez-Contreras[3], L. Vidal[2], F. González-Huix[1]. [1]*Gastroenterology, Clínica Girona, Girona,* [2]*Gastroenterology, Hospital de Palamós, Palamós - Girona,* [3]*Gastroenterology, Hospital Universitario Dr. Josep Trueta, Girona, Spain*

INTRODUCTION: An important percentage of patients have a peri-diverticular papilla of Vater (PD). It could hinder the biliary and/or pancreatic cannulation at endoscopic retrograde cholangiopancreatography (ERCP) and might change the outcomes in this procedure.
AIMS&METHODS: Aims: To compare the efficacy and complications rate in biliary cannulation at ERCP in patients with PD vs. patients without PD. **Material and methods:** Through a prospective informatic database were registered all consecutives patients with ''virgin'' papilla that underwent to ERCP from june 2002 to june 2012. The database included demographic data, patients' general status, indications and level of difficulty of the ERCP, anatomic features of the papilla and its localization with regard to the duodenal diverticulum, success and ease of cannulation (number of attempts, Freeman score), biliary cannulation techniques (standard techniques, placement of pancreatic guidewire or stent to assist biliary cannulation, precut ''access'' papillotomy), outcomes of the ERCP and its complications. The data were analyzed using the SPSS 15.0 software.
RESULTS: Between 2337 patients with ''virgin'' papilla (age: 71,7 $\pm$ 15 y; women: 44,7%) 551 (23,1%) had PD (31,4% within; 29,2% in the border and 39,4% adjacent to the diverticulum). In the PD group the cannulation rate was not different from the non PD group (92,3% vs. 92,2%), neither the number of attempts (5,0 vs 5,1) nor the Freeman score. The number of precuts were lesser (14,2% vs 21%; P=0.000) and these were made more frequently starting at the papillary orifice, as compared with ''fistulotomy'' starting above orifice. There were not differences, neither in the guidewire use for biliary cannulation nor in the diagnostic and therapeutic success. In the PD group, complication rate was slightly higher than the non PD group (14,2% vs 11,1%; p=0,035) at the expense of the number of post papillotomy bleeding (8,5% vs 4,6%; p=0,000), even though the most of these were mild (4,9% vs 1,8%) and were resolved during the same procedure. There were not differences between groups regarding pancreatitis, cholangitis, perforations, submucosal injection or abdominal pain.
CONCLUSION: The presence of a peri-papillary duodenal diverticulum does not involve a difficult biliary cannulation or lower cannulation rate. In these patients, complication rate is higher, although mainly represented by mild post-papillotomy bleeding easily solvable.

P193 COMPLEX BILIARY LEAK POST-HEPATECTOMY: IS ENDOSCOPIC TREATMENT EFFECTIVE?

M. A. Alburquerque[1,2,*], M. Figa[1,3], J. Figueras[4], S. López[4], M. Peréz-Contreras[3], F. González-Huix[1]. [1]*Gastroenterology, Clínica Girona, Girona,* [2]*Gastroenterology, Hospital de Palamós, Palamós - Girona,* [3]*Gastroenterology,* [4]*Surgery, Hospital Universitario Dr. Josep Trueta, Girona, Spain*

INTRODUCTION: The ERCP (papillotomy and/or stent) has become the elective treatment for post-cholecystectomy biliary leak (PCBL). Nowadays is unknown if this treatment is equally effective for post-hepatectomy biliary leak (PHBL).
AIMS&METHODS: Aims: To compare the efficacy between endoscopic treatment for PHBL and PCBL. **Methods:** From January 2002 to October 2012 were recorded in a prospective database all patients with post-surgical biliary leak (PSBL) that underwent to ERCP. The database included demographic data: age and sex; type of surgery and indication; PSBL features: localization, debit and associated findings (strictures, biloma/abscess, choledocolithiasis, etc); endoscopic treatment; papillotomy and/or stent, diagnostic success, technical success, efficacy and security. We defined as Diagnostic success: localization of PSBL by ERCP and as Technical success: Endoscopic drainage of PSBL. The sealing of PSBL was confirmed by ERCP and/or clinical evaluation. The data were analyzed using the SPSS 15.0 software.
RESULTS: Between 3785 ERCPs (2002 – 2012) there were 67 patients with PSBL (1,7%): 51 PCBL (67%) and 16 PHBL (33%). Age: 64,79 $\pm$ 15,07 years. Women: 20 (29,9%). In PCBL the surgical indication was cholelithiasis (100%), while in PHBL were liver metastases: 12 (75%), hepatic hydatid disease: 2 (12,5%), traumatism: 1 (6,25%) and gallbladder cancer:1 (6,25%). Cystic duct stump and common bile duct/common hepatic duct were the most frequents localization of PCBL: 58,82 vs. 0,00% (p=0,000) and 25,49 vs. 18,75% (p=0,000), respectively. In PHBL, primary and secondary intrahepatic bile ducts were the most frequents: 31,25 vs. 5,88% (p=0,000) and 37,5 vs. 5,88% (p=0,000), respectively. For PCBL, diagnostic success was higher than PHBL: 96,08 vs. 87,5% (p=0,000). There was not difference in PSBL debits. Strictures (57,14 vs. 22%, p=0,000) and biloma/abscess (87,5 vs. 26%, p=0,000) were more associated to PHBL than choledocolithiasis (7,14 vs. 48%, p=0,000). In regard to endoscopic treatment, there was not difference between both groups: papillotomy and stent was the most frequent procedure and technical success was above 93%. The endoscopic treatment efficacy for PHBL was much lower than for PCBL (25 vs. 84,31%, p=0,000). The complication rate was similar between both groups.
CONCLUSION: The endoscopic treatment efficacy (papillotomy and/or stent) for PHBL is much lower than for PCBL. This is related to their greater complexity: frequently intrahepatic and associated to strictures and biloma/abscess.

P194 USEFULNESS OF CARBON DIOXIDE INSUFFLATION IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

M. Wato[1,*], T. Inaba[1], S. Mizukawa[1], I. Sakakihara[1], K. Izumikawa[1], S. Ishikawa[1], N. Baba[2], M. Miyoshi[1], T. Senoh[2], T. Nagano[2], K. Takaguchi[2], K. kawai[1]. [1]*Gastroenterology,* [2]*Hepatology, Kagawa Prefectural Central Hospital, Takamatsu, Japan*

INTRODUCTION: The purpose of the present study is to clarify whether carbon dioxide insufflation at the time of ERCP is useful for stabilizing patient conditions during or after an operation or for reducing complications.
AIMS&METHODS: 289 subjects of ERCP cases performed consecutively at our hospital during a period from January 2010 through May 2011 were assigned randomly to a normal insufflation group (control group) and a CO_2 insufflation group (CO_2 group). The factors examined are: 1) success ratio of the treatment, 2) enteric tube images before and after the test that were evaluated for the blinded three stages, 3) evaluation of abdominal pain, feeling of abdominal fullness and nausea using the VAS (visual analog scale), 4) vomiting within 24 hours after the test or use of metoclopramide, 5) amount of sedative during the test and 6) status of respiratory circulation and the complications based on the Cotton definition. We conducted a comparative study using these factors.
RESULTS: 149 subjects in the control group consisted of 71 males and 78 females and the average age was 72.8 years old. The 140 subjects in the CO_2 group consisted of 77 males and 62 females and the average age was 71.1 years old. There were no significant differences in the causative diseases or treatment contents or average test times (22.0 minutes in the control group and 24.3 minutes in the CO_2 group. 1) The success ratio of the treatment was 136/149 (91.3%) in the control group and 128/140 (91.4%) in the CO_2 group, which indicated no significant difference. 2) The gas images were significantly less in the CO_2 group ($p=0.00001$). 3) Regarding the symptoms at the end of the test, there was no significant difference in the feeling of abdominal fullness between the two groups. However, abdominal pain and nausea were significantly lower in the CO_2 group ($p=0.0489$ and $p=0.0017$, respectively). 4) Vomiting after the test was found in 19 cases in the control group (12.8%) and 8 cases in the CO_2 group (5.7%) ($p=0.0370$), which indicated significantly lower effect. 5) There was no difference in the amount of use of sedatives.6) Regarding the complications, there were no significant differences.
CONCLUSION: Insufflation of CO_2 at the time of ERCP contributes to improvement in safety without having any influence on the results of the treatment.

P195 EFFICACY OF NOVEL FULLY COVERED SELF-EXPANDABLE METAL STENTS IN POST-LIVER TRANSPLANT ANASTOMOTIC BILIARY STRICTURES NOT RESPONDING TO STANDARD METAL STENT INSERTION

N. Azzopardi[1,*], N. Granata[1], G. Curcio[1], I. Tarantino[1], L. Barresi[1], M. Amata[2], M. Traina[1]. [1]*Endoscopia Digestiva, Istituto Mediterraneo per i Trapianti e Terapie ad Alta Specializzazione (ISMETT), Palermo,* [2]*Universita di Catania, Catania, Italy*

INTRODUCTION: Anastomotic biliary strictures account for 40% of the complications following liver transplantation. Most strictures are initially treated with plastic stent insertion or balloon dilation with stenting but recent studies have shown that fully covered, self-expandable metal stent (fcSEMS) are effective for benign biliary strictures (90% success) but are associated with a significant migration rate (24%).[1]
Bumpy (6-10cm) and *Short-Bumpy* fcSEMS (4cm, Taewoong Medical, Seoul) have bilateral flared ends and unfixed irregular cell size, which are believed to decrease the risk of migration. The aim of this study was to assess the efficacy and migratory rate of temporary placement of the *Bumpy* and *Short-Bumpy* fcSEMS in post-liver transplant anastomotic biliary strictures when previous treatment with standard metal stent insertion has failed.
AIMS&METHODS: Between July 2010-March 2013, 23 patients with post-liver transplant anastomotic strictures not resolved following metal stent insertion were included in the study. Bumpy stents were kept in place for 12 weeks, after which ERCP was performed to remove the stent and assess biliary morphology. 11 patients with treatment failure following Bumpy removal had a Short-Bumpy stent inserted for a period of 12 weeks. Patients were followed up clinically and with 3 monthly liver function tests following stent removal.
RESULTS: Mean follow up after Bumpy and Short Bumpy removal was 11 months and 9 months respectively. Placement of the stents was successful in all patients with no reported complications after insertion or removal. 12 patients (52%) had endoscopic resolution of the stricture at follow up ERCP after Bumpy insertion with 26% (6 patients) recurrence of the stricture. 10 patients (43%) had spontaneous stent migration and expulsion, including 4 patients (40%) who had treatment success not requiring further interventions after stent loss. 11 patients who had treatment failure with the Bumpy stent were subsequently managed with a Short Bumpy stent which was associated with 90% success (10 patients), 27% recurrence (3 patients) and 0% stent loss.

	Patients (n)	Treatment Success	Stricture Recurrence	Loss of Stent	Success after Stent Loss
Bumpy	23	12(52%)	6(26%)	10(43%)	4(40%)
Short Bumpy	11	10(90%)	3(27%)	0	-

CONCLUSION: Bumpy stents may be used in post-liver transplant anastomotic strictures refractory to treatment with standard metal stents. Short Bumpy stents are associated with very high success rates probably due to its low migration rate.

P196 SYSTEMIC AIR EMBOLISM DURING ERCP: DESCRIPTION OF 3 CASES

M. Rossi[1], R. Fasoli[1,*], D. Giacomin[1], F. Agugiaro[1], S. Mosna[2], E. Geat[2], D. Dallafior[3], G. de Pretis[1]. [1]*Dptm of Gastroenterology,* [2]*Dptm of Anesthesiology,* [3]*Dptm of Cardiology, H Santa Chiara, Trento, Italy*

INTRODUCTION: Scattered case reports describe the occurrence of systemic air embolism during ERCP -particularly during highly manipulating procedures- very often with ominous consequences.
The mechanism of action seems to be the escape of air to the portal system and then to hepatic veins, vena cava inferior and right heart, eventually with cardiocirculatory collapse.
AIMS&METHODS: We describe 3 such complications of ERCP experienced at our institution (≈500 ERCPs/year) in the past 3 years.
RESULTS: All patients were males (N.1:70 y;N.2:45 y;N.3:71 y).
N.1 and N.2 were done under propofol with the assistance of a anesthesiology team; N.3 received general anesthesia.
In all cases a choledochal stricture was the main finding. In N.1 and N.2 a biliary sphincterotomy was carried out; in N.1 and N.3 biopsies and brushing samples were obtained. In all pneumatic dilation to 6-8 mm and insertion of multiple plastic stents were performed.
In all cases - during the final part of the examination - a similar sudden onset clinical picture took place: hypoxia, hypotension, bradycardia and dramatic drop of end-tidal CO2, followed by cardiac arrest.
Standardized cardiopulmonary resuscitation maneuvers as well as a trial of aspiration of air through a catheter positioned in the right heart were performed.
In N.2 and N.3 the diagnostic suspicion has been confirmed by emergency cardiac ultrasonography, which revealed –respectively– air in the whole heart and air barrage of the right ventricle.
N.1 and N.3 had a, respectively, delayed and immediate fatal outcome. N.2 had an uneventful recovery.
CONCLUSION: The described cases share common clinical and imaging findings, all in favor of a diagnosis of systemic air embolism during complex ERCP procedures. Sudden onset cardio-vascular collapse, an abnormally distended abdomen, the inefficacy of chest compression in the presence of distended jugular veins all contribute to the clinical suspicion. Trans-thoracic echocardiography has contributed to the diagnosis in 2/3 cases; although not employed in the third case, a trans-esophageal echocardiography has been reported to help in the diagnosis. Such condition deserves in our opinion a note of caution, being probably less infrequent than reported and carrying a very high risk of fatal consequences. The management of complex strictures of the biliary tree may represent a risk factor due to length of the procedure and multiple highly manipulating maneuvers, possibly leading to microtraumas and relevant insufflation of air in the duodenum. To prevent this type of complication, we have decided at our institution to switch to CO2 utilization during ERCP.

P198 USE OF A SHORT SINGLE-BALLOON ENTEROSCOPY FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY: PRELIMINARY EXPERIENCES AT A SINGLE CENTER.

T. Kawamura[1,*], K. Uno[1], K. Tanaka[1], K. Yasuda[1]. [1]*Gastroenterology, Kyoto Second Red Cross Hospital, Kyoto, Japan*

INTRODUCTION: Single-balloon entroscopy (SBE) has been recognised as a useful method for performing endoscopic retrograde cholangiopancreatography (ERCP) in patients with a complex post-surgical anatomy. However, there are a limited number of ERCP accessories that are compatible with SBE because its inner channel diameter is 2.8 mm, and its working length is 2000 mm; this size is smaller and longer than that of a conventional duodenoscope.
AIMS&METHODS: We used a short single-balloon endoscope prototype (SIF-Y0004, Olympus medical systems, Tokyo, Japan), which has an inner channel diameter of 3.2 mm and a working length of 1520 mm, for ERCP in patients with surgically altered anatomy. The aim of this study was to determine the utility of this prototype endoscope.
From January 2012 to April 2013, we attempted 20 ERCP procedures on 13 patients with Roux-en-Y and Billroth II reconstruction using the short single-balloon endoscope prototype. We retrospectively analysed the rate of reaching the blind end, the diagnostic success rate, the therapeutic success rate and the frequency of incidence of related complications.
RESULTS: One case was excluded because of small intestinal stenosis. Thus, we analysed 19 procedures, including Billroth II reconstruction (B-II, $n = 2$), post-gastrectomy with Roux-en-Y reconstruction (RY-G, $n = 12$) and post-choledochojejunostomy with Roux-en-Y reconstruction (RY-CJ, $n = 5$). The rates of reaching the blind end were 2/2 (100%) for B-II, 11/12 (91.7%) for RY-G and 4/5 (80%) for RY-CJ. The diagnostic success rates were 2/2 (100%) for B-II, 8/11

(72.7%) for RY-G and 4/4 (100%) for RY-CJ. The therapeutic success rates were 1/2 (50%) for B-II, 8/11 (72.7%) for RY-G and 4/4 (100%) for RY-CJ. Endoscopic biliary drainage (9 patients), endoscopic sphincterotomy (2 patients), stone extraction (2 patients) and endoscopic papillary large-balloon dilation (1 patient) were performed using conventional endoscopic accessories. The mean procedure time was 56 min. We did not experience any related complications.
CONCLUSION: The blind end could be reached in most of the patients with an altered gastrointestinal anatomy, despite the short length of the prototype endoscope. This prototype endoscopy with a wide inner channel diameter was useful, notably because it allowed the use of the most conventional endoscopic accessories.

P199 LONG-TERM FOLLOW UP STUDY OF ENDOSCOPIC PAPILLECTOMY IN TUMORS OF THE PAPILLA OF VATER

T. Kin[1,*], H. Maguchi[1], K. Takahashi[1], A. Katanuma[1], M. Osanai[1], K. Yane[1], R. Takaki[1], K. Matsumoto[1], T. Matsumori[1], K. Gon[1], A. Tomonari[1]. [1]*Center for gastroenterology, TEINE KEIJINKAI HOSPITAL, Sapporo, Japan*

INTRODUCTION: Although Endoscopic papillectomy (EP) has reported to be feasible for the treatment of ampullary neoplasm, there is little data about long-term follow up results after EP.
AIMS&METHODS: The aim of this study was the assessment of local recurrence and late complication after EP. Forty of 129 patients with ampullary neoplasm underwent EP from April 1997 to March 2013, and 27 (68%) of them who were followed up for more than a year were eligible for this study (18 men and 9 women, mean age 64). Histological diagnosis of their tumors were adenoma in 24 and focal carcinoma in adenoma in 3. Twenty of them were placed biliary stent (EBS) and 24 of them were placed pancreatic stent (EPS) for a week after EP. All patients were followed with endoscopic surveillances every 6-12 months.
RESULTS: All 27 patients underwent EP successfully. Twenty-three (85%) patients achieved en bloc resection and the remaining 4 (15%) patients underwent piecemeal resection. Mean follow up time was 60 months (range, 15-144 months). Local recurrence occured in 2 (7%) patients, who received piecemeal resection. One patient had tumor spread to the bile duct 45 month after EP and was treated surgically. Another patient with a recurrence at the time of 14 months was re-treated with EP, although he had a second recurrence 36 months after first EP and ultimately required surgery. Late complication occured in 2 (7%) patients. One patients had scarring and stenosis of the pancreatic duct orifice 36 months after EP and improved by endoscopic pancreatic sphincterotomy and additional EPS. Another patient had focal stent-induced stricture in main pancreatic duct 21 months after EP and was treated with repeated EPS.
CONCLUSION: Although EP is an effective treatment for ampullary tumor, some recurrences or complications may occur even after a year. En bloc resection is important for the prevention of local recurrence. Prophylactic EPS should be placed carefully with an awareness of stent-induced stricture. Long-term follow up is important after EP treatment for ampullary tumors.

P200 IMPROVING BILIARY CANNULATION USING A NOVEL SEQUENTIAL PANCREATIC DUCT GUIDEWIRE PLACEMENT TECHNIQUE: A PROSPECTIVE ERCP PILOT STUDY

Q. Pei[1], X. Zou[1,*]. [1]*Department of Gastroenterology,, The Affiliated Drum Tower Hospital of Nanjing University, Medical School, Nanjing, China, Nanjing, China*

INTRODUCTION: Deep biliary cannulation is a fundamental and crucial step in ERCP[ss1]. Although various methods have been developed to facilitate biliary cannulation, the cannulation success rate remains unsatisfactory.
AIMS&METHODS: To compare the performance of sequential pancreatic duct guidewire placement (PDGP) technique and needle knife precut sphincterotomy (NKPS) technique in cases of difficult biliary cannulation.
RESULTS: Sequential PDGP technique had a higher overall cannulation success rate than the NKPS technique (93.7% vs. 70%, p=0.015), as well as a higher initial success rate despite the absence of statistical significance (88.9% vs. 70%, p=0.095). Sequential PDGP technique did not increase difficult cannulation time (7.49mins vs. 10.60mins, p=0.086), and had a comparable rate of post-ERCP pancreatitis as the NKPS technique (12.7% vs.10%, p=1.000)
Clinical outcomes of ERCP procedure

	PDGP group	NKPS group	P value
Initial success rate	56(88.9%)	14(70%)	0.095
Overall success rate	59(93.7%)	14(70%)	0.015
Total cannulation time (mean±SD, minute)	27.03±13.64	34.50±10.47	0.028
Difficult cannulation time (mean±SD, minute)	7.49±5.03	10.60±7.24	0.086
Hyperamylasemia	28(44.4%)	3(15%)	0.018
pancreatitis	8(12.7%)	2(10%)	1.000
Bleeding	9(14.3%)	4(20%)	0.795
Cholangitis	5(7.9%)	0(0%)	0.447
Perforation	0	0	NA

CONCLUSION: Sequential PDGP technique improved the overall success rate in difficult biliary cannulation cases without increasing cannulation time and major complications compared with the NKPS technique. Sequential PDGP technique is a promising method to facilitate biliary cannulation during ERCP.

P201 FEASIBILITY OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY RELATED PROCEDURES IN HEMODIALYSIS PATIENTS

Y. Hori[1,*], I. Naitoh[1], T. Nakazawa[1], K. Hayashi[1], K. Miyabe[1], S. Shimizu[1], H. Kondo[1], M. Yoshida[1], H. Yamashita[1], S. Umemura[1], T. Ban[2], T. Joh[1]. [1]*Department of Gastroenterology and Metabolism, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan,* [2]*Nagoya Daini Red Cross Hospital, Nagoya, Japan*

INTRODUCTION: The opportunities of endoscopic retrograde choangiopancreatography (ERCP)-related procedure for hemodialysis (HD) patients have been increasing recently. However, the complication rate of ERCP in HD patients was not evaluated sufficiently.
AIMS&METHODS: We aimed to clarify the feasibility of ERCP-related procedure for HD patients.We retrospectively reviewed 76 consecutive ERCP-related procedures for HD patients between January 2005 and December 2012 in one university hospital and three tertiary-care referral centers. Endoscopic sphincterotomy (EST) was performed in 21 HD patients. We evaluated the incidences and risk factors for complications of all ERCP-related procedures and EST in HD patients.
RESULTS: The incidences of pancreatitis, cholangitis and cardiopulmonary complications for ERCP-related procedures in HD patients were 7.9% (6/76), 1.3% (1/76) and 1.3% (1/76), respectively. The mortality rate was 2.6% (2/76) and it occurred after acute pancreatitis in one patient and pneumonia in the other patient. The incidences of hemorrhage and pancreatitis of EST were 19% (4/21) and 4.8% (1/21), respectively. The duration of HD was significantly longer in the patients with hemorrhage after EST than without (19.5 vs 6 years; p=0.029).
CONCLUSION: ERCP-related procedures except EST were feasible in HD patients. However, EST was inappropriate procedure for HD patients because of high rate of hemorrhage especially for patients with long HD duration.

P202 CLINICAL CHARACTERISTICS, ENDOSONOGRAPHIC FINDINGS AND ETIOLOGIES OF GASTRODUODENAL SUBEPITHELIAL LESIONS: A REFERRAL SINGLE CENTER STUDY.

B. Merino Rodríguez[1,*], C. González Asanza[1], Ó. Nogales Rincón[1], C. Padilla[1], A. Ahumada[1], M. López Ibáñez[1], D. Pérez Valderas[1], P. Menchén Fernández Pacheco[1]. [1]*Endoscopy, Gregorio Marañón Hospital, Madrid, Spain*

INTRODUCTION: Subepithelial lesions are a frequent incidental endoscopic finding. Knowledge is important given the potential for malignancy that associates some types of these injuries.
AIMS&METHODS: The aim of this study was to evaluate the demographic data, endoscopic ultrasonography characteristics, pathology results and complications of the patients with suspected extra luminal compression or subepithelial intramural lesions observed during upper gastrointestinal endoscopy.
From January 2008-march 2013, a total of 310 cases were referred for EUS evaluation due to extra luminal compression or subepithelial intramural lesions. The endoscopic reports, pathology results and the patients' medical records were reviewed
RESULTS: The mean age was 56 (range 25-82). 52% were female. Only 12.6% of the patients had symptoms. The mean size of the lesions was 14.6 mm (range 8-55 mm).The provisional diagnosis of the sub-epithelial lesions, regarding only clinical and endosonographic characteristics were GIST, neuroendocrine tumor, pancreatic rest, lipoma, vascular lesions, polyps, leiomyoma, extrinsic compression and cyst wall (35.6%, 6%, 3.8%, 31%, 2.3%, 3,1%, 15%, 1.6% and 1.6% respectively). All the lesions were diagnosed as GIST originating from either the forth layer (80.5%) or the second layer (19.5%) of gastric or duodenal wall. Fine needle aspiration (FNA) was performed in 85 patients (27.4%), 61 patients with suspected GIST, 15 patients with suspected leiomyoma, 4 patients with suspected cyst wall and 5 patients with suspected pancreatic rest. The positive predictive value, negative predictive value and accuracy of diagnosis of made by endosonographers based on only endosonographic characteristics were 75, 100 and 76% (95% CI: 52.4% > 84.4%) respectively. There were no procedure-related complications.
CONCLUSION: Most of the subepithelial lesions which were referred for EUS evaluation at Gregorio Marañón Hospital were GISTs. The diagnosis of GIST can be accurately made by using the EUS based on only endosonographic characteristics. FNA should be performed in large lesions or when there are diagnostic doubts.

P203 PANCREATIC CYSTS CONFOCAL ENDOMICROSCOPY STUDY: A FEASIBILITY STUDY OF NCLE (NEEDLE BASED CONFOCAL LASER ENDOMICROSCOPY) THROUGH FNA NEEDLE

H. Bertani[1,*], V. G. Mirante[1], R. Manta[1], M. Manno[1], A. Caruso[1], R. Conigliaro[1]. [1]*Endoscopy Unit, Nuovo Ospedale Civile S.Agostino Estense, Modena, Italy*

INTRODUCTION: Probe-based confocal laser endomicroscopy enables *in vivo* real time characterization of the mucosa layer and is a valid tool to differentiate neoplastic vs non neoplastic tissue in upper and lower GI tract.
Despite significant improvements in imaging technology and the advent of endoscopic-ultrasound (EUS)-guided fine-needle aspiration, the diagnosis and management of pancreatic cystic lesions remains a significant clinical challenge. Needle-based confocal laser endomicroscopy (nCLE) is a unique imaging technique, enabling microscopic observation of solid organs and cystic tumors, *in vivo* and in real-time, during an EUS-FNA procedure
AIMS&METHODS: This pilot study evaluates the feasibility of nCLE during EUS-FNA of pancreatic cystic lesions.
Six patients presenting for EUS-FNA of pancreatic cyst were enrolled for nCLE examination. The nCLE procedure was performed using the AQ-Flex 19 preloaded in a 19G needle. In order to obtain images the probe was put in contact with the tissue inside cyst , after IV injection of fluorescein, (2.5 mL of 10% fluorescein). After image acquisition, the probe was retrieved from the needle, and fluid acquisition was performed as appropriate for cytology and tumor markers (FNA).
RESULTS: Six cases included 6 cysts located in head, uncinate,and body of pancreas. No device malfunctions and no technical challenges were encountered. Technical feasibility to perform imaging with nCLE during a pancreatic EUS-FNA procedure was achieved in all of 6 cases with increased agility in probe manipulation. All cases had good to very good image quality. One serious adverse event occurred that required hospitalization for acute pancreatitis.
CONCLUSION: nCLE in the pancreatic cysts is technically feasible via a 19G needle under EUS guidance. Future studies will address identification of structures, diagnostic accuracy, and complication profiles.

P204 ROLE OF CONTRAST-ENHANCED ENDOSCOPIC ULTRASONOGRAPHY (CE-EUS) IN THE DIAGNOSIS OF BRUNCH DUCT INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM (BD-IPMN)

H. Harima[1,*], S. Kaino[1], M. Kawano[1], S. Suenaga[1], M. Sen-yo[1], I. Sakaida[1]. [1]*Department of Gastroenterology & Hepatology, Yamaguchi University Graduate School of Medicine, UBE , Japan*

INTRODUCTION: The international consensus guidelines for the management of intraductal papillary mucinous neoplasm of the pancreas were revised in 2012. The presence of a mural nodule in BD-IPMN is one of the important criteria for surgical indication.
AIMS&METHODS: The aim of this study was to retrospectively evaluate the ability of CE-EUS to diagnose a mural nodule in patient with BD-IPMN. From March 2009 to October 2012, we performed endoscopic ultrasonography (EUS) in 89 patients with BD-IPMN at our institute. In cases in which we suspected the presence of a mural nodule on EUS, we performed CE-EUS consecutively. Patients diagnosed with a mural nodule on CE-EUS underwent surgery.
RESULTS: CE-EUS was performed in 21 patients. A total of nine patients were diagnosed with a mural nodule on CE-EUS, all of whom underwent surgery. The remaining 12 patients were diagnosed with mucinous clots on CE-EUS, all of whom were observed without malignant findings. The pathological findings revealed mural nodules in all patients who underwent surgery. Seven of the nine patients who underwent surgery were diagnosed with intraductal papillary mucinous carcinoma (IPMC) and two were diagnosed with intraductal papillary mucinous adenoma (IPMA). Three of the seven IPMCs nodules were not detected on any other imaging modalities without CE-EUS. The mean height of the IPMC mural nodules on CE-EUS was 10.7 mm (7-15), and the mean height of the IPMA mural nodules on CE-EUS was 6.5 mm (3-10). With 7 mm taken as the cutoff value for the size of mural nodules measured on CE-EUS, the diagnosis of IPMC had a sensitivity of 100%, a specificity of 50%, and an accuracy of 88%.
CONCLUSION: Evaluating vascularity using CE-EUS is useful for discriminating a mural nodule from mucinous clots in patients with BD-IPMN. The presence of a mural nodule $\geqq$7 mm in size on CE-EUS may be a malignant indicator of BD-IPMN.

P205 NOVEL COMPUTER-AIDED QUANTITATIVE ANALYSIS OF CONTRAST-ENHANCED HARMONIC EUS IN THE DIFFERENTIATION BETWEEN PANCREATIC CARCINOMA AND CHRONIC PANCREATITIS

H. Imazu[1,*], T. Kato[1], N. Tamai[1], T. L. Ang[2], H. Tajiri[3]. [1]*Department of Endoscopy, The Jikei University School of Medicine, Tokyo, Japan,* [2]*Department of Gastroenterology, Changi General Hospital, Singapore, Singapore,* [3]*Division of Gastroenterology and Hepatology, Department of Internal Medicine , The Jikei University School of Medicine, Tokyo, Japan*

INTRODUCTION: Contrast-enhanced harmonic EUS (CH-EUS) has recently emerged as a useful diagnostic modality in the differentiation of pancreatic carcinoma (PC) and chronic pancreatitis (CP). However, discriminating between PC and CP is still challenging.
AIMS&METHODS: The aim of this study was to evaluate the utility of CH-EUS with the newly developed computer-aided diagnostic software (Inspeedia Inc., Kariya, Japan) that was able to quantify the heterogeneity of contrast-enhancement within pancreatic lesion. Consecutive patients with PC or CP with mass lesions who underwent CH-EUS at Jikei University Hospital from February 2011 to February 2013 were retrospectively analyzed. A curvilinear echoendoscope (GF-UCT260), Aloka Prosound α10 processor and intravenous administration of 0.015ml/kg of Sonazoid were used for CH-EUS. Using the software, a region of interest (ROI) which was subdivided into 100 cells could be placed to cover an area within pancreatic mass. The difference of grade of gray scale color between adjoining cells within ROI was detected, and the number of adjoining cells which showed the difference of grade of gray scale color was automatically calculated in each frame rate of CH-EUS (heterogeneity index: HI). The graph of HI curve was also automatically generated to depict the changes in HI over time. The mean HI from start to one minute after injection of Sonazoid in each patient was calculated. The final diagnosis of PC was based on the results of surgery or EUS-FNA and CP on the results of EUS-FNA, clinical course and other imaging tests.
RESULTS: Fifteen patients with PC and 12 patients with CP were analyzed. Isovascular pattern was observed in all patients with CP and 9 with PC, and hypovascular pattern in 6 with PC. The mean HI in patients with PC after injection of Sonazoid was significantly higher than CP (15.4 vs. 6.6, $p<0.0001$). On the basis of ROC curve data, the optimal cut-off value of mean HI to differentiate PC from CP was 11.17. The sensitivity and specificity were 86% and 100%, respectively, and area under the curve was 0.88. Moreover, the combination of vascular pattern and mean HI yielded the sensitivity and specificity of 100%.
CONCLUSION: CH-EUS with this novel diagnostic tool to quantify the heterogeneity of contrast-enhancement within pancreatic lesions might dramatically improve accuracy in the differential diagnosis between PC and CP.

P206 HISTOPATHOLOGICAL DIAGNOSIS OF BOTH LEFT AND RIGHT LESIONS BY ENDOSCOPIC ULTRASOUND-GUIDED ASPIRATION BIOPSY WITH A LARGE CALIBRE NEEDLE

I. Yasuda[1,*], S. Uemura[1], M. Mabuchi[1], S. Doi[1], T. Iwashita[1], H. Moriwaki[1]. [1]*First Dept. of Internal Medicine, Gifu University, Gifu, Japan*

INTRODUCTION: Adrenal masses are occasionally detected in clinical practice. Although most of these masses are benign adenomas, adrenal metastases are occasionally noted in patients with lung cancer; moreover, adrenal lymphomas are also not uncommon. In certain cases, it is difficult to accurately diagnose such masses using only the findings of imaging tests; therefore, pathological diagnosis is often required. The left adrenal gland is readily visible on endoscopic ultrasonography (EUS), and EUS-guided aspiration (EUS-FNA) has often been attempted in such patients. However, the right adrenal gland has been believed not as easily visible on EUS, and only a few studies have reported the use of EUS-FNA for the right adrenal gland. Furthermore, a diagnosis obtained using EUS-FNA with conventional (22- or 25-gauge) needles is usually based on cytological assessment. However, histopathological assessment is often required for the accurate diagnosis of adrenal lesions.
AIMS&METHODS: To evaluate the utility of EUS-guided aspiration biopsy (EUS-FNAB) using a large-calibre (19-gauge) needle for histopathological assessment of left and right adrenal lesions, we retrospectively reviewed patients in our EUS database who had undergone EUS-FNAB for the diagnosis of an adrenal lesion between April 2004 and April 2013. The patients' baseline characteristics, EUS findings, FNAB results, and follow-up data were assessed.
RESULTS: EUS-FNAB was attempted in a total of 45 adrenal lesions (left, 34; right, 11) in 38 patients. In all cases, the procedure was successful. The adrenal lesions were detected by CT in 22 patients and were incidentally detected during lung cancer staging, by EUS, in 16 patients. Thirty-four patients had extra-adrenal malignancies, including lung cancer in 24, lymphoma in 7, pancreatic cancer in 1, cervical cancer in 1, and gastric cancer in 1 patient. The median largest diameter of the lesions was 23 mm (range, 7–108 mm). Histopathological samples were successfully obtained from all lesions, and histopathological analyses provided diagnoses of adenoma in 19, adenocarcinoma in 9, diffuse large B-cell lymphoma in 11, small cell carcinoma in 3, and myelolipoma in 3 lesions. The final diagnoses were lung cancer metastasis in 12 (adenocarcinoma in 9 and small cell carcinoma in 3), diffuse large B-cell lymphoma in 11, adrenal myelolipoma in 3, and adrenal adenoma in 19 lesions. No significant complications developed in the patients who underwent EUS-FNAB.
CONCLUSION: Thus, we believe that EUS-FNAB, using a 19-gauge needle, is safe and useful for diagnosing both left and right adrenal lesions.

P207 USEFULNESS OF ENDOSCOPIC ULTRASOUND (EUS) ELASTOGRAPHY FOR THE DETECTION OF MALIGNANCY OF MEDIASTINAL AND ABDOMINAL LYMPH NODES (LN)

J. E. Dominguez-Muñoz[1,2], D. de la Iglesia-García[1,2], J. Lariño-Noia[1,2], J. Iglesias-García[1,2,*], N. Vallejo-Senra[1,2]. [1]*Gastroenterology, University Hospital of Santiago de Compostela,* [2]*Foundation for Research in Digestive Diseases, Santiago de Compostela, Spain*

INTRODUCTION: EUS-elastography allows analyzing tissue stiffness during a standard EUS examination, which may be of help in the differential diagnosis of solid lesions. Detection of malignant infiltration of LN is highly relevant to define the optimal therapeutic strategy for different tumors. We hypothesized that EUS-elastography may provide with additional information to the conventional EUS B-mode for the detection of malignancy in mediastinal and abdominal lymph nodes (LN).
AIMS&METHODS: **Aim** of the study was to evaluate the usefulness of EUS-elastography in this setting. **Methods**: Prospective study including consecutive patients who underwent EUS for the evaluation of LN. EUS-elastography was performed under conscious sedation by using the linear Pentax EUS (EG-3870-UTK) and the Hitachi-PREIRUS processor. Final diagnosis was based on surgical histopathology or, in non-operated cases, on imaging assessment; EUS-guided fine needle biopsy and clinical follow-up. Elastographic pattern of the different LN are described. Probability of malignancy according to the EUS-elastographic pattern was calculated.
RESULTS: 140 patients (mean age 61 years, 19-82, 94 males) with a total of 140 LN were evaluated. Size of LN was 22.3 mm as a mean (range 4-59mm). 115 LN were located in the mediastinum, and 25 in the abdomen. Malignancy was confirmed by reference methods in 82 cases, whereas the remaining 58 LN were finally considered as benign. Three different elastographic patterns were identified: 1) a heterogeneous blue-predominant pattern (n=62), 2) a heterogeneous green-predominant pattern (n=30), and 3) a heterogeneous mixed green-blue pattern with geographical appearance and no color predominance (n=48). Malignant LN showed a blue-predominant pattern in 59 cases (72%) and mixed green-blue pattern in 23 cases (28%). On the contrary, benign LN showed a green-predominant pattern in 25 cases (43%), a mixed green-blue pattern in 30 cases (51.2%) and a blue-predominant pattern in 3 cases (5.2%). The probability of malignancy in a LN showing a green-predominant pattern was of 0%, and of 95.2% in case of a blue-predominant pattern. Finally, the probability of malignancy in a LN showing a mixed green-blue pattern was of 47.9%.
CONCLUSION: EUS-elastography is a very useful tool for the differential diagnosis of mediastinal and abdominal LN. It provides with specific colour patterns supporting the malignant or benign nature of the LN

P208 ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION FOR GASTRIC SUBMUCOSAL TUMOR SMALLER THAN 2 CM

K. Akahoshi[1,*], M. Oya[2], Y. Motomura[1], M. Kubokawa[1], J. Gibo[1], K. Kanayama[1], S. Fukuda[1], S. Hamada[1], Y. Otsuka[1], T. Hosokawa[1], N. Tomoeda[1], T. Miyazaki[1], R. Utsunomiya[1], A. Miyagaki[1]. [1]*Gastroenterology,* [2]*Pathology, ASO IIZUKA HOSPITAL, Iizuka, Japan*

INTRODUCTION: Diagnosis and treatment of gastric submucosal tumor (SMT) smaller than 2 cm is very difficult. EUS-guided fine needle aspiration (EUS-FNA) is a promising technique to obtain tissue samples with minimal risks.
AIMS&METHODS: The aim of this study was to evaluate the efficacy and accuracy of EUS-FNA in the diagnosis of gastric SMT smaller than 2cm. From February 2003 to October 2012, 90 consecutive EUS-FNAs of gastric hypoechoic solid SMT smaller than 2 cm diagnosed by standard EUS were evaluated prospectively. The reference standards for the final diagnosis were surgery (n=43), and/or clinical follow-up (mean 30 months, follow-up only: n=47) including EGD, CT, and/or US. Additionally, immunophenotyping of specimens obtained by EUS-FNA and surgical resection specimens were compared.
RESULTS: In one case puncture was not performed because of severe intratumoral calcification. The diagnostic rate of the gastric hypoechoic solid SMT smaller than 2cm was 74% (66/89). Histological diagnosis of gastric SMT smaller than 2 cm by EUS-FNA were 47 (53%) malignant SMTs (44 GISTs, 1 Glomus tumor, 1 SMT like cancer, and 1 malignant lymphoma), 19 (21%) benign SMTs (14 leiomyomas, 4 ectopic pancreas, and 1neurinoma), and 23 (26%) undeterminated SMTs. In 43 surgically resected cases, the diagnostic accuracy of EUS-FNA using immunohistochemical analysis of gastric hypoechoic solid SMT smaller than 2 cm was 100% (43/43). No major complications were encountered. After surgery, there was no recurrence in 47 malignant SMTs. Appropriate management, including surgery, chemotherapy, and follow-up were performed in all 66 SMTs diagnosed by definitive EUS-FNA.
CONCLUSION: EUS-FNA with immunohistochemical analysis is an effective and accurate method in the pretherapeutic diagnosis of gastric SMT smaller than 2cm. Aggressive use of EUS-FNA for gastric SMTs smaller than 2cm is a promising way to improve its prognosis .

P209 THE COMBINATION OF EUS-FNA AND EUS-FNB IMPROVES THE DIAGNOSTIC ACCURACY COMPARED WITH EUS-FNA ALONE IN DIFFICULT LESIONS - A RANDOMISED COMPARATIVE STUDY

P. Hedenström[1], A. Demir[2], O. Nilsson[3], B. Lindkvist[1], R. Sadik[1,*]. [1]*Departement of Internal Medicine, Sahlgrenska University Hospital, Division of gastroenterology,* [2]*Department of clinical pathology and cytology, Sahlgrenska University Hospital, Unit of Cytology,* [3]*Department of clinical pathology and cytology, Sahlgrenska University Hospital, Unit of Pathology, Göteborg, Sweden*

INTRODUCTION: EUS-guided tissue sampling can be performed either by fine needle aspiration (FNA) for cytology or fine needle biopsy (FNB) for histological analysis. Tissue sampling is still challenging in lesions like GIST, cystic tumours and lymphomas.
AIMS&METHODS: The goal of this study was to examine the diagnostic accuracy of EUS-guided FNA, FNB and the combination of the two methods.
From March to October 2012 we asked patients referred for EUS to be enrolled in the study. Further enrollment is on-going. All EUS-procedures were performed by one experienced endosonographist (RS). Punctures were performed using FNA-needles (Cook Medical, Olympus, Boston Scientific) and FNB-needles (Pro-Core™, Cook Medical). A cytotechnician was present on-site. We aimed at performing both FNA and FNB in each case. Cases were randomised to either FNA first followed by FNB or vice versa. No puncture was performed if lesions were obviously benign. FNB was not performed in areas close to large vessels or to the papilla. We experienced prior to the study one severe pancreatitis after puncturing the papilla with a 22 gauge biopsy needle. One experienced cytopathologist (AD) and one experienced pathologist (ON) separately reviewed the majority of the samples. Histopathology after surgery or autopsy and clinical follow-up were used as end point.

RESULTS: 83 patients (mean age 62) were enrolled. 64 lesions were punctured. FNA and FNB were performed in 45 cases and FNA only in 19 cases. Mean lesion size was 35 mm. A total of 35/45 (78%) of cases punctured with both FNA and FNB had a malignant final diagnosis. The combination FNA/FNB had a higher sensitivity, 94.2 %, compared with FNA alone, 62.9 %, p =0.001. The overall diagnostic accuracy was also higher for the combination FNA/FNB versus FNA alone; 95.6% versus 68.9 %, p = 0.001. Sensitivity and overall accuracy for FNB alone was 88.6 % and 86.7 % respectively and showed no significant difference compared with the combination FNA/FNB. FNA however correctly diagnosed 3 lesions that could not be diagnosed by FNB. No complications were observed.

	Location (n)	Location (%)
Submucosal lesions	20	44
Pancreas (cystic and solid)	13	29
Paraintestinal lesions	7	16
Mediastinal lesions	3	7
Lymph nodes	2	4

CONCLUSION: The combination of EUS-FNA and EUS-FNB shows higher sensitivity and diagnostic accuracy compared with EUS-FNA alone. This combination can be considered in cases with an expected low sampling quality such as GIST or previously sampled lesions.

P210 DOUBLING TIME (DT) OF GASTROINTESTINAL SUBMUCOSAL TUMORS

S. Tokunaga[1,*], M. Kida[1], H. Yamauchi[1], K. Okuwaki[1], T. Iwai[1], S. Miyazawa[1], H. Kikuchi[1], M. Watanabe[1], H. Imaizumi[1], W. Koizumi[1]. [1]*Gastroenterology, Kitasato University Hospital, Kanagawa-ken, Japan*

INTRODUCTION: We retrospectively analyzed the Doubling Time (DT) of gastrointestinal submucosal tumors (SMT) by using sequential findings of endoscopic ultrasonography (EUS) to identify the growth rate.
AIMS&METHODS: A total of 297 patients with SMT in the gastrointestinal tract were underwent surgical resection or EUS-FNA and given a pathological diagnosis in Kitasato University Hospital and Kitasato University East Hospital from 1987 to March 2013. Forty-six patients (34: surgical resection, 12: follow-up after FNA) which were performed EUS more than twice during follow-up were enrolled. Each DT was calculated by using tumor diameter visualized by EUS.

RESULTS: We included forty-six patients (21 male / 25 female, mean age: 65 years old). They located in esophagus (three), stomach (forty-one), duodenum (two). Histological diagnosises were 34 GISTs, five Leiomyomas, three Schwannomas, one ectopic pancreas, one hamartoma, one cyst, one Brunner adenoma. The median of follow-up period was 31.7 months (range: 6.6-210). The median of times of EUS was three (range: 2-13). Compared with the median DT of GIST was 17.2 months, Leiomyoma / Schwannoma / ectopic pancreas / hamartoma / cyst / Brunner adenoma were 231.2 / 104.7 / 274.9 / 61.2 / 49.0 / 134.7 months. DT of GIST, high / intermediate / low, was 3.9 / 17.1 / 27.6 months. DT of the high and intermediate risk grade GIST (mean: 8.2 months) was significantly shorter than that of the low risk grade GIST (mean: 27.6 months) ($p<0.05$). DT of GISTs (mean: 17.2 months) was significantly shorter than that of the median of the total of Leiomyomas and Schwannomas ($p<0.05$).
CONCLUSION: We conclude that DT of GIST is shorter than that of other SMT such as Leiomyoma, Schwannoma, etc. And DT of the high and intermediate risk grade GIST which has more malignant potential is shorter than that of the low grade GIST.

P211 SMALL BOWEL CAPSULE ENDOSCOPY IN PATIENTS WITH UNEXPLAINED ANAEMIA / GASTROINTESTINAL BLEEDING AND CHRONIC KIDNEY DISEASE

E. Docherty[1], A. Koulaouzidis[2,*], S. Douglas[2], J. N. Plevris[1,2]. [1]*Medical School, The University of Edinburgh,* [2]*CLDD, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom*

INTRODUCTION: The use of small-bowel capsule endoscopy (SBCE) has revolutionised investigating the small-bowel. However, there are only few reports [1-3] on the Diagnostic Yield (DY) of SBCE in patients (pts) with chronic kidney disease (CKD) and unexplained anaemia and/or obscure gastrointestinal bleeding (OGIB).
AIMS&METHODS: Retrospective study; our SBCE database was searched (March 2005 to August 2012) for pts with estimated glomerular filtration rate (eGFR) $<60ml/min/1.73m^2$. Subsequently, electronic case notes of pts with low eGFR who underwent SBCE for anaemia and/or OGIB were retrieved and abstracted. A mean eGFR value -for up to **5** years prior to SBCE- was calculated for each case. Severity of CKD was defined according to Renal Association recommendations as: **stage 3** (eGFR: 30-59); **stage 4** (eGFR: 15-29); and, **stage 5** (eGFR <15 or on dialysis). Numerical values were expressed as mean±SD or median (range).
RESULTS: In the aforementioned period, 69 pts with eGFR <60 were referred for SBCE. 65/69 (92.8%) had CKD stage 3 (eGFR: 49±7.9) and 4/69 (7.2%) stage 4 (n=3) or stage 5 (n=1). 51/65 (78.5%) of stage 3 CKD pts were referred for SBCE due to unexplained iron deficiency anaemia and/or OGIB [43 (66.1%) & 8 (12.3%), respectively]. 25/51 (49%) had normal SBCE, while 17/51 (33.3%) had angioectasias; other findings were active bleeding (n=2), non-specific fold oedema (n=2), ileal erosions (n=1), adenocarcinoma (n=1) and inconclusive/ videos not available (n=3). All pts (n=4) with CKD 4 or 5 were referred due to unexplained anaemia. 3/4 (75%) had angioectasias and 1 normal SBCE. Faecal calprotectin (FC) was measured in 12 pts with CKD stage 3 and unexplained anaemia prior to SBCE; No sinister pathology or significant small-bowel inflammation was found in this subgroup.
CONCLUSION: SBCE has limited DY in CKD pts referred for investigation of unexplained anaemia. The most common finding is angioectasias, while sinister small-bowel pathology is rare. Furthermore, FC measurement pre-SBCE is not associated with increased DY.

P212 THE USE OF OESOPHAGEAL CAPSULE ENDOSCOPY IN PATIENTS WITH HAEMOPHILIA; EXPERIENCE FROM A TERTIARY CENTRE

Y.-L. Ang[1], A. Koulaouzidis[2,*], S. Douglas[2], J. N. Plevris[1,2]. [1]*Medical School, The University of Edinburgh,* [2]*CLDD, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom*

INTRODUCTION: A great proportion of patients with haemophilia are considered at risk of being co-infected with hepatitis C (HCV) and variant Creutzfeldt-Jakob disease (vCJD) [1] .Chronic hepatitis C leads to liver cirrhosis, which in turn causes portal hypertension and varices [2]. Alternative endoscopic modalities have been developed for the investigation of the upper gastrointestinal (GI) tract, such as oesophageal capsule endoscopy (OCE). However, OCE is widely accepted and its indications are still under evaluation. 3 Our aim was to evaluate the use of OCE in a tertiary referral centre for GI problems in Lothian, Southeast Scotland, giving a special focus on OCE in patients with haemophilia.
AIMS&METHODS: A retrospective review of the OCE database from May 2005 to March 2012. Electronic case notes and OCE reports were reviewed. Demographics and clinical background, in particular haemophilia, hepatitis C, HIV and cirrhosis, reason for referral and OCE findings were abstracted.
RESULTS: A total of 65 OCEs (50 patients; 27 M/23 F; mean age: 52.7 ±13.7 years) were carried out in the aforementioned period. 32% pts had haemophilia (16/50 patients/all male; mean age: 51.6 ± 9.8 years; range 31-78 years; 28 OCEs); 5 pts had repeat OCEs (1 pt: 1 repeat, 2 pts: 2 repeat, 1 pt: 3 repeat & 1 patient: 4 repeat OCEs). All haemophiliacs were infected with HCV; 2 pts were co-infected with HIV. 3/16 (18.75%) of haemophiliacs had established cirrhosis, 5/16 (31.25%) probable cirrhosis. In haemophiliacs, indications for OCE were: variceal surveillance (OCEs **group A**: 17/28; 60.7%) and/or other upper GI symptoms (OCEs **group B**: 11/28; 39.3%). PillCam®ESO1 was used in 15/28 (53.6%) occasions and PillCam®ESO2 for the rest (13/28; 46.4%). The overall diagnostic yield (DY) of OCE in haemophiliacs was 78% (21/28). The DY was similar in OCEs group A: 64.7% (findings in 11/17) and OCEs group B: 54.5% (findings in 6/11), P =1.0. Oesophageal transit times were mean: 166s; range: 3-1171s. All capsules reached the stomach, but only 8/28 (28.5%) capsules entered the duodenum.
CONCLUSION: OCE is a useful and acceptable alternative to conventional endoscopy in selected groups of patients. In particular, OCE in haemophiliacs has a high DY and should be considered a first line investigation to guide further endoscopic intervention.

P213 NEGATIVE FAECAL CALPROTECTIN (FC) IS A STRONG PREDICTOR OF NEGATIVE SMALL BOWEL CAPSULE ENDOSCOPY

B. Polewiczowska[1,*], W. Ashraf[1], S. Grainger[1], S. R. Khan[1], K. Sandhu[1]. [1]*Gastroenterology, King Geroge Hospital, London, United Kingdom*

INTRODUCTION: Capsule Endoscopy (CE) is a standard investigation in the diagnosis of small bowel disease. Increase in CE activity has inevitably increased the frequency of negative CE. Patients having CE frequently undergo other diagnostic tests such as CT Enterography (CTE), MR Enterography (MRE) and Faecal Calprotectin (FC), a non-specific marker of bowel inflammation.
AIMS&METHODS: Our aim was to retrospectively analyse our small bowel CE data to see if CTE, MRE or FC predicts result of a CE study.
144 patients (67M, 77F) were investigated with CE over 2yrs. Referral indications included Iron Deficiency Anaemia (75), Crohn's assessment (28), GI Bleed (13), Chronic diarrhoea and Malabsorption (13), Abdominal pain and weight loss (11), others (4). 78 of 144 (54%) were also investigated with CTE (44), MRE (12), CTE&MRE (3) and FC (19).
RESULTS: 92 of 144 (64%) had positive findings on CE. 16/59 scanned patients had positive findings on CTE (8) and MRE (8). 11/19 patients tested strongly positive for FC. 4/8 (50%) of CTE+ and 5/8 (62%) of MRE+ also had significantly positive findings on CE. 6/11 (54%) of FC+ had significant positive findings on CE. However, 100% of FC negative patients had negative CE. Sub-group analysis showed that 2/4 CTE+ and CE+ patients were tested for FC and both were positive. Only 1/5 MRE+ and CE+ patient was tested for FC and proved positive.
CONCLUSION: CTE, MRE and FC individually predicted positive CE result in roughly 50% of cases.

In a small sample, combined FC and CTE or MRE positivity predicted positive CE result in 100% of cases.
Negative FC is a strong predictor of a negative CE in IBD setting.

P214 CAPSULE ENDOSCOPY: THE EFFECTS OF BMI AND WAIST CIRCUMFERENCE ON LOCATION PICK UP SENSORS

F. Leet[1,*], Y. Al-nae'eb[1], S. Altun[1], Y. Miao[1], P. Bradley[2]. [1]*Gastroenterolgy,* [2]*Clinical Audit, Ipswich Hospital NHS Trust, Ipswich, United Kingdom*

INTRODUCTION: Capsule endoscopy is an extremely valuable non-invasive tool to examine the entire gastrointestinal tract in particular the small bowel. A variety of reasons for technical failure has been reported [1, 2] like gaps in recording, battery malfunction, failure of sensor localization and failure in downloading images obtained. In a review of 733 cases, the authors reported 8.46% of patients had technical failure or clinical complications which prevented or hampered diagnosis.
AIMS&METHODS: This retrospective analysis looked at the effect of BMI and waist circumference on the location sensors during capsule endoscopy. The data were collected retrospectively from the notes of 143 patients who had capsule endoscopy at Ipswich Hospital during 2006-2011. Patients were divided in two groups one with location sensor signal failure (Group A) and other with detected signal (Group B). In twenty two (15%) patient's location sensor failed to pick up the signal (Group A). Two patients died in the follow up period so the notes were unable to be retrieved. In three out of 20 patients notes BMI were not recorded at the time of procedure and in 10 patients we were unable to obtain the waist circumference. To decrease selection bias we randomly selected 20 case notes from group B. In this cohort, all patients had their BMI noted but we were unable to obtain the waist circumference of nine patients.
RESULTS: The two groups had an equal gender spread (52.6% female and 47.4% male), median age of 58 (18-89 yrs.) with a 99% Caucasians ethnicity. In group A, no one had normal BMI, eight were overweight (BMI 25-29), eight were obese (BMI 30-39) and one patient was severely obese (BMI > 40). Out of eleven patients, three patient had normal waist circumference, two were high (female > 80-88cm and male > 94-104 cm) while the remaining seven were even higher (female > 88cm and male > 104 cm). In group B nine patients had normal BMI, seven overweight, two obese and 2 were very obese. Out of eleven patient, seven had normal (< 80 cm female/< 94 cm male) and four had higher waist circumference. The average BMI of the group A and B were 32.22 (median 35.1) vs 28.49 (median 26.15) kg/m2 and the average waist circumference 95.58cm (median 99.05) vs 85.48 (median 86.4) cm.
CONCLUSION: The results would suggest that the localization sensors may find it difficult to pick up images in patient with either a relatively high BMI or high waist circumference during capsule endoscopy. Further prospective studies are needed to evaluate this further and to determine whether there is a threshold BMI or waist circumference by which the location sensors may be rendered inadequate.

P215 FINDING THE SOLUTION FOR INCOMPLETE SMALL-BOWEL CAPSULE ENDOSCOPY

F. Dias De Castro[1,*], J. Magalhaes[1], B. Rosa[1], M. J. Moreira[1], J. Cotter[1]. [1]*Gastroenterology, Centro Hospitalar do Alto Ave – Guimarães, Portugal, Guimarães, Portugal*

INTRODUCTION: Capsule endoscopy (CE) is an established technology for the evaluation of small bowel diseases, including obscure gastrointestinal bleeding. An important technique limitation is incomplete examination of the small bowel, which occurs in approximately 20% of the procedures. This means that the capsule did not reach the cecum within the recording time.
AIMS&METHODS: The aim of our study was to assess the benefit of prokinetics, in association with *Real Time Viewer* (RTV), in decreasing the rate of incomplete examinations.
Between June 2012 and February 2013 capsule's location was determined, 1h after its ingestion, through RTV included in the new Given ® recorder (DR3). If the capsule was still in the stomach the patient received 10 mg of domperidone *per os*. The results of this group were compared with CE carried out between January 2009 and May 2012. Statistics were performed with SPSS v 17.0.
RESULTS: Between January 2009 and May 2012, 307 CE were performed, in 15,6% (n=48) the procedure was incomplete. The group analyzed prospectively included 82 CE, with three IE (3,7%). The difference between the rates of IE between the two groups was statistically significant (p=0,003). The two groups were similar with regard to age, sex, indications for performing CE, inpatient status and surgical history. In the first group the average gastric time was significantly longer in patients with IE than in patients with complete examination (77 minutes vs 26 minutes, p=0,003).
In the second group 14 patients received domperidone (17%). There was no difference in mean small bowel transit time in those who received or did not receive prokinetic (247 minutes vs 290 minutes), p=0,15.
CONCLUSION: The administration of prokinetic, in association with RTV, with the aim of decreasing gastric transit time reduces the rate of IE with no effect on small bowel transit time.

P216 VALIDATION THE LEWIS SCORE – INDISPENSABLE INSTRUMENT IN EVALUATING MUCOSAL ACTIVITY IN ISOLATED SMALL-BOWEL CROHN'S DISEASE

F. Dias De Castro[1,*], J. Magalhaes[1], B. Rosa[1], M. J. Moreira[1], J. Cotter[1]. [1]*Gastroenterology, Centro Hospitalar do Alto Ave – Guimarães, Portugal, Guimarães, Portugal*

INTRODUCTION: The Lewis Score (LS) was devised to measure mucosal disease activity using capsule enteroscopy (CE). However this score has not been prospectively validated in daily practice.
AIMS&METHODS: The aim of this study was to verify interobserver agreement for LS.
We performed a retrospective, single-center, double-blind study including patients with isolated small-bowel Crohn's disease (CD) submitted to CE. The LS based on three endoscopic parameters: villous edema, ulcer and stenosis/stricture calculated for which tertile. For each CE, LS was calculated by the coordinator and by one of the investigators. The interobserver correlation was measured by the Pearson test and the interobserver agreement was calculated by the Kappa score.
RESULTS: Forty two CE were included, the cecum was reached in 76% and 81% of examinations according to investigators and coordinator, respectively, (p>0,05). The average global LS was 1385 and 1291, for the coordinator and investigators, respectively. We verified a strong correlation between the investigators and the coordinator either in scores obtained by tertile (first tertile r=0,752, second tertile r=0,768 and third tertile r=0,769) or in total LS (r=0,774), p<0,0001. The interobserver agreement, calculated by Kappa score, taking into account the classification: normal (LS<135), mild disease (LS between 135 and 790) and moderate to severe disease (LS≥790), was good (0,737), (p<0,001).
CONCLUSION: This study has demonstrated a strong interobserver agreement to the LS, validating this score in reporting small-bowel inflammation. The LS might be used in staging, follow-up and therapeutic assessment in patients with isolated small-bowel CD.

P217 UPPER GASTROINTESTINAL FINDINGS DETECTED BY CAPSULE ENDOSCOPY PERFORMED FOR OBSCURE GASTROINTESTINAL BLEEDING

J. L. T. Magalhães[1,*], M. J. Moreira[1], B. Rosa[1], M. Barbosa[1], A. Rebelo[1], F. Dias de Castro[1], S. Leite[1], J. Cotter[1]. [1]*Serviço de Gastrenterologia, CENTRO HOSPITALAR DO ALTO AVE - GUIMARÃES, Guimarães, Portugal*

INTRODUCTION: Patients with Obscure Gastrointestinal Bleeding (OGIB) with a previous negative workup on esophagogastroduodenoscopy (EGD) and colonoscopy need comprehensive evaluation, including Capsule Endoscopy (CE). Sometimes, during the observation of CE images we can see potential bleeding lesions from stomach and duodenum which were overlooked by first EGD.
AIMS&METHODS: The aim of our study was to evaluate the frequency of lesions identified in the upper gastrointestinal tract and to analyze their significance in terms of its role in reducing unnecessary CE studies. We retrospectively study 152 consecutive patients who underwent CE for OGIB at our center, with a normal initial EGD. Patients with a definite cause of bleeding within reach of conventional EGD were identified. For the statistical analysis SPSS18.0 was used. A p value $<$ 0,05 was considered as significant. Percentages were used for categorical variables and mean±SD were used to summarize data for continuous variables.
RESULTS: The most common indication for CE was occult OGIB (76.3%). CE results showed gastrointestinal lesions in 66 (43.4%) patients. In 11 (7.2%) patients, CE showed relevant gastric or duodenal lesions not previously noted during initial EGD. In 9 (5.9%) of these 11 patients gastroduodenal lesions were the only pathological finding discovered in the digestive tract. In the remaining 2 (1.3%) patients found synchronous potential bleeding lesions in the upper tract and small bowel. Nine (81.8%) of patients with upper gastrointestinal findings had a duodenal lesion. All upper gastrointestinal lesions were angioectasias. In patients which CE showed upper gastrointestinal lesions the commonest indication was occult OGIB (63.6%). A second EGD was performed in 10 patients, in all of these patients CE findings were confirmed and treatment with argon plasma coagulation was performed.
CONCLUSION: CE provided information about upper gastrointestinal findings that was considered sufficient to explain the OGIB etiology and recommended a second-look EGD in 7,2% of patients. In 5,9% patients the upper gastrointestinal findings were the only findings that explain the OGIB, so in these cases a second EDG previous to CE should avoid an unnecessary procedure

P218 COLON CAPSULE ENDOSCOPY: CAN MOVIPREP® BE USED AS BOWEL PREPARATION AS WELL AS BOOSTER? OBSERVATION STUDY IN 95 PATIENTS.

L. Jean Christophe[1,*], A. L. patrick[1], C. michel[2]. [1]*hepato-gastroenterologie, polyclinique poitiers, poitiers,* [2]*37 Rue Louis Rouquier, , 92300 Levallois Perret, France*

INTRODUCTION: Pillcam colon capsule endoscopy (CCE) enables colon visualization without the need of general anesthesia (Given Imaging, Ltd, Yoqnéam, Israel). The study goal was to observe and assess the quality of the colon preparation with 2L of Moviprep® (PEG + ascorbic acid + ascorbate and Na sulfate) as well as its efficacy when used as a booster when substituted to Fleet® to perform a CCE in 95 consecutive patients.
AIMS&METHODS: Patients were prepared according to two consecutive protocols:
Protocol #1 (70 patients): low-residue diet (D5 to D2), pursenide (D2), clear liquid diet and 2L of Moviprep® on D1, capsule ingestion at 8.00 a.m., booster #1 with 45mL of Fleet® 2 hours later and booster# 2 with 22.5mL of Fleet® 6 hours after ingestion if the capsule had not been egested.
Protocol #2 (25 patients): low-residue diet (D5 to D2), pursenide (D2), clear liquid diet on D1, 2L of Moviprep® the morning of the examination, capsule ingestion at 11.30 a.m., booster #1 with 500mL of Moviprep® 2 hours later and booster #2 with 500mL of Moviprep® 6 hours after ingestion if the capsule had not been egested.
RESULTS: In protocol #1, 60 examinations (85.7%) were complete, 10 (14.3%) were incomplete including 5 cases of sigmoid retention, 4 cases of dark rectal residual liquids and one case of premature recording termination. Preparation was rated adequate in 59 patients (84.2%). Mean colic and oro-caecal transit times were respectively 2 hours 47 min and 3 hours 22 min.
In protocol #2, 13 examinations (52%) were complete, 12 (48%) were incomplete including 7 cases of sigmoid retention and 5 cases of dark rectal residual liquids. Preparation was rated adequate in 14 patients (56%). Mean colic and oro-caecal transit times were respectively 3 hours and 6 hours 07 min.
CONCLUSION: Thanks to the bowel preparation with 2 liters of Moviprep® the day before, the quality of the examination was good with 84.2 % of adequate preparations and a complete colic examination in 85.7%, when associated with Fleet® as a booster. When used as a booster, Moviprep® was less efficient on the colic peristalsis than Fleet®, with twice as long colic transit times.

P219 PILLCAM COLON2 AFTER INCOMPLETE COLONOSCOPY-FIRST PRELIMINARY RESULTS OF A MULTICENTER STUDY

P. Baltes[1,*], M. Bota[1], J. Albert[2], M. Philipper[3], F. Hagenmüller[4], I. Steinbrück[4], R. Jakobs[5], M. Bechtler[5], D. Hartmann[5], H. Neuhaus[6], J.-P. Charton[6], R. Mayershofer[7], H.-G. Hörster[8], H. Hohn[9], M. Keuchel[1]. [1]*Bethesda Krankenhaus Bergedorf, Hamburg,* [2]*Klinikum der J. W. Goethe Universität, Frankfurt,* [3]*Gastroenterologische Schwerpunktpraxis, Düsseldorf,* [4]*Asklepios Klinikum Altona, Hamburg,* [5]*Klinikum der Stadt Ludwigshafen am Rhein, Ludwigshafen,* [6]*Evangelisches Krankenhaus, Düsseldorf,* [7]*Gastroenterologie am Burgweiher, Bonn,* [8]*Gastropraxis Rheydt, Mönchengladbach,* [9]*Schwerpunktpraxis Gastroenterologie, Koblenz, Germany*

INTRODUCTION: Colonoscopy is the gold standard for colorectal diseases but may be incomplete e.g. in case of redundant colon, severe inflammation or intolerance of sedation. PillCam Colon1 has been used to complement colonoscopy. We report preliminary data from a multicenter study using colon capsule endoscopy (CCE) with PillCam Colon2 after incomplete colonoscopy.
AIMS&METHODS: This prospective multicenter study (supported by Given Imaging) included patients after incomplete colonoscopy without stenosis performed by an experienced gastroenterologist. Primary endpoint was the ability of CCE to visualize missed colon segments. CCE was performed either on the day after colonoscopy with additional cleansing solution (Moviprep) in the morning. Alternatively, CCE was performed within 30 days using new bowel cleansing (Clear liquids day before + split-dose Moviprep). Additional boosts consisted of 0,75 or 0,25 l Moviprep and NaP only as additional rescue boosting if capsule was not excreted after 9 hours.
RESULTS: Data of 45 patients could be analyzed. In 71% CCE was performed the day after colonoscopy. Cleansing levels were adequate in 69%. CCE visualized the entire colon in 80%. CCE visualized missing colonic segments in 87%. In 16/45 (36%) polyps were detected, in 8/45 (18%) polyps were located in segments not reached by colonoscopy. In one case an adenocarcinoma was diagnosed after detection of a 26 mm cecal polyp. Other findings at CCE were detected in 58% (26/45). One capsule was retained in the small bowel (2%). Surgical resection lead to the previously unknown diagnosis of stenosing and fistulating Crohn's disease. In one case (2%) recording failed due to technical problems.
CONCLUSION: In our study complementation of incomplete colonoscopy with PillCam Colon2 and Moviprep regimen was in concordance with previous data for PillCam Colon1 and for device assisted colonoscopy, also showing a relevant amount of additional findings. Previously described low volume cleansing protocol was also effective in our setting. Slow transit due to functional stenosis or motility disorder may be a risk factor for incomplete CCE. Generally the procedure was tolerated well. In one case retention lead to a relevant diagnosis affecting treatment.

P220 DOMPERIDONE IMPROVES COMPLETION RATE IN SMALL BOWEL CAPSULE ENDOSCOPY

S. Dimitriadis[1,*], A. Koulaouzidis[2], S. Douglas[2], J. N. Plevris[2,3]. [1]*Department of Internal Medicine, St. Vinzenz-Hospital, Düsseldorf, Germany,* [2]*CLDD, The Royal Infirmary of Edinburgh,* [3]*Medical School, The University of Edinburgh, Edinburgh, United Kingdom*

INTRODUCTION: The completion rate (CR) of small bowel capsule endoscopy (SBCE) has been reported at 81.3-84.8% [1]. Incomplete examinations can be due to delayed gastric emptying, strictures, intestinal dysmotility and/or capsule battery life. Prokinetic agents are used to increase CR and theoretically SBCE diagnostic yield (DY). Domperidone, an antidopaminergic agent, has not been widely used in SBCE [2,3]; unlike Metoclopramide, it lacks extrapyramidal adverse effects.
AIMS&METHODS: Retrospective study; to assess gastric transit time (GTT), small-bowel transit time (SBTT) and the CR of SBCE when using Domperidone. Furthermore, we aimed to compare the CR of 2 different SBCE systems (MiroCam® , PillCam®). Consecutive SBCE examinations from 2008 to 2012 from a tertiary referral centre in Scotland were analysed; in the first 203, no prokinetics were used; Domperidone was given orally to the subsequent 449, reflecting changes in clinical practice.
RESULTS: In the aforementioned period, a total of 652 SBCE examinations were performed [265 (40.6%) men & 387 (59.4%) women]; 385/652 (59%) were performed with PillCam® and 267 (41%) with Mirocam®. The most common indications for SBCE were obscure gastrointestinal bleeding, anaemia, Crohn's disease (known and/or suspected) and abdominal pain. In 449/652 (68.9%) liquid Domperidone (5 mg) was administered for capsule ingestion, while in 203 (31.1%) the capsule was ingested without any Domperidone.
In our series, the overall CR of SBCE was (86.7%). The 2 SBCE systems showed equivalent CR (PillCam® 87.5%, MiroCam® 85.4%; P=0.43). The use of liquid Domperidone increased CR (88.6% vs. 82.3%, P=0.027). A higher CR was noted when Domperidone was used with PillCam® than with MiroCam® (82.2 vs. 92.5%; P=0.002 and 83.3 vs. 85.5%, respectively; P=0.8). Furthermore, the median GTT and the median SBTT did not differ between the two groups (GTT/SBTT with Domperidone 27.0'/222.0' and without Domperidone 30.5'/228.0', respectively; P=0.436 / P=0.477).The median age of patients who received Domperidone was higher compared with patients who did not receive (58y vs. 48y, P=0.009), although CR was not affected by patient's age (complete: 55y, incomplete: 61y, P=0.331).

CONCLUSION: The use of Domperidone in SBCE increases the CR particularly with PillCam®, although does not affect the median GTT and SBTT and should be routinely used to improve CR in SBCE.

P221 PREDICTING THE PRESENCE OF INTESTINAL ANGIOECTASIAS: IS THAT POSSIBLE?

T. C. Gonçalves[1,*], J. Magalhães[1], P. B. Carvalho[1], M. J. Moreira[1], J. Cotter[1]. [1]*Gastroenterology Department, Centro Hospitalar do Alto Ave, Guimarães, Portugal*

INTRODUCTION: Angioectasias are the most common vascular anomalies found in the gastrointestinal tract. When localized in the small bowel (SB) they can cause obscure gastrointestinal bleeding (OGIB) and in this setting, wireless capsule endoscopy (WCE) is currently an important diagnostic tool.

AIMS&METHODS: This study aimed to identify predictive factors for the presence of SB angioectasias, detected by WCE. We retrospectively analyzed the results of 284 WCE performed consecutively between April 2006 and December 2012, whose indication was OGIB. From these, 47 cases with SB angioectasias and 53 controls without identifiable lesions were chosen. For each selected patient demographic, clinical and laboratorial information on the exam date was collected. Statistical analysis was performed using SPSS v17.0.

RESULTS: The mean age of subjects with angioectasias (70,9±14,7) was significantly higher than in controls (53,1±18,6; $p<0,05$). Angioectasias were found in 56,1% of men and in 40,6% of women, although this difference did not reach statistical significance. The presence of angioectasias in SB was significantly higher when the indication for the exam was overt OGIB ($p<0,05$). From past medical history, hypertension and dyslipidemia were the most significantly associated factors with the presence of SB angioectasias ($p<0,05$), while smoking and chronic kidney disease were only marginally associated (p=0,084; p=0,145). Diabetes, aortic stenosis, chronic liver disease, previous abdominal surgery, and use of antiplatelet or anticoagulant drugs were not significantly associated with SB angioectasias. There was no relationship found with platelet count.

CONCLUSION: In OGIB, factors such older age, overt OGIB, dyslipidemia or hypertension are predictive for the presence of SB angioectasias found by WCE.

P222 WIRELESS CAPSULE ENDOSCOPY IN OBSCURE GASTROINTESTINAL BLEEDING - NORMALCY IS NOT REASSURING.

T. C. Gonçalves[1,*], F. D. Castro[1], M. J. Moreira[1], J. Cotter[1]. [1]*Gastroenterology Department, Centro Hospitalar do Alto Ave, Guimarães, Portugal*

INTRODUCTION: Wireless capsule endoscopy (WCE) is currently a fundamental tool in the etiological study of obscure gastrointestinal bleeding (OGIB). However, the impact of a negative exam and the rebleeding risk are not consensual in different studies.

AIMS&METHODS: The aim of this study was to describe the follow up of patients with OGIB and a normal WCE examination, and assess the presence of rebleeding and possible associated factors. We analyzed 79 patients who consecutively underwent WCE examination for the study of OGIB between April 2006 and December 2011, whose results excluded potentially bleeding lesions. Pre- and post-WCE information was collected, including follow up interval and presence of rebleeding (defined as admission to the hospital for symptomatic anemia, need for blood transfusion, decrease in hemoglobin value of >2g/dL, or evidence of melena or hematochezia).

RESULTS: Of the 79 patients initially selected, 4 were excluded because there was no available information. Of the remainder, 61,3% were female and the mean age was 52 years. The indication for the examination was occult OGIB in 59 patients (78,7%) and overt OGIB in 16 patients (21,3%). 68 patients (90,7%) had hospital follow up, with a mean follow up interval of 32 months. From these, 39 patients (57,4%) were posteriorly subjected to further investigation and a diagnosis was established in 11 of them. Rebleeding was documented in 16 (23,5%) of the 68 followed up patients, having occurred on average 15 months after WCE. From the analyzed factors (age, gender, indication for OGIB, past medical history, and hemoglobin value), only male gender was significantly associated with rebleeding (p=0,007).

CONCLUSION: Approximately a quarter of patients with OGIB and normal WCE examination will suffer from rebleeding, which is more significant in men. This result should imply a more regular medical surveillance, and possibly a more exhaustive attempt to clarify the etiology of the OGIB.

P223 COMPARISON OF CAPSULE ENDOSCOPY READING MODE: CONCERN ABOUT EFFICIENCY AND TIME SAVING

Y. T. Jeen[1,*], J. M. Lee[1], H. S. Choi[1], E. S. Kim[1], B. Keum[1], H. S. Lee[1], H. J. Chun[1], S. H. Um[1], C. D. Kim[1], H. S. Ryu[1]. [1]*Gastroenterology, Korea University Anam Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Capsule endoscopy is a useful method of detecting and diagnosing small-bowel diseases such as obscure gastrointestinal bleeding, small-bowel tumors, and inflammatory bowel disease. In a survey of 530 members of the American College of Gastroenterology, 23.7% used Singleview, 40.0% used DualView, and 54.5% used Quadview. Each physician should decide the reading settings based on his own experience with CE. These different reading methods may account for some of the reported discrepancies in diagnostic yield and interobserver agreement on capsule interpretation.

AIMS&METHODS: . The aim of this study was to investigate evaluation times and false negative rates in three different reading modes to find the most appropriate mode for evaluation of capsule endoscopy.

Three trainee endoscopists reviewed capsule endoscopy studies performed at our institution from 5/2007 to 6/2012. Each trainee endoscopist read a total of 30 capsule endoscopy videos. Three endoscopists compared three different capsule endoscopic software modes: automatic view at a speed of 20 frames per second (fps) and automatic quadview at a speed of 20 fps, quickview at a speed of 4 fps. Each endoscopist read the same capsule endoscopic record by using one of three different software modes. Capsule endoscopic reading time was recorded, and the number of detected lesions was counted.

RESULTS: The mean evaluation time using quickview was significantly shorter than with automatic view (automatic single view: 18 min 48 sec, quadview: 19 min, quickview: 2 min 7 sec). The false negative rates of ulcers, erosions were higher when reading in quickview compared with reading in automatic view. However, the detection rate of bleeding was similar when reading in quickview compared with automatic view. Automatic quadview 20fps has minimal diagnostic miss rates and can safely replace slower modes in clinical practice. A theoretical advantage of quadview is a longer single frame exposure time compared with singleview

CONCLUSION: Quickview can be used confidently in small bowel bleeding and can be performed in a short time. However, quickview mode has a high false negative rate for the other lesions, such as ulcers or erosions. Selection among time-saving methods should be made on the basis of the clinical indication for the capsule endoscopy.

P224 DIAGNOSIS AND QUANTITATIVE ASSESSMENT OF DUODENOGASTRIC REFLUX IN PATIENTS AFTER CHOLECYSTECTOMY

M. V. Repin[1,*], A. V. Popov[2], V. Y. Mikryukov[1], T. E. Vagner[1]. [1]*Department of advanced training,* [2]*Department of hospital surgery, Perm State Medical Academy named after E.A. Vagner, Perm, Russian Federation*

INTRODUCTION: Symptoms of duodenogastric reflux as heartburn, eructation, feeling of bitterness in the mouth and etc. are often observed in patients after cholecystectomy. X-ray and endoscopic examinations are used for the diagnosis of this condition. However, quantitative characteristics of these methods is rather subjective.

AIMS&METHODS: The aim of the research was to give a quantitative assessment of the duodenogastric reflux (DGR) in patients after cholecystectomy. 98 patients (11 men and 87 women, aged 24-82 years) after cholecystectomy were x-rayed, underwent endoscopic examination of upper gastrointestinal tract and hepatobiliary scintigraphy. To estimate the bile passage a radionuclide tracer 99 mTc HIDA was used, with fatty meal ingestion after 45 minutes. The degree of DGR was defined by a percentage ratio of total radioactivity in a stomach area to radioactivity in the duodenal area which exceeded 15% of the background radiation. DGR was distributed to 4 degrees: I - from 16 to 35%; II - 36-55%; III - 56-75%; IV - more than 75%.

RESULTS: DGR was revealed in 47 (47.9%) post-cholecystectomy patients. The I^{st} degree was revealed in 22 (46.8%), II^{nd} - in 7 (14.9%), III^{rd} - in 13 (27.7%), IV^{th}- in 5 (10.6%) patients. Intensity of DGR correlated with radiological data of the duodenal antiperistalsis (Rs=0.45; $p<0.05$) and regurgitation of contrast substance from the duodenum to the stomach (Rs=0.54; $p<0.05$). The stage of DGR had an association with endoscopic signs of pyloric sphincter function decrease (Rs=0.45; $p<0.05$). Moreover, the patients with the III^{rd} and IV^{th} degrees of DGR had gastroesophageal reflux disease manifestations. Gastroesophageal reflux, determined by x-ray examination, was confirmed during endoscopy by reflux esophagitis manifestation.

Patients with DGR more often demonstrated symptoms of duodenal antiperistalsis ($p<0.001$) and incompetence of the cardia (p=0.02) than those who did not have isotope reflux to the stomach. Pyloric incompetence ($p<0.001$) and a bile reflux ($p<0.001$) of the patients with DGR were more often revealed during endoscopy procedure. Sensitivity of the endoscopic diagnostic procedures of DGR made up 81%, specificity – 72%.

CONCLUSION: Hepatobiliary scintigraphy may be accepted as an informative diagnostic method and quantitative assessment of DGR in patients after cholecystectomy. On an increase of bile regurgitation to the stomach the reflux extends and reaches the gullet, forming "a double reflux". The findings of this method can be used in anti-reflux treatment selection.

P225 DIFFUSION-WEIGHTED IMAGING IN THE FOLLOW-UP OF PATIENTS AFTER PRIMARY SURGICAL AND NON-SURGICAL TREATMENT FOR RECTAL CANCER

D. M. Lambregts[1], W. M. Palm[1], L. A. Heijnen[1], M. J. Lahaye[1], M. H. Martens[1], B. E. Heidemann[1], M. Maas[1], **G. L. Beets**[2,*], R. G. Beets-Tan[1]. [1]*Radiology,* [2]*Surgery, Maastricht University Medical Center, Maastricht, Netherlands*

INTRODUCTION: Accurate detection of recurrent disease after primary rectal cancer treatment is crucial to allow for curative salvage surgery. Standard imaging is known to experience difficulties in differentiating between post-treatment effects (inflammation and fibrotic scar tissue) and recurrent disease. Diffusion-weighted MRI (DWI) is a technique that analyses differences in tissue cellular density to differentiate between hypercellular (tumour) and low or normocellular tissues (fibrosis and inflammation).
AIMS&METHODS: Aim of this study was to evaluate the value of DWI in the follow-up of patients after primary surgical or non-surgical treatment for rectal cancer. The study group (n=117) consisted of 36 patients who had previously undergone rectal cancer treatment, consisting of either standard surgical resection with or without neoadjuvant (chemo-)radiotherapy (n=36), a local transanal excision (n=40, of which 15 after chemoradiotherapy) or a non-operative 'wait-and-see'-policy (n=41). During clinical follow-up (FU) patients underwent on or more FU-MRIs (1.5T) including DWI (highest b-value b1000), as part of routine FU or because of a suspected local recurrence after surgery. Two readers in consensus evaluated each MRI and scored the b1000 DWI-images as 'no high signal', 'high signal suspected of recurrence' or 'not adequately assessable due to artefacts'.
RESULTS: Patients underwent a mean number of 3 FU-scans (range 1-11) with a mean FU-time of 44 months (4-144). 27/117 patients developed a local recurrence, of which 23 (85%) were accurately detected on DWI. The other 90 patients (without recurrence) together underwent a total of 261 FU scans, of which 194 (74%) remained consistently true negative (no high signal) on DWI. 57 DWI-scans (19%) could not adequately be assessed due to artefacts. 14 DWI-scans were false positive (mainly at the first FU-scan after surgery/local excision), of which 50% again normalised during further FU.
CONCLUSION: DWI is a useful tool in the follow-up of patients after primary rectal cancer treatment. False positives may occur immediately after surgery, but the DWI signal normalises again during follow-up.

P226 ACCURATE IDENTIFICATION OF COMPLETE RESPONDERS AFTER CRT FOR RECTAL CANCER WITH ENDOSCOPY AND MRI

M. Maas[1], W. M. Palm[1], L. A. Heijnen[1], D. M. Lambregts[1], M. H. Martens[1], E. Van Drie[1], L. P. Stassen[2], S. O. Breukink[2], J. W. Leijtens[3], M. N. Sosef[4], K. W. Hulsewe[5], **G. L. Beets**[2,*], R. G. Beets-Tan[1]. [1]*Radiology,* [2]*Surgery, Maastricht University Medical Center, Maastricht,* [3]*Surgery, Laurentius Hospital, Roermond,* [4]*Surgery, Atrium Medical Centre, Heerlen,* [5]*Surgery, Orbis Medical Centre, Sittard, Netherlands*

INTRODUCTION: Chemoradiotherapy (CRT) for rectal cancer leads to complete tumour response (CR) in up to 15-25%. Accurate identification of a CR is necessary to allow for less invasive treatments (i.e. local excision or wait-and-see policy). Standard imaging cannot accurately identify a CR. Other techniques, such as functional MRI (diffusion-weighted MRI 'DWI') or endoscopy may prove more valuable.
AIMS&METHODS: Aim was to evaluate the accuracy of [1] endoscopy and [2] MRI including DWI for identification of a CR and compare it to standard MRI. Forty-nine patients who underwent CRT followed by response evaluation by means of MRI including DWI and endoscopy 8 weeks after completion of CRT were retrospectively included. One experienced reader scored [1] the standard (T2-weighted) MR images, followed by [2] the MR images including DWI. A second reader scored the endoscopy images. Scoring was performed with a confidence level score (0=definitely residual tumour, 4=definitely CR) and results were compared with histology (CR vs non-CR). Readers were blinded for histology and each others' results.
RESULTS: Of the 49 patients, 31 had residual tumour and 18 had a CR. The AUCs for standard MRI, standard MRI + DWI, and endoscopy were 0.71, 0.78, and 0.88 respectively. Corresponding sensitivities and specificities were 39% and 87% for standard MRI, 39% and 93% for standard MRI + DWI, and 67% and 97% for endoscopy.
CONCLUSION: Although the addition of DWI improves the performance of MRI in identifying a CR, endoscopy provides superior results. With a higher sensitivity, endoscopy corrects for understaging of a CR with MRI. However, MRI remains crucial to evaluate the presence of any extramural residual tumour and/or involved nodes. A combination of endoscopy and MRI + DWI is therefore recommendable to identify patients with a CR after CRT, making less invasive treatments after CRT feasible.

P227 LONG-TERM OUTCOME IN PATIENTS WITH BENIGN ESOPHAGEAL REFRACTORY STRICTURES TREATED WITH SINGLE OR SEQUENTIAL BIODEGRADABLE STENT: A PROSPECTIVE FOLLOW-UP STUDY.

A. Repici[1,*], M. Jovani[1], M. Bianchetti[1], C. Genco[1], E. C. Ferrara[1], C. Ciscato[1], G. Strangio[1], L. Ghezzo[2], P. D. Omodei[1], S. Carrara[1], R. Rosati[3], A. Malesci[1]. [1]*Gastroenterology and Endoscopy, Istituto Clinico Humanitas, Milan,* [2]*Gastroenterology, Azienda Ospedaliera S. Croce E Carle , Cuneo,* [3]*General and Miniinvasive Surgery, Istituto Clinico Humanitas, Milan, Italy*

INTRODUCTION: Management of benign esophageal strictures refractory to standard dilation therapy (BERS) is challenging. Plastic or metal stents (MS) have been used with inconclusive results. Biodegradable stents (BDS) have recently been described in BERS.
AIMS&METHODS: Long-term outcome and safety of BDS in patients with BERS. Data from consecutive patients with BDS placement for BERS between 2008 and 2012 were prospectively included. Technical/clinical outcomes and complication rates were recorded. Clinical/endoscopic follow-up was scheduled at 1, 3, and 6 months and in case of dysphagia recurrence. Stricture etiology was: caustic 5(18%), post-radiotherapy 5(18%), surgery 12(43%), mixed 6 (21%). Previous treatment included MS in 7 (25%) patients and mechanic or pneumatic dilation in the rest, for a median time of 169 days (range 15-864).
RESULTS: 46 BDS (median 1, range: 1-5) were placed in 28 patients (17 male; median age 58y, range 21-75) and were followed for a median of 354 days (range 19-1611). A single BDS was placed in 19 patients (68%), two BDS in 9 patients (32%), four patients (14%) received a third and a fourth BDS, one (3.5%) received 5 BDS. Technical success rate was 98%. Severe post-stenting thoracic pain requiring analgesia occurred in 3 patients (11%). Median dysphagia-free period (DFP) was 111 days (range 33–341), 183 days (range 15-1209), 121 days (range 85-176) and 74 days (range 70-134), after the placement of the first to fourth BDS respectively. No significant differences, in terms of DFP, were observed when patients were stratified according to etiology or stricture length. At the end of follow-up, 11 patients (39%) were dysphagia free. Recurrence of dysphagia was treated with MS in 5 patients (18%) and periodic mechanic/pneumatic dilation in the rest. Four patients (14%) underwent surgery. An esophagotracheal fistula was developed in two patients (7.1%) after 103 and 134 days from BD placement. One of these patients died of surgical complications related to the treatment of the fistula and the other refused surgery and is treated periodically with metal stents. BDS migration occurred 3 in 3 pts (6.5%).
CONCLUSION: BD stent placement in patients with BERS is associated with high technical success rate and acceptable early complication rate. Two patients (7.1%) developed a major late adverse event. Long-term efficacy of this treatment for refractory strictures remains unsatisfactory with only 39% of patients free of dysphagia at the end of follow-up period.

P228 EFFECTIVENESS OF ENDOSCOPIC PNEUMATIC DILATATION IN THE TREATMENT OF DYSPHAGIA AFTER FUNDOPLICATION

A. T. Oliveira[1,*], D. Branquinho[1], S. Campos[1], T. Correia[1], C. Gregório[1], D. Gomes[1], C. Agostinho[1], C. Sofia[1]. [1]*Gastroenterology, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal*

INTRODUCTION: Fundoplication is used for the treatment of gastro-esophageal reflux disease. Dysphagia is common after surgery, being usually transient and related to postoperative edema. However, in 3-24% of cases, dysphagia may persist and is associated with dysmotility or stricture of the esophagus. Although pneumatic dilatation is done in these cases, there are not many studies that evaluate its effectiveness.
AIMS&METHODS: The aim of this work is to evaluate the efficacy and possible complications of endoscopic pneumatic dilatation in the treatment of dysphagia after fundoplication surgery. Study between January 2007 and December 2012 of the patients who developed dysphagia after fundoplication surgery and required endoscopic therapy. We analyzed the endoscopic data, interval and number of dilations, dysphagia severity before and after dilatation and need for surgical reintervention. Dysphagia was evaluated using the Mellow-Pinkas Scale, by telephone survey.
RESULTS: We included 20 patients with a mean age of 54 ± 13 years, mostly female (80%). The average time between surgery and the first dilatation was 18 months (minimum - 1, maximum - 84). The total number of dilatations performed per patient was: fifteen patients - 1; one patient - 2; four patients - 3. The maximum caliber reached was, on average, 16 mm (minimum - 15; maximum - 20). None of the patients were re-operated. Prior to pneumatic dilatation, seven patients had dysphagia for solid food, seven to semi-solid, two to liquids and four, total dysphagia. After dilation, thirteen reported no dysphagia, five had dysphagia for solids and two for semi-solids. In the subjective assessing by patients, 75% reported improvement in symptoms and 25% remained with the same degree of dysphagia. There were no immediate complications related to the procedure.
CONCLUSION: The endoscopic pneumatic dilatation in cases of dysphagia after fundoplication surgery is a safe procedure with an appreciable success rate, representing a gain in our therapeutic armamentarium.

P229 A NEW FULLY COVERED METAL STENT (HANARO-UTRECHT STENT) FOR THE TREATMENT OF MALIGNANT ESOPHAGEAL STRICTURES: A PROSPECTIVE FOLLOW-UP STUDY

D. Walter[1,*], M. W. van den Berg[2], J. E. van Hooft[2], H. Boot[3], R. C. Scheffer[4], F. P. Vleggaar[1], P. D. Siersema[1]. [1]*Departement of Gastroenterology and Hepatology, University Medical Center Utrecht, Utrecht,* [2]*Departement of Gastroenterology and Hepatology, Academic Medical Center,* [3]*Departement of Gastroenterology and Hepatology, Netherlands Cancer Institute, Amsterdam,*

[4]Departement of Gastroenterology and Hepatology, Jeroen Bosch Hospital, Den Bosch, Netherlands

INTRODUCTION: Insertion of self-expandable metal stents (SEMS) provides effective palliation in patients with malignant dysphagia. Although fully covered SEMS are increasingly used to prevent tissue ingrowth, they are prone to migration. In order to reduce migration, the HANARO-Utrecht stent was developed, a fully covered 20-mm diameter SEMS combining bilateral flared ends and three rows of anchoring silicone flaps on the stent body. Our aim was to evaluate the clinical efficacy and safety of the HANARO-Utrecht stent for the palliation of malignant dysphagia.
AIMS&METHODS: Consecutive patients who underwent HANARO-Utrecht stent placement for palliation of malignant dysphagia in four centers from 6/11 - 10/12 were included. Patients were contacted after 2 weeks and monthly thereafter until death. Intervention- or stent related major complications were defined as complications for which repeat endoscopic intervention or admission was required.
RESULTS: Forty patients (29 men (73%), mean age 68±11 years) were included. Malignant dysphagia was caused by esophageal cancer(n=32), malignant extrinsic compression(n=5), tumor recurrence after esophagectomy(n=2) and gastric cancer(n=1). Four patients (10%) had a fistula and 26 patients (65%) had undergone previous radiation and/or chemotherapy (RCT). Stent placement was technically successful in 39 patients (98%) while in 1 patient the stent collapsed during repositioning for which a second stent was inserted. Thirty-two patients (80%) remained dysphagia-free until end of follow up (median 59 days, range 2-223). Eight patients (20%) had recurrent dysphagia after a median of 46 days (range 9-132), due to tissue overgrowth (n=2) and stent migration (n=6), including partial migration in 5 patients for which successful endoscopic repositioning was performed. In total, 17 intervention- or stent related major complications occurred in 14 patients (35%), including hemorrhage(n=6), aspiration pneumonia(n=2), nausea/vomiting(n=3), fistula formation(n=2), severe pain(n=2), tracheal compression(n=1) and stent migration resulting in an unsealed fistula(n=1). No association was found between prior RCT and increased risk of major complications (p=0.53, OR0.64[95%CI, 0.157–2.603).
CONCLUSION: Our results demonstrate that the HANARO-Utrecht stent is effectively palliating dysphagia with a major complication rate in the same range as seen with other stents. Although the overall recurrent dysphagia rate was low, stent migration, although partially in the majority of patients, still occurred.

P230 CLINICAL OUTCOME OF SELF-EXPANDING METAL STENTS FOR ACUTE COLONIC OBSTRUCTION BASED ON RADIOLOGICAL POSITION: A SINGLE-CENTRE COHORT STUDY

E. H. van den Berg[1,*], J. F. Bergmann[1], M. Ledeboer[1], R. A. van Dijk[2], R. J. Bosker[3], F. ter Borg[1]. [1]*Gastroenterology*, [2]*Radiology*, [3]*Surgery, Deventer Hospital, Deventer, Netherlands*

INTRODUCTION: Self-expanding metal stents (SEMS) are used to resolve colonic obstructions. The correct placement of a SEMS remains a difficult endoscopic procedure and is not always successful. In addition, complications such as perforation may occur. Data evaluating function and complications of SEMS in relation to the radiological position during or shortly after the procedure are very limited.
AIMS&METHODS: Patients receiving SEMS between June 1998 and August 2012 were retrospectively analyzed in this single-centre study. We analyzed radiological symmetry of deployment and position in relation to the stenosis, angulation, minimal/maximal lumen ratio and number of stents. The primary endpoint was non-elective surgery (NES) within 21 days after SEMS placement. Secondary endpoints were immediate endoscopic relief of feces, production of feces within 24 hours, perforation and bleeding. Using multivariate logistic regression, outcomes were corrected for type of obstruction (benign/malignant/extrinsic), location in the colon and intent (bridge to surgery (BTS) or palliation).
RESULTS: In total 137 patients were included (BTS n=75, palliative n=62). In 39 patients (28.5%) the stent was placed proximal to the splenic flexure. A total of 18 patients (13.1%) underwent NES (unresolved ileus n=15, perforation n=2, invagination n=1). Four out of 5 patients with a benign obstruction and 3 out of 6 patients that received a second stent for elongation (n=1) or malposition (n=2) underwent NES. A more symmetrically placed SEMS was associated with direct endoscopic relief (p=0.007) and a straight position of the stent with at least moderate defecation after 24 hours (p=0.004). None of the radiological features were associated with the risk of NES in univariate analysis. Logistic regression confirmed that the placement of two stents (p=0.007) and benign obstructions (p=0.034) were associated with NES, but none of the radiological parameters. There were no associations between radiological parameters and perforation or bleeding.
CONCLUSION: Although a more symmetrically and straight positioned stent is associated with direct endoscopic relief and defecation within 24 hours, we could not detect a statistically significant association between radiological position of SEMS and occurrence of emergency surgery or complications. Patients with two SEMS or benign obstructions are at higher risk for non-elective surgery.

P231 EFFICACY OF GASTRIC HYDROSTATIC DILATION IN THE FUNCTIONAL OBSTRUCTION AFTER SLEEVE GASTRECTOMY

E. BOUEYRE[1,*], O. TOUCHAIS[1], O. FOULATIER[2], E. HUET[3], T. DELAUNAY[4], T. VAN OVERSTRAETEN[4], P. DUCROTTE[5], F. MICHOT[3], G. GOURCEROL[1]. [1]*Physiologie digestive, CHU Rouen,* [2]*Chirurgie viscérale, Clinique Mathilde,* [3]*Chirurgie viscérale, CHU Rouen,* [4]*Chirurgie viscérale, Clinique Saint-Hilaire,* [5]*Gastro-entérologie, CHU Rouen, Rouen, France*

INTRODUCTION: After sleeve gastrectomy, some patients report postprandial dysphagia and epigastric pain, that is relieved by vomiting. The aims of this study are 1/to identify a food stasis using perprandial videofluoroscopy or barium meal, defining a functional obstruction 2/to estimate the efficacy of a gastric hydrostatic dilation in these patients
AIMS&METHODS: Nine patients (1 men and 8 women ; age: 45.6 ± 4.8 years) were referred for postprandial dysphagia and epigastric pain, that was relieved by vomiting in 7/9 patients after a mean of 14.3 months after surgery. All patients had a gastric endoscopy that did not identify any stenosis, then a barium meal or perprandial videofluroscopy to assess barium stasis. A mediogastric and pyloric hydrostatic dilation was made by using a Boston Scientific CRE Balloon of 20 mm, using the pressure of 6 atmospheres for one minute. Patients symptoms (dysphagia, epigastric pain and vomiting) were evaluated before and 6 months after dilation with a pain visual analog scale (0-10)
RESULTS: A food mediogastric and/or pyloric stasis was identified in all the patients. At 6 months, the score of dysphagia (8.7 ± 0.5 vs 3.0 ± 1.0 ; $p<0.01$), epigastric pain (7.0 ± 1.4 vs 1.6 ± 0.9 ; $p = 0.02$) and vomiting (6.7 ± 1.3 vs 2.2 ± 0.9 ; p=0.02) was improved by hydrostatic dilation (only one session per patient). At the end of the follow up, no patient had regained weight following the dilation. An epigastric pain was reported in 4 patients, that disappeared within 48 hours after dilation. No severe complication was noted.
CONCLUSION: In the patients reporting postprandial dysphagia and epigastric pain relieved by vomiting after sleeve gastrectomy, a functional obstruction is worth to be assessed using a barium meal and/or a perprandial videofluoroscopy. The mediogastric and pyloric hydrostatic dilation is an therapeutic option with an efficacy that lasted over 6 months. This phase I study should be further confirmed on the long term and using randomized trials.

P232 USEFULLNESS OF COVERED SELF-EXPANDABLE METAL STENT INSERTION FOR THE TREATMENT OF ANASTOMOTIC LEAKS AND TRACHEOESOPHAGEAL FISTULAS AFTER UPPER GI SURGERY.

H. J. Ahn[1,*], C.-H. Lim[1], J.-Y. Lee[1], J.-S. Kim[1], J.-M. Park[1], I.-S. Lee[1], S.-W. Kim[1], M.-G. Choi[1], K.-Y. Choi[1]. [1]*Department of Internal Medicine, The Catholic University of Korea, College of Medicine, Seoul Korea, Seoul, Korea, Republic Of*

INTRODUCTION: Anastomotic leaks and tracheoesophageal fistulas (TEFs) are severe complications of upper gastrointestinal surgery with serious morbidity and mortality. Endoscopic placement of covered self-expandable metal stent (cSEMS) is emerging as a less-invasive alternative to surgery for the treatment of leaks and TEFs.
AIMS&METHODS: The aim of this study is to investigate treatment success rate of cSEMS, removal rate of successful cSEMS and complications of procedure.
Patients with postsurgical gastrointestinal leaks and TEFs treated with cSEMS (fully covered, CHOO/HANARO) between September 2009 and September 2012 were retrospectively reviewed. Treatment success was defined as complete and persistent closure of leaks or TEFs after cSEMS removal (primary closure) or after complementary endoscopic treatment (reposition or reinsertion).
RESULTS: 19 patients were treated with covered self-expandable metal stent (cSEMS). Included patients had anastomotic leaks or TEFs after total gastrectomy(9), esophagectomy(6) and etc(4, esophageal diverticulectomy, submucosal tumor enuclation, transcervical mediastinal drainage, primary esophageal closure). Overall treatment success rate of the leaks or TEFs occurred in 89 % (17 out of 19, including multiple procedures). Repositioning was done in 26% (5 out of 19, due to migration) and successful repositioning was done in 4 out of 5. (additional reinsertion was needed in 1 case and was successful.) Reinsertion was done in 16% (3 out of 19, due to migration) and 2 out of 3 were successful.(1 case was failed due to stent site erosion.) Stent removal after successful treatment was done in 94% (16 out of 17, average 30.6 days, range 11 ∼ 43 days, 1 was lost to follow-up.)
There was no procedure-related complication including perforation or death.
CONCLUSION: cSEMSs are a minimally invasive, safe and useful alternative for treating postsurgical leaks and TEFs in the upper gastrointestinal tract and can be easily removed after successful insertion.
Migration is a major problem, but most of cases can be cured by complementary endoscopic procedure (reposition or reinsertion).

P233 RISK FACTORS FOR UNSUCCESSFUL SURGICAL OUTCOMES AFTER COLONIC STENTING AS A BRIDGE TO SURGERY IN ACUTE LEFT-SIDED MALIGNANT COLORECTAL OBSTRUCTION

J. H. Kim[1,*], K. A. Kwon[1], M. Ha[1], J. J. Lee[1], J.-W. Chung[1], Y. J. Kim[1], K. O. Kim[1], D. K. Park[1], Y. S. Kim[1]. [1]*DEPARTMENT OF INTERNAL MEDICINE, GACHON UNIVERSITY GIL MEDICAL CENTER, Incheon, Korea, Republic Of*

INTRODUCTION: Although self-expanding metal stents (SEMS) as a bridge to surgery (BTS) is an alternative to emergency surgery in patients with malignant colonic obstruction (MCO), risk factors for unsuccessful surgical outcomes after stenting as a BTS is uncertain.
AIMS&METHODS: The aim of our study was to identify risk factors predictive of poor postsurgical outcomes for SEMS as a BTS. The medical records of patients who underwent SEMS insertion in colorectal obstruction between February 2004 and August 2012 were retrospectively reviewed. A total of 181 patients underwent SEMS insertion during the study period, 68 patients who underwent SEMS insertion as a BTS in acute left-sided MCO were included.
RESULTS: The mean age was 64.9 years (range, 38-89), and 70.6% (48/68) were male. The most common obstruction site was in the rectosigmoid area (25/68, 36.8%). Covered SEMS were used in 33/66 (50.0%) of patients with technical success. The technical and clinical success rates of SEMS were 97.1% (66/68) and 88.2% (60/68), respectively. 85.3% (58/68) of patients underwent primary tumor resection and primary anastomosis, with a mean interval of 11.3 days (range, 0-26) between SEMS insertion and surgery. Surgical success rate of SEMS as a BTS was achieved in 77.9% (53/68). On multivariate analysis, multiple SEMS [$\geq$2 stents or $\geq$2 stent insertion sessions (OR, 28.872; 95% CI, 1.939-429.956; p=0.015)] was a significant independent risk factor for surgical failure of SEMS as a BTS.
CONCLUSION: Although SEMS is an effective BTS therapy in most patients, the possibility of surgical failure should not be ignored. Multiple SEMS, turned out to be a risk factor for surgical failure, should be able to help clinicians decided to appropriate treatment strategy in subgroup of patients with acute left-sided MCO.

P234 FUNCTIONAL OUTCOME FOLLOWING SUCCESSFUL ENDOSCOPIC RECONSTITUTION OF PATIENTS WITH RADIATION-INDUCED COMPLETE ESOPHAGEAL OBSTRUCTION

K. V. Grooteman[1,*], F. P. Vleggaar[1], P. D. Siersema[1], T. H. Baron[2]. [1]*Gastroenterology and hepatology, University Medical Center Utrecht, Netherlands, Utrecht, Netherlands,* [2]*Gastroenterology and hepatology, Mayo Clinic, Rochester, United States*

INTRODUCTION: Combined anterograde - retrograde (CARD) endoscopic recanalization is safe and effective in restoring an esophageal lumen in patients with radiation-induced complete esophageal obstruction. In the few small case-series subsequent removal of a gastrostomy feeding tube is feasible in approximately 50%.
AIMS&METHODS: To investigate the long-term functional outcome and factors predictive of failure of clinical success in patients with radiation-induced complete esophageal obstruction after successful endoscopic lumen recanalization performed in a tertiary center. A retrospective chart review was performed. In 35 patients treated from August 2001 to February 2013 (median age 65 years, 23 males) recanalization was technically successful.
RESULTS: Procedural-related adverse events occurred in four patients (11.2%); three were perforations, all managed conservatively. The mean number of total dilations, including the recanalization procedure was 4.9. A mean esophageal dilation of 16mm was achieved. Only 6 patients (19%) were dysphagia-free after the final treatment, 2 patients had dysphagia to solids, 3 to semi-solids, 6 to liquids and 13 (42%) had complete dysphagia. Of 11 patients that had some ability to swallow the feeding tube could be removed in 7, though 6 were dilation-dependent. Only 4 (11%) patients were treatment free and 20 (57%) patients remained with gastrostomy feeding tubes. Head and neck cancer surgery was predictive of clinical success ($p = 0.05$). A trend towards clinical success was seen when the duration between radiation therapy and onset of dysphagia was longer (9.5 months vs. 1.2 months, $p = 0.07$). Mean follow-up was 1.8 years.
CONCLUSION: The ability to swallow after successful endoscopic recanalization of radiation-induced complete esophageal obstruction is low. A predictive factor for clinical success is a history of surgery for head and neck cancer.

P235 VIOLATION OF THE "RULE OF THREE" DOES NOT INCREASE THE RISK OF PERFORATION FOLLOWING ESOPHAGEAL DILATION

K. V. Grooteman[1,*], F. P. Vleggaar[1], P. D. Siersema[1], T. H. Baron[2]. [1]*Gastroenterology and hepatology, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Gastroenterology and hepatology, Mayo Clinic, Rochester, United States*

INTRODUCTION: The "rule of three" for esophageal dilation applies to rigid dilators and was arbitrarily proposed to prevent overaggressive dilation and consequent perforation. However, there is no evidence to support its utility.
AIMS&METHODS: To investigate whether violation of the "rule of three" increases adverse events (AEs) following esophageal dilation. Retrospective chart review of 300 patients (median age 63 years, 59% men) who underwent esophageal dilation between December 1991 and February 2013 at a tertiary hospital was performed. Demographics, indication, stricture and procedural characteristics, AE's and follow-up data were recorded. Adherence to the "rule of three" was defined for rigid dilators as passage of only 3 consecutive dilators in increments of 1 mm in a single session after moderate resistance was encountered and for balloon dilators as the dilation diameter was $\leq$ 3 mm than the initial diameter of the esophageal lumen as assessed endoscopic.
RESULTS: In 2,225 rigid or balloon esophageal dilations performed, 22 (1.0%) major AE's occurred, of which 11 perforations (0.5%), 4 fistulas, 3 admissions for pain management, 2 bleedings, 1 fever and 1 leaking tracheoesophageal voice prosthesis. The majority of dilated strictures were benign (n = 277, 93%) and complex (n = 201, 67%). The "rule of three" was not adhered to in 622 dilations. Of the 16 AEs occurring after over-the-wire rigid dilation the "rule of three" was violated once ($p = 0.17$). No correlation was found between AEs and complex strictures ($p = 0.69$), over-the-wire rigid dilators ($p = 0.10$), non-adherence to the "rule of three" ($p = 0.15$), diameter of dilation >3 mm ($p = 0.09$) and another maneuver performed during dilation ($p = 0.48$). No significant difference in perforation rate was seen when the "rule of three" was violated or not (8 vs. 3, $p = 0.15$). Likewise no correlation was found between perforations and complex strictures ($p = 0.39$), over-the-wire rigid dilators ($p = 0.49$) or diameter of dilation > 3 mm in one session ($p = 0.14$). However, a trend towards more perforations was seen when an additional maneuver was performed during dilation ($p = 0.065$). The percentage of AEs and perforations were equally distributed to the number of dilation sessions per patient.
CONCLUSION: Non-adherence to the "rule of three" does not appear to increase the risk of AEs, particularly perforation, following esophageal dilation using rigid dilators. Nonetheless, it needs to be determined whether other factors, like stricture etiology, affect the risk of developing an AE in esophageal strictures.

P236 SAFETY AND EFFICACY OF A BIODEGRADABLE STENT DURING NEOADJUVANT THERAPY IN PATIENTS WITH ADVANCED OESOPHAGEAL CANCER (ESNEBIO).

M. W. van den Berg[1,*], E. M. de Vries[1], D. Walter[2], F. P. Vleggaar[2], M. I. van Berge Henegouwen[1], R. van Hillegersberg[2], P. D. Siersema[2], P. Fockens[1], J. E. van Hooft[1]. [1]*Academic Medical Center, Amsterdam,* [2]*University Medical Center, Utrecht, Netherlands*

INTRODUCTION: An increasing number of patients with locally advanced esophageal cancer undergo treatment with chemoradiotherapy prior to surgery. This neoadjuvant therapy often causes acute inflammation and edema of the esophageal mucosa which could increase dysphagia symptoms and potentially jeopardize nutritional status. Initial data on self-expanding plastic stents placement prior to neoadjuvant treatment have shown promising results with regard to improvement of dysphagia and safety, but major drawbacks include stent migration and the need for stent removal prior to surgery. We hypothesized that placement of an uncovered biodegradable (BD) stent (SX-ELLA BD stent, Ella-CS, s.r.o., Czech Republic) might refute these problems while the improvement of dysphagia persists.
AIMS&METHODS: This is a prospective 2-center feasibility study aiming to include 16 patients with resectable esophageal carcinoma scheduled for neoadjuvant chemoradiotherapy and complaints of dysphagia for solid food (grade $\geq$ 2 [scale 0-4]). The BD-stent is placed prior to the start of neoadjuvant treatment. The primary outcome is safety, defined as the absence of intervention-related major complications (perforation, bleeding and pain requiring IV analgesics). Secondary outcomes include technical success, clinical success, other intervention related complications and weight change.
RESULTS: Nine patients have been included until May 1st 2013 (7 male, mean age 68 $\pm$ 8.1, median dysphagia grade 3 [range 2-4], 8 adenocarcinoma, 1 squamous cell carcinoma). No procedure-related or stent-related major complications were seen. Technical success rate was 100%. Clinical success was achieved 100% as well. Adverse events included pain after stent placement (n=6) and stent obstruction (due to necrotic tissue) (n=1). Weight loss occurred in 5 patients (relative median weight loss 6.5% [range 0.4-11.3]) despite additional nasogastric feeding tube placement through the stent in 4 patients after a median of 56 days (range 41-82). One patient had a relative weight gain of 5.6% after 8 weeks of follow-up. In the remaining 3 patients follow-up is still too short to report weight changes.
CONCLUSION: Preliminary results of this study do not reveal major complications and good technical and clinical success rates. Post procedural pain and persisting weight loss after BD stent placement are features which may hamper its future use during neoadjuvant chemoradiotherapy in patients with locally advanced esophageal cancer. We will complete the study as planned in order to draw firm conclusions.

P237 SAFETY AND EFFICACY OF A FULLY COVERED LARGE DIAMETER STENT (HANARO CCI STENT) FOR THE TREATMENT OF OESOPHAGEAL PERFORATIONS, ANASTOMOTIC LEAKS AND FISTULA.

M. W. van den Berg[1,*], A. C. Kerbert[1], E. J. van Soest[2], M. P. Schwartz[3], L. P. Gilissen[4], J. E. van Hooft[1]. [1]*Academic Medical Center, Amsterdam,* [2]*Kennemer Gasthuis, Haarlem,* [3]*Meander Medical Center, Amersfoort,* [4]*Catharina Hospital, Eindhoven, Netherlands*

INTRODUCTION: Oesophageal perforations, fistula and anastomotic leaks are severe conditions with high morbidity and mortality rates. Temporary placement of fully covered self expanding metal (fSEMS) or plastic stents has emerged as a treatment option. A high stent migration rate is a major drawback of the self-expandable stents currently used for these indications. In general, migration is often attributed to a relatively too small stent diameter. Therefore this study aimed to investigate the safety and efficacy of a large diameter fSEMS with a 24 mm body and 32 mm flares (Hanaro CCI stent, M.I.Tech, South-Korea) for treatment of these conditions.
AIMS&METHODS: Data were retrospectively collected from medical records of all patients who received the Hanaro CCI stent in the Netherlands between July 2009 and August 2012. The primary outcome was the number of severe stent(-placement)-related complications. Secondary outcomes were non-severe complications, technical and clinical success. Severity of complications was graded according the American Society for Gastrointestinal Endoscopy grading system.(1) Clinical success was defined as sufficient closure of the lesion as confirmed by endoscopy or X-ray with oral barium contrast without the need for an additional stent or surgical intervention.
RESULTS: Stent placement was performed in 21 patients (males 13 [62%], mean age 57 ± 10.4) for the following indications: perforation (n=3), anastomotic leak (n=16) and fistula (n=2). The technical success rate was 95%. Severe stent-related complications did not occur. However, 3 patients died because of persistent intrathoracic sepsis (n=2) and pre-existent bowel ischemia (n=1). A total of 12 patients (57%) experienced 13 non-severe stent-related complications, which consisted out of stent migration (partial n=4, complete n=5), bleeding (n=2), aspiration pneumonia (n=1) and tissue overgrowth (n=1). The overall clinical success rate was 52% (11/21). Median time to stent-removal following clinical success was 39 days (interquartile range 33-56). Clinical failures were caused by technical failure (n=1), premature death (n=3), stent migration (n=5) and insufficient sealing of the lesion (n=1). The 4 partial migrations were treated with endoscopic repositioning and were not considered clinical failures.
CONCLUSION: Placement of the Hanaro CCI stent is an easy to perform and safe treatment for oesophageal perforations, fistula and anastomotic leaks. However, efficacy is still hampered by stent migration despite the relatively large stent diameter.

P238 HIGH PROXIMAL MIGRATION RATE OF A PARTIALLY COVERED BIG CUP DUODENAL STENT (HANARO DPC-STENT) IN PATIENTS WITH MALIGNANT GASTRIC OUTLET OBSTRUCTION.

M. W. Van Den Berg[1,*], D. Walter[2], F. P. Vleggaar[2], P. D. Siersema[2], P. Fockens[1], J. E. van Hooft[1]. [1]*Academic Medical Center, Amsterdam,* [2]*University Medical Center, Utrecht, Netherlands*

INTRODUCTION: Enteral stent placement has emerged as a safe and effective palliative treatment option for patients with malignant gastric outlet obstruction (GOO). However, long term efficacy of conventional duodenal stents is hampered by stent dysfunction. The most frequently observed causes of dysfunction are tumour ingrowth in uncovered stents and stent migration in covered stents. We hypothesized that a newly designed partially covered big-cup enteral stent (Hanaro, M.I. Tech, Ltd., Seoul, Korea) would refute these problems. The objective of the covered part of the stent is to withstand tumour ingrowth while the proximal uncovered big cup should prevent distal migration by anchoring the stent at the pylorus.
AIMS&METHODS: This study was designed as a prospective two-center single-cohort study aiming to evaluate safety and efficacy of the Hanaro DPC stent in 40 patients with incurable malignant gastric outlet obstruction. Stent placement was performed through-the-scope under endo-fluoroscopic guidance. The primary outcome was stent patency, defined as the time between stent placement and re-obstruction caused by an endoscopically proven stent dysfunction. Secondary outcomes included technical success, clinical success (improvement of GOO-symptoms one week after stent placement) and complications. Follow-up continued until death or stent-dysfunction requiring a second stent, whichever came first.
RESULTS: Six patients (4 pancreatic cancer, 1 cholangiocarcinoma, 1 gastric cancer) were included (4 males, median age 63 [range 47-83], median follow-up 49 days [range 2-228]). Technical success rate was 100%. Clinical success was achieved in 4/6 patients (67%). Clinical failure in 2 patients was caused by proximal stent migration after 2 and 4 days respectively and another proximal stent migration occurred in a third patient, 29 days following stent placement. These 3 patients were treated with endoscopic removal of the Hanaro DPC stent and placement of a conventional uncovered stent. Other complications included biliary obstruction 45 days after duodenal stent placement (n=1) and obstructive symptoms most likely caused by a motility disorder (n=1). The high number of proximal migrations occurring after a relatively short time interval after stent placement made us deciding to stop the study prematurely. One patient is still alive with a functional stent after 228 days of follow-up.
CONCLUSION: The Hanaro DPC-stent is associated with a high proximal migration rate in patients with malignant GOO and can therefore not be recommended in this clinical setting.

P239 BIODEGRADABLE STENTS FOR CAUSTIC ESOPHAGEAL STRICTURES : DO THEY WORK ?

R. Kochhar[2], G. Choudhuri[1], S. Lakhtakia[3], A. Khaliq[2], S. Appasani[2,*], J. Basha[2], D. N. Reddy[3]. [1]*Gastroenterology, SGPGI, Lucknow,* [2]*Gastroenterology, PGIMER, Chandigarh,* [3]*Gastroenterology, AIG, Hyderabad, India*

INTRODUCTION: Refractory esophageal strcitures present challenging situatuions to the endoscopist. Biodegradable stents curcumvent the tissue reaction and tissue embedment issues seen with metallic stents known to be useful in malignant strictures. There is an upcoming role for biodegradable stents in the management of benign refractory esophgageal strcitures.
AIMS&METHODS: ***Aims*** : To study the response of biodegradable stents(BD)(ELLA, Chech Republic) in patients with refractory caustic esophageal strictures(CES).
Material and methods : 13 patients(18-72 yr, 9males) of refractory CES were subjected to placement of BD stents. Patients were followed up every week for 1 month and then every month for six months. Periodically endoscopy was repeated. Immediate and delayed complications were noted.
RESULTS: The BD stent was placed successfully in all 13 patients with no immediate complication of bleeding, or perforation or migration. 1 patient had retention of the olive of the stent in the stomach which was removed the next day. The size of the stent was 23mm in width in all with 80 mm of length in 12 patients and 115 mm of length in 1 patient. Pain in retrosternal area was reported by all the 13 patients post-procedure. It persisted till 1 week in 10 patients, till 2 weeks in 6 patients and till 8 weeks in 2 patients. 1 patient had stent migration at 4 weeks. Tissue hyperplasia was noted in 6 patients at the proximal end at 3-4 weeks. Stent disintegration was complete by 12 weeks in all the 12 patients with stent in-situ. 9/13 patients had restenosis at 3 months, 10/12 at 6 months and 11/13 at 1 year. Patients with recurrence of stricture were subjected to dilatation (n=9) or surgery (n=2). At esophagectomy, in one patient, no residue of the stent or tissue reaction was found. 2 patients(16%) were free of symptoms at 1 year including the one with migration of stent.
CONCLUSION: Biodegradable stents do not provide long term relief in a majority of patients with CES. Stents with longer time to degradation may be more effective.

P240 EVALUATION OF NINE PERFORATED CASES RELATED TO SELF EXPANDING METAL STENT PLACEMENT WITH MALIGNANT GASTRODUODENAL OBSTRUCTION.

T. Kayahara[1,*], M. Kikuyama[2], Y. Yamashita[3], H. Yamamoto[1]. [1]*Gastroenteology and Hepatology, Kurashiki Central Hospital, Kurashiki,* [2]*Gastroenteology and Hepatology, Shizuoka General Hospital, Shizuoka,* [3]*Gastroenteology and Hepatology, Japanese Red Cross Society of Wakayama Medical center, Wakayama, Japan*

INTRODUCTION: Self expanding metal stent (SEMS) placement is a useful palliative method for the patients with malignant gastrointestinal obstructions. But etiologies of the adverse events are still unclear. Perforation should be mentioned in particular as a one of most severe events related to SEMS.
AIMS&METHODS: We focused on the perforated cases and evaluated risk factors and conformation of SEMS after insertion. One hundred and forty seven patients of gastroduoedenal obstruction with SEMS placement were enrolled this study. We performed with an over the wire technique for Ultraflex (Boston Scientific) and HANARO stent (Diagmed healthcare) and a through the scope technique for Niti-S (Taewoong medical) and WallFlex (Boston Scientific).
RESULTS: Perforations were occured in 9 patients (6.1%) related to SEMS treatment. Three patients were treated with radiotherapy before SEMS placement. Two of two patients with urothelial cancers resulted in perforation and they were treated with neither chemotherapy nor radiotherapy. Radiotherapy increased perforation risk with significance (OR 6.40, 95% C.I:1.3886-29.4983, p=0.008). Four autopsies were carried out and all perforations were confirmed in oral side edge of SEMS. All stents extend in stenosis, and SEMS with fixed braid tend to be stiff under the incomplete expansion.
CONCLUSION: From our result, a radiotherapy before SEMS placement and urothelial carcinomas are one of most critical factors predicting perforation. Furthermore, we speculate that conformation change of SEMS and peristalsis might cause perforation.

P241 GASTROINTESTINAL SAFETY OF LONG-TERM PEG-J USED FOR CONTINUOUS INFUSION OF LEVODOPA-CARBIDOPA INTESTINAL GEL

M. Epstein[1], D. Johnson[2], R. Hawes[3], N. Schmulewitz[4], A. Vanagunas[5,*], R. Gossen[6], S. Eaton[7], J. Dubow[7], K. Chatamra[7], W. Z. Robieson[7], J. Benesh[7]. *[1]Digestive Disease Associates, Annapolis, [2]Eastern Virginia Medical School, Norfolk, [3]University of Central Florida College of Medicine, Orlando, [4]University of Cincinnati, Cincinnati, [5]Northwestern University Feinberg School of Medicine, Chicago, United States, [6]OptumInsight, Saint-Laurent, Canada, [7]AbbVie, North Chicago, United States*

INTRODUCTION: Motor complications observed in patients with advanced Parkinson's disease (PD) on oral medications might be due to impaired gastric emptying and fluctuating drug plasma levels. A new treatment for PD involves the use of a percutaneous endoscopic gastrostomy with jejunal extension tube (PEG-J) to provide continuous delivery of levodopa-carbidopa intestinal gel (LCIG) directly to the jejunum.
AIMS&METHODS: An independent adjudication committee of 3 gastroenterologists reviewed GI procedure- and device-related adverse events (AEs) from long-term, integrated safety data from Phase 3 LCIG studies (total N=395). After elimination of redundant AE coding, the rate, clinical significance, and relationship to procedure/device for the AEs were determined by a comprehensive adjudication process.
RESULTS: The median exposure to PEG-J was 480 days; 180 subjects had ≥540 days, 113 of whom had ≥730 days. At end of year 1, 91.3% of subjects retained the original PEG tube and 62.9% retained the original J-tube. 4.3% of subjects discontinued treatment due to a GI procedure- or device- related AE. Nonserious AEs occurring in ≥5% of subjects: abdominal pain (31.1%), procedural pain (23.0%), postoperative wound infection (20.0%), excessive granulation tissue (18.0%), incision site erythema (15.9%), procedural site reaction (10.1%), and postprocedural discharge (10.1%). Serious AEs (SAEs) occurred in 17.0% of subjects. 41.9% of SAEs occurred during the first 4 wks of treatment.
Table 1. Major and minor SAEs occurring in ≥1% of patients

Major SAEs	Incidence[a]	Procedural Incidence[b]
Abdominal pain[c]	6(1.5%)	1.3%
Peritonitis	9 (2.3%)	1.9%
Pneumonia	7 (1.8%)	1.5%
Minor SAEs		
Abdominal pain	7 (1.8%)	1.5%
Pneumoperitoneum	7 (1.8%)	1.5%

[a]Incidence (%) = proportion of all patients who received a PEG-J (N = 395). [b]Procedural incidence (%) = proportion of all the PEG-J procedures performed (N = 468). [c]Major abdominal pain required hospitalization without other diagnosis.
CONCLUSION: PEG-J longevity exceeded committee expectations. The incidence of PEG-J AEs with the LCIG delivery system was within ranges quoted in the PEG literature. A low discontinuation rate suggests acceptable procedural outcomes and complication rates in this advanced PD patient population. Support: AbbVie

P242 BPC 157 FISTULA-HEALING EFFECT CLOSES TRACHEOTOMY WOUND IN RATS

G. Madzarac[1,*], D. Hirsl[1], T. Becejac[1], D. Stancic Rokotov[2], S. Seiwerth[3], P. Sikiric[1]. *[1]Pharmacology, [2]Surgery, [3]Pathology, Medical Faculty, University of Zagreb, Zagreb, Croatia*

INTRODUCTION: BPC 157 is an original anti-ulcer peptide (GEPPPGKPADDAGLV, M.W. 1419) stable in human gastric juice more than 24 hours, successful in trials for inflammatory bowel disease, phase II, wound treatment, no toxicity or side effects were reported, LD1 was not achieved, effective alone without carrier. BPC 157 also closes gastrocutaneous, colocutaneous and esophagocutaneous fistulas. Thereby, we investigate whether BPC 157-fistulas healing may be relevant in tracheotomy wound healing.
AIMS&METHODS: Rats were underwent to standard horizontal tracheotomy, trachea opened horizontally, no cannula was inserted and edges of the trachea were sutured on to a skin. BPC 157 (10 μg/kg, 10 ng/kg) was applied (i) in drinking water until the animals were euthanized, or (ii) once a day intraperitoneally (first application 30 min following surgery, last 24 h before euthanization, at 3rd postoperative day. With 3 mm diameters, trachea was opened on the opposite side of the tracheotomy wound and inner part of the wound was also measured.

RESULTS: BPC 157 administered parenterally or perorally accelerated healing of tracheotomy wound and showed functional, macroscopic and histological healing improvements. In average, with respect to initial size, both outer and inner part of the tracheotomy wound were improved: i.e., 10 ug/kg of BPC 157 in drinking water improved healing by 40 -100% for the outer part (skin), and by 60-100% for the inner part (trachea) of the wound. Contrary, controls showed only poor by 0-37.5% for the outer part (skin), and by 0-50% for the inner part (trachea) of the tracheotomy wound. Further, animals treated with BPC 157 showed slower weight loss than the control.
CONCLUSION: BPC 157 fistula-healing effect may close tracheotomy wound.

P243 MEDIUM TERM OUTCOME FOLLOWING 3D ROBOTIC HELLER'S CARDIOMYOTOMY (HC) WITHOUT AN ANTI-REFLUX PROCEDURE (ARP) FOR THE TREATMENT OF ACHALASIA.

H. Winter[1,*], E. Yazaki[1], P. Siriwardana[1], C. B. Tang[1], V. Jayanthi[1], M. Harvey[1], S. Kadirkamanathan[1]. *[1]Upper GI Surgery, Broomfield Hospital, Chelmsford, Chelmsford, United Kingdom*

INTRODUCTION: Robotic surgery allows precise and accurate surgery. Mucosal breaches occur in up to 12% of patients with conventional laparoscopic HC and recurrent symptoms are not uncommon (Boeckxstaens et al, 2011). Accuracy and precision is essential when performing HC to avoid incomplete myotomy and mucosal breach. The need for ARP at the time of HC remains controversial. HC with anterior or Toupet fundoplication is common practice, despite lack of evidence from published studies (Andreollo & Earlam, 1987). We present a single centre experience with performing robotic HC for achalasia.
AIMS&METHODS: Retrospective analysis of patients who underwent robotic HC for achalasia between 2009 - 2013 was performed. HC was performed using a Da Vinci robot (Intuitive Surgical Inc.) with 4 laparoscopic ports. Anterior mobilization of the oesophagus was performed leaving the posterior component of phreno-oesophageal ligament intact. A longitudinal myotomy was made extending into the proximal stomach. 3D vision facilitated accurate division of all fibres up to the mucosa. Outcomes were assessed with regards to mucosal integrity, hospital stay and symptom improvement.
RESULTS: 15 patients underwent surgery (8 male) with a median age of 45 years (range 19-67). 2 had simultaneous ARP for; small hiatus hernia (1), early in the series (1). Two cases were for recurrent dysphagia following laparoscopic HC at different centres. Median length of myotomy was 6cm (5-10). No mucosal breaches were identified at surgery, and there were no postoperative leaks. Median length of hospital stay was 1 day (1-28). One patient with multiple comorbidities developed a chest infection and had a prolonged hospital stay. Median follow up was 36 weeks (3-146). All patients had symptomatic improvement in dysphagia, resuming normal diets. None of the patients developed recurrent dysphagia or clinically significant reflux.
CONCLUSION: Robotic surgery offers superior visualization and definition of the oesophageal muscle fibers, along with improved dexterity and ergonomic comfort. This allows precise and complete division of the muscle fibers which is more difficult to achieve with conventional laparoscopy. This may explain the absence of both oesophageal perforation or recurrent dysphagia following surgery in our series. Anterior mobilization of the oesophagus alone may preserve some antireflux mechanisms which may reflect the absence of reflux symptoms following HC such that an additional ARP may not be necessary. Long-term studies are required to evaluate this further.

P244 PARA-OESOPHAGEAL HERNIA REPAIR IS ASSOCIATED WITH IMPROVEMENT QUALITY OF LIFE AND RESOLUTION OF ASSOCIATED ANAEMIA.

H. P. Siriwardana[1,*], N.V. Jayanthi[1], H. Winter[1], C.-B. Tang[1], M. H. Harvey[1], S. S. Kadirkamanathan[1]. *[1]Upper GI Surgery, Broomfield Hospital, Chelmsford, United Kingdom*

INTRODUCTION: Para-oesophageal herniae (PEH) present with varying symptoms including shortness of breath, post-prandial epigastric pain, vomiting with or without haemetemesis. Recent studies have described associated anaemia in these patients.
AIMS&METHODS: Our aim was to evaluate the prevalence of anaemia in patients with PEH and assess the effect of surgery on this alongside changes to quality of life.

All patients who underwent PEH repair between March 1997 and October 2012 were included. All anaemic patients (Haemoglobin [Hb] <13gm/dl in males, <12gm/dl in females) were investigated appropriately. Blood tests were compared pre and post operatively (Hb, Mean Corpuscular Volume [MCV], Haematocrit [Hct]). Physical and mental health components of quality of life (QoL) were also measured pre and post operatively with SF 36 questionnaire. Statistical analysis was performed with Student's t test.

RESULTS: A total of 64 patients had PEH repair (37 male). Median age was 68yrs (40–88). Over half of patients were ASA III or IV (54%) and majority had Type III or IV PEH (76%). Laparoscopic repair was performed in 42 patients. One elderly patient (88yrs) died with aspiration pneumonia. There were no other major complications. 39 (62%) were anaemic at presentation, 8 (13%) being symptomatic from this and incidentally diagnosed with PEH on endoscopy. Preoperative endoscopy revealed oesophageal or gastric ulceration/erosions in 21 patients (54%). Pre and post-operative blood tests are shown in Table 1. Treatment for anaemia consisted of oral iron supplements (33), intravenous iron infusion (1) and blood transfusion (5). In those with preoperative anaemia, detailed follow-up was available in 33 (85%) with a median of 49 months (3-114). Anaemia resolved in 26 (78%). Anaemia improved in the remaining 7 who continued on oral iron supplementation. The median follow-up in these patients did not differ from those with resolution of anaemia ($p = 0.14$). Recurrent hernia was found in 2 of these 7 patients.

There was no significant improvement in Hct. No patients required transfusion or intravenous iron infusion after PEH repair.

Repair of PEH was also demonstrated to significantly improve quality of life as assessed by SF 36 questionnaire ($p < 0.05$).

CONCLUSION: Our data suggests that PEH repair is safe and effective in high anaesthetic risk patients. Anaemia appears to be common in patients with PEH and surgical repair can be seen to improve Hb levels significantly. In addition to this, improvements in quality of life after surgical repair of PEH have been demonstrated.

P245 CLINICAL OUTCOMES OF UNDIFFERENTIATED EARLY GASTRIC CANCER WITH HISTOLOGIC DISCREPANCY AFTER ENDOSCOPIC RESECTION

K. Kang[1,*], B.-H. Min[2], J. H. Lee[2], Y. W. Min[2]. [1]*Hallym University Sacred Heart Hospital, Anyang,* [2]*Samsung Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Endoscopic resection (ER) has become an important curative option for early gastric cancer (EGC). However, the application of ER for undifferentiated EGC, including histologic discrepancy (HD), remains controversial.

AIMS&METHODS: The aim of this study was to evaluate the clinical outcomes for undifferentiated EGC with HD. From October 2002 to June 2011, 59 lesions in 59 patients were finally enrolled (42 poorly differentiated adenocarcinoma (PD) & 17 signet ring cell carcinoma (SRC)). The therapeutic efficacy of ER was assessed according to en bloc resection rate, complete resection rate, and recurrence rate during follow-up.

RESULTS: Of 59 undifferentiated EGCs, 48 cases (81.3%) showed HD (pre-ER biopsy: differentiated cancer (n=39) and atypical gland and/or high grade dysplasia (n=9)). The mean size of lesions was 2.1 cm (range 0.1 to 5.2 cm). The rates of en bloc resection and CR were 94.9% and 76.3%, respectively. The en bloc resection and CR rates in PD were 95.2% and 78.6%, and those in SRC were 94.1% and 70.6%, respectively. There were no significant differences between two histologic subtypes. Of 59 cases, 38 cases (26 mucosal lesions and 12 submucosal lesions) with HD were resected by surgical gastrectomy. In surgical specimen, no case showed lymph node metastasis. Of 15 cases not undergoing surgery, no recurrence occurred during median follow-up of 27.5 months (range 8 to 109 months).

CONCLUSION: ER might be a feasible local treatment in selective cases of undifferentiated EGC with HD

P246 ROLE OF SENTINEL NODE IN ESOPHAGECTOMY FOR ESOPHAGEAL CANCER: A SYSTEMATIC REVIEW

B. Filip[1], M. Scarpa[2,*], F. Cavallin[2], R. Alfieri[2], M. Cagol[2], C. Castoro[2]. [1]*Dept of Surgery, University of Medicine of Iasi, Iasi, Romania,* [2]*Oncological Surgery Unit, Veneto Institute of Oncology (IOV-IRCCS), Padova, Italy*

INTRODUCTION: Sentinel node (SN) biopsy might provide surgeons an extra tool to limit unnecessarily extended lymphadenectomy. In esophaeal surgery this might be applied to early cancer of the esophageal gastric junction.

AIMS&METHODS: The aim of our study was to review all the available literature data about the use of SN biopsy in esophageal surgery for malignancy.

The review was conducted according to the PRISMA guidelines. A systematic search was performed in the PubMed, EMBASE, and Cochrane database to identify all original articles on the role of SNB in esophageal cancer. Data on methodologies used, tumor stage and localisation, and results were summarized and used to address relevant clinical questions related to the application of the SNB technique in esophageal cancer.

RESULTS: Twelve studies were included with a total of 492 patients. Different methods for SN identification were used (radionuclide, blue-dye, CT lymphography). The pooled values estimated using the random effects model were, respectively: for Tc99m overall detection rate (DR) 0.970 (95% CI: 0.814- 0.996), accuracy (ACC) 0.902 (95% CI: 0.736- 0.968), sensitivity (SE) 0.860 (95% CI: 0.814- 0.895) and negative predicting value (NPV) 0.811 (95% CI: 0.745- 0.863); for blue-dye DR 0.971 (95% CI: 0.890- 0.993), ACC 0.790 (95% CI: 0.681-0.870), SE 0.811 (95% CI: 0.669- 0.901) and NPV 0.673 (95% CI: 0.476-0.824); for CT lymphoscintigraphy DR 0.970 (95% CI: 0.814- 0.996), ACC 0.902 (95% CI: 0.736- 0.968), SE 0.831 (95% CI: 0.452- 0.967) and NPV of 0.938 (95% CI: 0.742- 0.987).

CONCLUSION: Based on these results, the concept of SN in esophageal cancer is technically feasible with an acceptable detection rate and accuracy. Further studies focused on a single tumor type and localisations are needed in order to predict the correct utilisation of this concept in esophageal cancer.

P247 PREDICTING POSTOPERATIVE OUTCOME AFTER ESOPHAGECTOMY FOR CANCER: NUTRITIONAL STATUS IS THE MISSING RING IN THE CURRENT PROGNOSTIC SCORES

M. Scarpa[2,*], B. Filip[1], F. Cavallin[2], M. Cagol[2], R. Alfieri[2], E. Ancona[2], C. Castoro[2]. [1]*Dept of Surgery, University of Medicine of Iasi, Iasi, Romania,* [2]*Oncological Surgery Unit, Veneto Institute of Oncology (IOV-IRCCS), Padova, Italy*

INTRODUCTION: Several preoperative prognostic scores based either on physiology of the patient or on the operative findings were designed in order to give a good estimation of the risk of postoperative adverse events. Preoperative nutrition status received minor interest in risk analysis; none of the above mentioned scores includes a parameter linked to nutrition (albumin, percentage of weight loss or BMI). These parameters had already been included in some prognostic scores [1-4] but they had never been used for esophageal cancer.

AIMS&METHODS: The aims of the study were the validation of risk-adjusted models for early outcomes after esophagectomy and to develop a score for severe complication prediction with special consideration regarding nutritional status. A comparison of POSSUM and its derivates, ASA, Charlson score and nutritional indexes was performed on 171 patients undergoing esophagectomy for cancer. A new prognostic score was created for severe morbidity prediction using all the significant components of the mentioned scores and a model.

RESULTS: Postoperative mortality (1.8%) was best predicted by O-POSSUM score. Overall morbidity was 36.3% (62 cases), severe complications (grade III-V) occurred in 23 cases. All the scores had a low discriminatory ability for severe complication prediction (AUC<0.66). Stepwise selection identified four independent predictors of severe morbidity: pulse (OR 8.77; 95%C.I. 2.91-26.44), altered pulmonary status (OR 3.44; 95%C.I. 1.19-9.95), albumin (OR 0.89; 95%C.I. 0.80-0.98) and neoadjuvant therapy (OR 7.43; 95%C.I. 0.84-65.88). The score based on those variables was internally validated using standard bootstrapping techniques and showed a good discrimination (AUC=0.81) and calibration (goodness-of-fit test: p=0.44).

CONCLUSION: Nutrition is an independent risk factor for major complications and an improvement of the current prognostic scores used in oncologic surgery can be made through the introduction in the formulas for the calculation of different physiological scores of a nutritional status coefficient.

P248 PET-CT AFTER NEOADJUVANT CHEMORADIOTHERAPY CAN PREVENT NON-CURATIVE SURGICAL INTERVENTIONS FOR ESOPHAGEAL CANCER PATIENTS

M. Anderegg[1,*], S. Gisbertz[1], R. Bennink[2], J. Bergman[3], M. van Berge Henegouwen[1]. [1]*Surgery,* [2]*Nuclear Medicine,* [3]*Gastroenterology & Hepatology, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Esophageal cancer is notorious for its rapid dissemination. Accurate staging at the time of diagnosis is essential to identify patients eligible for curative treatment. For the majority of these patients the preferred strategy consists of neoadjuvant chemoradiotherapy (nCRT) followed by esophagectomy. Given the aggressive nature of esophageal tumours, it is conceivable that in a significant portion of patients treated with nCRT, dissemination becomes manifest during this preoperative course. Since metastatic disease is a contraindication for esophagectomy, we added a post-neoadjuvant therapy PET-CT to the standard work-up of patients with potentially resectable esophageal carcinoma.

AIMS&METHODS: The aim of this study was to determine the value and diagnostic accuracy of PET-CT after nCRT in identifying patients with metastases preoperatively.

From January 2011 until February 2013 all esophageal cancer patients deemed eligible for a curative approach with nCRT and surgical resection underwent a PET-CT after completion of nCRT (median interval 18 days). Initial staging consisted of endoscopy with biopsy, EUS, external ultrasonography of the

neck and a thoracoabdominal CT scan. A PET scan was not part of the initial staging. Neoadjuvant therapy consisted of 5 cycles of carboplatin/paclitaxel and concurrent radiotherapy (41.4 Gy). If abnormalities on PET-CT were suspect of metastases, histologic proof was acquired. We designed a clinical decision model to assess the cost-effectiveness of this diagnostic strategy.
RESULTS: During the study period 173 patients underwent a PET-CT after nCRT. In 37 patients (21.4%) PET-CT showed abnormalities suspicious for dissemination requiring additional imaging and/or biopsy, resulting in 20 cases of proven metastasis (11.6%) and a risk of false-positive results of 9.8%. Of the patients without proven metastases 147 patients have been operated at this time. In 7 of these 147 cases distant metastases were detected intraoperatively, leading to a risk of false-negative results of 4.8%. The introduction of a post-neoadjuvant therapy PET-CT has led to a reduction of overall health care costs per patient in comparison with the scenario in which no restaging occurs (€26880 vs. €28970).
CONCLUSION: In 11.6 percent of esophageal cancer patients distant metastases are seen on PET-CT after neoadjuvant chemoradiotherapy. To avoid non-curative resections we advocate post-neoadjuvant therapy PET-CT as a cost-effective part of the standard work-up of candidates for surgery.

P249 SENTINEL NODE NAVIGATION SURGERY FOR GASTRIC CANCER BY USE OF INDOCYANINE GREEN

M. Hirata[1,*]. [1]*Gastrointestinal Surgery, Japan Railway Tokyo General Hospital, Tokyo, Japan*

INTRODUCTION: The sentinel node (SN) is the first lymph node to receive drainage from the primary tumor. In order to detect the sentinel node, there are various kinds of tracers (radiolabeled particles and vital dyes). The prediction of node status in breast cancer or malignant melanoma has been reported to exceed 95 %. However, it is not clear whether sentinel node navigation surgery is applicable to gastric cancer surgery or not. We investigated the feasibility of sentinel node staining and its accuracy in predicting the lymph node status in patients with gastric cancer.
AIMS&METHODS: 45 gastric cancer cases who underwent curative surgery from April 2001 to December 2011 at Japan Railway Tokyo General Hospital (Male 33 cases, Female 12 cases, 62.3 ± 10.0 years (45-80) IA 38 cases, IB 5 cases, II 2 cases). In all patients, the absence of cancer invasion to the serosal layer of the stomach was macroscopically confirmed. [Method] After laparotomy, a fine needle (26-gauge) was inserted into the subserosal layer around the primary tumor and ICG was injected. Total amount of injected ICG was 25 mg (5 ml) for each patient. SN were defined as lymph nodes those were stained green within 5 minutes after ICG injection and were removed before therapeutic surgery with extended lymph node dissection (D2 procedure according to the Japanese classification of gastric carcinoma). Stained nodes (SN), unstained nodes (non-SN), and resected stomach were fixed in 20 % formalin and embedded in paraffin, and 5-micrometer sections were cut to be stained with hematoxylin and eosin for histologic examination. We compared the location and numbers of SN and histological diagnosis of SN and non-SN. We calculated patient survival by Kaplan Meier mehod and compared between sentinel node navigation surgery and standard surgery.
RESULTS: The rate of staining of SN was 97.5 % (44/45). The number of SN was 3.6 ± 2.4 (1-8), and that of non-SN was 19.2 ± 8.5 (13-37). The number of cases with LN metastasis was 20.5 % (9/45). Five year patient survival in Stage IA group was 95.5 %, which revealed no significant difference to 96.7 % among Stage IA gastric cancer patients who underwent standard surgery in the same time.
CONCLUSION: In 44 cases (97.8 %) out of 45 patients, SN could be found by use of ICG staining method. In 9 cases, LN metastasis were histopathologically diagnosed. In all the 9 cases, we found metastasis also in SN. SN status can predict the lymph node status accurately in patients with T1 and T2 gastric cancer. When you find no metastases in SN in T1 or T2 gastric cancer patients, you can perform partial resection of stomach with more limited lymph node dissection. Sentinel node navigation surgery was comparable to standard surgery for relatively early stage gastric cancer patients.

P250 NEW CONCEPT OF MINIMALLY-INVASIVE GASTRECTOMY FOR EARLY GASTRIC CANCER: FEASIBILITY OF NON-EXPOSED ENDOSCOPIC WALL-INVERSION SURGERY (NEWS) WITH SENTINEL NODE NAVIGATION SURGERY (SNNS) IN A PORCINE SURVIVAL MODEL

O. Goto[1,*], H. Takeuchi[2], S. Matsuda[2], H. Kawakubo[2], M. Sasaki[1], A. Fujimoto[1], J. Horii[1], T. Uraoka[1], Y. Kitagawa[2], N. Yahagi[1]. [1]*Division of Research and Development for Minimally Invasive Treatment, Cancer Center,* [2]*Surgery, Keio University, School of Medicine, Tokyo, Japan*

INTRODUCTION: Non-exposed endoscopic wall-inversion surgery (NEWS) has been invented as endoscopic full-thickness resection without transluminal communication to avoid contamination or tumor seeding into the peritoneum[1)].
AIMS&METHODS: In this porcine survival study, we aimed to investigate feasibility and safety of NEWS with sentinel node navigation surgery (SNNS)[2)], which could minimize the area of lymph node dissection for early gastric cancer (EGC), as a new surgical concept of minimally-invasive gastrectomy. The study protocol was approved by the institutional ethical review board of the laboratory in advance. NEWS with SNNS was performed in three live female pigs weighing 25-35kg. After marking around a simulating lesion on both the mucosal and serosal surfaces, 0.5ml of indocyanine green (ICG) fluid (5mg/ml) was endoscopically injected into the submucosa at four points around the lesion. Subsequently, sentinel nodes basin stained with ICG were identified and dissected laparoscopically, followed by circumferential seromuscular incision and suturing around the lesion. Finally, circumferential mucosubmucosal incision was made endoscopically followed by endoscopic handsuturing of the mucosal edges. The pigs resumed feeding from the day after the operation. Antibiotic with cefazolin sodium hydrate, 0.5g once daily, was administered intramuscularly on the day of operation and perorally on the following three days. They were monitored daily over a period of seven days and sacrificed for necropsy.
RESULTS: Each lesion was created on the anterior wall, the posterior wall and the greater curvature of the gastric body in the three pigs respectively. The procedure was successfully completed without complications and survived without adverse events during the observatory period in all cases. The median of the specimen size and the procedure duration was 35 (range, 25-50) mm and 203 (range, 189-253) min, respectively. Necropsy revealed mild adhesion of the suture site to surrounding organs, but no anastomotic leak or peritonitis.
CONCLUSION: This study demonstrated that NEWS with SNNS was feasible in a live animal model. It can provide patients with early gastric cancer out of the indication for endoscopic resection a minimally-sized gastrectomy and minimally-ranged lymph node dissection without the risk of contamination or tumor dissemination.

P251 LONG-TERM POSTOPERATIVE EVALUATION OF JEJUNAL POUCH INTERPOSITION RECONSTRACTION AFTER TOTAL GASTRECTOMY IN TERMS OF FUNCTIONAL PRESERVATION AND QUALITY OF LIFE

R. Matsuura[1,*], T. Yumiba[1], Y. Akamaru[1], M. Fujii[1], Y. Morimoto[1], K. Yasumasa[1], E. Kono[1], H. Kasashima[1], K. Kawai[1], Y. Okubo[1], Y. Taniguchi[1], T. Aoki[1], K. Iwamoto[1], Y. Yamasaki[2]. [1]*Surgery,* [2]*Osaka Kosei-Nenkin Hospital, Osaka, Japan*

INTRODUCTION: Jejunal pouch interposition (JPI) reconstruction has been chosen for preserving the function of the stomach after total gastrectomy, but the long-term results have not yet been determined.
AIMS&METHODS: The aim of this study is to evaluate the functional preservation and QOL of Jejunal pouch interposition reconstruction in patients after total gastrectomy for the long term. We studied 94 patients with gastric cancer who underwent total gastrectomy. Thirty eight patients were reconstructed with JPI (Group J) and 56 patients with Roux Y (Group R). Dietary intake (compared to preoperative condition), body weight (compared to preoperative condition), gastroesophageal reflux, and dumping syndrome were evaluated by means of a QOL questionnaire. Dietary intake and body weight after 1 year of surgery were compared between the two groups. The nutrition status and the QOL questionnaire were assessed annually for 22 patients of Group J who were investigated more than 3 years (until 10 years) after surgery.
RESULTS: % dietary intake in Group J (83.4±13.0%) (mean±SD) was significantly higher than that in Group R (69.8±18.1%) ($p<0.05$). The ratio of the patients under 80 % body weight compared to preoperative condition is significantly lower in Group J (13.1%) than in Group R (32.1%). In 22 patients of Group J with more than 3 years observation, dietary intake, body weight, total protein, albumin and total cholesterol was significantly decreased one year after surgery, but there were no more significant decreases in these levels later. There was no chronological difference in lymphocyte count over the observation period. There was no deterioration in gastroesophageal reflux or dumping syndrome for the observational period either.
CONCLUSION: JPI is more beneficial to maintain dietary intake and body weight than Roux Y reconstruction after total gastrectomy. Dietary intake, body weight and nutrition status were significantly decreased for the first year after surgery, but after one year has lapsed, the levels remain constant in the JPI group.

P252 VISCERAL ADIPOSE TISSUE CD4+CD25+FOXP3+ REGULATORY T CELLS - A NOVEL TISSUE-SPECIFIC PREDICTOR FOR EARLY WEIGHT LOSS FOLLOWING SLEEVE GASTRECTOMY

T. Adar[1,*], R. M. Spira[1], S. Shteingart[1], S. Abu-Khalaf[1], A. Bar-Gil Shitrit[1], M. Mahamid[1], B. Koslowsky[1], B. Melamud[1], E. Goldin[1]. [1]*Digestive Diseases Institute, Shaare Zedek Medical Center, Jerusalem, Israel*

INTRODUCTION: Adipose tissue has been recognized as an inflammatory active organ, which plays an important role in local and systemic inflammation.

Regulatory T cells (Tregs) have been identified as major regulatory components in adipose tissue inflammation. Metabolic changes after sleeve gastrectomy (SG), such as improvement in insulin resistance, may appear early after surgery, prior to significant weight loss. A favorable inflammatory cells' milieu within the adipose tissue may predict clinical outcomes following SG.
AIMS&METHODS: AIM - To evaluate the correlation between Tregs within the visceral adipose tissue and weight loss in obese patients undergoing SG
METHODS - Peripheral blood samples and intra-operative visceral adipose tissue biopsies were collected form consenting female patients undergoing elective SG (n=9). Weight loss was measured as excess weight loss (%EWL). Lymphocytes were isolated from each sample, counted and stained for flow cytometry analysis (FACS). CD4+CD25+FOXP3+ markers were used for Tregs identification. FACS analysis results were then correlated with %EWL at post-operative follow up.
RESULTS: The mean study group's age, weight and BMI were 34.7 years, 111.22 kg and 42.99 respectively. All patients underwent SG without complications. Follow up evaluation was performed 3 times: after 9.4, 76 and 164.1 days (n=5, 4 and 8 respectively), with %EWL of 10.5, 31.8 and 49.7 respectively. The percent of Tregs within the peripheral blood and visceral adipose tissue was 4.34% and 4.23% respectively. A strong correlation was demonstrated between the visceral adipose tissue Tregs and %EWL at the second follow up ($r = 0.9$). However, this correlation was not demonstrated in the third follow-up.
CONCLUSION: Baseline levels of Tregs in the intrinsic visceral adipose tissue, may predict early weight loss following SG. This correlation, emphasizes the value of the local inflammatory milieu within the adipose tissue in predicting early clinical outcomes following SG, and may indicate their potential as future therapeutic targets.

P253 TNM STAGING IN ESOPHAGEAL SQUAMOUS CELL CARCINOMA AFTER ESOPHAGECTOMY WITH EXTENSIVE LYMPHADENECTOMY : PROGNOSTIC VALUE OF STAGE AND PROGNOSTIC GROUPING

T. Tanaka[1,*], S. Matono[1], N. Mori[1], K. Nishimura[1], K. Shirouzu[1], H. Fujita[1]. [1]*Surgery, Kurume University, Kurume, Japan*

INTRODUCTION: The 7th edition of the TNM Classification (TNM7) uses tumor location and histologic grading with conventional T, N (number of the positive nodes), and M category for stage or prognostic grouping of esophageal squamous cell carcinoma (ESCC). However, the prognostic value of TNM7 in esophageal cancer after esophagectomy with extensive lymphadenectomy remains unclear.
AIMS&METHODS: The aim of this study was to evaluate the prognostic value of TNM7 in patients with ESCC who underwent transthoracic esophagectomy with 2- or 3-field lymphadenectomy. A total of 268 patients with pT3 ESCC underwent esophagectomy with extensive lymphadenectomy, between 1988 and 2010, and are included in this study. The survival rates at each stage or prognostic group of pT3 ESCC patients were evaluated using the log-rank method. Three-field dissection was performed for patients with a cancer in the upper or middle esophagus who were aged 70 years or younger. The median follow-up was 98 months.
RESULTS: 249 patients (93%) received R0 resection, and 152 patients (57%) had 3-field dissection. The median number of resected lymph nodes was 61 (range, 17-150). The numbers of patients at Stage IIA/IIIA/IIIB/IIIC/IV were 65/68/67/35/33, and those in Group IB/IIA/IIB/IIIA/IIIB/IIIC/IV were 18/33/14/68/67/35/33. The overall 5-year survival rate for all patients was 45.5%. The 5-year survival rate for Stage IIA, IIIA, IIIB, IIIC and IV was 71.6%, 51.4%, 42.8%, 20% and 15.2% (IIA vs IIIA, $P = 0.0265$; IIIA vs IIIB, $P = 0.1388$; IIIB vs IIIC, $P = 0.0183$; IIIC vs IV, $P = 0.3056$). The 5-year survival for Group IB, IIA and IIB was 77.8%, 65.1% and 78.6% (IB vs IIA, $P = 0.5807$; IIA vs IIB, $P = 0.8353$). The survival rate was not affected by either histologic grade or tumor location in the T3N0 ESCC patients.
CONCLUSION: Overall, introduction of a third tier for nodal involvement in TNM7 has good performance in survival stratification for T3 ESCC patients after transthoracic esophagectomy with extensive lymphadenectomy. Findings suggested that histologic grade and tumor location in prognostic grouping had no significant influence on survival in T3N0 ESCC patients with extensive lymphadenectomy.

P254 CHOICE OF RADICAL GASTRECTOMY MODALITY IN MIDDLE ONE-THIRD GASTRIC CANCER

W. Hui[1,*], H. Yu-long[1]. [1]*Surgical Department of Gastroenterology, the First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

INTRODUCTION: In cases with resectable gastric cancer, distal or total gastrectomy is recommended. However, there remains controversy for choice of gastectomy modality in middle one-third gastric cancer. This study analyzed the differences between total gastrectomy (TG) and distal gastrectomy (DG).
AIMS&METHODS: To evaluate the rationality of radical distal and total gastrectomy in middle one-third gastric cancer. A total of 293 cases with middle one-third gastric cancer undergoing radical dissection in Gastrointestinal Department of Sun Yat-sen University from Aug. 1994 to Jan. 2008 were divided into distal gastrectomy(DG, n=94) and total gastrectomy group(RTG, n=199). The clinicopathological features, information of surgical procedure, operation complications, postoperative quality of life and prognosis were compared between 2 groups.
RESULTS: No significant difference had been found in gender, age, tumor histological type, and serum CEA level between 2 groups(all $P > 0.05$). Tumor size, infiltration depth, ratio of lymph node(LN) metastasis, distal metastasis, TNM stage IV and Borrmann infiltration type was significant higher in TG than that in DG (all $P < 0.05$). No significant difference existed in number of LN dissected, surgical complications between 2 groups(all $P > 0.05$). Postoperative hospital day, operation duration, volume of blood transfusion, ratio of combined organ dissection increased significantly in TG than in DG (all $P < 0.05$). Ratio of postoperative normal diet in DG(88.7%) was significantly higher than that in TG (68.8%)($P < 0.05$). Logistic regression analysis showed that tumor size, Borrmann type, and adjacent organ invasion were the major influencing factors of gastectomy modality. Multivaritate analysis showed that LN metastasis, distal metastasis, Borrmann type, and tumor size were independent prognostic factors for all cases. Prognosis of RDG group was significantly better than that of RTG group($P < 0.05$). Stratified analysis(stratified by tumor size, organ invasion, LN metastasis, distal metastasis, Borrmann type) showed that prognosis in TG was not better than that in DG.
CONCLUSION: For cases with resectable middle one-third gastric cancer, radical distal gastrectomy should be considered as first-line choice. Compared with radical distal gastrectomy, radical total gastrectomy had more serious surgical trauma, and no beneficial to the postoperative quality of life and prognosis.

P255 EVALUATION OF CURRENT T STAGE OF TRANSVERSE MESOCOLON INVASION IN ADVANCED GASTRIC CANCER

W. Hui[1,*], H. Yao[2], H. Yu-long[1]. [1]*Surgical Department of Gastroenterology,* [2]*Department of Gastroenterology, the First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

INTRODUCTION: There remains controversy for T classification of transverse mesocolon invasion in advanced gastric cancer(AGC). This study was performed to evaluate the appropriate T stage for transverse mesocolon invasion in AGC.
AIMS&METHODS: To evaluate T stage of transverse mesocolon invasion in advanced gastric cancer. According to status of transverse mesocolon invasion, 808 cases of gastric cancer with T4a+b stage undergoing surgical treatment(form Jan. 1996 to Jan. 2008, cases were screened form data base of Gastric Cancer Center of Sun Yat-sen University) were divided into group of Non-organic invasion(T4a stage, NOI, n=638), Non-transverse mesolon invaded (T4b stage, NTMI, n=126), TMI (Transverse mesocolon invaded, n=44). The clinicopathological features, surgical procedure and prognosis were compared in three groups.
RESULTS: No significant difference were found in gender, age, lymph nodes metastasis, heptic metastasis, tumor's Borrmann type, histological type, differentiation degree, value of serum CEA among 3 groups(all $P > 0.05$). In group of NOI, NTMI and TMI, significant difference had been found in tumor size, distal metastasis, peritoneal metastasis, TNM IV stage, ratio of radical resection ($P < 0.01$), and pairwise comparisons showed these parameters with significant difference between NOI and TMI group($P < 0.05$), but without significant difference between NTMI and TMI group($P > 0.05$). Significant difference existed in median survival time in 3groups ($P < 0.05$), and pairwise comparisons showed the prognosis with significant difference between NOI and TMI group($P < 0.05$), but without significant difference between NTMI and TMI group($P > 0.05$). In cases received radical resection, the median survival time in 3 groups had significant difference($P < 0.05$), and pairwise comparisons showed the prognosis with

significant difference between NOI and TMI group($P<0.05$), but without significant difference between NTMI and TMI group($P>0.05$).

CONCLUSION: The major clinicopathological features, surgical procedure and prognosis of gastric cancer with transverse mesocolon invasion was similar to that of T4b gastric cancer, but was significant different from that of T4a gastric cancer. Gastric cancer with transverse mesocolon invasion should be regarded as T4b stage.

P256 ASSISTANT-BASED STANDARDIZATION OF PRONE POSITION THORACOSCOPIC ESOPHAGECTOMY

Y. Shirakawa[1,*], K. Noma[1], N. Maeda[1], R. Katsube[1], S. Tanabe[1], T. Ohara[1], K. Sakurama[1], T. Fujiwara[1]. [1]*Department of Gastroenterological Surgery, Okayama University,Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*

INTRODUCTION: In recent years, the popularity of thoracoscopic esophagectomy in the prone position is increasing because of the excellent exposure of the surgical field and ergonomic advantages for the surgeon. Solo-surgery is also possible in most cases requiring resection of the esophagus and surrounding lymph nodes. However, no consistent approach that can be used for all cases of extensive lymphadenectomy (as conducted in Japan) has been described. In April 2012, we developed the standardization of assistant-based procedure for exposure of the surgical field during thoracoscopic esophagectomy in the prone position. The purpose of the present study is to introduce and evaluate this technique.

AIMS&METHODS: We performed thoracoscopic esophagectomy in the prone position on 65 patients (62 males, 3 females) at our facility from June 2011 to September 2012. The preoperative diagnosis was squamous cell carcinoma in 61 patients, adenocarcinoma in 2, and mixed squamous cell carcinoma combined with neuroendocrine tumor in 2. Preoperative adjuvant chemotherapy was administered to 45 patients. Three patients underwent salvage surgery following radical chemoradiotherapy. Patients were divided into two groups: a pre-standardization group ($n = 35$) that was operated before April 2012 and a post-standardization group ($n = 37$) that was operated after April, 2012. We examined the thoracoscopic operative time and the clinical outcomes of these two groups.

RESULTS: The thoracoscopic operative time was significantly lesser ($P = 0.0037$) in the post-standardization group (after April 2012; $n = 28$; 266.8 ± 31.3 min) than in the pre-standardization group (before April 2012; $n = 37$; 301.0 ± 52.5 min). The learning curve analysis using the moving average method showed the stabilization after the standardization. No significant differences were found in the number of mediastinal lymph nodes dissected, blood loss during thoracic surgery. There were no significant differences in the overall complication rate and incidence rate of pneumonia or recurrent nerve palsy between the 2 groups.

CONCLUSION: Thoracoscopic esophagectomy in the prone position decreased the operative time even in patients requiring extensive lymphadenectomy by an excellent and safe surgical field maintained by assistant-based surgery and standardization of procedure.

P257 PROCEDURE TIME ONLY AFFECTS THE ULCER HEALING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

Y. Horikawa[1,*], H. Mizutamari[1], N. Mimori[1], Y. Kato[1], S. Okubo[1]. [1]*Gastroenterology, HIRAKA GENERAL HOSPITAL, Yokote city, Japan*

INTRODUCTION: In recent years, the technique of gastric endoscopic submucosal dissection (ESD) has markedly improved. However, major complications, especially delayed bleeding, occur in approximately 5% of all patients who undergo gastric ESD. For prevention of delayed bleeding, it is necessary to accelerate healing of the artificial ulcer. Several reports showed the accelerated effect of acid-suppressive drugs or mucosal-protective agents and the delayed effect of ulcerative or scarring lesion. However, the effects of these factors on artificial ulcers that occur after ESD remain unclear. Therefore, we investigated the diminution rates of the ulcers 4 weeks after ESD to clarify the factors regulating artificial ulcer healing.

AIMS&METHODS: Between January 2009 and February 2013, 282 early gastric neoplasms in 315 consecutive patients who underwent gastric ESD, performed by a single physician, were enrolled in this study. All patients were divided into 2 groups: A) $<90\%$ diminution group and B) $\geq 90\%$ diminution group, and retrospectively investigated by univariate and multivariate analysis in terms of location/size/depth of tumor, daily use of gastric mucosal injury drugs, procedural time, sufficient post-ESD coagulation, drugs administered (PPI or PPI+mucosal-protective agents), and *Helicobactor pylori* status.

RESULTS: The average ($\pm$SD) procedure time was 74.60 ± 53.45 min; the rate of en bloc resection was 99.29%; and the rate of complete resection was 93.26%. Perforation complications were 0%, while the rate of delayed bleeding was 2.86%. The diminution rate after 4 weeks was $95.43 \pm 8.12\%$. In the $<90\%$ diminution group and $\geq 90\%$ diminution group, it was 12% and 88%, respectively. Only longer procedural time ($P = 0.042$; OR, 0.45; 95% CI, 0.20–0.97) was independent factors, indicating a diminution rate of $\geq 90\%$.

CONCLUSION: Our results showed that gastric ulcer healing after ESD was regulated by only procedural time, not others. Procedural time under technical stability means difficulty of vascular treatment and/or dissection itself. Therefore, it indicates that electrical injury of ulcer bed during the ESD procedure only affects ulcer healing.

P258 STOOL CALPROTECTIN LEVELS IN PRETERM INFANTS WITH AND WITHOUT NECROTISING ENTEROCOLITIS

L. Beattie[1,1,*], D. J. Morrison[2], C. A. Edwards[2], A. R. Barclay[2], J. H. Simpson[1], K. Gerasimidis[2]. [1]*Neonatal Unit, Royal Hospital for Sick Children, Glasgow,* [2]*Department of Human Nutrition, University of Glasgow, Glasgow, United Kingdom*

INTRODUCTION: Necrotising enterocolitis (NEC) remains the most devastating disease of the gut of preterm infants. Early signs can be non-specific and present diagnostic challenges. Faecal calprotectin (FC) is an established marker of intestinal inflammation, but its role in the management of NEC is uncertain. We assessed this as a diagnostic tool for preterm infants with NEC.

AIMS&METHODS: We recruited infants <32 weeks gestation and <1.5Kg birth weight within week 1 of life from 3 Neonatal Units. NEC was confirmed by an external observer and radiologist, with staging according to Bell's Criteria. Weekly FC measurements were performed by ELISA (PhiCal, Norway).

RESULTS: N=56 (61% female). 32 were diagnosed with NEC (56%). 20 had $\geq$Bells' 2a. 8 required surgical intervention.

There were no significant differences in FC levels between each week in infants with or without NEC, although the former illustrated a trend to lower levels by week 4 (p=0.096). Many NEC infants developed concurrent ileus with lower stool production. There were no significant differences in NEC before and after clinical signs were apparent (p=0.1179), or in those before NEC and after stoma formation for stage 3b NEC (p=0.3026). However, significantly lower FC levels were noted in stage 3b NEC requiring ileostomy post-operative compared to the immediate sample before (p=0.0327).

Table 2: FC Values (μg/g)

Parameter	NEC (20) [n with samples]	Non-NEC (24) [n with samples]	P value
Week 1 (med, r)	285.6, 113 – 699 [10]	291.2, 49 – 2011 [22]	NS
Week 2 (med, r)	275.1, 81.7 – 2003 [13]	207.1, 89 – 2249 [24]	NS
Week 3 (med, r)	274.2, <5 - 968.3 [15]	273.1, 74 – 2414 [23]	NS
Week 4 (med, r)	220.5, 5 - 587.4 [13]	378.1, <5 – 2413 [22]	NS

CONCLUSION: FC levels were high in those with and without NEC, and the only significant change noted was lower levels after ileostomy formation. A limitation was the onset of severe NEC resulting in prolonged paralytic ileus with low stool production.

P259 ENDOSCOPIC SUBMUCOSAL INJECTION OF ADIPOSE-DERIVED STEM CELLS AMELIORATES TNBS-INDUCED COLITIS IN RATS

E. Martin Arranz[1,2,*], M. D. Martin Arranz[1], T. Robredo[3], P. Macheño[4], R. Menta[4], J. Diez[3], E. Lombardo[4], F. de Miguel Pedrero[3]. *[1]Gastroenterology, Hospital Universitario La Paz, Madrid, [2]Gastroenterology, Hospital Universitario Rey Juan Carlos, Mostoles, [3]Instituto Investigacion, Hospital Universitario La Paz, Madrid, [4]Tigenix SAU, Tres Cantos, Spain*

INTRODUCTION: TNBS-colitis is a well studied model resembling inflammatory bowel disease. Adipose-derived mesenchymal stem cells (ASC), due to their immunomodulatory properties have a potential role in IBD therapy.
AIMS&METHODS: Aim: To evaluate the feasibility, safety and efficacy of endoscopic administration of expanded human ASC (h-eASC) in a TNBS-induced colitis model in rats.
On day 0, colitis was induced in SD-OFA male rats (375-400 g) by rectal instillations of 0.5 ml of Trinitrobenzensulfonic acid (TNBS) 30 mg/ml in 50% ethanol. On day 1 a colonoscopy was performed with a 5.9 mm endoscope (GIF-XP160, Olympus Optical Co). Rats were randomly assigned to treatment group (ASC: 10^7 cells, endoscopically injected divided in 4 spots in the submucosa using a 22 G endoscopic needle) or placebo (phosphate buffered saline, PBS). h-eASC were provided by Tigenix SAU (Tres Cantos, Spain), isolated and cultured from healthy donors and characterized as usual. Superficial markers were: HLA-II, CD40, CD80, CD86, CD34, CD14, CD18, CD45 negative; HLA-I, D90, CD105 positive. On day 11 another colonoscopy was performed and rats sacrificed.
The following variables were analysed: a)Daily weight (% from day 0); b)Endoscopic score (day 1-11) including inflammation degree (0-6), length (0-10), ulcer appearance (0-5), stenosis (0-2), colon thickening (0-3) and bleeding (0-1); c)Colon length; d)Macroscopic appearance in necropsy scored 0-3 for each: colon vascularisation, wall thickening and adherences.
RESULTS: Colitis was induced in 46 rats: 25 e-hASC group/21 PBS group. 26 rats were used as healthy controls.
Injection was successful in all rats, with visible submucosal bleb formation. No significant adverse events nor mortality due to the procedure occurred.
Weight recovery was significantly better in ASC group on day 9 (-8.45% vs -3.66%, p 0.034), 10 (-8.42% vs -1.94%, p0.013) and 11 (-6.72% vs -0.84%, p0.037).
Colon length significantly recovered (ASC 222 mm vs PBS 193 mm vs healthy controls 235 mm) ASC vs PBS p0.000.
Endoscopic score change between day 1 and 11 improved in ASC group -6.65 points vs -3.53 in PBS group p0.011.
Correlation between endoscopic score and weight loss was excellent r0.75 on day 1 p0.000 and r0.77 on day 11 p0.000.
Stenosis more frequently developed in PBS group (41.2% vs 4.8%) p0.01
Macroscopic necropsy score showed a trend towards less inflammation although it didn't achieve statistic signification. There were no differences in mortality.
CONCLUSION: h-ASC submucosal endoscopic injection is feasible, safe and ameliorates TNBS-induced colitis.

P260 IDENTIFICATION OF CD68+ NEUTROPHIL GRANULOCYTES IN IN VITRO MODEL OF ACUTE INFLAMMATION AND INFLAMMATORY BOWEL DISEASE

A. Amanzada[1], I. Malik[1], G. Ramadori[1], F. Moriconi[1,*]. *[1]Gastroenterology and Endocrinology, University Hospital Göttingen, Germany, Göttingen, Germany*

INTRODUCTION: CD-68 is widely regarded as a selective marker for human monocytes and macrophages and is commonly used in human pathology studies. The purpose of this study was to investigate the expression of CD-68 in human peripheral blood mononuclear cells (PBMCs), neutrophil granulocytes (NGs) and in inflamed intestinal tissue samples for comparison
AIMS&METHODS: PBMCs and NGs were isolated from heparinized human blood samples. Intestinal biopsies were obtained during routine endoscopic procedures from patients with inflammatory bowel disease (IBD), e.g. ulcerative colitis and Crohn's disease. Gene and protein expression was analyzed by real-time RT-PCR, Western blot and immunohistochemistry.
RESULTS: Both PBMCs and NGs preparations contained cells that were positive for CD-68 and either neutrophil elastase (NE), or myeloperoxidase (MPO). $CD\text{-}68^+/NE^-/MPO^-$ cells were regarded as monocytes. CD-68 mRNA expression was detected in PBMCs and NGs preparations. With Western blot and by performing immunoprecipitation of cell lysate, we could clearly detect CD-68 in NGs, U-937, THP-1, Hep-G2, Jurkat cells and PBMCs. Identification of inflammatory cells in acutely inflamed colonic mucosa obtained from patients with IBD revealed a strong accumulation of $CD\text{-}68^+/MPO^+$ cells compared to normal colonic mucosa. The uptake of the marker by phagocytosis was excluded by performing a double staining with CD-163/NE and CD-163/MPO in PBMCs, NGs cultures and in inflamed colonic mucosa.
CONCLUSION: These results identify $CD\text{-}68^+$ neutrophil granulocytes in peripheral blood and inflamed colonic mucosa from patients with inflammatory bowel disease. CD-68 is not only a marker for the macrophages-monocytes but also for NGs. The presence of $CD\text{-}68^+$ neutrophils could be an index of the disease inflammatory activity in patients with inflammatory bowel disease.

P261 BENEFICIAL THERAPEUTIC EFFECTS OF INTRAVENOUSLY ADMINISTERED FREE-CIRCULATING DNA OF COLITIC ORIGIN IN DSS-COLITIC MICE

F. Sipos[1,*], G. Műzes[1], I. Füri[1], B. Wichmann[1], S. Spisák[1], T. M. Germann[1], M. Constantinovits[1], K. Barták[1], G. Valcz[1], T. Krenács[2], Z. Tulassay[1], B. Molnár[1]. *[1]2nd Department of Internal Medicine, [2]1st Department of Pathology and Experimental Oncology, Semmelweis University, Budapest, Hungary*

INTRODUCTION: Inflammatory bowel diseases (IBD) are characterized by aberrant innate and adaptive immune responses to commensal bacteria. The presence of free-circulating DNA (fcDNA) sequences in the serum is an established phenomenon in IBD. A close correlation between the quantity of fcDNA and the course or prognosis of several pathologic conditions has already been described. Diagnostic, prognostic, and therapy monitoring roles of fcDNA in regards to chronic colonic disorders have also been examined, however, its biological function still remains unclear.
AIMS&METHODS: The immunobiological effects of isolated, intravenously administered fcDNA of normal and colitic origin were assayed in both a murine model of DSS-colitis and in control mice. After disease- and histological activity evaluations, the changes in Toll-like receptor 9 signaling and the pro- and anti-inflammatory cytokine profile were assayed in isolated immune cells of the lamina propria by real-time quantitative PCR array cards.
RESULTS: Intravenously administered colitis-derived fcDNA has a more prominent beneficial effect on the clinical and histological severity of DSS-induced colitis in mice than fcDNA of normal origin. The systemic administration of colitis-derived fcDNA alters both TLR9-related signaling (i.e. Tollip, IRAK, TRAF6, IkB) and the pro-inflammatory cytokine profile (IFN-A, -B) in a favorable manner, while it has no significant effect on anti-inflammatory interleukin 10 expression.
CONCLUSION: Our study unveiled a novel function of intravenously administered fcDNA in a murine model of DSS-colitis. Induction of colitis itself may result in producing fcDNA with a potential to down-regulate inflammation, hence intravenous administration of fcDNA appears to be a promising novel approach in the treatment strategies of colitis.

P262 MODULATION OF VIPERGIC PHENOTYPE OF ENTERIC NEURONS BY COLONIC BIOPSY SUPERNATANTS FROM PATIENTS WITH INFLAMMATORY BOWEL DISEASES: INVOLVEMENT OF IL-6 IN CROHN'S DISEASE

F. Soufflet[1,*], M. Biraud[1], B. Lardeux[1], M. Derkinderen[1], S. Bruley des Varannes[1], M. Neunlist[1], A. Bourreille[1]. *[1]IMAD - Gastroenterology - Inserm U913, UNIVERSITY HOSPITAL, Nantes, France*

INTRODUCTION: Neuroplastic changes in the enteric nervous system (ENS) observed during inflammatory bowel diseases (IBD) might participate in physiopathological process. The involvement of mucosal microenvironment in these changes remains unknown
AIMS&METHODS: Colonic biopsies and their supernatants (SUP) (obtained following 25 min incubation of biopsies in Krebs solution) were collected in inflamed (I) and non-inflamed (NI) area of patients with Crohn's diseases (CD; n=12), Ulcerative Colitis (UC; n=6) and in healthy controls (HC; n=12). ENS primary cultures were incubated with SUP or cytokines and VIP concentration in ENS was measured by ELISA and RT-qPCR. VIP and cytokines profile were quantified in biopsies by RT-qPCR
RESULTS: In biopsies, VIP mRNA expression was lower in patients with CD than with UC ($p = 0.006$), but was similar to HC. VIP mRNA and protein expression were significantly lower in ENS incubated with SUP-CD than with SUP-UC ($p = 0.002$ and $p < 0.01$, respectively). Disease differentially modulated VIP in ENS as a function of inflammation. In particular, SUP-CD-I reduced VIP concentration in ENS as compared to SUP-CD-NI ($p = 0.03$) while SUP-UC-I tended to increase VIP concentration in ENS compared to SUP-UC-NI ($p = 0.07$). In biopsies, VIP mRNA expression was correlated to IL-6 mRNA expression ($r = 0.429$, $p = 0.009$). In the ENS, IL-6 dose dependently reduced VIP mRNA and protein expression and the effects of SUP upon VIP expression were blocked by anti IL-6 antibody.
CONCLUSION: Our study demonstrates that colonic mucosal soluble factors differentially modulate neuroplastic changes observed in IBD according to the disease. IL-6 was responsible for reduced VIP expression in CD. Therefore, approaches aimed at blocking IL-6 might restore normal VIP level and thereby enhance barrier functions as well as reduce inflammation

P263 ACTIVATION OF TOLL-LIKE RECEPTOR (TLR) 5 BY FLAGELLIN INDUCES A PRO-FIBROGENIC PHENOTYPE IN HUMAN INTESTINAL FIBROBLASTS (HIF) – A NOVEL PATHWAY MEDIATED BY MYD88 AND CASPASE 1

F. Rieder[1,*], S. Bhilocha[1], A. Schirbel[1], Z. Ouyang[1], G. West[1], H. Rho[1], C. de la Motte[1], C. Fiocchi[1]. [1]*CLEVELAND CLINIC FOUNDATION, Cleveland, United States*

INTRODUCTION: Intestinal fibrosis is caused by excessive extracellular matrix deposition by myofibroblasts. Activation of TLRs and Nod-like receptors (NLRs) by gut bacteria mediates an abnormal innate immune response in inflammatory bowel disease (IBD).

AIMS&METHODS: We investigated whether TLR or NLR ligands also induce a fibrogenic response in HIF.

HIF from Crohn's disease, ulcerative colitis and control normal mucosa were exposed to ligands for TLR2/6, 4, 5, Nod1, TGF-β1, BzATP (extracellular ATP), *S. typhimurium* and its flagellin-negative *FljB/FliC* variant, and supernatants assessed for fibronectin (FN), collagen I (Col1), TGF-β1 and IL-6 content. TLR signaling, VCAM1 and ICAM1 expression were investigated and inhibition of TGF-β1, MyD88 and p38MAPK signaling or inhibition of caspase-1 activation was performed using siRNA and blocking agents, immunoblotting, flow cytometry and immunoprecipitation.

RESULTS: All TLR and NLR ligands failed to induce FN or Col1 production by HIF except for flagellin which, alone or combined with Nod1, TLR2/6 or TLR4, significantly increased FN and Col 1 production. This TLR5-mediated response was independent of TGF-β1 signaling. Combined with TGF-β1, TLR5 augmented FN secretion and sensitized HIF to the subsequent action of TGF-β1. All TLR and NLR ligands induced IL-6 secretion, and while flagellin-positive *S. typhimurium* induced FN production by HIF, its flagellin-negative variant failed to do so. Interestingly, the inflammasome activator BzATP enhanced TLR5-induced FN production by HIF. The TLR5 ligand-induced FN secretion was dependent on MyD88, p38MAPK signaling and caspase-1 activation.

To investigate additional effects on fibrogenesis, we found that flagellin, alone or in combination with other TLR or NLR ligands, upregulated VCAM-1, but not ICAM-1, expression by HIF. This enhanced the ability of HIF to bind primary human monocytes, the predominant source of TGF-β1. In fact, monocyte-derived TGF-β1 appeared to be critical for activation of HIF.

CONCLUSION: Activation of TLR5 by flagellin induces a fibrogenic response by HIF that is dependent on MyD88, p38MAPK and caspase-1, but independent of TGF-β1. TLR5 activity on HIF could be boosted by the inflammasome activator BzATP. This direct fibrogenic response is distinct from the inflammatory response, but flagellin also induces fibrogenesis indirectly by promoting HIF-monocyte binding. These results suggest a functional network among bacterial immunity, the inflammasome and excessive matrix production in IBD-associated fibrosis.

INTRODUCTION: Inflammatory bowel diseases (IBD) are characterized by aberrant innate and adaptive immune responses to commensal bacteria. The presence of free-circulating DNA (fcDNA) sequences in the serum is an established phenomenon in IBD. A close correlation between the quantity of fcDNA and the course or prognosis of several pathologic conditions has already been described. Diagnostic, prognostic, and therapy monitoring roles of fcDNA in regards to chronic colonic disorders have also been examined, however, its biological function and preventive immunobiologic effects still remains unclear.

AIMS&METHODS: The colitis preventive immunobiological effects of isolated, intravenously administered fcDNA of normal and colitic origin were assayed in both a murine model of DSS-colitis and in control mice. DSS-colitis was induced 5 days after intravenous fcDNA administration in C57bl/6 mice. After disease- and histological activity evaluations, the changes in Toll- like receptor 9 signaling and the pro- and anti-inflammatory cytokine profile were assayed in isolated immune cells of the lamina propria by real-time quantitative PCR array cards.

RESULTS: Intravenously administered colitis-derived fcDNA has a more prominent preventive effect on the clinical and histological severity of DSS-induced colitis in mice than fcDNA of normal origin. The systemic administration of colitis-derived fcDNA alters TLR9-related signaling (i.e. Myd88, IRAK, TRAF6, IkB), the pro-inflammatory (i.e. IL-6, TNF-alpha) and the anti-inflammatory cytokine (i.e. IL-10) profile in a favorable manner.

CONCLUSION: Our study unveiled a novel function of intravenously administered fcDNA in DSS-colitic mice. Preventive intravenous administration of fcDNA appears to be a promising novel approach to the treatment modalities of colitis.

P265 CD24-BASED ASSESSMENT OF NOD2-INFLUENCE ON PANETH-CELL NUMBERS USING INTESTINAL STEM CELL CULTURES AND GENETIC ASSOCIATION ANALYSIS OF CD24 IN IBD

J. Van Limbergen[1,*], K. Geddes[2], P. Henderson[1], R. K. Russell[3], H. E. Drummond[4], J. Satsangi[4], A. Griffiths[5], D. J. Philpott[2], D. C. Wilson[1]. [1]*Child Life and Health, University of Edinburgh, Edinburgh, United Kingdom,* [2]*Dept of Immunology, University of Toronto, Toronto, Canada,* [3]*Dept of Paediatric Gastroenterology, Yorkhill Hospital, Glasgow,* [4]*Gastrointestinal Unit, University of Edinburgh, Edinburgh, United Kingdom,* [5]*Division of Paediatric Gastroenterology, Hepatology and Nutrition, Hospital for Sick Children, Toronto, Canada*

INTRODUCTION: Environmental conditions, notably co-housing with WT littermates, and mouse genetic background influence NOD2-dependent defensin production.[1] An increase in the number of Paneth-cells, could compensate for a NOD2-dependent reduction in the level of defensin-production in Paneth-cells. CD24, a marker of intestinal crypt stem cells and Paneth-cells, is upregulated in Inflammatory Bowel Disease (IBD).[2, 3] A deletion polymorphism (rs3838646) in the 3' Untranslated Region, which reduces the stability of CD24mRNA, has been associated with susceptibility to Crohn's Disease(CD) (OR 1.61) plus protection against chronic Hepatitis B Virus infection, systemic lupus erythematosus and multiple sclerosis.[4, 5]

AIMS&METHODS: Our aims were to assess the influence of NOD2-status on Paneth-cell numbers (by CD24-based flow cytometry) using mouse intestinal stem cell cultures (organoids), and to determine the role of the CD24 gene polymorphism (rs3838646) in the genetic susceptibility to IBD, in the high incidence Scottish population characterized by a low allelic frequency of the "common" CD-associated NOD2 variants.[6]

Small intestinal stem cell crypts were isolated from C57BL/6 NOD2WT and NOD2KO mice, housed separately in specific pathogen-free conditions.[2] Intestinal crypts were cultured in Matrigel and organoid medium containing R-Spondin, murine recombinant Noggin and Epidermal Growth Factor.[2] We performed a genetic association analysis of the rs3838646 polymorphism in 1038 adult IBD patients, 351 childhood onset IBD and 940 healthy controls.[7]

RESULTS: There was no difference in Paneth-cell numbers (CD24hi, Side Scatter +) between NOD2WT and NOD2KO intestinal organoids using flow cytometry(3.83% vs. 3.9%). Due to the presence of a CD24-pseudogene on the Y-chromosome, only female IBD patients (n=737) vs. female controls (n=498) were analysed to avoid non-specific amplification of the TaqMan assay. Our study had 80% power to detect association with OR 1.46 and OR 1.62 (with IBD and CD, respectively). Genotype frequencies and allelic frequency did not differ between IBD/CD and controls ($p > 0.5$).

CONCLUSION: Using intestinal stem cell cultures from NOD2WT and NOD2KO, we have demonstrated by means of CD24-based flow cytometry that NOD2-status does not influence Paneth-cell numbers. In the high-incidence Scottish IBD population, the CD24 gene polymorphism (rs3838646) is not an important determinant of genetic susceptibility to IBD/CD.

INTRODUCTION: Inflammatory bowel disease (IBD) is believed to be caused by an inappropriate immune response to gut microbiota in genetic susceptible individuals. Several serologic markers to microbial antigens have been observed in Crohn's disease. In contrast, ulcerative colitis has been associated with perinuclear antineutrophil cytoplasmic antibodies (pANCA) only. The significance of pANCA in the pathophysiology of ulcerative colitis remains largely unknown. Early observations reported an increased presence of pANCA in first-degree relatives of patients with ulcerative colitis, indicating that shared environment or genetic predisposition might play a role. However, these findings have not been replicated in all subsequent studies.

AIMS&METHODS: We aimed to determine whether genetics predispose to presence of pANCA in an European collaborative twin study. In total, 48 twin pairs with ulcerative colitis (Leuven, Belgium n=4, Maastricht, The Netherlands n=5 and Örebro, Sweden n=39) participated: (concordant monozygotic n=3, discordant monozygotic n=15, concordant dizygotic n=1, discordant dizygotic

n=28 and one monozygotic twin pair with both CD and UC). pANCA was analyzed by ELISA and indirect immunofluorescence as previously described. The intraclass correlation coefficient (ICC) was used to assess agreement in concentrations of ANCA within twin pairs.
RESULTS: pANCA was present in 16/52 (31%) twins with UC compared with 4/43 (9%) healthy twin siblings (p=0.01). Consistently, mean (range) concentrations of ANCA were higher in twins with UC [18.7 (1.5-91.1) EU/ml] than in their healthy twin siblings [7.5 (0-30.5) EU/ml], ratio for mean concentrations 2.1 (95% CI 1.5-3.0). However, pANCA was not more frequently present in healthy monozygotic- [1/15 (7%)] than healthy dizygotic twin siblings [3/28 (11%)] (p > 0.99). Similarly, no agreement was observed in monozygotic- or dizygotic discordant twin pairs with UC, ICC=0.11 and ICC=-0.22, respectively.
CONCLUSION: pANCA was more often present in twins with UC than in their healthy twin siblings, reflecting that pANCA status has a specificity for UC. However, pANCA was not more often present in healthy monozygotic- than in healthy dizygotic twin siblings. No agreement in concentration of ANCA was observed in monozygotic or dizygotic twin pairs with ulcerative colitis. Thus, genetic factors do not seem to drive pANCA expression, whereas disease status/phenotype does.

P267 CO-INHIBITION OF COX-1 AND COX-2 IS PREREQUISITE FOR CHEMOPREVENTION OF COLITIS-ASSOCIATED CANCER

K. B. Hahm[1,*], E. H. Kim[1], S. P. Hong[1], J. M. Park[1]. [1]*Gastroenterology, CHA UNIVERSITY OF MEDICINE AND SCIENCE, Seongnam, Korea, Republic Of*

INTRODUCTION: Cyclooxygenase-2 (COX-2) inhibition has known to be very efficient way of preventing colitis associated cancer because COX-2 is principally engaged as an inflammatory or carcinogenic mediator in colitic cancer. However, there has been reported to the incomplete prevention with COXIBs, for which we investigated the effects of inhibition of COX-2 only and both COX-1 and -2 on the colitis-associated carcinogenesis.
AIMS&METHODS: Mice were exposed to 10 mg/kg AOM followed by 2.5% DSS in drinking water for 7 days with or without aspirin or celecoxib. To further verify the role of COX-2 in the colon carcinogenesis, we compared the incidence and the multiplicity of AOM plus DSS induced colon carcinogenesis in the COX-2 wildtype and knockout mice. After 16 weeks, all mice were sacrificed by cervical dislocation for further analysis.
RESULTS: The 84% mice developed colorectal carcinoma after AOM plus DSS treated mice at the 16 weeks. The expression of COX-2 was markedly elevated in the colon tumors. COX-2 inhibition using celecoxib or genetic ablation using COX-$2^{-/-}$ mice could attenuate colon cancarcinogenesis. Administration of celecoxib lowered incidence and the multiplicity of colon carcinogenesis, and attenuated expression of COX-2 and iNOS as well as activation of NF-κB. However, inhibition of COX-1 and COX-2 with aspirin showed much more inhibitory effects on the expression of inflammatory and carcinogenic markers, the tumor incidence and multiplicity of colon cancer than the only inhibition of COX-2 with celecoxib or COX-$2^{-/-}$ mice. Chemoprevention of colorectal cancer is already possible with celecoxib, but it is still not the ultimate drug of choice.
CONCLUSION: Since COX-1 or COX-2 inhibition achieved 60% of chemoprevention, COX-1 should also be inhibited as well as COX-2 to achieve optimal chemoprevention of colitis-associated colon carcinogenesis.

P268 THE ROLE OF NALP3 INFLAMMASOME IN INFLAMMATORY BOWEL DISEASE

L. D. Lazaridis[1], A. Pistiki[2], E. J. Giamarellos-Bourboulis[2,3], M. Georgitsi[2], G. Damoraki[2], D. Polymeros[1,*], G. D. Dimitriadis[1], K. Triantafyllou[1]. [1]*2nd Department of Internal Medicine and Research Institute, [2]4th Department of Internal Medicine, Attikon University General Hospital, Medical School Athens University, Athens, Greece, [3]Integrated Research and Treatment Center, Center for Sepsis Control and Care (CSCC), Jena University Hospital, Jena, Germany*

INTRODUCTION: Traditionally, inflammatory bowel disease (IBD) is considered a state of hyper-inflammation of the gut mucosa. In the present abstract, we challenge this concept by investigating cytokine production by peripheral mononuclear cells (PBMCs) of the patients.
AIMS&METHODS: PBMCs were isolated from 11 healthy controls, 12 patients with Crohn disease (CD) and 10 patients with Ulcerative Colitis (UC) after gradient centrifugation of heparinized whole blood over Ficoll. PBMCs were stimulated with the TLR4 ligand lipopolysaccharide (LPS) and with the NLRP3 ligand monosodium urate (MSU). After 24-hour incubation, cytokine concentrations were measured in supernatants; after 4-hour incubation PBMCs were lyzed for measurement of mRNA transcripts of interleukin (IL)-1β by RT-qPCR.
RESULTS: As shown in the table, cytokine production was lower among patients with IBD than healthy controls (*indicates significant differences compared to controls) and this was most prominent in CD. Activation of NLRP3 is expressed as the % increase of IL-1β production in the presence of MSU. Mean relative IL-1β copies in PBMCs of controls, of UC and of CD were 3.12, 16.3 and 55.3 (p=NS).

	IL-1β (Mean ± SE)	IL-6 (Mean ± SE)	TNFα (Mean ± SE)	NLRP3 (Mean ± SE)
Controls	4720.5 ±1674.8	33134 ± 10519.7	3519.1 ± 1310.9	12.3 ± 22.7
CD	*1327.9 ± 434.3	*6560 ± 1578.6	*212 ± 75.3	*-24.9 ± 14.47
UC	*1110.85 ± 409.1	9940.5 ± 1883.03	624 ± 246	*143.84 ± 88.29

CONCLUSION: Cytokine production by PBMCs is significantly modulated in IBD. Main characteristics are down-regulation after LPS stimulation and activation of NLRP3 inflammasome.

P269 T CELL EXPRESSION OF CD25 AND TNF RECEPTOR 2 AND IL-1B RELEASE MAY PREDICT ANTI-TNF THERAPY RESPONSE IN PATIENTS WITH ULCERATIVE COLITIS

M. K. Magnusson[1,2,*], H. Strid[2], R. Dahlén[1,2], S. Isaksson[1,2], A. Lasson[3], K.-A. Ung[4], A. Bajor[2], L. Öhman[1,2]. [1]*Dept for Microbiology and Immunology, Inst of Biomedicine, [2]Dept for Internal Medicine, Inst of Medicine, Göteborg, [3]Dept for Gastroenterology, Södra Älvsborg Hospital, Borås, [4]Dept for Internal Medicine, Kärnsjukhuset, Skövde, Sweden*

INTRODUCTION: Anti-tumor necrosis factor (anti-TNF) agents are effective treatment options for patients with ulcerative colitis (UC). However, not all patients respond to treatment and cellular mechanisms leading to therapy response are incompletely known. Also, biomarkers which can predict if patients are responders or non-responders before therapy start are needed.
AIMS&METHODS: The overall aim of this study was to identify immunological mechanisms involved in anti-TNF therapy in patients with UC in order to predict therapy response.
UC patients treated with anti-TNF (infliximab) were followed from start to evaluation of treatment efficacy. Blood samples were obtained before the first treatment and cells were stimulated ex vivo with influenza vaccine with and without anti-TNF. Cells and supernatants were analysed using flow cytometry. Disease activity was assessed by Mayo score before treatment start and at an evaluation visit prior to the fourth treatment dose. Response was defined as a decrease in Mayo score of ≥3.
RESULTS: We have included 28 UC patients into the study. Sixteen patients responded to anti-TNF therapy, whereas twelve patients did not respond. Presence of anti-TNF at stimulation induced a more pronounced reduction in the frequencies of $CD4^+CD25^+$ (61.9 (34.7-81.2) vs. 74.9 (61.7-96.1) %; p=0.006) and $CD3^+TNFR2^+$ (51.8 (21.4-69.8) vs. 66.3 (53.9-92.6) %; p=0.03) T cells in therapy responders as compared to non-responders. The same trend was seen for $CD4^+$ T cells expressing the gut homing receptor a4b7. The reduction of activated T cells in responders was accompanied by a reduction of IFN-g expression when comparing stimulated cells with and without addition of anti-TNF (33.2 (0-469.1) vs. 174.4 (0-479.1) pg/ml; p=0.02). However, no reduction of IFN-g was detected in non-responders. In addition, stimulation of blood cells with vaccine alone resulted in increased levels of the pro-inflammatory cytokine IL-1b in non-responders as compared to responders (27.7 (0-118.3) vs. 0 (0-38.1) pg/ml; p=0.04).
CONCLUSION: This study indicates that suppression of the frequencies of $CD25^+$ T cells and $TNFR2^+$ T cells cultured in the presence of anti-TNF may be used as biomarkers to predict therapy response to anti-TNF treatment in IBD patients. Also, therapy non-responders have a higher production of IL-1b upon antigen stimulation which may counteract the anti-inflammatory effects of anti-TNF.

P270 TELOMERE LENGTH IN NON-NEOPLASTIC COLONIC MUCOSA IN ULCERATIVE COLITIS AND ITS RELATIONSHIP TO THE SEVERE CLINICAL PHENOTYPES

M. Okubo[1,*], T. Tahara[1], T. Shibata[1], T. Ishizuka[1], Y. Ichikawa[1], M. Miyata[1], K. Sumi[2], T. Kawamura[2], M. Nakamura[3], M. Nagasaka[1], Y. Nakagawa[1], N. Ohmiya[1], T. Arisawa[3], I. Hirata[1]. [1]*Gastroenterology, [2]Fujita Health University School of Medicine, Toyoake, [3]Gastroenterology, Kanazawa Medical University, Ishikawa, Japan*

INTRODUCTION: Telomere shortening occurs with human aging in many organs and tissues and is accelerated by rapid cell turnover and oxidative injury.
AIMS&METHODS: To clarify the clinical importance of telomere shortening in colonic mucosa in ulcerative colitis (UC), we measured average telomere length using quantitative real-time PCR in non-neoplastic colonic mucosa in UC patients and assessed its relationship to various clinical subtypes. Colonic biopsies were obtained from rectal inflammatory mucosa from 86 UC patients. Paired non-inflammatory proximal colonic mucosae were also collected from 10

patients. Relative telomere length in genomic DNA was measured by determining the ratio of telomere repeat copy number (T) to single copy gene (S) copy number(T/S ratio) in individual samples relative to a reference pooled DNA from healthy blood samples.
RESULTS: In 10 cases, average relative T/S ratios of rectal inflammatory mucosa and adjacent normal proximal colon were 3.62+/-2.16 (Mean+/-SD), 2.29+/-1.88, respectively, and were reduced in rectal inflammatory mucosa among 8 out of 10 cases (p=0.01). Relative T/S ratios were also reduced in cases that needed surgery due to toxic megacolon or cancer occurrence (2+/-0.16 *vs*. 0.75+/-0.69: p=0.04). When the severe clinical phenotype was defined as having at least one of following phenotypes; more than two times of hospitalization, steroid dependent, refractory, or needing operation, average relative T/S ratio was significantly reduced in severe phenotypes than the others (2.22+/-0.23 *vs*. 1.57+/-0.21: p=0.04).
CONCLUSION: Telomere shortening is associated with more severe clinical phenotypes of UC, reflecting severe inflammatory state in the colonic mucosa.

P271 IL-7 PROMOTES LONG-TERM IN VITRO SURVIVAL OF UNIQUE LONG-LIVED MEMORY SUBSET GENERATED FROM MUCOSAL EFFECTOR MEMORY CD4+ T CELLS IN CHRONIC COLITIS MICE

M. Takahara[1,2,*], Y. Nemoto[1], S. Oshima[1], K. Yamamoto[2], M. Watanabe[1]. [1]*Gastroenterology and Hepatology, Tokyo Medical and Dental University, Bunkyo-ku Tokyo,* [2]*Gastroenterology and Hepatology, Okayama University, Okayama, Japan*

INTRODUCTION: We have reported that colitogenic memory $CD4^+$ T cells, which can survive even in remission for life-long, play an important role for the perpetuation of inflammatory bowel disease (IBD). Memory T cells are heterogeneous and can be divided into subpopulations. Recently, memory stem cells (T_{SCM}), with high potential for survival, self-renewal and multi-differentiation, were identified in both mice and humans. However, it is unclear whether a similar subset is present in IBD.
AIMS&METHODS: We sought to identify and purify a long-lived subset of colitogenic memory $CD4^+$ T cells, which may be ultimate target for the treatment of IBD. First, we checked the role of each subset of memory $CD4^+$ T cells in IBD model mice. Second, a long-lived subset of colitogenic memory $CD4^+$ T cells was purified using a long-term culture system and the characteristics of these cells were assessed.
RESULTS: In multiple IBD model mice, there was no T_{SCM} and most of $CD4^+$ T cells in each organ were effector memory T cells (T_{EM}), which are believed as short-lived terminally differentiated cells. In addition, T_{EM} induced severe colitis to the same extent as central memory T cells (T_{CM}), which are believed as long-lived highly proliferative cells, when they were transferred into new SCID mice. Therefore, we though that hierarchy of memory T cells previously reported cannot apply to IBD model mice, and that T_{EM} in colitic mice are not short-lived cells but include long-lived cells. Next, we tried to purify long-lived subset from colitic lamina propria (LP) $CD4^+$ T cells by culturing with IL-7, which is the most important factor for the maintenance of memory $CD4^+$ T cells.
Colitic LP $CD4^+$ T cells could be maintained *in vitro* with IL-7 for more than 8 weeks, while normal $CD4^+$ T cells could not be maintained. During culture, these cells were quiescent and divided intermittently, which is very similar to their maintenance *in vivo*.
After the culture, LP $CD4^+$ T cells expressed high level of Bcl-2, which suggests these cells are long-lived. Cultured-LP $CD4^+$ T cells expressed unique surface markers, which were different from any memory subsets, and produced large amount of IL-2, which is similar to T_{CM}. Finally, LP $CD4^+$ T cells obtained from colitic mice and cultured with IL-7 for 8 weeks induced more severe colitis than LP $CD4^+$ T cells cultured for 4 weeks.
CONCLUSION: We here developed for the first time long-term culture system to purify long-lived and highly pathogenic memory subset from activated LP $CD4^+$ T cells. IL-7 promoted long-term *in vitro* survival of this subset in a quiescent state.

P272 THE ROLE OF IL-9 AND ITS RECEPTOR IN ULCERATIVE COLITIS

N. Nalleweg[1,*], M. T. Chiriac[1,2], E. Podstawa[1], C. Lehmann[3], T. Rau[4], R. Atreya[1], E. Krauss[1], B. Weigmann[1], M. F. Neurath[1], J. Mudter[1]. [1]*Medical Clinic 1, University of Erlangen-Nuremberg, Erlangen, Germany,* [2]*Molecular Biology Center, IRI-BNS, and Department of Biology, University of Babes-Bolyai, Cluj-Napoca, Romania,* [3]*Department of Dermatology,* [4]*Institute of Pathology, University of Erlangen-Nuremberg, Erlangen, Germany*

INTRODUCTION: It is currently assumed that the pathogenesis of ulcerative colitis (UC) is due to an altered Th2/Th17 response. However, various aspects of disease development are incompatible with this model. IL-9 has been described as the key cytokine of a new $CD4^+$ T cell population, referred to as Th9 cells. The role of IL-9 in inflammatory bowel disease (IBD) has so far not been investigated.
AIMS&METHODS: In this study we addressed the function of IL-9 in UC. qPCR of colonic biopsies for IL-9, IL-9R, IL-6, IL-17A, IL-21, IRF4, PU.1, S100A8, STAT1, STAT3, STAT5a, STAT5b and TNFα mRNA. IL-9 and IL-9R immunofluorescence (IF) single stainings and IL-9 + IRF4/PU.1/CD3 IF double stainings on gut surgical specimens and biopsies. Histological classification of the inflammation score (IS) 0-3. IL9-R and IL-9 FACS staining of intestinal epithelial cells. Western blot (WB) of colonic biopsies for claudin-2. TEER-measurement of Caco-2 cells after stimulation with IL-9 and WB of the cells for claudin-2.
RESULTS: IL-9 mRNA was expressed by UC patients with active colitis. The IL-9 level strongly correlated with the inflammation marker S100A8 and IL-9 dependent transcription factors. UC patients with active colitis showed a higher number of $IL\text{-}9^+$ cells in the IF. IL-9 was expressed by $CD3^+$ cells in the lamina propria. In patients with active colitis, IL-9 expression correlated to a high degree with its transcription factor PU.1. Apart from that, a high correlation between PU.1 and IRF4 was shown. The colocalization of IL-9 and PU.1 as well as IL-9 and IRF4 in the lamina propria was detected by IF. The number of $IL\text{-}9^+PU.1^+$ and $IL\text{-}9^+IRF4^+$ increased with IS. Using IF and FACS, the expression of the IL-9R on intestinal epithelial cells could be shown. IL-9R expression increased in UC patients with IS. The stimulation of Caco-2 colon epithelial cells with IL-9 resulted in a disturbed barrier function of the epithelium by a STAT- and claudin-2-dependent mechanism.
CONCLUSION: Our data show for the first time that IL-9 produced by $CD3^+$ and $PU.1^+/IRF4^+$ cells is decisively involved in the pathogenesis of UC through the direct damage of the barrier function of the colon epithelium. The modulation of this signaling pathway could represent a further valuable treatment option for UC.

P273 COMMD10, AN NF-KAPPAB INHIBITOR, IS REDUCED IN IBD PATIENTS AND IN PRO-INFLAMMATORY INFILTRATING MONONUCLEAR PHAGOCYTES OF COLITIC MICE AND IBD PATIENTS.

N. Gluck[1,*], S. Ben Shlomo[1], Z. Halpern[1], E. Santo[1], C. Varol[1]. [1]*Research Center for Digestive and Liver Diseases, Department of Gastroenterology, Sourasky Medical Center, Tel-Aviv, Israel*

INTRODUCTION: The COMMD proteins family is involved in NF-kB ubiquitination, thus "switching off" transcription of pro-inflammatory genes[1]. In the inflamed mouse intestine, a subset of mononuclear phagocytes (MPs), expressing $Ly6C^{hi}$ and $CX3CR1^{int}$, dominates the macrophage (MF) population. These cells are highly responsive to TLR/NOD2 activation and exhibit upregulation of NF-kB stimulated genes and pro-inflammatory cytokine secretion[2]. A similar dominant population expressing CD14 was identified in human IBD[3].
AIMS&METHODS: Aims: To investigate the expression pattern of COMMD10 in subsets of intestinal MPs in health and IBD in both mouse models and humans.
Methods: Ileocolonic biopsies, circulating leukocytes as well specific blood MP subtypes were isolated from IBD and control patients. MP populations were sorted from the colon of mice with DSS-induced acute and chronic colitis. COMMD10 expression was determined by qRT-PCR. COMMD10 was silenced by siRNA in intestinal epithelial cells and the expression of NF-kB induced pro-inflammatory genes was determined by qRT-PCR and western blot in response to LPS treatment.
RESULTS: Our findings in a wide cohort of patients demonstrate the broad decrease of *COMMD* gene expression in intestinal tissue and circulating leukocytes of both Crohn's disease and ulcerative colitis patients. Contrary to our expectations, this decline did not correlate well with disease severity and could be observed in uninvolved areas of the intestine as well as inflamed areas. Interestingly, we show that the CD14+ MPs, which become dominant in IBD, but not CD16+ MPs, exhibit decreased COMMD10 expression. In correlation with the human data, the infiltrating MFs that express $Ly6C^{hi}$ and $CX3CR1^{int}$ show reduced COMMD10 expression relative to residents MFs both in acute and chronic DSS-induced colitis. Intestinal epithelial cells expressing lower COMMD10 levels *in vitro* are more pro-inflammatory and express higher levels of TNFa, IL-6, IL-32 and ICAM-1.
CONCLUSION: COMMD10 is reduced in the setting of inflammation, specifically in infiltrating MFs in both mice and humans. An acquired state of "COMMD10 deficiency" in infiltrating MFs may unleash NF-kB signaling and participate in the induction and maintenance of IBD. Therefore restoring COMMD10 levels in this specific MF subtype may help to control the inflammatory state in IBD patients.

P274 EXPERIMENTALLY PROVOKED RECURRENT INFLAMMATION IMPROVES MUCOSAL HEALING AND RESTORATION OF IMPAIRED MORPHOLOGY OF MYENTERIC NEURONS IN A RAT MODEL OF CROHN'S DISEASE

P. Talapka[1,*], L. Nagy[2], A. Pál[1], L. G. Puskás[2], M. Poles[1], M. Bagyánszki[1], É. Fekete[1], N. Bódi[1]. [1]*Department of Physiology, Anatomy and Neuroscience, University of Szeged,* [2]*Avidin Ltd., Szeged, Hungary*

INTRODUCTION: Crohn's disease (CD) is a chronic relapsing inflammatory bowel disease (IBD) associated with marked abnormalities in intestinal motility suggesting that impairment in the enteric nervous system (ENS) underlines some of the functional abnormalities observed in patients with IBD. Although there have been numerous studies of the ENS in inflammation, the structural and molecular changes to the ENS under the repetitive relapsing inflammations (RRI) has not been studied yet.
AIMS&METHODS: We aimed to establish a rat model of chronic colitis suitable to investigate the ENS and its intestinal microenvironment in RRI. Colitis was induced by an enema of 2,4,6-trinitrobenzenesulfonic acid (TNBS, 10 mg) in 25% ethanol. RRI was provoked by repeated TNBS treatments. Tissue samples were taken from control, as well as 1x, 2x and 3x treated rats from the ulcered, and also proximal and distal to the ulcered segments of the colon in different timepoints between 2 and 120 days. The quantitative and morphometrical features of myenteric neurons under RRI were investigated by immunohistochemistry using HuC/D as a pan-neuronal marker. The expression of endogenous antioxidant enzyme, heme oxygenase-1 (HO-1) was determined by real time PCR.
RESULTS: Severe mucosal inflammation, decreased myenteric neuronal density and shrinkage of neuronal cell bodies were demonstrated in the acute phase of inflammation induced by the first TNBS treatment. Nevertheless, after the second and even more after the third TNBS treatment the measure of ulcerousness decreased markedly and the soma sizes of myenteric neurons were nearly the same as in the controls. The length of the acute phase of inflammation was also reduced. Mucosal healing was completed 8 days after the first treatment, while complete mucosal recovery was noticed already 6 and 4 days after the second and third treatment, respectively. HO-1 mRNA level was elevated in the acute phase of the inflammation in all three colonic segment, and remained high until day 120th.
CONCLUSION: This study demonstrates for the first time that experimentally provoked RRI in rat model of CD develops preconditioning effect by speeding up mucosal healing and restoring impaired morphology of myenteric neurons. Decreased severity of TNBS induced inflammation in RRI might be associated with the persistent upregulation of HO-1 expression throughout the 120 days experimental period. Therefore, targeted induction of HO-1 might be of therapeutic interest.

P275 NATURAL KILLER CELLS REGULATE THE EARLY STAGE OF PATHOGENIC T CELL DEVELOPMENT IN AN IBD MODEL

T. Nagaishi[1,*], O. Yamaji[1], M. Suzuki[1], M. Yamazaki[2], M. Watanabe[1]. [1]*Gastroenterology, Tokyo Medical and Dental University,* [2]*Obstetrics and Gynecology, Nihon University, Tokyo, Japan*

INTRODUCTION: We previously reported that mice lacking IL-7 and RAG ($IL\text{-}7^{-/-}$ $RAG^{-/-}$) receiving naïve T cells failed to induce colitis. Such abrogation of colitis may be associated not only with incomplete T cell maintenance due to the lack of IL-7, but also with the induction of colitogenic T cell apoptosis at an early stage of colitis development. Natural killer (NK) cells may be associated with the suppression of autoimmune diseases and may induce apoptosis of $CD4^+$ T cells, although the mechanisms have not been well described. We therefore focused our analysis of this phenomenon on NK cells.
AIMS&METHODS: To further investigate these roles of NK cells, $RAG^{-/-}$ and $IL\text{-}7^{-/-}$ $RAG^{-/-}$ mice receiving naïve T cells were depleted of NK cells using anti-asialo GM1 or anti-NK1.1 antibodies.
RESULTS: NK cell depletion at an early stage, but not at a later stage, during colitogenic effecter/memory T cell (T_{EM}) development resulted in elicited colitis in recipient mice even in the absence of IL-7. The isolated NK cells derived from $RAG^{-/-}$ and $IL\text{-}7^{-/-}$ $RAG^{-/-}$ mice indicated that the lack of IL-7 does not affect the differentiation and cell-mediated cytotoxicity of NK cells either in vitro or in vivo. Increased $CD44^+$ $CD62L^-$ T_{EM} and unique $CD44^-$ $CD62L^-$ (double negative, DN) T cell subsets were observed in the T cell-reconstituted $RAG^{-/-}$ recipients when NK cells were depleted. Fas, DR5, which are the specific receptors of Fas-L and TRAIL, respectively, and IL-7R expressions in the DN T cell subset differed from that in T_{EM} subset, indicating that the mechanism by which NK cells suppress the DN T cells is different from that by which they suppress the T_{EM} cells, which is due to the apoptosis via Fas and/or DR5.
CONCLUSION: These results suggest that NK cells suppress colitis severity in the T cell-reconstituted recipient mice through targeting of T_{EM} and, possibly, of the DN subset present at an early stage of pathogenic T cell development.

P276 EFFICACY OF SELECTIVE MYELOID LINEAGE LEUCOCYTE DEPLETION IN PYODERMA GANGRENOSUM AND PSORIASIS ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE.

T. Ohmori[1,*], A. R. Saniabadi[2], S. Ikeda[3], T. Kanekura[4]. [1]*Gastrointestinal Clinic, Ageo, Saitama 362-0075,* [2]*OTSUKA, Takasaki,* [3]*Department of Dermatology and Allergology, Juntendo University Graduate School of Medicin, Tokyo,* [4]*Department of Dermatology, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan*

INTRODUCTION: A minority of patients with inflammatory bowel diseases (IBD) develop pyoderma gangrenosum (PG) or psoriatic skin lesions, but this is now increasing significantly by the appearance of new onset psoriasis associated with anti-tumour necrosis factor-alpha therapy (Cullen G, et al. Aliment Pharmacol Ther 2011). The conditions are life-long neutrophilic inflammatory disorders, which do not respond well to pharmacologicals. We thought that patients with PG and psoriasis should respond favourably to selective depletion of myeloid lineage leucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with the Adacolumn.
AIMS&METHODS: A 19-year-old patient developed exacerbated Crohn's disease (CD) complicated by PG while on conventional medication. His symptoms included severe anal pain, bloody diarrhoea more than 20 times/day, and fever. Laboratory variables included C-reactive protein (CRP) 19.9mg/dL, erythrocyte sedimentation rate (ESR) 55mm/hr and leucocyte count $17.9x10^6$/mL. GMA was decided at a flow rate of 40mL/minx90min = one GMA session. Following this case, a study in 15 patients with drug refractory generalized pustular psoriasis (GPP) was undertaken with 5 GMA sessions over 5 consecutive weeks.
RESULTS: In the CD case, after 5, once a week GMA sessions, there was a striking improvement of the PG lesions. The outcomes encouraged us to proceed with a second course of 5 GMA sessions. After the second course, pustular lesions re-epithelialized and colonoscopy showed no active ulcer, but ulcer scars covered by regenerated mucosa in the anal canal, rectum and the sigmoid colon. Stool frequency was 2-3/day, CRP 0.6mg/dL, leucocyte count $4.7x10^6$/mL and normal ESR. The therapeutic outcomes in the 15 patients with GPP were encouraging as well. After 5 GMA sessions, the overall GPP scores improved (n=14, P=0.0027), and the area of erythroderma (P=0.0042), pustules (P=0.0031), and oedema (P=0.0014) decreased. Likewise, Dermatology Life Quality Index improved (P=0.0016), reflecting better daily function, and quality of life.
CONCLUSION: Regarding the mechanisms of clinical efficacy of GMA in patients with PG or psoriasis, post treatment data indicate that GMA down-modulates the expression of the chemokine receptor, CXCR3 (CD183) on leucocytes. CXCR3 is known to have a major role in neutrophilic skin lesions. The outcomes indicate a major role for neutrophils in the immunopathogenesis of PG and psoriasis.

P277 AUTOPHAGY IS INDUCED BY ERSTRESS MAINLY THROUGH IRE1ALFA IN HUMAN COLON CANCER CELLS AND IT PLAYS A CYTOPROTECTIVE ROLE.

Y. Shimodaira[1,*], S. Takahashi[1], H. Shiga[1], K. Endo[1], Y. Kinouchi[1], T. Shimosegawa[1]. [1]*Tohoku University, Sendai-shi, Miyagi-ken, Japan*

INTRODUCTION: X-box binding protein1(XBP1), which is activated by ER stress, and ATG16L1, Immunity-related GTPase family M protein(IRGM) , which are proteins related to induce Autophagy , are also identified as disease susceptibility genes of Crohn's disease in genome wide association study.
AIMS&METHODS: In colon epithelium, the relation between Unfolded Protein Response(UPR) and Autophagy is unknown, so we intended to elucidate about "Do ERstress induce Autophagy? ", "Which way in three canonical UPR pathway(PERK, IRE1α, ATF6 pathway) is most reliable for Autophagy indumed by ERstress?"and "How do this pathway contribute to cell survival? " We used three kinds of human colon cancer cell lines,HT29,SW480 and Caco-2. They are treated by tunicamycin(tm) or thapsigargin(tg) to activate UPR. We studied phosphorylation of PERK, cleavage of ATF6, splicing of XBP1 and CHOP as a marker of UPR by Western blotting or Polymerase Chain Reaction and LC3II as a marker of Autophagy by Western blotting ,and dots in GFP,RFP-LC3 transfected cells by confocal microscopy. A number of apoptotic cells is studied by flow cytometry.
RESULTS: The up-regulation of UPR and Autophagy was observed in Cells treated by tm or tg. Knock-down of IRE1α gene by RNA silencing inhibited the up-regulation of Autophagy in chemically treated cells while knockdown of PERK and ATF6 did not influence. The inhibitor of Autophagy, 3-methyl-adenine, augmented apoptotic cells, in chemically treated cells.
CONCLUSION: In human colon cancer cell lines, UPR-mediated Autophagy is mainly passed through IRE1α, and UPR-mediated Autophagy plays a cytoprotective role. In future, ERstressor of colon epithelium in human body should be clarified. It is our concern that how the functional disorder of UPR, Autophagy or both influence the Crohn's disease.

P278 THE EFFECT OF MELATONIN TREATMENT ON DSS INDUCED COLITIS AND PROBABLE MECHANISM BY MICROARRAY: AQUAPORIN8 AND ADIPONECTIN PATHWAY

Y. S. Park[1,*], J. H. Lee[1], S. C. Kim[1], S. H. Kim[1], Y. J. Jo[1], S. B. Ahn[1], B. K. Son[1], Y. K. Jo[1]. [1]*Gastroenterology, Eulji University, Eulji Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: There are complex and various causes in the pathogenesis of inflammatory bowel disease. Stressful condition has reported aggravation or reactivation of inflammatory bowel disease. Thus, we tried to investigate the effect of stress caused by sleep deprivation(SD) on DSS induced colitis model. Also, we designed to evaluate the mechanism of melatonin on such condition by gene expression after melatonin treatment.
AIMS&METHODS: We used the 5 groups of C57BL/6 mice. Group I: control, Group II: 2% DSS induced colitis for 7days, Group III: 2% DSS induced colitis and melatonin treatment, Group IV: 2% DSS induced colitis with sleep deprivation(SD, 20hr/d) and Group V: 2% DSS induced colitis with SD and melatonin treatment. Specially designed modified multiple platform water baths for sleep deprivation were used. Melatonin(10mg/kg) or saline was injected daily by intraperitoneal route. The mice were sacrificed after finishing administration of melatonin or saline for 4 days.
We checked body weight and stool color daily. Degree of colitis was evaluated after H&E stain. Also proinflammatory cytokines from serum were checked using Bio-Plex Pro Mouse Cytokine assay kit (Bio-Rad, Hercules, CA, USA). RNA was isolated from the colon of mice in each group and collected to analyze by microarray and ontology. We confirmed significant changes of expression of important genes by RT-PCR and immunohistochemical staining
RESULTS: Sleep deprivation worsens body weight reduction of mice and exacerbate the severity of colonic inflammation. Administration of melatonin reduced the rate of weight loss and severity of mucosa injury compared with saline injection group. Increased expression of pro-inflammatory cytokines such as IL-6, TNF-α, IFN-γ was significantly reduced with melatonin supplementation.
About 68 genes were significantly changed by 2% DSS, sleep deprivation and melatonin in microarray. In real time PCR there are significant change of adipoq and Aqp8 gene, which are related with adiponectin and aqaoporin-8 protein. We also performed immunohistochemical stain of adiponectin and aqaoporin-8.
CONCLUSION: Sleep deprivation acts as an aggravating factor, whereas melatonin acts as an improving factor of inflammation. This study shows melatonin affects both inflammation and sleep control. Especially genetic microarray study revealed that melatonin may regulate inflammation by modulating adiponectin and aquaporin pathway in DSS induced colitis.

P279 RISK OF SKIN CANCER IN IBD; A NATIONWIDE STUDY IN FINLAND

A. Jussila[1,*], L. Virta[2], E. Pukkala[3], M. Färkkilä[4]. [1]*TAMPERE UNIVERSITY HOSPITAL, TAMPERE,* [2]*The Social Insurance Institution of Finland, Turku,* [3]*Finnish Cancer Registry, Helsinki, Finland,* [4]*Helsinki University, Helsinki, Finland*

INTRODUCTION: Recent studies have shown an increased risk of non-melanoma skin cancers (NMSCs) in IBD patients, especially in those using thiopurines. An increased incidence of melanoma has also been suggested.
AIMS&METHODS: Our aim was to assess the risk of skin cancer overall among patients with IBD diagnosed between 1987-1993 and 2000-2007 in Finland. In the register of the Social Insurance Institution of Finland, separate codes for Crohn's disease (CD) and ulcerative colitis (UC) were available for IBD patients from 1986-1993 and 2000-2010. The 21,964 patients with IBD (16,649 with UC and 5,315 with CD) were followed until the end of 2010 (236,129 person-years) in a linkage with the nationwide database of the Finnish Cancer Registry. The observed numbers of skin cancers were assessed, and compared to those expected, and standardized incidence ratio (SIR) given
RESULTS: The risk of basal cell carcinoma of the skin was increased in UC (SIR 1.21; 95% CI 1.02-1.40 in males and SIR 1.22; 95% CI 1.01-1.45 in females) and in CD (SIR 1.68; 95% CI 1.19-2.29 in males and 1.60 95% CI 1.15-2.15 in females) in both genders. The risk of basal cell carcinoma of the skin was most pronounced in ages 30-44 over three years after the diagnosis of UC (SIR 3.12; 95% CI 1.64-5.54 in males and SIR 2.07; 95% CI 1.04- 3.71 in females) and in CD over three years after the diagnosis of CD among males in ages 30-44 (SIR 3.84; 95% CI 1.05-9.83) and among females in ages 45-59 (SIR 2.90; 95% CI 1.59- 4.86). A slightly increased risk of melanoma was also seen among male CD patients (SIR 2.33 95% CI 1.12-4.28), especially in ages 30-44 over three years after the diagnosis of CD (SIR 5.70; 95% CI 1.17-16.65).
CONCLUSION: Increased risk of basal cell carcinoma of the skin was found among CD and UC patients and risk of melanoma was increased among males with CD.

P280 RISK OF COLORECTAL CANCER IN CD PATIENTS WITH COLONIC INVOLVEMENT AND STENOSING DISEASE 1977-2012. RESULTS FROM A POPULATION-BASED STUDY

B. D. Lovasz[1,*], L. Lakatos[2], P. A. Golovics[1], G. David[2], T. Pandur[2], Z. Erdelyi[2], G. Mester[3], M. Balogh[3], I. Szita[2], C. Molnar[4], E. Komaromi[5], Z. Vegh[1], M. Mandel[1], L. S. Kiss[1], P. L. Lakatos[1]. [1]*1st Department of Medicine, SEMMELWEIS UNIVERSITY, Budapest,* [2]*Department of Medicine, Csolnoky F. Province Hospital, Veszprem,* [3]*Department of Medicine, Grof Eszterhazy Hospital, Papa,* [4]*Department of Infectious Diseases, Magyar Imre Hospital, Ajka,* [5]*Department of Gastroenterology, Municipal Hospital, Varpalota, Hungary*

INTRODUCTION: Data are limited.
AIMS&METHODS: Our aim was to study the risk of colorectal cancer (CRC) in patients Crohn's disease (CD) presenting with stenosing colonic lesions in the population-based, Veszprem province database, which included incident patients diagnosed between January 1, 1977 and December 31, 2011.
The data of 640 incident CD patients were analyzed (m/f: 321/319, age-at-diagnosis: 31.5, SD: 13.9 years). Both hospital and outpatient records were collected and comprehensively reviewed.
RESULTS: CRC was diagnosed in total 6 CD patients (total follow-up: 7759 person-years) during follow-up. 62 patients presented with colonic/ileocolonic disease and a stenotic lesion in the colon. The total follow-up was 702 person-years (mean: 11.3 SD 8.1 years). CRC developed in 6.5%, equalling 0.57 /100 person-years and an increased SIR (6.53, 95%CI: 2.45-17.4) with 4 patients observed and 0.61 expected. In a Kaplan-Meier analysis the probability of developing CRC was 5.5% after 5-years and 7.5% after 10-years of disease duration. In a sensitivity analysis, we included all patients who presented with colonic/ileocolonic disease and a stenosing colonic lesion at diagnosis or during follow-up (n=91, total follow-up: 1180 person-years, mean: 12.9 SD 8.8 years). The prevalence of cancer was overall 4.4% (0.34/100 person-years). In a Kaplan-Meier analysis the probability of developing CRC was 3.6% and 4.9% after 5- and 10-years of disease duration.
CONCLUSION: The risk to develop CRC in colonic CD patients presenting with or developing a stenotic lesion in the colon is high already after relatively short disease duration suggesting the need for careful surveillance of these patients.

P281 IRRITABLE BOWEL SYNDROME-TYPE SYMPTOMS IN INFLAMMATORY BOWEL DISEASE PATIENTS IN REMISSION: A CROSS-SECTIONAL SURVEY

C. J. M. Williams[1,*], S. Mumtaz[1], J. Hamlin[1], A. C. Ford[1,2]. [1]*Leeds Gastroenterology Insitute, Leeds General Infirmary,* [2]*Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, United Kingdom*

INTRODUCTION: Several studies have reported that patients with inflammatory bowel disease (IBD) may report symptoms compatible with irritable bowel syndrome (IBS). Patients who report these symptoms may have therapy escalated, due to concerns about ongoing disease activity. Few studies have examined patient characteristics that may be associated with the presence of IBS-type symptoms.
AIMS&METHODS: This was a prospective cross-sectional survey conducted among consecutive patients with Crohn's disease (CD) or ulcerative colitis (UC) attending an IBD clinic in a single teaching hospital. All patients completed questionnaires and provided a blood sample for C-reactive protein (normal CRP defined as <5.0mg/L). Presence of IBS-type symptoms was defined according to the Rome III criteria. Remission was confirmed using the Harvey-Bradshaw index (HBI score ≤ 4) for CD, and the simple clinical colitis activity index (SCCAI score ≤ 4) for UC. Participants also completed the patient health questionnaire-15, a validated somatisation score, and the hospital anxiety and depression score. Demographic data, including previous surgery and Montreal distribution of IBD, were collected for all patients. The effect of all these patient characteristics on presence of IBS-type symptoms was examined by univariate analysis, with results expressed as odds ratios (ORs) with 99% confidence intervals (CI).
RESULTS: 161 patients with IBD in remission were recruited (75 (46.6%) female, 87 (54.0%) CD, mean age 48.4 years). In total, 42 (26.1%) reported symptoms compatible with IBS (13 (8.1%) diarrhoea-predominant, 3 (1.9%) constipation-predominant, 26 (16.1%) mixed stool pattern). Mean age was not significantly different among those meeting criteria for IBS (45.5 years vs. 49.5), but mean CRP was slightly lower (5.6mg/L vs. 7.7mg/L, $P = 0.06$). Gender, smoking status, alcohol use, previous surgery, and type or Montreal distribution of IBD were not significantly associated with presence of IBS-type symptoms. However, prevalence of co-existent anxiety (OR 3.86; 99% CI 1.10-13.5), depression (OR 10.3; 99% CI 1.18-90.2), or somatisation (OR 5.32; 99% CI 1.13-25.1) were significantly greater among those meeting criteria for IBS.
CONCLUSION: One-in-four IBD patients in remission reported symptoms compatible with IBS. These were commoner in those with co-existent anxiety, depression, or somatisation. This, together with the fact that mean CRP levels were lower among those with IBS-type symptoms, suggests this may not necessarily be related to ongoing disease activity. Strategies for dealing with these types of symptoms in IBD patients are required.

P282 PREVALENCE OF SOMATISATION IN INFLAMMATORY BOWEL DISEASE PATIENTS: A CROSS-SECTIONAL SURVEY

C. Williams[1,*], S. Mumtaz[1], J. Hamlin[1], A. C. Ford[1,2]. [1]*Leeds Gastroenterology Insitute, Leeds General Infirmary,* [2]*Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, United Kingdom*

INTRODUCTION: Inflammatory bowel disease (IBD) may be associated with psychological illness, such as anxiety or depression, and reduced quality of life. However, few studies have examined the prevalence of somatisation in patients with IBD, or patient characteristics that may be associated with such behaviour.
AIMS&METHODS: This was a prospective cross-sectional survey conducted among consecutive patients with Crohn's disease (CD) or ulcerative colitis (UC) attending an IBD clinic in a single teaching hospital. All patients completed questionnaires and provided a blood sample for C-reactive protein (normal CRP defined as <5.0mg/L). Participants completed the patient health questionnaire-15, a validated somatisation score, with a score of ≥ 15 used to define presence of somatisation, and the hospital anxiety and depression score. Demographic data, including previous surgery and Montreal distribution of IBD, were collected for all patients. The effect of all these patient characteristics on presence of somatisation was examined by univariate analysis, with results expressed as odds ratios (ORs) with 99% confidence intervals (CI).
RESULTS: 287 patients with IBD were recruited (148 (51.6%) female, 160 (55.7%) CD, mean age 46.3 years). In total, 48 (16.7%) met criteria for somatisation. Mean age was significantly lower among those meeting criteria for somatisation (41.9 years vs. 47.2, $P = 0.02$), but mean CRP was not different (7.2mg/L vs. 9.0mg/L). Females (OR 2.95; 99% CI 1.20-7.3), smokers (OR 3.77; 99% CI 1.49-9.51), those who did not drink alcohol (OR 5.74; 99% CI 2.27-14.5), and those with co-existent anxiety (OR 12.25; 99% CI 3.80-39.5) or depression (OR 12.9; 99% CI 4.41-37.9) were more likely to meet criteria for somatisation. Ethnicity, educational level, previous surgery, and type or Montreal distribution of IBD were not significantly associated with presence of IBS-type somatisation.
CONCLUSION: One-in-six IBD patients reported symptoms compatible with IBS. These were commoner in females, smokers, those who did not drink alcohol, and those with co-existent anxiety or depression. Whether this relates to ongoing disease activity, extra-intestinal manifestations of IBD, or true somatisation remains unclear.
Disclosure of Interest: None Declared

P283 NATURAL HISTORY OF NON-SEVERE INFLAMMATORY BOWEL DISEASES AT DIAGNOSIS

C. Pirard[1,*], E. Louis[1], C. Reenaers[1]. [1]*Hepato-Gastroenterology, CHU Sart Tilman, Liege, Belgium, Liege, Belgium*

INTRODUCTION: Crohn's disease (CD) and ulcerative colitis (UC) are progressive diseases characterized by the occurrence of complications requiring immunomodulators and surgery. Few data are available for the prevalence and the factors associated with long-term non-severe (NS) inflammatory bowel diseases(IBD) .
AIMS&METHODS: Our aim was to assess the natural history of NS CD and NC UC at diagnosis and to identify predictive factors of mild evolution over the long term.
A retrospective study of the IBD patients registred in the database of the university hospital of Liège, Belgium. NS CD was defined as the absence of stricturing, penetrating or perianal disease, no treatment with immunomodulators and anti-TNF, no need for surgery in the course of the disease. NS UC was defined as no requirement for immunomodulators, anti-TNF and colectomy. Patients were assessed at 1 year, 5 years and at the maximum follow-up. Patients with less than 5 years of follow-up were excluded.
RESULTS: Among 887 patients, a subgroup of 439 CD and 173 UC were included with a mean follow-up of 19 and 15 years respectively. One year after the diagnosis 147 CD patients had NS CD. At 5 years and at the maximum follow-up respectively, 83/147 (56%) and 15/147 (10%)of the patients still had NS CD. Complications were strictures (29%), fistulizing disease (18%), perianal disease (37%). Immunomodulators and anti-TNF were required in 79% and 54% of patients respectively. Prognostic factors for persistent NS CD were older age at diagnosis (38 vs 26 years, p=0.005), no corticosteroid during the first year (p=0.036). In UC, 142 patients had NS disease one year after the diagnosis. 102/142 (72%) and 62/142 patients (44%) had NS UC after 5 years and at the maximum follow-up respectively. Surgery occurred in 19 patients (13%) after a mean time à 164 months. Immunomodulators were needed in 66 patients (47%) and anti-TNF in 37 patients (26%). NS UC was associated with absence of hospitalization for active UC over the first 5 years (p=0.009) and during the total course of UC ($p<0.0001$), no intake of corticosteroid during the first year (p=0,03).
CONCLUSION: In our cohort representing referral centre recruitment, nearly all CD patients and 2/3 of UC with NS disease at diagnosis became severe with time. Old age at diagnosis was associated with NS CD outcome while absence of hospitalisation during the first year was associated with NS UC outcome. Absence of steroid use during the first year was associated with NS outcome in both diseases.

P284 THE RELATIONSHIP BETWEEN MICROSCOPIC COLITIS AND DRUG INTAKE: AN OPEN ISSUE

D. Guagnozzi[1,*], A. J. Lucendo[1], T. Angueira[1], S. Gonzalez-Castillo[1], J. M. Tenias[2]. [1]*Gastroenterology unit, GENERAL HOSPITAL OF TOMELLOSO, Tomelloso (Ciudad Real),* [2]*Research Support Unit, HOSPITAL GENERAL LA MANCHA CENTRO, Alcazar de San Juan (Ciudad Real), Spain*

INTRODUCTION: Microscopic colitis (MC), including collagenous colitis and lymphocytic colitis, has now emerged as a common cause of chronic diarrhoea, but its aetiology remains unknown. Some studies suggest that it may be trigger by some commonly prescribed drugs.
AIMS&METHODS: To evaluate the prevalence of drug intake in patients with MC compared to chronic diarrhoea controls. We performed a case-control study with all adult consecutive patients attended for chronic diarrhoea at the Department of Gastroenterology of our hospital from April 2008 to December 2011. Complete colonoscopies with mucosal biopsies were carried out in all patients. MC was diagnosed on the basic of commonly accepted histopathological criteria. Patients with normal colonoscopy including biopsies were considered as control group. Detailed history of drug consumption was documented in every recruited patient.
RESULTS: 46 consecutive new cases of MC (25 female/21 male; median age 50.2±20.2y) and 317 consecutive chronic diarrhoea controls (196 female/ 121 male; median age 48.6±17.8y) were included. There were no significant differences regarding to age, gender, prevalence of co-morbidities, family history, smoking habit and fulfilment of the Rome III criteria for irritable bowel syndrome (IBS) among MC cases and control group. MC was more frequently associated with the presence of autoimmune diseases than in control patients (19.6% *vs.* 9.8%; $p<0.05$). Particularly, the prevalence of celiac disease was 10-folds higher among MC patients (13% *vs.* 1.3%; $p<0.05$). Some drug had been prescribed in most of patients (77.1% in MC group and 67.8% in control group; p=ns). Overall, no differences in the intake of drugs were documented between MC and control group. However, the intake of non-steroidal anti-inflammatory drugs (NSAIDs) was significantly associated with MC in the subgroup of patients aged <50 y who fulfilled Rome III criteria for IBS, compared to controls (38.5% *vs.* 10.8%; $p<0.017$), with a higher prevalence of metamizol intake among patients with MC.
CONCLUSION: MC showed association with autoimmune diseases, but not with drug intake. Only in a sub-group of patients fulfilling diagnostic criteria for IBS a significant association between MC and NSAIDs intake was documented.

P285 TREATMENT INFERRED NATURAL COURSE OF IBD IN A SOUTH EUROPEAN IBD REFERRAL CENTER.

K. Katsanos[1,*], I. Tsianos[1], V. Zampira[1], A. Tatsioni[2,3], D. Sygounas[1], I. Mitselos[1], D. Christodoulou[1], E. Tsianos[1], Northwest Greece IBD Study Group. [1]*Gastroenterology,* [2]*Family Medicine , Medical School of Ioannina, Ioannina, Greece,* [3]*Tufts University, New England Medical Center, Boston, MA, United States*

INTRODUCTION: The increasingly frequent appearance of inflammatory bowel disease (IBD) in people of all age groups has caused great concern within the scientific community since their etiology still remains unclear. So far, there is lack of studies bringing to light data on the natural history of IBD in southern Europe. We aimed to describe the treatment inferred natural course of IBD in a well-defined southern European IBD referral center.
AIMS&METHODS: We retrospectively reviewed all clinical data of our IBD patients from 1981 to 2011 (30 years) in order to overview IBD natural course, hospitalisations and pharmaceutical treatment during relapses. In our area the population is approximately 430,000 inhabitants and the migration rate is below 5%.
RESULTS: The study included data on 529 IBD patients (303 males) of whom 373 were diagnosed with UC (ulcerative colitis) and 148 with CD (Crohn's disease). We clearly recorded a CD upward trend in incidence over the past thirty years while UC incidence seems quite stable, the ratio UC:CD being currently 2.8:1. During the cumulative 30-year follow up, the majority of patients experienced 1 to 3 relapses per year (median 1.7) and these relapses were mainly treated with corticosteroids (30%), shifts to biologicals (11%) and surgeries (10%). Men relapsed more frequently compared to women (2.1 vs 1.8 relapses/year) and 36.7% of UC and 52.7% of CD required at least one hospitalization during follow up. Extraintestinal manifestations were more frequent in CD compared to UC (29.7% VS 8.8%) patients. A remarkable reduction of relapses during the last decade was observed. By contrast, in the last decade we observed a trend for more complicated and more severe CD patient cases compared to the past two decades.
CONCLUSION: In this south European IBD center UC and CD seem to have shared a rising trend for the last 30 years with a CD increasing preponderance and severity. By contrast, the number of relapses was markedly decreased during the last decade and this was probably related to the use of biologicals.

P286 TIME-RELATED BIAS IN STUDIES OF INFLAMMATORY BOWEL DISEASE INCIDENCE USING ADMINISTRATIVE HEALTH DATABASES

M. Vutcovici[1,*], P. Brassard[2], S. Suissa[2], V. Patenaude[2], M. Sewitch[3], A. Bitton[1]. [1]*Division of Gastroenterology, McGill University Health Centre,* [2]*LDI Centre for Clinical Epidemiology, Jewish General Hospital,* [3]*Department of Medicine, McGill University, Montreal, Canada*

INTRODUCTION: Administrative databases are used extensively to describe the epidemiology, burden of disease and health outcomes of chronic diseases such as inflammatory bowel disease (IBD). Time-related biases may have been introduced in studies using administrative databases to estimate the incidence of IBD.

AIMS&METHODS: To illustrate and quantify the impact of time-related bias on estimates of IBD incidence rates using multiple validated case definitions.

A population-based cohort study was conducted using the administrative databases of the Régie de l'Assurance Maladie du Québec to identify all people with an IBD diagnosis code associated with physician billings or hospital admissions during the period 1996-2009. The IBD cases occurring during follow-up were identified using 5 different case definitions validated for use with IBD administrative databases. The definitions had as criteria varying combinations of physician claims and hospital discharge summaries with an IBD diagnosis code. Two of the definitions further specified a fixed time period to meet all criteria. Age and sex standardized incidence rates for IBD were calculated for 2 distinct time periods: 1996 to 2004 and 1996 to 2009.

RESULTS: A total of 240937 Québec residents had at least one diagnosis code of IBD during 1996-2009. When disease diagnosis was considered at the first IBD contact in the data, the incidence in 2001 calculated for the 1996-2004 period using the case definitions without a fixed time to meet criteria ranged from 22 to 56 cases/100,000 person-years (p-y). Using the 1996-2009 period, the incidence in 2001 increased by 10 to 23% (range: 27 to 62 cases/100,000 p-y). The use of a two year IBD free period prior to the first IBD contact in the data slightly reduced IBD incidence but did not influence the time-related bias. The bias was significantly reduced when using the two case definitions which specified a fixed time period for meeting the criteria. There was no time-related bias in estimates for the 1996-2004 period when disease diagnosis was considered at the time all criteria were met.

CONCLUSION: Time-related bias in estimates of disease occurrence can be minimized in administrative health database research when disease diagnosis is considered at the moment when all criteria are met, regardless of the case definition used. Implementing a disease free period is recommended to avoid overestimating the incidence rates.

P287 THE PRESENCE OF PERIANAL DISEASE IN PATIENTS WITH OROFACIAL GRANULOMATOSIS INCREASES THE RISK OF DEVELOPING INTESTINAL CROHN'S DISEASE

R. Goel[1,*], K. V. Patel[1], V. Kariyawasam[1], M. Ward[1], S. Nayee[2], N. Shah[2], P. Blaker[1], M. Escudier[2], S. Anderson[1], P. Irving[1], J. Sanderson[1]. [1]*Gastroenterology, St Thomas' Hospital,* [2]*Oral Medicine, Guys & St Thomas' Hospitals, London, United Kingdom*

INTRODUCTION: Orofacial Granulomatosis (OFG) is a rare chronic inflammatory condition of unknown aetiology, characterised by lip swelling, orofacial erythema and ulceration. A proportion of OFG patients present with perianal disease in conjunction with their oral disease ('top and tail' disease). Perianal disease occurs in approximately one-third of Crohn's Disease (CD) patients and is associated with significant morbidity and a more severe disease course[1]. Perianal disease has been shown to occur in 12% of patients with ileal CD (L1), 41-92% of colonic CD (L2) and 15% of ileocolonic disease (L3)[2].

AIMS&METHODS: We retrospectively analysed a database of OFG patients. Patients with perianal disease were identified and compared to patients without perianal disease. The Montreal classification was used to classify the sites of patient's CD. We set out to determine how many of our OFG patients had concurrent perianal disease and how many of them developed intestinal CD.

RESULTS: 263 patients with OFG were identified, of which 208 patients (79.09%) had OFG only and 55 patients (20.91%) had concurrent intestinal CD. 36 patients (13.69%) had intestinal CD and no perianal disease. 19 patients ((7.22%) 13 male, median age 38 (IQR 25-49)) had intestinal CD and concurrent perianal disease.

Within the perianal group, all patients had concurrent intestinal CD. The commonest sites were colonic (L2)(8/19; 42.11%) and ileocolonic (L3)(8/19; 42.11%). The ileum (L1) was affected in 1 patient (1/19; 5.26%) and 2 patients had concomitant upper gastrointestinal CD with ileocolonic disease (L3+L4)(2/19; 10.53%).

The presence of OFG and perianal disease significantly increased the chances of developing intestinal CD (OR = 222, p = 0.0002, 2-tail Fisher Test).

In the perianal group, 11/19 patients (11/19; 57.89%) were diagnosed with CD prior to developing OFG. The median time to diagnosis of OFG was 10 years after the diagnosis of intestinal CD.

CONCLUSION: Perianal disease in Crohn's disease is common and is associated with a more severe disease course.[1] Perianal disease in OFG patients is less common, however, where it does occur it is always associated with intestinal CD in our cohort. Therefore, these patients should be investigated accordingly.

P288 THE ROLE OF SERUM BETA 2 MICROGLOBULIN IN EVALUATING DISEASE ACTIVITY IN INFLAMMATORY BOWEL DISEASE

B. Yilmaz[1,*], O. Yüksel[1], S. Köklü[1], S. Arslan[1]. [1]*gastroenterology, hacettepe university school of medicine, ankara, Turkey*

INTRODUCTION: The inflammatory bowel diseases (IBD) are chronic inflammation of the digestive tract. The mucosa of the colon and small intestine of patients are common lymphoplasmacytoid cell infiltration. The inflammatory markers plays role in this inflammatory reaction such as lymphokines, cytokines and leukotriene. Beta 2 microglobulin (β2M) is a low molecular weight protein mainly released from activated lymphocytes. . Erytrocyte sedimantation rate (ESR), white blood cell count (WBC) and C-reactive protein (CRP) are known to be good predictors of disease activity in IBD. Serum β2M levels increase in all chronic inflammatory and autoimmune disease. This increase is linked to the severity and extant of inflammation.

AIMS&METHODS: In the study we examined β2M serum levels in patients suffering from IBD, to assess the extent of the disease and the possible correlation between these serum levels and the activity of IBD. Overall, 78 IBD patients and 30 healthy controls were enrolled. We examined β2M serum levels in 43 ulcerative colitis (UC) patients, 35 with Crohn's disease (CD) and 30 control subjects, using an enzymatic method. UC and CD patients were divided into two groups according to disease activity: Active and remission. Subjects were divided into two groups according to extend of disease: Left and pancolitis for UC ; İleitis and ileocolitis for CD. All groups were compared for the mean serum β2M levels.

RESULTS: Mean β2M values were significantly higher in UC and CD patients than in healthy controls. Mean β2M values were significantly higher in IBD activity than remission. The difference between groups (UC and CD) in terms of serum β2M levels was statistically insignificant

CONCLUSION: Serum β2M levels may be used as indicator to demostrate disease activity in patient with İBH.

P289 IS THERE A DIURNAL VARIATION IN FAECAL CALPROTECTIN IN INFLAMMATORY BOWEL DISEASE PATIENTS?

C. Dobrzanski[1,*], N. Pedersen[1], V. Voxen Hansen[2], H. Fuglsang[2], P. Munkholm[1]. [1]*Department of Gastroenterology,* [2]*Gastroenterology Research Laboratory, Herlev University Hospital, Copenhagen, Denmark*

INTRODUCTION: Faecal calprotectin (FC) exhibits day to day variability in healthy subjects [1] and in patients with Crohn's disease [2;3]. However, the diurnal variation of FC in ulcerative colitis (UC), Crohn's Disease (CD) and in healthy controls has not yet been studied.
AIMS&METHODS: To investigate the magnitude of FC diurnal variation in inactive (SCCAI$\leq$2) and active (SCCAI$>$2) UC patients, inactive (HBI$\leq$5) and active (HBI$>$5) CD patients and in healthy controls.
Inflammatory bowel disease (IBD) patients were consecutively recruited from the out-patient clinic at Herlev Hospital during 2012. Controls were healthy healthcare workers and friends. All study subjects were asked to deliver a faecal sample from each stool they had during 3 days. Time and date had to be provided for each sample before sending them by post to the gastroenterology research laboratory for FC analysis by ELISA (CALPRO Inc.). The subject's individual FC diurnal variation was defined as the largest difference between the highest (FC high) and the lowest (FC low) FC values on the same day. Statistical analysis was done by non-parametric Wilcoxon signed-rank and Kruskal-Wallis tests.
RESULTS: A total of 514 FC samples were collected from 51 IBD patients (15 inactive UC (UCI), 14 active UC (UCA), 12 inactive CD (CDI), 10 active CD (CDA); total 55% female) and 30 healthy controls (53% female).

	UCI	UCA	CDI	CDA	Healthy controls
FC diurnal variation, mg/kg (mean ±SD)	229 ±295	581 ±573	137 ±117	289 ±234	18,2 ±20,9
Mean FC, mg/kg (mean ±SD)	237 ±352	752 ±611	371 ±434	232 ±277	20,4 ±24,3
FC high, mg/kg (mean ±SD)	337 ±388	899 ±640	463 ±451	504 ±428	29,8 ±33,0
FC low, mg/kg (mean ±SD)	108 ±135	318 ±332	326 ±399	215 ±317	11,65 ±15,7
Defecations per subject per day (mean ±SD)	2,4 ±0,8	3,3 ±2,7	2,4 ±0,8	3,9 ±2,0	1,8 ±0,5
No. of FC tests	83	106	74	92	159

FC diurnal variation in healthy controls differed significantly from UCI (p=0,001), UCA (p$<$0,0001), CDI (p=0,018) and CDA (p$<$0,0001). Mean FC in healthy controls differed significantly from UCI (p$<$0,0001), UCA (p$<$0,0001), CDI (p$<$0,0001) and CDA (p$<$0,0001). Mean FC in UCA differed significantly from UCI (p$<$0,0001), CDI (p$<$0,032) and CDA (p=0,001).
CONCLUSION: FC diurnal variation in healthy controls is negligible. In both inactive and active CD patients and in inactive UC patients the FC diurnal variation is acceptable when monitoring disease activity by FC in routine clinical practice. In UC patients with active disease, FC diurnal variation is substantial and clinically considerable. We suspect, however, that blood, pus and mucus in the stool could influence FC levels in these patients. Further studies are needed to clarify this issue.

P290 ASSESSMENT OF DAILY PHYSICAL ACTIVITY IN PATIENTS WITH CONTROLLED INFLAMMATORY BOWEL DISEASE - RELATIONSHIP WITH DISEASE PHENOTYPE AND OSTEOPOROSIS OR OSTEOPENIA

C. M. Bastos[1], W. D. S. Briza[1], F. J. A. de Paula[1], L. E. A. Troncon[1,*]. [1]*Medicine, University of Sao Paulo, Ribeirao Preto, Brazil*

INTRODUCTION: Physical activity (PA) has been thought as having beneficial effects in patients with inflammatory bowel disease (IBD), including the

prevention of low bone mineral density [1]. Nevertheless, knowledge concerning the relationships between PA and phenotype and occurrence of bone metabolic disease in IBD is still limited.
AIMS&METHODS: This study aimed at evaluating daily PA in IBD patients and control volunteers using a standard inventory, and at determining differences regarding PA between subgroups of IBD patients stratified according to phenotype and the presence of osteoporosis or osteopenia. Crohn's disease (CD, N=35) and ulcerative colitis (UC, N=25) patients in remission or low disease activity and healthy controls (N=42) answered the long form of the International Physical Activity Questionnaire [2]. Results were expressed as minutes/week in four domains (work, transportation, home and leisure), and classified in three grades (walking, moderate or vigorous). IBD patients also underwent dual X-ray absorptiometry scanning to detect osteoporosis or osteopenia. CD and UC patients were stratified regarding disease extent and the presence or absence of osteopenia or osteoporosis. CD patients were further stratified according to disease behavior.
RESULTS: Total daily PA in CD patients were lower than in the UC group in the four domains assessed, but differences were not statistically significant. PA levels in DC patients in the leisure domain were significantly lower than in controls (164±491 min/week vs. 686±1069 min/week; $p < 0.01$). Also, the proportion of CD patients exerting total daily vigorous activity was lower than in controls (10/35 vs. 20/42), but again statistical significance was not reached (p=0.10). In CD there were no differences concerning PA between patients with and without stenosing or penetrating behavior, as well as between patients with ileal or ileocolonic CD compared to those with exclusive colonic disease. In UC, there was no difference in total daily PA between patients with pancolitis and those with left-side colitis or proctitis. Both CD and UC patients with osteoporosis or osteopenia had lower levels of total daily PA, but statistical significance was not reached ($p > 0.05$).
CONCLUSION: Physical activity in controlled ulcerative colitis seems to be less affected than in Crohn's disease. In controlled IBD patients there seems to be no relationships between physical activity and disease phenotype. Lower levels of daily physical activity in IBD patients seem to be associated with osteopenia and/or osteoporosis, which suggest a role for this factor in the reduction of bone mineral density.

P291 CLINICAL DECISION MAKING IN CROHN'S DISEASE USING SMALL INTESTINE CONTRAST ULTRASONOGRAPHY

E. Calabrese[1,*], F. Zorzi[1], E. Stasi[1], S. Onali[1], E. Lolli[1], G. Condino[1], C. Petruzziello[1], L. Biancone[1], F. Pallone[1]. [1]*Gastroenterology Unit, University of Roma of Tor Vergata, Rome, Italy*

INTRODUCTION: While there is sufficient data to support the use of small intestine contrast ultrasonography (SICUS) as a valuable and radiation-free tool in the detection of intestinal damage of small bowel Crohn's disease (CD), there is limited data showing its impact on patient management. Our aim was to evaluate whether SICUS has an impact in the clinical management of CD.
AIMS&METHODS: We performed a retrospective analysis of data from patients with CD who underwent SICUS through one year (2011) and were followed up for at least one year. A total of 216 CD pts (121 M; median age 44 yrs; disease duration: median 139 mos; CD site: ileal in 171 pts, ileo-colonic in 45 pts; CD behavior: non-stricturing non-penetrating in 77 pts, penetrating in 44 pts, stricturing in 95 pts; previous ileocolonic resection in 113 pts) were included. CD therapy at the time of the examination included: 49% on mesalamine, 26% on steroids, 1% on antibiotics, 8% on thiopurines, 13% on biological drugs, 2% on SMAD7 antisense oligonucleotide (GED0301), and 1% no therapy. Indications of patient evaluations were assessment of disease activity, obstructive symptoms, pre-surgical evaluation, and monitoring therapy.
RESULTS: After SICUS variation in clinical management was made in 109/216 pts (50.5%). Eighteen pts underwent surgery and 91 pts experienced changes in medical therapy. Twenty-seven out of 91 pts started a steroid course; 14 pts started an antibiotic course; 20 pts were treated with immunosuppressives. Twelve pts started biological treatment. Six pts optimized anti-TNFs maintenance dose. Three pts stopped biological therapy and one pt switched from Adalimumab to Infliximab. Eight pts were enrolled in the clinical trial GED0301. After SICUS median time of follow-up of pts who underwent a change in clinical management was 15.9 mos. One hundred and seven pts continued their treatment after SICUS with a median time of follow up of 16.4 mos. Abnormal sonographic findings (bowel wall thickness, lesion extent, stenosis with or without dilation, fistula, and abscess) yielded significantly more in the group who experienced a change in clinical management compared with pts who continued previous treatment (p=0.001).
CONCLUSION: More than half CD pts had a change in clinical management on the basis of SICUS. SICUS is a non-invasive, radiation-free and easily available imaging modality therefore its use might be implemented as part of a focused diagnostic examination in CD.

P292 COLONIC MUCOSAL HEALING IN IBD PATIENTS DURING CLINICAL REMISSION. A PROSPECTIVE STUDY USING COLONOSCOPY, CONFOCAL LASER ENDOMICROSCOPY (CLE) AND HISTOLOGY

E. Coron[1,*], J.-P. Galmiche[1], A. Boureille[1], D. Moussata[2], J. Branche[3], J.-F. Mosnier[1], T. Matysiak-Budnik[1]. [1]*CHU Nantes, Nantes,* [2]*CHU Lyon,* [3]*CHRU Lille, Lyon, France*

INTRODUCTION: In IBD, mucosal healing seems associated with a lower relapse rate. Very few studies have used confocal laser endomicroscropy (CLE).
AIMS&METHODS: Our aims were: 1) to prospectively assess and characterize the inflammatory pattern of colonic lesions in IBD patients during full clinical remission, 2) to compare results of real-time CLE with classical histology.
73 patients (44 years, 35 males) with ulcerative Colitis (n=41), Crohn's Disease (n=29), or indeterminate (n=3) gave their informed consent. All patients had long duration IBD (18.4 years) and were in clinical remission (Harvey-Bradshaw < 3 or CDAI < 150). Colonoscopy was performed first, followed by CLE (with fluorescein). Colon was divided in 4 segments and systematic optical biopsies were taken. Then, biopsies were obtained at the same spots for histology (30 to 40 in total). Inflammatory lesions were scored according to previously defined grades.
RESULTS: Among 73 patients, 18 were excluded from the analysis for various reasons (2 stenosis, 2 CLE technical failures, 14 others). Out of remaining 55 patients, 16 showed mucosal erosions or ulcerations at colonoscopy. Among the 39 patients completely healed, only 10 had no inflammatory lesions at both CLE and histology. Finally, in 29 patients, despite complete healing at colonoscopy, various degrees of inflammation persisted in at least one segment. Globally the results of CLE and histology were well correlated with only 5 cases of major discrepancy. The procedures were well tolerated.
CONCLUSION: 1) Despite complete healing at endoscopy, the majority of IBD patients in remission still have inflammatory lesions at microscopic examination. The role of this residual inflammation in further relapse of IBD remains to be further elucidated. 2) Since the information obtained by CLE is well correlated with routine histology, CLE may help better characterize the phenotype of patients in remission as well as reduce the need for numerous biopsies.

P293 RESTORATION OF HEALTH RELATED QUALITY OF LIFE IN CROHN'S DISEASE PATIENTS WITH ADALIMUMAB MAINTENANCE THERAPY.

F. Casellas[1,*], V. Robles[1], A. Torrejón[1], E. Navarro[1], E. Ruiz[1], N. Borruel[1]. [1]*Unitat Atenció Crohn-Colitis, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

INTRODUCTION: In Crohn's disease (CD), adalimumab maintenance therapy provides sustained clinical remission and improvement of health related quality of life (HRQOL). However, there is scarce information about its long-term effect on HRQOL and whether it is able to induce a sustained restoration of normal patient's perception of health.
AIMS&METHODS: AIMS: To determine HRQOL and restoration of normal perception of health in patients with adalimumab induced long-term CD clinical remission. METHODS: Observational study in patients with CD in clinical remission (CDAI index < 150) for at least 12 months, treated with long-term adalimumab 40 mg every other week, with or without thiopurines. Patients were followed each year during 4 years or until clinical relapse (CDAI index > 150), intensification or surgery was needed. HRQOL was evaluated with the specific IBDQ-36 items version validated to Spanish. Restoration of health was defined as an overall IBDQ score ≥ 209 [JCC 2010;4:637-41]).
RESULTS: From 63 eligible patients, 43 patients with CD in stable clinical remission sustained over one year were included. During the follow-up, at 12 months 43 patients remained in remission, at 24 months 30 patients, at 36 months 15 and in the last visit at 48 months remained 9 patients in clinical remission. Overall score of IBDQ-36 remained unchanged in patients with stable inactive CD, even with a tendency to score better with time (median global score of 226 at 12 months and 241 at 4 years). Restoration of health increased with time (72 % to 100 % at 1 and 4 years follow-up respectively).
CONCLUSION: Sustained clinical remission of CD achieved with maintenance adalimumab treatment restores HRQOL, which remains stable at long-term follow-up.

P294 LONG-TERM PROGRESSION OF BOWEL DAMAGE IN CROHN'S DISEASE PATIENTS TREATED WITH ANTI-TNF THERAPY: A PROSPECTIVE OBSERVATIONAL COHORT STUDY.

G. Fiorino[1,*], C. Bonifacio[2], P. Naccarato[1], F. Mrakic Sposta[2], L. Balzarini[2], A. Spinelli[3], S. Danese[1]. [1]*IBD Center,* [2]*Radiology,* [3]*Surgery, IRCCS Humanitas, Rozzano, Italy*

INTRODUCTION: Crohn's disease (CD) leads to complications and consequent bowel damage (BD). Magnetic resonance imaging (MRI) can assess BD and its progression during disease course. There are no data on the role of current medications on CD-related damage progression.
AIMS&METHODS: We aimed to explore the long-term progression of BD in a cohort of CD patients treated with anti TNF. This was a prospective observational cohort study on consecutive CD subjects followed within 3 years. They all underwent an abdominal MRI and colonoscopy, and a pelvic MRI in case of

perianal disease, before starting anti-TNF therapy and then each year. CD-related BD at baseline and at follow-up was graded by a semiquantitative scale from 0 to 3 for strictures, abscesses and penetrating lesions per bowel segment. BD progression and regression were defined as an increase or a reduction in the sum of scores from baseline, respectively. The primary outcome was to assess the progression of BD. Secondary outcomes were to assess the role of MRI findings in detecting and predicting BD progression, and the rate of surgery and its correlation with damage progression. Statistical analysis included χ^2 test, logistic regression and survival analysis by Kaplan-Meyer curves and log-rank test. Any difference was considered statistically significant if $p<0.05$.

RESULTS: Twenty-eight CD patients were enrolled,11 infliximab (IFX), 17 adalimumab (ADA). The mean baseline damage score in the whole study population was 4.19 (range 0.19-32.42). Ten subjects (35%) had perianal disease. Mean follow up was 35 months. At follow-up, 67.9% had BD regression (IFX=9; ADA=6), while 29.6% of had BD progression (IFX=2; ADA=6),. Mean difference in the BD score between baseline and follow-up was -0.30 (range -0.28-1.92). Seven subjects (25%) of the whole population had major bowel surgery due to symptomatic complications (IFX=2; ADA=5), 2 for refractory disease, and 5 for stricturing and penetrating disease. Subjects with BD progression were more likely to undergo major surgery in the following 12 months (HR 0.23, CI 95% 0.02-0.87, p=0.03). MRI findings suggestive for BD alone was significantly predictive of global BD (OR 30.0, CI 95% 2.5-354, p=0.007). No other significant predictive factors of surgery were found. No statistically significant differences were found between IFX and ADA.

CONCLUSION: In the majority of subjects treated by anti-TNF, a reduction of BD can be achieved in the long term. BD progression assessed by MRI is predictive of major surgery within 12 months.

P295 CORRELATION BETWEEN ADALIMUMAB TROUGH SERUM CONCENTRATION, ANTI-ADALIMUMAB ANTIBODIES AND TNF-A LEVELS WITH CLINICAL OUTCOME IN PATIENTS AFFECTED BY CROHN'S DISEASE

G. Bodini[1,*], V. Savarino[1], P. Dulbecco[1], L. Assandri[1], E. Savarino[2].
[1]*Department of Internal Medicine, Gastroenterology Unit, University of Genoa, Genoa,* [2]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, Italy*

INTRODUCTION: Few data are available on the role of Adalimumab (ADA) trough serum concentrations and anti-ADA antibodies (AAA) in influencing the therapeutic response of Crohn's Disease (CD), and even less, on the importance of analyzing TNF-α serum levels in ADA-treated patients during long-term follow-up

AIMS&METHODS: To evaluate the course of ADA trough serum concentrations, AAA formation and TNF-α serum levels and their clinical relevance during a long-term follow-up period of patients with CD.

In this prospective study, 21 consecutive CD patients (13M/8F; mean age 41), who achieved remission and in maintenance treatment with ADA, were included in a 2-years follow-up program. Blood samples were drawn at standardized time points (at 6, 12, 18, 24 months and in case of CD relapse) just before ADA injection. Trough ADA serum concentrations and AAA were measured using an enzyme-linked immunosorbent assay (Matriks biotek). Moreover, TNF-α serum levels were measured using a human TNF-α ELISA (DIACLONE). Disease activity was assessed at the same time points by means of the Harvey-Bradshaw Index (HBI; remission <5, mild disease 5-7, moderate disease 8-16, severe disease >16) and CRP blood level (normal if <5 mg/L).

RESULTS: During follow-up, 16 (76%) patients maintained clinical remission and continued ADA therapy until 96 weeks, while 5 (24%) patients withdrew ADA because of perianal abscess development (n=1) and lack of response despite escalation of ADA administration (n=4). At the time of recurrence, patients who relapsed had lower median ADA serum concentrations compared to those in remission [3.7 mcg/ml (range 0.0-6.1) vs. 7.8 mcg/ml (6.8-9.1), (p=0.0001)]. There was a good correlation between ADA serum concentration and disease activity expressed by HBI (r^2=0,6583, $p<0.001$). Values of CRP were higher in patients who relapsed than in those in remission [(3.3 mg/l (0.8-4.8) vs. 8.3 (3.3-36.2)] (p=0.0018). In addition, median TNF-α serum levels were not different between these two groups (51.4 pg/ml [1-143.2] vs. 28.1 [3.3-72.9], p=0.1). No correlation was found between ADA serum concentrations and TNF-α levels (r^2=0,0084, $p<0.692$). AAA were found in only 2 (9%) patients and did not affect ADA serum concentrations (8.8 mcg/ml before and after AAA development) and outcome.

CONCLUSION: Earlier ADA therapy discontinuation and disease relapse correlated well with lower ADA serum concentrations during a 2 year follow-up period. The measurement of TNF-α serum levels seems of limited value in the management of CD patients and ADA efficacy. Development of AAA does to not influence ADA serum concentrations and good outcome.

P296 SCREENING FOR DYSPLASIA AND COLORECTAL CANCER IN ULCERATIVE COLITIS

H. Saoula[1,*], A. F. Boutaleb, M. Aissaoui, H. Mahiou, A. Salah, Y. Zmiri, F. Chemandji, D. Hamidouche, L. Malaoui, R. Osmane, K. Belhocine, L. Gamar, N. Aliarous, L. Kecili, N. Bounab, F. Asselah, H. Asselah, N. Baiod, T. Boucekkine, ZC. Amir, M. Nakmouche. [1]*gastroenterology, CHU de bab el oued, bab el oued, Algeria*

INTRODUCTION: Patients with longstanding extensive ulcerative colitis have an increased risk of colorectal cancer.

AIMS&METHODS: The aims of this study were:

To determine the incidence of dysplasia and colorectal cancer, in patients with longstanding ulcerative colitis

To evaluate the proportion of dysplastic lesions detected from targeted biopsies of macroscopically visible abnormalities, as opposed to non-targeted biopsies of colonic mucosa.

In this prospective study, consecutive patients with clinically inactive, longstanding UC (8 years) were recruted from 3 centers; colonoscopy with chromoendoscopy using 0.1% methylene blue was performed for each patient.

Four mucosal biopsy specimens were taken every 10 cm between the coecum and the rectum, with additional biopsies or removal of any abnormality mucosal. All the endoscopy were performed by a single endoscopiste, all the biopsies have beneficied of a second lecture by a pathologist experienced in gastroenterology

RESULTS: 177 chromoendoscopy were performed in 100 patients (45 men and 55 women); Median age of patients at inclusion was 50 years (range 22–78); median age at onset of ulcerative colitis was 34,4 years (range 15–66); and the median duration of colitis was 15.70 years ±6.79 .

The proximal extent of macroscopic inflammation at diagnostic of ulcerative colitis was pancolonic in 50 patients (50%), Left-sided colitis in 26 (26%), Proctosigmoiditis 24 (24 %)

Overall, 324 suspicious mucosal areas were biopsied or removed in 76 patients: there were 5 adenocarcinomas,3 high grade dysplasia with 2 DALM , 14 low grade dysplasia, 5 villous adenomas with low grade dysplasia, 7 serrated adenomas, and 289 post-inflammatory polyps.

Non-targeted quadrantic biopsies detected: high grade dysplasia in one patient and low grade dysplasia in 5 patients.

A total of 33 neoplastic lesions were identified in 25 patients (25%): 5 adenocarcinomas and 28 dysplasia. 81.81% of these lesions were macroscopically visible at colonoscopies, whereas18.18% were detected only by random biopsies. All the adenocarcinomas were perfectly visible at endoscopy before coloration

Dysplasia was endoscopically visible in 22 patients, in 2 patients dysplasia was detected both by random biopsies and target biopsies; in 3 patients dysplasia was invisible at endoscopy, detected only by random biopsies.

CONCLUSION: Colonoscopic surveillance is actually the only way to detect colorectal cancer at an early stage in ulcerative colitis

P297 EVALUATION OF MUCOSAL INFLAMMATION OF CROHN'S DISEASE OR ULCERATIVE COLITIS BY A QUANTITATIVE FECAL IMMUNOCHEMICAL TEST

H. W. Hwang[1,*], H.-S. Kim[1], H. Y. Ryu[1], J. W. Kim[1], H. J. Park[1], Y. Z. Cho[1].
[1]*Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Wonju, Korea, Republic Of*

INTRODUCTION: Colonoscopy is gold standard for evaluating colon mucosal inflammation in Crohn's disease (CD) or ulcerative colitis (UC). But it is invasive, time-consuming and expensive test. Quantitative fecal immunochemical tests (FITs), which have been used recently to screen for colorectal neoplasia are rapid, easy and economic method.

AIMS&METHODS: The aim of this study is to determine whether quantitative FIT can reflect the colonic mucosal inflammation in CD or UC patients. Feces collected from CD or UC patients who underwent colonoscopy were examined by FITs, and results were compared with colonoscopic findings. Mucosal inflammation status was assessed using the simple endoscopic score for Crohn's Disease (SES-CD) in CD and the Mayo endoscopic subscore classification in UC.

RESULTS: FIT results were evaluated in conjunction with 70 colonoscopies that were performed in 55 CD patients and 118 colonoscopies in 99 UC patients. When the positive FIT was defined as $\geq$100 ng/ml, the proportion of positive FIT results increased with increased in the SES-CD (SES-CD 0-3: 17.4%, SES-CD 4-10: 54.2%, SES-CD 11-19: 60.0% and SES-CD$\geq$20: 100%, $p<0.001$, Chi Square test for trend) and Mayo endoscopic subscore (Mayo 0: 0%, Mayo 1: 33.3%, Mayo 2: 65.8% and Mayo 3: 88.2%, $p<0.001$, Chi Square test for trend). The mean of SES-CD and Mayo endoscopic subscore were significantly different according to the quantitative levels of FIT (One way ANOVA, $p<0.001$). When mucosal inflammation was defined as SES-CD$\geq$4 and Mayo 2 or 3, the sensitivity, specificity, positive predictive value and negative predictive value of a positive FIT for mucosal inflammation were 63.8%, 82.6%, 88.2% and 52.8% in CD and 76.4%, 71.7%, 80.9% and 66.0% in UC, respectively.

CONCLUSION: The FITs could be a potential alternative method for crude evaluating and monitoring mucosal inflammation.

P298 QUALITY OF LIFE IN INFLAMMATORY BOWEL DISEASE PATIENTS: CLINICAL, DEMOGRAPHIC AND SOCIAL FACTORS

J. L. T. Magalhães[1,*], F. Dias de Castro[1], P. Boal[1], M. J. Moreira[1], S. Leite[1], J. Cotter[1]. [1]*Serviço de Gastrenterologia, CENTRO HOSPITALAR DO ALTO AVE - GUIMARÃES, Guimarães, Portugal*

INTRODUCTION: Inflammatory Bowel Disease (IBD) causes physical, psychological and social consequences that can affect the Quality of Life (QOL) of patients.
AIMS&METHODS: The aim of our study was to analyze the relationship between clinical, demographic and social factors and the QOL in patients with IBD. A total of 150 patients, 98 with Crohn' disease and 58 with ulcerative colitis, filled in a specific questionnaire to assess QOL in IBD patients (Inflammatory Bowel Disease Questionnaire, IBDQ-32) and a questionnaire to collect demographic and clinical data.The association between categorical variables and IBDQ-32 scores was determined using Student t test. Factors statistically significant in the univariate analysis were included in multiple linear regression model. The statistical level of significance was established at 5%. Statistical analysis was performed with SPSS (version 18.0).
RESULTS: Univariate analysis revealed QOL scores significantly lower in patients with an individual perception of a lack of awareness of co-workers ($p < 0.001$), decreased employment success ($p < 0.001$) and need for psychological support ($p = 0.010$). Female patients ($p < 0.001$), patients requiring pharmacological treatment of anxiety or depression ($p = 0.002$) or that resorted to alternative therapies ($p = 0.027$) also presented with significantly lower QOL scores. A multiple linear regression analysis identified as significant predictors of impaired QOL female gender ($p < 0.001$), individual perception of a lack of awareness of co-workers ($p = 0.037$) and decreased employment success ($p = 0.001$). This model was highly significant ($p < 0.001$) and explained 32.3% of the variation in QOL scores in patients with IBD.
CONCLUSION: The decrease in quality of life was significantly related with female gender and personal perception of disease impact in success and social relations. These factors deserve a special attention, so timely measures can be implemented in other to improve the quality of life of these patients.

P299 MEASUREMENT OF FECAL CALPROTECTIN IN ULCERATIVE COLITIS: CORRELATION TO ULCERATIVE COLITIS ENDOSCOPIC INDEX OF SEVERITY, MAYO ENDOSCOPIC SCORE AND HISTOLOGICAL INFLAMMATORY ACTIVITY SCORE

K. Theede[1,*], S. Holck[2], P. Ibsen[2], I. Nordgaard-Lassen[1], A. Mertz Nielsen[1]. [1]*Gastrounit, Medical Section,* [2]*Department of Pathology, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark*

INTRODUCTION: Mucosal healing in ulcerative colitis (UC) has emerged as a treatment goal in international guidelines because mucosal healing implies decreased risk of relapse. Therefore reliable non-invasive methods to assess the grade of inflammation and mucosal healing need to be developed and validated. In this study we evaluate the correlation between fecal calprotectin (FC) and two endoscopic score modalities as well as histological inflammatory activity score.
AIMS&METHODS: In a prospective cross-sectional study, 54 patients including subjects with both clinically active and inactive UC underwent sigmoidoscopy. Mayo Endoscopic Score (MES) and the newly developed Ulcerative Colitis Endoscopic Index of Severity (UCEIS) were used to evaluate the endoscopic inflammation. Rectal biopsies were evaluated for the grade of inflammation using a histological activity score with 4 categories based on the extent of cryptitis, crypt abscesses and the presence of erosions/ulcers. Prior to the sigmoidoscopy stool samples were obtained and FC was determined. We used Kruskal-Wallis test to compare FC with MES and histology and linear regression to compare FC with UCEIS. Wilcoxon Rank Sum Test was used to compare FC between groups.
RESULTS: The median age was 38 years, 32 (59%) were female and the median disease duration was 6 years. 23 (43 %) had endoscopic remission. We found a significant difference in FC between the MES-groups (0-3) (Chi-square=24,4090, p=<0,0001) and in FC between the histological groups (0-3) (Chi-square=19,3668, p=0,0002). We found a significant relationship between FC and UCEIS with an estimate (slope) for UCEIS on 376,18 g/kg (CI95%: 268,13;484,24 g/kg, p=<0.0001). Specifically we found a significant difference in FC between MES=0 and MES=1 (p=0,0088) as well as between UCEIS=3 and UCEIS=4 (p<0,0001)
CONCLUSION: We compared FC with MES, UCEIS and histological inflammatory activity score and in all cases significant correlations was demonstrated. The correlation between FC and MES has been shown in previous studies and confirmed by our data. Especially we found that FC is able to discriminate between MES 0 and 1 as well as between UCEIS 3 and 4, an important message regarding the evaluation of mucosal healing. Studies comparing FC with UCEIS and histological inflammation are lacking but in our study significant correlation between both of them were obtained. With mucosal healing as an important treatment goal in ulcerative colitis FC might have a place in determining the grade of inflammation and achievement of mucosal healing.

P300 FETAL RISKS IN INFLAMMATORY BOWEL DISEASE PREGNANT PATIENTS. A PROSPECTIVE STUDY

L. Kecili[1,1,*], A. Balamane[1], N. Bounab[1], M. Nakmouche[1], A. Bousseloub[1], K. Belhocine[1], N. Kaddache[1], L. Gamar[1], K. Layaida[1], N. Debzi[1], N. Afredj[1], N. Guessab[1], T. Boucekkine[1]. [1]*Faculty of Medicine, Algiers, Algeria*

INTRODUCTION: During pregnancy(P) of inflammatory bowel disease (IBD) patients ,fetal risk is generally considered as low.
AIMS&METHODS: To evaluate influence of IBD on P,we have in a 5-year follow-up prospective study, compared the fetal prognosis in pregnant IBD patients to that of a control group (CG) of 104099 non IBD pregnant women who have had 1 or several pregnancies during the same period.Fetal risk was assessed for the last P by evaluating,in the two groups,the rate of normal childbirth ,abortions,premature births,stillbirths,low birth weight and congenital abnormalities.In IBD patients outcome of P was also evaluated as regards to the evolutive statute of the disease at conception and to their gestational status;Statistical analysis:Student Fisher's test and Mann Whitney's U test.
RESULTS: Regarding the last pregnancy :1/The rate of caesareans was surprisingly lower in UC patients than in the CG (7,1% vs 23,3%; p=0,0001);In return abortions (3,6% vs 3%; p=0,9244),premature births (6,2% vs 4%; p=0,3441), stillbirths (1,8% vs 1,4%; p=0,9663),low birth weight (8% vs 5,2%; p=0,2624) were more frequent in UC patients but they did not reach SSD.2/The same results were found in CD vs CG pregnant patients:caesareans (11,8% vs 23,3%; p=0,045), abortions (7,1% vs 3% ; p=0,0236), stillbirths (1,8% vs 1,4% ;p=0,9147), premature births (6,2% vs 4%; p=0,3441), low birth weight (8,5% vs 5,2%;p=0,1742). 3/Caesareans and abortions rates were higher in CD than in UC ;11,5% vs 7,1% (p=0,3662) and 7,1% vs 3,6% (p=0,3859) respectively but didn't reach SSD.Concerning the whole number of pregnancies after onset of the disease:1/Complications were more frequent in primiparous than in multiparous UC and in CD pregnant patients:caesareans (UC:19,2% vs 2,7%: p<0,0001; CD:35,7% vs 6,7%: p<0,0001), stillbirths (UC=3,8% vs 1%; p<0,2237; CD=3,6% vs 1,7%, p=0,9528), congenital abnormalities (UC = 3,8% vs 0%, p=0,0318; CD=3,6% vs 0,5%, p=0,5947). Those complications seem to be due to the gestational status himself than to IBD as they were found to the same extent in the CG.2/Fetal risk was proportional to the disease activity at conception in UC as well as in CD pregnant patients.
CONCLUSION: During P of IBD patients fetal risk is relatively low as well in UC as in CD.Complications are proportional to the level of disease activity at conception and seems to be higher in primipary pregnant IBD patients.

P301 LEVELS OF ANTI-DOUBLE-STRAINED DNA BUT NOT ANTINUCLEAR ANTIBODIES IN PATIENTS WITH IBD TREATED BY ANTI-TNFS ARE ASSOCIATED WITH ADVERSE OUTCOMES

L. S. Kiss[1,*], B. D. Lovasz[1], P. A. Golovics[1], Z. Vegh[1], K. Farkas[2], T. Molnar[2], K. Palatka[3], A. Mohas[1], B. K. Szilagyi[1], S. A. Fekete[1], P. L. Lakatos[1]. [1]*1st Department of Medicine, SEMMELWEIS UNIVERSITY, Budapest,* [2]*1st Department of Medicine, University of Szeged, Szeged,* [3]*2nd Department of Medicine, University of Debrecen, Debrecen, Hungary*

INTRODUCTION: Treatment of Crohn's disease (CD) by infliximab has been associated with the induction of antinuclear (ANA) and anti-double stranded DNA (dsDNA) autoantibodies and in some studies the formation of dsDNA antibodies was associated with lupus-like syndromes.
AIMS&METHODS: The aim of this study was to analyze the relationship between the development ANA and ds-DNA antibodies during anti TNF therapy and adverse outcome (LOR, allergy, lupus like syndrome, induced autoimmune disorders) in patients with inflammatory bowel diseases (IBD). Data of 105 (96 CD, age at diagnosis: 27.1 SD: 10.05 years, duration: 8.2 SD 6.6 years, males/females 48/57) patients treated with anti-TNFs for at least one-year. Records of a total of 198 one-year treatment cycles were collected and levels of auto antibodies were determined at induction and after the one-year period.
RESULTS: The majority of CD patients had ileocolonic (67.4%) and complicated (B2-B3: 72.6%) with perianal lesions (63.2%). ANA (12.3%) but not dsDNA positivity was frequent already and induction. Any time ANA or dsDNA positivity was 28.6% and 18%. Elevated level of ANA at induction time or during anti-TNF therapy was not associated with the efficacy of the therapy or the development of adverse outcomes. In contrast, treatment efficacy (no/partial response, dsDNA positivity: 31.5% vs. 68.5%, p=0.003) was inferior and adverse outcomes were more frequent (dsDNA positivity: 38.7% vs. 14.6%, p=0.01, OR: 3.71, 95%CI: 1.31-10.5) in patients with dsDNA positivity.
CONCLUSION: Our data suggest that development of ds-DNA during biological therapy is associated with treatment efficacy and adverse outcomes.

P302 EFFECTS OF DIET AND PHYSICAL ACTIVITY INTERVENTIONS ON FATIGUE IN PATIENTS WITH QUIESCENT ULCERATIVE COLITIS

M. Sanges[1,*], O. Donatore[1], D. Trio[1], M. Miniero[1], R. Sollazzo[1], D. Mattera[1], A. D'Arienzo[1]. [1]*Departmento of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy*

INTRODUCTION: Fatigue in ulcerative colitis (UC) is often to be considered an effect of disease activity. But when the disease is clinically inactive, many patients still suffer from fatigue suggesting that fatigue is related to other factors which could be important to identify to improve UC patients' well-being.
AIMS&METHODS: The aim of our study was to evaluate the effects of diet and physical activity interventions on fatigue in patients with quiescent UC. Seventy patients (M/F=40/30, median age 44 years) with quiescent UC were enrolled in the study. A six-month lifestyle intervention which included diet and physical activity was performed. All participants were prescribed a diet in which the estimated daily caloric needs was carried out according to physical activity and ideal body weight and the daily intake of individual nutrients was carried out according to recommended daily intake of nutrients. Moreover, moderate-intensity physical activity progressed to 60 minutes, 3 days per week was prescribed. Fatigue was assessed by the Multidimensional Fatigue Inventory (MFI), a 20-item, self-report instrument designed to measure five fatigue dimensions: general fatigue, physical fatigue, reduced activity, reduced motivation, and mental fatigue.
RESULTS: Fifty-six patients completed the study. Two patients showed a reactivation of UC and were excluded. After six months of diet and physical activity interventions a significant reduction of MFI scores for general fatigue (12.93 ± 2.46 vs 10.4 6 ±2.37; p=0.01), physical fatigue (12.64 ± 3.03 vs 10.17 ± 2.37; p=0.03), reduced activity (13.14 ± 2.63 vs 10.77 ± 2.05; p=0.01), and mental fatigue (12.57 ± 1.99 vs 10.31 ± 1.49; p= 0.002) was seen. On the other hand a not significant reduction of MFI score for reduced motivation (11.79 ± 1.89 vs 10.29 ± 2.37; p=0.07) was seen. Moreover, the percentage of patients with MFI score for general fatigue >12 was significantly reduced (51.8% vs 27.7%; p= 0.01).
CONCLUSION: The high prevalence of significant fatigue in patients with quiescent UC has implications for the clinician. The pathogenesis of fatigue in these patients is almost certainly multifactorial. Our data have shown that diet and physical activity interventions can improve fatigue in quiescent UC. If the improvement was due to psychological or biological factors remains to be elucidated.

P303 CLINICAL COMPARISON OF TWO DIFFERENT FECAL CALPROTECTIN IMMUNOASSAYS FOR THE DIAGNOSIS AND FOLLOW-UP OF INFLAMMATORY BOWEL DISEASE.

M. Oyaert[1,*], C. Trouvé[2], F. Baert[3], M. Langlois[2], H. Vanpoucke[1]. [1]*Laboratory Medicine, Heilig Hart Ziekenhuis Roeselare Menen, Roeselare,* [2]*Laboratory Medicine, AZ Sint Jan Brugge Oostende, Brugge,* [3]*Gastro Enterology, Heilig Hart Ziekenhuis Roeselare Menen, Roeselare, Belgium*

INTRODUCTION: Backgrounds: Fecal calprotectin (FC) is a useful marker for diagnosis and follow-up of inflammatory bowel disease (IBD). Recently, a fast and automated test has been introduced for detection of FC. We prospectively evaluated the performance of 2 different calprotectin immunoassays for the diagnosis of IBD and for monitoring disease activity in patients with Crohn's disease (CD).
AIMS&METHODS: Materials and Methods: 183 consecutive patients with suspected IBD were prospectively included over a two- month period. Additionally, 26 patients in follow-up provided consecutive stool samples over a 26-week period for FC measurement. We determined FC by a quantitative immuno-chromatographic point-of-care-test (POCT) Quantum Blue (Bühlmann) and a fully automated immunoassay (Thermo-Fisher). Results were compared with endoscopic and histological findings.
RESULTS: Results: Among the study population, the prevalence of IBD was 27.9% (51/183). After adjusting the optimal cut-off by ROC-curve analysis, sensitivity and specificity for diagnosis of IBD were comparable for both assays. For the Quantum Blue POCT (cut-off 113 µg/g), a sensitivity and specificity of 90.2% and 90.9% were obtained, respectively; for the EliA Calprotectin assay (cut-off 56 µg/g), a sensitivity and specificity of respectively 94.12% and 87.9% were obtained. For the Quantum Blue POCT and the EliA Calprotectin assay, we found an area under the curve of respectively 0.955 and 0.962 (P=0.586). The overall accuracy was 90.2% for the POCT assay and 89.6% for the EliA assay.
When using the manufacturer's cut-offs (both 50 µg/g), the sensitivity of the POCT assay increased up to 100%; although a decrease in specificity was obtained (72.0%). For the EliA assay, the same sensitivity (87.9%) and specificity (94.12%) as for the optimal cut –off were determined.
For the follow-up patients, we noticed a similar pattern throughout the period for both assays, but the results with the EliA calprotectin assay were lower.
CONCLUSION: Conclusions: Both FC assays showed acceptable and comparable clinical performance for diagnosis if IBD. Sensitivity varies with the chosen cut-off. For follow-up of known IBD, performance of both assays was equally. Although a similar pattern was noticed, multiple follow-up samples of one patient must be measured by the same assay. The automated EliA immune-assay is a good alternative to the more labor intensive POCT as the first screening assay in patients with IBD.

P304 HOSPITALIZATION RATES BEFORE AND AFTER ANTI-TNF THERAPY, RESULTS FROM A SINGLE CENTER

P. A. Golovics[1,*], M. Mandel[1], B. D. Lovasz[1], Z. Vegh[1], A. Mohas[1], B. K. Szilagyi[1], S. A. Fekete[1], A. Szabo[1], B. Csako[1], L. S. Kiss[1], P. L. Lakatos[1]. [1]*1st Department of Medicine, SEMMELWEIS UNIVERSITY, Budapest, Hungary*

INTRODUCTION: Hospitalization is an important outcome measure and a major driver of costs in patients with IBD.
AIMS&METHODS: Our aim was to analyze prospectively the prevalence and predictors of hospitalization and re-hospitalization before and after anti-TNF therapy.
Data of 91 consecutive IBD (77 CD, 14 UC) patients were analyzed (male/female: 45/46, median age at diagnosis: 24.0; SD: 9.8 years) in whom anti-TNF therapy was started after January 1, 2009. Total follow-up was 859 patient-years and 251 patient-years with anti-TNF exposure. Both in- and outpatient records were collected and comprehensively reviewed.
RESULTS: The hospitalization rate in the 2 years preceding anti-TNF therapy was significantly higher compared to the hospitalization rate after the start of continuous anti-TNF therapy (47.2/100 patient-years vs. 19.1/100 anti-TNF exposed patient-years, OR: 0.40, 95%CO 0.27-0.61, $p < 0.001$). The risk for hospitalization before or after the anti TNF-therapy was not associated to any clinical or treatment parameter assessed in this study (e.g. gender, sex, age, disease type, location/extent, phenotype, steroid or immunosuppressive exposure, surgery or anti-TNF type).
CONCLUSION: Hospitalization rates decreased significantly in this referral IBD cohort after the introduction of anti-TNF therapy. We were unable to identify any predictors for hospitalizations preceding or during anti-TNF therapy.

P305 ABERRANT CRYPT FOCI IN THE RECTUM OF PATIENTS WITH ULCERATIVE COLITIS - ANY ASSOCIATION WITH THE RISK OF NEOPLASIA?

P. Freire[1], P. Figueiredo[1,2], R. Cardoso[1,*], M. Manuela Ferreira[1], S. Mendes[1], M. A. Cipriano[3], M. R. Silva[3], A. M. Ferreira[1], M. J. Campos[1], H. Vasconcelos[4], F. Portela[1], C. Sofia[1,2]. [1]*Department of Gastroenterology, Centro Hospitalar e Universitário de Coimbra,* [2]*Center of Gastroenterology, Faculty of Medicine, University of Coimbra,* [3]*Department of Pathology, Centro Hospitalar e Universitário de Coimbra, Coimbra,* [4]*Department of Gastroenterology, Centro Hospitalar Leiria-Pombal, Leiria, Portugal*

INTRODUCTION: Ulcerative colitis (UC) is associated with an increased risk of colorectal cancer. Concomitant primary sclerosing cholangitis (PSC) and disease extent are the only factors that influence the start and periodicity of colonoscopy surveillance in these patients. Optimization of this screening strategy requires identification of additional risk factors. Aberrant crypt foci (ACF) have been associated with increased risk of sporadic colorectal cancer. Their correlation with the risk of neoplasia in UC remains controversial.
AIMS&METHODS: Aim: To determine if the existence and number of ACF have any relation with the risk of intraepithelial neoplasia (IEN) in patients with long-standing UC.
Patients and methods: 58 patients with distal/extensive UC with ≥ 8 years of disease and no history of PSC and/or IEN, were prospectively screened by chromoendoscopy-guided endomicroscopy and targeted biopsy/polypectomy of the detected lesions. The existence and number of ACF were evaluated in the distal rectum. Patients were divided into two groups: group I = with IEN, group II = without IEN.
RESULTS: Of the 88 circumscribed lesions identified by screening colonoscopy and biopsied, low-grade IEN was found in 5 (belonging to 4 patients). Distribution of patients: group I = 4 patients, group II = 54 patients. ACF were detected in all patients of group I and in only 28 (51.8%) of group II ($p = 0.085$). ACF performance in predicting the existence of IEN was: sensitivity = 100.0%, specificity = 48.1%, positive predictive value = 12.5% and negative predictive value (NPV) = 100.0%. Regarding the number of ACF, 5.3±2.2 were detected in group I and 2.1±2.9 in group II ($p = 0.037$).
CONCLUSION: In patients with long-standing UC and without history of PSC and/or IEN, there seems to be a significant association between the existence/number of ACF and the risk of IEN. ACF have high sensitivity and high NPV in predicting the existence of IEN.

P306 FAECAL S100A12 IS NO BETTER THAN FAECAL CALPROTECTIN (F-CP) IN THE NON-INVASIVE ASSESSMENT OF INFLAMMATORY BOWEL DISEASE (IBD).

S. Whitehead[1,*], C. Morgese[2], B. McKaig[2], P. Banerjee[2], A. ali[2], J. Waldron[2], C. Ford[1], R. Gamma[1], M. J. Brookes[2]. [1]*Clinical Chemistry,* [2]*Gastroenterology Unit, WOLVERHAMPTON HOSPITAL, Wolverhampton, United Kingdom*

INTRODUCTION: Faecal calprotection (F-Cp), is currently in clinical use within the UK for distinguishing between functional (IBS) and organic (IBD) bowel disease. Another neutrophilic protein S100A12 is, like f-Cp, also strongly up-regulated in chronic active IBD. However, unlike f-Cp which is expressed in a variety of different cell types, S100A12 is predominantly expressed in granulocytes thus potentially making it more specific than f-Cp. S100A12 elevation is a highly sensitive and specific discriminator of chronic IBD from functional non-organic disease.
AIMS&METHODS: Patients with ulcerative colitis (UC), Crohns disease or irritable bowel syndrome (IBS) were prospectively evaluated and the following were collected to define clinical activity of IBD: (i) demographic data, (ii) clinical activity indices (Harvey-Bradshaw index or Mayo score), and (iii) serum and whole blood samples for inflammatory markers. F-Cp was measured using a standard commercially available assay. S100A12 was measured according to manufacturer's instructions by ELISA.
RESULTS: 60 patients provided specimens; 28.3 % had IBS (n=17), 25% Crohns (n= 15) and 46.7% had UC (n=28). S100A12 was significantly higher in patients with UC (median = 75.4 ug/g; $p<0.0001$) and patients with Crohns (median = 47.2 ug/g; p=0.0001) compared to those with IBS (0.71 ug/g). The sensitivity and specificity of faecal S100A12 (91.9% and 94.1% respectively) was similar to f-Cp (97.7% and 82.3% respectively) in differentiating disease groups and there was a strong correlation between these results (r=0.808; 95% CI 0.6865 to 0.8856; $p<0.0001$). There was no correlation between S100A12 and disease activity in Crohns disease (Harvey-Bradshaw index). There was a significant difference in faecal S100A12 comparing patients who had severe UC compared to moderate UC disease activity (p=0.0004), but this was equally well identified with f-Cp (p=0.0109).
CONCLUSION: S100A12 demonstrated similar results to f-Cp in discriminating between functional and inflammatory bowel disease. The use of faecal S100A12 did not improve the assessment of disease activity in IBD compared to the use of f-Cp. This study does not support the previously published data suggesting that S100A12 may be more specific for the identification of inflammatory bowel disease.

P307 THE EFFECT IMMUNOSUPPRESSIVE DRUGS ON PERFORMANCE OF INTERFERON-GAMMA RELEASE ASSAY FOR TUBERCULOSIS SCREENING IN INFLAMMATORY BOWEL DISEASE

S. H. Wong[1,*], L. Zheng[2], M. Ip[2], W. Tang[1], J. Choi[1], K. M. Kee[1], N. L. Lee[3], F. K. Chan[1], J. C. Wu[1], J. J. Sung[1], S. C. Ng[1]. [1]*Institute of Digestive Disease,* [2]*Department of Microbiology,* [3]*Department of Medicine and Therapeutics, Chinese University of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: It is mandatory that patients with inflammatory bowel disease (IBD) receive tuberculosis screening prior to anti-tumour necrosis factor therapy. Interferon Gamma Release Assay (IGRA) has higher sensitivity and specificity than Tuberculin skin test (TST) but it is not clear whether immunosuppressive (IS) therapy can affect the sensitivity of IGRA.
AIMS&METHODS: This prospective study aims to evaluate the effect of IS therapy on Quantiferon TB Gold (QFT-G) results in IBD subjects in a TB endemic region. QFT-G was performed on 426 consecutive subjects (111 Crohn's disease, 134 ulcerative colitis, 5 indeterminate colitis, and 176 controls). IBD subjects on IS drugs (corticosteroids, azathioprine, mercaptopurine or methotrexate) had both TST and QFT-G performed.
RESULTS: 89.5% of all subjects have been vaccinated with Bacille-Calmette-Guérin (BCG); 21.2% IBD subjects and 19.9% of controls tested positive for QFT-G. There were no significant differences between IBD subjects and controls for history of or contact with TB. 44.4% of IBD subjects were receiving at least one IS therapy. Significantly fewer patients on IS therapy tested positive for QFT-G than did patients not receiving IS therapy (15.3% vs. 25.9%; p=0.044). Further stratification suggested that individuals receiving more IS drugs were less likely positive for QFT-G (p=0.0097), and had lower interferon gamma responses to TB antigens (p=0.043). Female gender and older age were associated with higher rate of QFT-G positivity in IBD ($p=2.35x10^{-5}$and p=0.0134, respectively). The mean age for QFT-G-positive IBD patients was 54.0 years and that for QFT-G negative patients was 42.7 years. Smoking, appendectomy and previous BCG did not affect QFT-G results. There were 5 indeterminate QFT-G results among BCG vaccinated individuals, but none among non-vaccinated individuals. Comparison of QFT-G with TST showed a concordance rate of 85% (kappa=0.23).
CONCLUSION: In a TB-endemic area, QFT-G test results are negatively impacted by IS therapy. Current guidelines suggesting TB screening before anti-TNF therapy may be inadequate in patients already on IS drugs. Latent TB testing appears best performed prior to the initiation of IS or corticosteroid therapies in IBD patients.

P308 FAECAL CALPROTECTION AND LACTOFERRIN ARE RELEVANT MARKERS FOR MONITORING DISEASE ACTIVITY AND PREDICTING RECURRENCE IN PATIENTS WITH QUIESCENT CROHN'S DISEASE FOLLOWING ILEOCOLONIC RESECTION

T. Yamamoto[1,*], M. Shiraki[1], S. Umegae[1], K. Matsumoto[1]. [1]*Inflammatory Bowel Disease Centre, YOKKAICHI SOCIAL INSURANCE HOSPITAL, Yokkaichi, Japan*

INTRODUCTION: The assessment of intestinal inflammation in patients with inflammatory bowel disease remains a challenge. Endoscopy is the most reliable and the gold standard method for assessing intestinal inflammation, but it is invasive, and time-consuming. To overcome these limitations, a non-invasive marker to monitor inflammatory activity would be desirable. The clinical significance of faecal calprotectin or lactoferrin in postoperative Crohn's disease (CD) is not evaluated.
AIMS&METHODS: This prospective study was to investigate the relationship between endoscopic activity, and faecal calprotectin and lactoferrin, and assess the predictive value of these markers for future recurrence. Twenty patients who remained in remission during 6-12 months after ileocolonic resection for CD were included. All patients underwent ileocolonoscopy for assessing endoscopic activity (Rutgeerts score) in the neo-terminal ileum. A stool sample was collected for measurement of calprotectin and lactoferrin. All patients were then following for 12 months, and clinical recurrence was defined as CD activity index (CDAI) $\geq$150.
RESULTS: The endoscopic scores were i0 or i1 in 10 patients, i2 in 6 patients, i3 in 3 patients, and i4 in 1 patient. Both calprotectin and lactoferrin positively correlated with the endoscopic scores (P=0.0001 and P=0.038, respectively). Six patients developed clinical recurrence during the 12-month follow-up. Both calprotectin and lactoferrin levels were significantly higher in patients with clinical recurrence than those in remission (P=0.0007 and P=0.025, respectively). A cutoff value of 170 μg/g for calprotectin had a sensitivity of 83% and a specificity of 93% to predict a risk of clinical recurrence, while a cutoff value of 140 μg/g for lactoferrin had a sensitivity of 67% and a specificity of 71%.
CONCLUSION: This study showed that both calprotectin and lactoferrin levels correlate well with endoscopic activity after ileocolonic resection for CD. Assays of faecal calprotectin and lactoferrin should serve as low cost, and non-invasive biomarkers to monitor disease activity and predict recurrence after surgery for CD.

P309 THE IMPACT OF EARLY ENDOSCOPIC LESIONS ON THE CLINICAL COURSE OF PATIENTS AFTER ILEOCOLONIC RESECTION FOR CROHN'S DISEASE: A FIVE-YEAR PROSPECTIVE COHORT STUDY

T. Yamamoto[1,*], M. Shiraki[1], S. Umegae[1], K. Matsumoto[1]. [1]*Inflammatory Bowel Disease Centre, YOKKAICHI SOCIAL INSURANCE HOSPITAL, Yokkaichi, Japan*

INTRODUCTION: Early endoscopic lesions following resection for Crohn's disease (CD) are often observed. The severity of the endoscopic inflammation at the proximal site of the anastomosis during the first year after resection is considered to be a reliable predictive risk factor for future clinical recurrence. Currently, the relationship between this endoscopic observation and subsequent occurrence of CD lesions or recurrence is not understood well, but should be valuable in the context of predicting CD course.
AIMS&METHODS: This prospective study was to investigate the impact of early endoscopic lesions on future clinical recurrence rates following ileocolonic resection for CD. Forty patients who had maintained clinical remission, CD activity index (CDAI) $<$150 with mesalazine during 6 months after ileocolonic resection for CD were included. At 6 months after surgery, ileocolonoscopy was performed, and the endoscopic activity score at the proximal site of the anastomosis was determined according to Rutgeerts. All patients were regularly monitored for 5 years, and clinical recurrence was defined as CDAI $\geq$150. Corticosteroids, immunosuppressants or biologic agents were not given unless there was clinical recurrence.
RESULTS: At 6 months after surgery, the endoscopic scores were i0 or i1 in 27 patients, i2 in 7 patients, i3 in 4 patients, and i4 in 2 patients. During the following 5 years, the clinical recurrence occurred in 3 (11%) of the 27 patients with endoscopic score of i0 or i1, 4 (57%) of the 7 patients with i2 score, 3 (75%) of the 4 patients with i3 score, and 2 (100%) of the 2 patients with i4 score, showing a significant positive correlation (P=0.001) between the endoscopic severity of the proximal site of the anastomosis at 6 months after surgery and the clinical recurrence rate during the following 5 years.
CONCLUSION: The assessment of endoscopic lesions at the proximal site of the anastomosis appeared to be valuable for predicting subsequent clinical recurrence after ileocolonic resection for CD. The results in the present study are valuable not only for identifying patients with a high risk of recurrence after surgery for CD but also for creating an integrated management strategy for prevention of postoperative recurrence. Further studies in larger cohorts of patients are warranted to strengthen our findings.

P310 MR ENTEROCOLONOGRAPHY IS USEFUL TO PREDICT CLINICAL RECURRENCE OF CROHN'S DISEASE AND IDENTIFY PATIENTS WHO NEED MORE AGGRESSIVE TREATMENT.

T. Fujii[1,*], M. Naganuma[2], Y. Kitazume[3], E. Saito[1], M. Nagahori[1], K. Ohtsuka[1], M. Watanabe[1]. [1]*Gastroenterology, TOKYO MEDICAL AND DENTAL UNIV,* [2]*Gastroenterology, Keio University School of Medicine,* [3]*Radiology, TOKYO MEDICAL AND DENTAL UNIV, Tokyo, Japan*

INTRODUCTION: Assessing the extension and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn's disease (CD). MR enteroclysis or enterography(MRE) can assess both intestinal walls and and extraintestinal structures without radiation exposure and anesthesia, which makes it appropriate for repeated evaluation in CD patients. We developed novel magnetic resonance enterocolonography (MREC) for simultaneously evaluating both small and large bowel lesions in patients with CD and reported its excellent correlation with endoscopy. However, there is few report about predictability of CD recurrence by MRE. The aim of this study was to evaluate the capability of MREC for prediction of clinical recurrence in CD.
AIMS&METHODS: One hundred and thirty-three patients with established CD were prospectively examined by MREC between July 2009 and February 2013. Patients underwent ileocolonoscopy (ICS) or double-balloon endoscopy (DBE) after MREC on the same day. MREC score (0-60) was defined by modifying SES-CD. Presence and size of ulcers, extent of ulcerated surface, extent of affected surface and presence of narrowings were scored (0-3) in each segment of small and large intestine. MREC score, simplified endoscopic activity score for Crohn's disease (SES-CD), Chrohn's Dease Activity Index (CDAI) and CRP was evaluated. Patients were followed up for a maximum of 4 years unless clinical recurrence occurred earlier.
RESULTS: The median follow up time was 15.8 months (±1.2(se)), 76 patients recurred, 31 needed hospitalization and 24 had operation. Patients who recurred more often had higher MREC score (≧2; reflected active disease), higher SES-CD, higher CDAI and higher CRP, at baseline than those who didn't. But only higher MREC score was predictor for both hospitalization and operation (27.3% vs 0%, $p < 0.001$). Especially, in patients with remission (CDAI < 150), higher MREC score group had more recurrence (43/56, 76.8% vs 2.4%, $p < 0.001$) and operation (16.0% vs 0%, p=0.06). Even in 73 patients in remission with negative CRP, higher MREC score group had recurrence significantly more often (24/36, 66.7% vs 0%, $p < 0.001$) and had operation (6/36, 16.7% vs 0%, $p < 0.001$).
CONCLUSION: This data suggest that MR enterocolonography is useful for prediction for recurrence of Crohn's disease.

P311 THERAPEUTIC DRUG MONITORING OF INFLIXIMAB AND MUCOSAL HEALING IN INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE STUDY

S. paul[1], H. marotte[1], E. del tedesco[1], L. peyrin-biroulet[2], X. Roblin[1,*]. [1]*University of saint etienne, saint etienne,* [2]*CHU Nancy, Nancy, France*

INTRODUCTION: Whether therapeutic drug monitoring of infliximab (IFX) trough levels and antibodies to infliximab (ATI) concentrations) could be useful in predicting mucosal healing (MH) in inflammatory bowel diseases (IBD) after infliximab optimization is unknown.
AIMS&METHODS: All consecutive IBD patients receiving ongoing IFX 5 mg/kg treatment and developing secondary failure to IFX were enrolled in a prospective observational study between June 2010 and May 2011. Dose was increased to 10 mg/kg in all patients. A clinical relapse was defined by a CDAI > 220, a fecal calprotectin > 400 μg/g and a C-reactive protein (CRP) level > 10 mg/L for Crohn's disease. In UC, clinical relapse was defined by a Mayo score > 7 with a Mayo endoscopic subscore > 1. IFX trough levels, antibodies to IFX concentrations (ATI), CRP levels, and fecal calprotectin were measured before infliximab optimization and at week 8. A proctosigmoidoscopy was performed the day of first infliximab optimization and at week 8 in all UC patients.
RESULTS: We included 52 IBD patients: 34 had CD (mean CDAI: 280; C-reactive protein: 28+/- 10 mg/L; fecal calprotectin : 705 +/- 300 μg/g) and 18 UC patients. Following IFX dose intensification, half of IBD patients achieved mucosal healing. Increase in infliximab trough levels (called "delta infliximab", μg/mL) was associated with mucosal healing (MH) (irrespective of IBD type) (P;001). A parallel increase in MH rates was observed according to the four quartiles (0%, 7%, 30%, and 70%, respectively; P=0.001). A "delta infliximab" > 0.5μg/mL was associated with HM (sensitivity (se): 0.88, specificity (sp): 0.77, positive predictive value (PPV): 0.79, negative predicitve value (NPV): 0.87; p = 0.0001, AUROC: 0.89). An IFX trough level < 2μg/l before drug optimization without ATI beyond 200 nanog/mL had a strong predictive value for achieving MH. On multivariate analysis, the only factor associated with HM after iIFX optimization was a delta infliximab IFX > 0.5 µg/mL (Likelihood ratio (LHR), =2.02, 95% CI,: 1.01-4.08; p=0.048). There was a strong tendency between IFX trough level IFX < 2 before drug optimization and MH : LHR=5.3, 95%: 0.82-34.2; p=0.08). The type of IBD was not associated with HM (p=0.26).
CONCLUSION: Therapeutic drug monitoring of IFX strongly predicts the likelihood of achieving mucosal healing following IFX dose intensification in both CD and UC. Measurement of IFX trough levels and ATI may be useful to guide decisions in IBD patients with secondary failure to IFX.

P312 MULTIVARIATE ANALYSIS REVEALS DISCERNIBLY DIFFERENT CYTOKINE PATTERNS BETWEEN INFLAMED MUCOSA OF ULCERATIVE COLITIS AND CROHN'S DISEASE

Y. Iboshi[1,*], K. Nakamura[1], E. Ihara[1], K. Fukaura[1], T. Iwasa[1], N. Harada[2], M. Nakamuta[2], R. Takayanagi[1]. [1]*Department of Medicine and Bioregulatory Science, Graduate School of Medical Sciences, Kyushu University,* [2]*Department of Gastroenterology, Kyushu Medical Center, National Hospital Organization, Fukuoka, Japan*

INTRODUCTION: Many previous studies have shown that various pro-inflammatory cytokines are upregulated in affected mucosa of patients with inflammatory bowel disease (IBD). But in most of these studies, expressions of each cytokine in relation to disease phenotypes were individually analyzed, not yielding phenotype-specific cytokine expression patterns in diseased tissues. To take into account the correlations and interactions of multiple targets, we conducted multivariate analysis on the gene expression data after analysing mucosal biopsy samples from patients with ulcerative colitis (UC) and Crohn's disease (CD) for helper T cell-related cytokines and transcription factors by quantitative real-time PCR (qRT-PCR).
AIMS&METHODS: Total of 154 biopsy samples (87 from UC, 42 from CD and 25 from control) were obtained by endoscopy from inflamed and non-inflamed mucosa of 47 UC, 20 CD patients and 14 control subjects. Total RNA was extracted from the specimens and mRNA expressions of Th1-related (IFNG, IL12A, IL12B, TBX21 and TNFA), Th2-related (IL13, IL33 and GATA3), Th17-related (IL17A, IL17F, IL21, IL22, IL6, IL23A and RORC) and Treg-related (TGFB and FOXP3) cytokines and transcription factors were evaluated by qRT-PCR using TaqMan probes. Linear discriminant analysis was applied to the observed data for the differentiation of IBD phenotypes.
RESULTS: Marked gene expression differences, especially of pro-inflammatory cytokines like IL6, IFNG and IL17A, were observed between inflamed and non-inflamed mucosa, particularly in UC. IL6 alone, for example, was able to discriminate inflamed from non-inflamed mucosa with an AUC value of 0.90. In contrast, gene expression profiles of inflamed mucosa of UC (UCI, n=40) and CD (CDI, n=20) seemed almost comparable and only expressions of IL13 and IL21 were significantly different with AUC values of 0.66 and 0.70 respectively. Stepwise linear discriminant analysis yielded a set of 5 genes (IFNG, IL12A, TBX21, GATA3, IL21), which discriminated UCI from CDI with an AUC value of 0.95 and an accuracy of 91.7% on the training data, which remained 86.7% after internal leave-one-out cross validation.
CONCLUSION: Multigene analysis discriminated between inflamed mucosa of UC and CD, which were similar in single-gene analysis, with high accuracy, reflecting possible differences in pathogenesis. This method might be useful for evaluation of cases initially diagnosed with indeterminate colitis.

P313 IBD PATIENTS' PARTNER- HOW IMPORTANT IS THEIR SUPPORT?

A. Lahat[1,*], S. Neuman[1]. [1]*Gastroenterology, CHAIM SHEBA MEDICAL CENTER, Ramat Gan, Israel*

INTRODUCTION: Chronic inflammatory disease of the bowel causes significant distress to the patients and his family. Data assessing the need of these patients for support and sharing with their partners is scarce.
AIMS&METHODS: Our aim was to assess patients' view regarding information sharing with their partners.
All IBD patients treated at the Sheba Medical center between 1.2011-1.2013 were asked to fill an anonymous questionnaire. Only patients that had a stable partner and that completed more than 95% of the questionnaire were included.
RESULTS: One hundred thirty four patient filled the questionnaire, of them 101 were included.53 were men. Mean age:45±15. 50% had academic education. Only 42% of patients reported that their partner accompanies them to the doctor. 93% of patients share health problems with their partner. 64% would like their partner to receive more medical information, and 70% would like their partner to be more involved. 88% of patients believe that more partners' involvement can help them deal better with the disease. 70% think that support group for partners should be established. No association was found between patients' demographic data to their answers. Patients that felt that their partner's involvement can help them dealing with the disease tended to share with them medical information and wanted them to be more involved in health decisions ($p < 0.001$)
CONCLUSION: Most IBD patients want their partner to be more involved with their health problems, and believe that greater involvement can help them deal better with their disease. Therefore, more attention should be attributed towards better cooperation with patients' families.

P314 A SYSTEMATIC REVIEW: THIOPURINE MONITORING IN CHILDREN WITH INFLAMMATORY BOWEL DISEASE

A. Konidari[1,*], A. Anagnostopoulos[2], L. J. Bonnett[3], M. Pirmohamed[4], W. El Matary[5]. [1]*Clinical and Molecular Pharmacology,* [2]*Women's and Children's Health, Institute of Translational Medicine,* [3]*Department of Biostatistics, University of Liverpool,* [4]*Clinical and Molecular Pharmacology, Institute of Translation Medicine, Liverpool, United Kingdom,* [5]*Department of Paediatrics, Section of Paediatric Gastroenterology, University of Manitoba, Winnipeg, Canada*

INTRODUCTION: Thiopurines are widely used for maintenance of remission in children with inflammatory bowel disease (IBD). Current evidence on importance of thiopurine metabolite and peripheral blood count monitoring for assessment of therapeutic response and thiopurine toxicity is controversial.
AIMS&METHODS: To systematically review the evidence on the utility of thiopurine metabolite and peripheral blood count monitoring in assessing therapeutic response and thiopurine induced haematologic and hepatic toxicity in children with IBD.
Medline, Embase, Cochrane Central Register of Controlled trials and www.clinicaltrials.gov. were searched. Randomised controlled trials (RCTs), cohort studies and large case series were eligible. Primary outcome was the clinical usefulness of routine thiopurine metabolite and peripheral blood count monitoring in assessing therapeutic response and toxicity in children with IBD. Secondary outcome was to investigate a possible correlation between these markers.
RESULTS: Sixteen studies of variable quality were included (n=1093). None of the studies were RCTs. While high 6TGN levels were not consistently associated with leucopenia, a positive correlation between 6TGN levels and optimal clinical outcome was frequently reported. Several studies supported the use of high 6MMP levels as an indicator of hepatotoxicity.
CONCLUSION: Thiopurine metabolite testing does not safely represent therapeutic response or thiopurine toxicity. Current evidence does not support routine metabolite monitoring, however favours a combination of metabolite and white blood count testing for safe dose escalation in cases of suboptimal response. Leucopenia is not necessary for achievement of optimal therapeutic response. Well designed RCTs and identification of additional surrogate markers of thiopurine efficacy and toxicity are required.

P315 RISK ASSESSMENT AND MINIMIZATION FOR PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY (PML) (RAMP): A PROGRAM TO ASSESS FOR POTENTIAL EARLY SIGNS AND SYMPTOMS OF PML DURING CLINICAL DEVELOPMENT OF VEDOLIZUMAB

A. Parikh[1,*], M. McAuliffe[2], K. Stephens[2], E. Major[3], I. Fox[2], C. Milch[2], S. Sankoh[2], J. Provenzale[4], M. Lev[5], E. Freedland[2], J. Berger[6], D. Clifford[7]. *[1]Takeda Pharmaceuticals International, Inc, Deerfield, [2]Millennium Pharmaceuticals, Inc, Cambridge, [3]National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, [4]Duke University Medical Center, Durham, [5]Massachusetts General Hospital, Boston, [6]University of Kentucky, Lexington, [7]Washington University School of Medicine, St. Louis, United States*

INTRODUCTION: Since 2007, the RAMP program, involving education and a stepwise screening algorithm, has been used to monitor all patients treated with vedolizumab (VDZ), a gut-selective $\alpha_4\beta_7$ integrin antagonist, for potential early PML signs/symptoms in ulcerative colitis (UC) and Crohn's disease (CD) clinical studies.
AIMS&METHODS: All patients completed a subjective checklist on recent changes in vision, speech, gait, sensation, comprehension, coordination, and personality at screening, at each study visit, and whenever new neurologic symptoms presented. Positive findings led to VDZ cessation and a site investigator–administered neurologic evaluation, followed by referral to a neurologist familiar with the study for patients in whom objective findings confirmed symptoms. In some cases, patients without objective findings were also referred. If PML remained in the differential, an independent adjudication committee (IAC) of PML experts expedited a centralized real-time review of results from the neurologic evaluation, brain MRI, and lumbar puncture with PCR analysis of cerebrospinal fluid (CSF) for JC virus (JCV) DNA to determine PML likelihood. Site investigators received IAC guidance on further management of patient safety.
RESULTS: As of March 2013, 2913 patients (UC, 1142; CD, 1771) completed 57,986 subjective checklists (UC, 24,919; CD, 33,067). Positive subjective findings led to completion of 165 and 341 objective checklists in 95 UC and 189 CD patients, respectively. Results from 83 patients (UC, 24; CD, 59) were evaluated by the IAC, including 62 patients with abnormal objective checklist results (UC, 17; CD, 45) and 21 (UC, 7; CD, 14) referred without objective findings. Among these, 56 patients underwent brain MRI (UC, 15; CD, 41) and 5 underwent lumbar puncture with PCR analysis of CSF for JCV (UC, 2; CD, 3). MRI results were inconsistent with PML, and no JCV was detected in CSF. No PML cases have been identified by the IAC to date.
CONCLUSION: No PML cases have been reported to date in VDZ trials. The RAMP program is an important, practical monitoring tool for early PML detection and elimination of false positives, which can be applied on a global scale.

P316 THE TEMPORAL EVOLUTION OF ANTI-DRUG ANTIBODIES IN INFLAMMATORY BOWEL DISEASE PATIENTS TREATED WITH INFLIXIMAB

B. Ungar[1,*], Y. Chowers[2], M. Yavzori[3], O. Picard[3], E. Fudim[3], O. Har-Noy[3], U. Kopylov[3], R. Eliakim[3], S. Ben-Horin[3]. *[1]Internal Medicine D, Sheba Medical Center, Ramat Gan, [2]Gastroenterology, Rambam Health Care Center, Haifa, [3]Gastroenterology, Sheba Medical Center, Ramat Gan, Israel*

INTRODUCTION: Despite ample research on the prevalence of antibodies to infliximab (ATI), their incidence during therapy is poorly defined. This knowledge gap may hamper the understanding of the clinical impact of anti-TNFs immunogenicity. We aimed to characterize the temporal evolution of ATI.
AIMS&METHODS: This was a tertiary-center prospective observational study of all infliximab-treated IBD patients between 2009-2012. Trough levels of infliximab were determined and ATI were measured before each infusion by anti-lambda ELISA. Patients were monitored for disease activity by clinical activity indexes and for dose-intensification or infliximab cessation. The occurrence of transient ATI disappearing spontaneously without any intervention was recorded separately.
RESULTS: 125 patients were included (98 CD, 27 UC, Median follow 11.5±22 months) and 1119 sera were analyzed for infliximab and ATI levels during the 4-year study. Kaplan-Meyer analysis showed that 42% of patients remained ATI-free by 4 years of treatment. Most (90%) of the patients who developed ATI did so within the first 12 months of therapy, whereas transient ATIs were detected throughout the duration of infliximab therapy ($P<0.001$). ATI incidence was similar between patients who received infliximab previously (episodic patients, n=14) and scheduled therapy patients (n=111). In the scheduled therapy group, combination immunomodulator+infliximab resulted in longer ATI-free survival compared to monotherapy (p=0.003, log rank test). Survival free of clinical loss of response was enjoyed by 51% of patients, and serial measurements showed that ATI development often preceded the onset of clinical flare.
CONCLUSION: When followed prospectively, most patients who develop ATI do so within the first 12 months of therapy, and this incidence is reduced by combination immunomodulator even in scheduled therapy patients. In contrast, transient ATIs, which are of little clinical significance, can appear haphazardly at any time during treatment. The onset of clinical loss of response may lag behind the appearance of anti-infliximab antibodies.

P317 BENEFIT OF INFLIXIMAB RE-INTRODUCTION AFTER SUCCESSIVE FAILURE OF INFLIXIMAB AND ADALIMUMAB IN INFLAMMATORY BOWEL DISEASES

C. Gagniere[1,*], L. Beaugerie[1], B. Pariente[2], P. Seksik[1], A. Amiot[3], V. Abitbol[4], M. Allez[2], J. Cosnes[1], H. Sokol[1]. *[1]Gastroenterology department, Saint Antoine Hospital, [2]Gastroenterology department, Saint Louis Hospital, Paris, [3]Gastroenterology department, Mondor Hospital, Creteil, [4]Gastroenterology department, Cochin Hospital, Paris, France*

INTRODUCTION: Infliximab (IFX) and adalimumab (ADA) are effective in inflammatory bowel disease (IBD) for induction and maintenance therapy. However, high annual rate of discontinuation for loss of response or intolerance may lead to a switch for another anti-TNF agent. In clinical practice, patients with successive failure to IFX and ADA are more and more frequent. The aim of this study was to assess whether re-treatment with IFX in patients who successively failed to IFX and ADA is feasible.
AIMS&METHODS: Sixty nine IBD patients (21 males, 65 Crohn's disease, 1 ulcerative colitis, 3 IBD unclassified, 14 L1, 22 L2, 30 L3, 12 L4, 20 p, 1 E3) who received and discontinued successively IFX and ADA, and who were re-exposed to IFX were indentified in 4 French tertiary centres and retrospectively analyzed. Clinical data, response to IFX, follow-up and outcome were abstracted from electronic database or medical records. For statistical analysis, Mann Whitney test, Chi2 test, logrank test or Cox regression model were used when appropriate.
RESULTS: Median age at second IFX treatment start was 29.1 years (15.9-84.3), and 22% had prior surgery. Median duration of the first IFX treatment was 14

months (0-127), and reasons for discontinuation were loss of response (38), intolerance (16), primary non response (4) and other (11). Median duration between the two IFX treatment periods was 37.6 months (3.2-144.3). Concomitant-immunosuppression (co-IS) with thiopurine or methotrexate was given in 61% and 49% of cases during first and second IFX treatments respectively. Remission (Harvey-Bradshaw Index <5) was achieved in 46% of cases at week 6-8 after IFX re-induction. 64% and 52% of patients were still under IFX therapy 12 and 24 months after IFX re-induction, respectively. Twenty nine patients had to discontinue the second IFX treatment due to intolerance (14), primary non response (11), loss of response (3) and other (1). In multivariate analysis, receiving co-IS in both first and second IFX treatment (p=0.006) and shorter interval between first and second IFX treatment (p=0.0006) were independently associated with longer duration of second IFX treatment.

CONCLUSION: For IBD patients who successively failed IFX and ADA, re-introducing IFX is feasible and often clinically efficient. More than half patients are still under treatment at 12 months. This strategy is particularly interesting in patients who received co-IS during both first and second IFX treatment.

P318 GRANULO-MONOCYTOAPHERESIS IS MORE EFFECTIVE IN INDUCING AND MAINTAINING CLINICAL RESPONSE AT 24 WEEKS IN MILD ULCERATIVE COLITIS THAN IN MODERATE TO SEVERE DISEASE

C. De Cassan[1,*], P. Marson[2], E. V. Savarino[1], G. Hatem[1], R. Caccaro[1], G. C. Sturniolo[1], A. Buda[1], R. D'Incà[1]. [1]*Department of Surgical and Gastroenterological Sciences,* [2]*Apheresis Unit, Blood Transfusion Service, University of Padua, Padua, Italy*

INTRODUCTION: Granulo-monocytoapheresis (GMA) consists on extracorporeal removal of granulocytes and monocytes from the peripheral blood. It has been used in patients with mild to severe disease active ulcerative colitis (UC) in order to modulate intestinal inflammation with conflicting results.

AIMS&METHODS: To evaluate whether GMA effectiveness varies according to severity of UC. This study is designed as a retrospective review of prospectively collected medical records of patients undergoing GMA at our center, with a median follow-up period of 6 months. Demographics, clinical and laboratory data were extracted from the patients' charts and electronic records. Severity of UC was measured according to Modified Truelove Witts Severity Index (MTWSI). Clinical response was defined as a decrease from baseline in MTWSI of $\geq$2 points or a value of MTWSI $\leq$2 points .

RESULTS: A total of 35 [21M/14F; mean age 48(19-82)] patients were included (table 1). At 1-month follow-up period after GMA, 75% (n=18/24) of mild UC underwent clinical response compared to 54% (n=6/11) of patients with moderate to severe disease (p=0.26). At 6-months, 55% (n= 13/24) of mild UC maintained clinical response compared to 18% (n=2/11) of patients with moderate to severe disease(p=0.06).

	Mild (n=24)		**Moderate to severe** (n=11)		*p value*
	n	%	n	%

CONCLUSION: Our data show that patients with mild disease could benefit of GMA more than patients with moderate to severe disease. Thus, in patients with mild disease, GMA can be considered as a valid and alternative therapeutic approach, particularly in case of contraindications to immunosuppressors/ corticosteroids.

P319 MALIGNANCIES WITH ANTI-TUMOR NECROSIS FACTOR-ALPHA THERAPY IN INFLAMMATORY BOWEL DISEASE: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

C. J. M. Williams[1,*], L. Peyrin-Biroulet[2,3], A. C. Ford[1,4]. [1]*Leeds Gastroenterology Insitute, Leeds General Infirmary, Leeds, United Kingdom,* [2]*Department of Hepatogastroenterology, Nancy University Hospital,* [3]*Inflammatory Bowel Disease Unit, INSERM, Nancy, France,* [4]*Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, United Kingdom*

INTRODUCTION: Several anti-tumour necrosis factor-α (TNFα) antibodies have demonstrated efficacy in Crohn's disease (CD) and ulcerative colitis (UC). These drugs carry a theoretical risk of malignancy, particularly lymphoma, but no systematic review and meta-analysis has examined this issue specifically.

AIMS&METHODS: We pooled data from all available placebo-controlled studies to estimate the risk of malignancy with anti-TNFα therapy. MEDLINE, EMBASE and the Cochrane central register of controlled trials were searched to November 2012. Randomized controlled trials (RCTs) comparing anti-TNFα therapy with placebo in adults with CD or UC were eligible. Data were pooled to obtain a relative risk (RR) of malignancy with a 95% confidence interval (CI).

RESULTS: The search strategy identified 20,563 citations, of which 22 RCTs were eligible (11 infliximab, six adalimumab, four certolizumab and one golimumab) involving 7,054 patients (4,566 CD and 2,488 UC). In total, there were 16 (0.4%) malignancies in 4,135 patients allocated to anti-TNFα therapy, compared with 13 (0.45%) in 2,919 assigned to placebo. Among patients receiving anti-TNFα therapy these included two basal cell carcinomas, two rectal adenocarcinomas, one hypernephroma, one breast cancer, one bladder carcinoma, one prostate adenocarcinoma, one lung cancer, one gastric cancer, one cutaneous squamous cell carcinoma, one adenocarcinoma of unknown origin, and four cancers of unspecified type. There were no cases of lymphoma in the active treatment group compared with three (0.1%) in the control group. The RR of malignancy for patients receiving anti-TNFα therapy was 0.77 (95% CI 0.37 to 1.59). There was no statistically significant heterogeneity detected between studies ($I^2 = 0\%$, $P = 0.82$) and no evidence of funnel plot asymmetry (Egger test, $P = 0.37$). We performed sensitivity analyses excluding trials where placebo patients were exposed to anti-TNFα during induction of remission, and trials of eight weeks duration or less. The RR of malignancy with anti-TNFα compared with placebo, excluding trials where placebo patients were exposed to anti-TNFα, was 0.81 (95% CI 0.30 to 2.16). The RR of malignancy with anti-TNFα compared with placebo, excluding trials of eight weeks duration or less, was 0.80 (95% CI 0.37 to 1.73).

CONCLUSION: Anti-TNFα therapy was not associated with an increased risk of malignancy in patients with inflammatory bowel disease. No trials provided data for risk of malignancy beyond one year of treatment meaning that the long-term effect of anti-TNFα therapy could not be addressed by the current study.

P320 CLINICAL RESPONSE, QUALITY OF LIFE AND WORK ACTIVITY IN PATIENTS WITH CROHN'S DISEASE TREATED WITH ADALIMUMAB IN ROUTINE CLINICAL PRACTICE.

F. Muñoz[1], C. Saro[2,*], D. Ceballos[3], C. de la Coba[2], M. D. Aguilar[4], P. Lázaro[4], EFICADEC researchers. [1]*Hospital de León, León,* [2]*Hospital Cabueñes, Gijón,* [3]*Hospital Dr. Negrin, Las Palmas,* [4]*Research, TAISS, Madrid, Spain*

INTRODUCTION: Several clinical trials have demonstrated the efficacy of adalimumab (ADA) for inducing and maintaining clinical response in patients with Crohn's disease (CD).

AIMS&METHODS: The aim of the study was to determine the effectiveness, measured as clinical response, quality of life (QoL) and work activity, of ADA in CD patients in routine clinical practice.

Methodology: Multicentre prospective observational cohort study with follow up of 12 months. Inclusion criteria: Patients with CD naïve to biologics, in which the doctor prescribes ADA according to routine clinical practice. In the medical visit at the beginning of the biologic treatment (V0), sociodemographic variables, Crohn's Disease Activity Index (CDAI), Perianal Disease Activity Index (PDAI), quality of life (QoL) indices (Inflammatory Bowel Disease Questionnaire (IBDQ-9) and EuroQol five dimensions (EQ-5D)) and Work Productivity Activity Index (WPAI) were collected. Such data were again recorded 12 months later (V12). When the data distribution was normal, the mean ($\pm$SD) were used as statistics. When the data distribution was not normal, the median (Percentil25-percentil75) were used. For hypothesis testing, parametric or nonparametric tests were used according to the data distribution. Differences were considered significant at $p < 0.05$.

RESULTS: 126 patients (50.8% men; age 39.1$\pm$13.8 years; 60.3% active workers) from 33 centres were included. The proportion of patients in remission (CDAI$<$150) increased from 34.1% in V0 to 83.0% in V12. The CDAI decreased from 194 (21-269) to 48 (10-122) ($p<0.001$). The PDAI decreased from 4.0 (0.0-4.0) to 0.0 (0.0-4.0) ($p<0.001$). The quality of life measured by

the EQ-5D improved from 0.735 (0.633-0.790) to 0.797 (0.726-1.000) ($p<0.001$). The IBDQ-9 score increased ($p<0.001$) from 56.7 (51.6-61.5) to 66.5 (60.1-73.6) ($p<0.001$). The work hours lost by the EC in the previous week decreased from 2.0 (0.0-27.0) at V0 to 0.0 (0.0-1.0) at V12 ($p=0.004$) and the work productivity (0-10 scale) decreased from 3.0 (0.3-5.8) to 1.0 (0.0 to 2.0) ($p=0.006$).

CONCLUSION: In clinical practice, ADA has proven to be effective with a statistically significant improvement in clinical variables, quality of life, and work productivity.

P321 CHANGES IN RESOURCE UTILISATION IN PATIENTS WITH CROHN'S DISEASE TREATED WITH ADALIMUMAB IN ROUTINE CLINICAL PRACTICE

D. Ceballos[1], C. Saro[2,*], C. de la Coba[2], F. Muñoz[3], M. D. Aguilar[4], P. Lázaro[4], EFICADEC researchers. [1]*Hospital Dr. Negrin, Las Palmas,* [2]*Hospital Cabueñes, Gijón,* [3]*Hospital de León, León,* [4]*Research, TAISS, Madrid, Spain*

INTRODUCTION: Crohn's disease (CD) is a chronic and recurrent disease with numerous complications, producing a high consumption of health and social resources. It could be suggested that because of the efficacy of biologic treatments, their use could reduce the resource utilisation.

AIMS&METHODS: The aim of the study is to compare the resource utilisation during the 12 months prior to treatment with adalimumab (ADA) in the EC with respect to the following 12 months in routine clinical practice.

Methodology: Multicentre prospective observational cohort study with follow up of 12 months. Inclusion criteria: Patients with CD naïve to biologics, in which the doctor prescribes ADA according to routine clinical practice. In the medical visit at the beginning of the biologic treatment, direct (hospitalisations, medical visits, surgeries, diagnostic tests and medications) and indirect resource (Work Productivity and Activity Impairment (WPAI)) consumption during year previous (Y-1) to the ADA treatment were retrospectively collected. Such data were again recorded prospectively in 5 visits during the following year (Y-2). Y-1 and Y-2 data were compared. For hypothesis testing, parametric or nonparametric tests were used according to the data distribution.

RESULTS: 126 patients (50.8% men; age 39.1±13.8 years; 60.3% active workers) from 33 centres were included. The respective means for Y-1 vs. Y-2 of the following resources per patient were: 12.4 vs. 7.4 ($p<0.001$) medical visits, 1.2 vs. 0.7 ($p<0.001$) emergency room visits, 4.4 vs. 3.7 (NS) hospitalisation days, 0.0 vs. 0.1 (NS) days in intensive care units, 0.9 vs. 1.5 (NS) days in day hospital, 5.3 vs. 2.4 ($p<0.001$) diagnostic tests. The number of surgeries decreased from 33 during Y-1 to 29 during Y-2. The consumption of non-biologic drugs during Y-2 decreased with respect Y-1 ($p<0.001$). The mean of work hours lost by the EC decreased from 12.9 to 4.0 ($p=0.004$) and lost by other causes from 3.7 to 0.9 (NS). The work productivity impact (scale 0-10) decreased from 3.3 to 1.6 ($p=0.006$) and the impact in non-work activities (scale 0-10) decreased from 5.0 to 2.3 ($p<0.001$).

CONCLUSION: In clinical practice, the treatment with ADA decreases the direct and indirect resources utilisation comparing the 12 months before the treatment with the following 12 months.

P322 FREQUENCY, TYPE AND OUTCOME OF REPORTED SIDE EFFECTS AND ADVERSE EVENTS OF NON-BIOLOGIC DRUGS USED IN INFLAMMATORY BOWEL DISEASE: A NATIONWIDE COHORT STUDY USING THE GERMAN FEDERAL INSTITUTE FOR DRUGS AND MEDICAL DEVICES (BFARM) PHARMACOVIGILANCE DATABASE

D. C. Baumgart[1,*], U. Grittner[2]. [1]*Department of Medicine, Division of Gastroenterology and Hepatology,* [2]*Institute of Biometry and Clinical Epidemiology, Charité Medical Center - Medical School of the Humboldt-University of Berlin, Berlin, Germany*

INTRODUCTION: Inflammatory bowel disease (IBD) patients are treated with a variety of conventional and biologic medications with a diverse safety profile. Comprehensive, real world safety data, particularly of non-biologic agents are sparse.

AIMS&METHODS: We systematically searched all cases (n=233.000) reported to the German Federal Institute for Drugs and Medical Devices (BfArM) - the independent higher federal authority for risk monitoring of medicinal products, medical devices and the legal traffic of controlled substances - from 1993 to 2009. We extracted all reports involving Crohn's disease (CD) and ulcerative colitis (UC) and analyzed the results using the Medical Dictionary for Regulatory Activities (MedDRA) terminology grouped by system organ class (SOC), high level group term (HLGT), high level term (HLT), preferred term (PT), lowest level term (LLT).

RESULTS: We identified 1102 reports concerning IBD and focused on the established cases (CD=461, 44.4% male, age 40.8 ± 17.7 SD, BMI 23 ± 5.8 SD; UC=470, 49.6% male, 45.7 ± 20 SD, BMI 23.3 ± 6 SD). Event severity (CD vs. UC serious 86 / 85.5%, life threatening 10.4 / 11%, deadly 5.2 / 5.7% and disabling 2 /1.7% and hospitalization rates (49.2 /52.3%) were comparable among both conditions. The five most common SOC in CD vs. UC were: gastrointestinal disorders 36.7 / 30.2%, general disorders and administration side conditions 21 / 23.2%, investigations 17.4 / 17.7%, nervous system disorders 15.8 / 15.5% and blood lymphatic disorders 15.2 / 15.5%, respectively. The top five most frequently suspected or interacting drugs (percent of affected patients, median dose, median duration of administration) were in CD azathioprine (27.3%, 113 mg, 36 days), mesalamine (11.1%, 3000 mg, 60 days), sulphasalazine (3.7%, 3000 mg, 26 days), mercaptopurine (3.5%, 75 mg, 21 days) and prednisolone (2.8%, 25 mg, 7 days) and in UC mesalazine (18.5%, 2700 mg, 86 days), azathioprine (14.0%, 100 mg, 39 days), prednisolone (5.1%, 30 mg, 49 days), sulfasalazine (3.8%, 1500 mg, N/A), and mercaptopurine (3.6%, 87.5 mg, 45 days).

CONCLUSION: The overall low fraction (0.47% of all reported cases) of suspected medication related complications in this 16 year national cohort is likely owed to the relatively low prevalence of IBD in the population. However, the majority of reported cases classified in the serious or life threatening categories and half of them requiring hospitalization emphasize the importance of pharmacovigilance among clinicians caring and prescribing medicines for IBD patients.

P323 THERAPEUTIC ESCALATION IN PATIENTS WITH ULCERATIVE COLITIS: SYSTEMATIC ANALYSIS OF THE PREVALENCE AND RISK FACTORS IN THE SWISS IBD COHORT

E. Safroneeva[1,*], S. Vavricka[2], N. Fournier[3], G. Rogler[2], A. Straumann[4], A. Schoepfer[5], Swiss IBD Cohort Study Group. [1]*Institute of Social and Preventive Medicine, University of Bern, Bern,* [2]*Gastroenterology and Hepatology, University Hospital Zurich, Zurich,* [3]*Institute of Social and Preventive Medicine, University of Lausanne / CHUV, Lausanne,* [4]*Gastroenterology and Hepatology, University Hospital Basel, Basel,* [5]*Gastroenterology and Hepatology, University Hospital Lausanne / CHUV, Lausanne, Switzerland*

INTRODUCTION: There is a paucity of large cohort studies having systematically assessed the need for therapeutic escalation in patients with ulcerative colitis (UC).

AIMS&METHODS: We aimed to assess in what percentage of UC patients a therapeutic escalation is needed over time and to identify escalation-associated risk factors. Data from the Swiss IBD Cohort Study (SIBDCS) were analyzed. The frequencies of patients under the following medications were assessed according to disease duration: 5-aminosalicylates (5-ASA), steroids, immunomodulators (IM, azathioprine and 6-mercaptopurine), anti-TNF drugs (infliximab, adalimumab), and calcineurin-inhibitors (cyclosporine, tacrolimus). Patients without any therapy and UC related surgery were also evaluated.

RESULTS: A total of 901 UC patients were included (45.3% females), median age 41 [32-52] years. Median age at diagnosis was 31 [24-40] years, disease duration was 6 [2-14] years. Forty two percent presented with pancolitis, 42% with left-sided colitis, and 16% with proctitis. A progressive decrease of patients treated solely with 5-ASA and an increase of patients needing immunomodulators and/or steroids as well as surgery was noted over time. The following treatments regimens were observed: for a disease duration of 0 to 2 years: 5-ASA 28%, steroids and/or IM 51%, anti-TNF and/or calcineurin inhibitors 18.3%, surgery 2.3%, no therapy 0.4%; disease duration of 3-6 years: 5-ASA 18.9%, steroids and/or IM 49.5%, anti-TNF and/or calcineurin inhibitors 28.6%, surgery 2%, no therapy 1%; disease 7-14 years: 5-ASA 16.3%, steroids and/or IM 57.5%, anti-TNF and/or calcineurin inhibitors 20.4%, surgery 5%, no therapy 0.8%; disease duration ≥15 years: 5-ASA 15%, steroids and/or IM 60.9%, anti-TNF and/or calcineurin inhibitors 9.7%, surgery 14%, no therapy 1.4%. Young age at UC diagnosis (OR 0.955, 95% CI 0.929-0.981, $p = 0.001$) as well as pancolitis (OR 2.404, 95% CI 1.261-4.584, $p = 0.007$) were the main risk factors for a rapid therapeutic stepup with need for treatment by anti-TNF drugs and/or calcineurin inhibitors within the first two years after UC diagnosis.

CONCLUSION: A relatively small proportion of our UC patients could be treated in the long-term run by 5-ASA only, which may be related to the fact that 80% of patients were recruited by hospitals and only 20% by gastroenterologists in private practice. Young age at disease onset and pancolitis are the major risk factor for a need for a rapid stepup within the first two years of disease course.

P324 IMPACT OF TREATMENT OF INTESTINAL PARASITES ON THE ACTIVITY OF ULCERATIVE COLITIS

E. A. Saad[1], A. A. Mourad[1], A. M. Mahmoud[1], H. I. Hussien[1], S. M. Ahmed[2], S. A. Elhawari[1], M. H. Emara[1,*]. [1]*Tropical Medicine,* [2]*Parasitology, ZAGAZIG UNIVERSITY, Zagazig, Egypt*

INTRODUCTION: Ulcerative colitis (UC) is most common in Western industrialized countries, while it is uncommon in developing countries where helminthes are frequent. People with helminthic infection have an altered immunological response to antigens.

AIMS&METHODS: We aimed to study the impact of treatment of intestinal parasites on the activity of ulcerative colitis. Twenty patients with ulcerative colitis and intestinal parasite infection were selected out of 57 patients with UC, after 3 successive days stool analysis and anal swab. They were randomized into two groups: group I was treated for intestinal parasites while group II was not. Patients were evaluated using simple clinical colitis activity (SCCA) index, laboratory investigations and colonoscopy, before and one month after

treatment of intestinal parasites in group I, one month from the first visit in group II to evaluate the activity of the disease.
RESULTS: Patients who were treated for intestinal parasites had statistical significant deterioration in bowel frequency/day (p=0.04), and bowel frequency/night (p=0.038) .On the other side, the untreated group showed non significant change in all parameters of SCCA index after one month, but, their bowel frequency/day, bowel frequency/night and the general condition were significantly ameliorated in comparison with the treated group. There was statistically significant deterioration in hemoglobin (p=0.049), WBC's (p=0.01) in the treated group, while the platelets count, ESR and CRP which remained unchanged in treated group showed significant improvement in the untreated group in addition to improved hemoglobin levels after one month, finally, WBC's and CRP were significantly lower in the untreated group in comparison with the treated group after one month. There was statistically significant increased friability, exudation and spontaneous hemorrhage among the treated group without significant change in colonoscopic finding among the untreated group, the treated group had more severe colonoscopic finding in comparison with the untreated group after one month (p=0.02).
CONCLUSION: Treatment of intestinal parasites in ulcerative colitis patients deteriorates the clinical activity of the ulcerative colitis.

P325 EFFICACY AND SAFETY OF IBD98E, A SODIUM HYALURONATE TOPICAL PREPARATION, IN THE INDUCTION OF CLINICAL AND ENDOSCOPIC REMISSION IN PATIENTS WITH DISTAL ULCERATIVE COLITIS: AN OPEN LABEL PILOT STUDY

G. Fiorino[1,*], D. Gilardi[1], P. Naccarato[1], O. R. Sociale[1], S. Danese[1]. [1]*IBD Center, IRCCS Humanitas, Rozzano, Italy*

INTRODUCTION: Ulcerative colitis (UC) is characterized by inflammation and ulcers in the rectum and colon. Sodium hyaluronate (Na-HA) can contribute significantly to the hydration and maintenance of the integrity of the intestinal mucosa. Altered mucosal layer found in UC is associated to the inflammation. Enhancement of the mucosal repair mechanisms may provide a new potential way of treating UC. Restoration of the protective layer with Na-HA may contribute to the induction of remission of UC.
AIMS&METHODS: We aimed to investigate whether supplementation of the mucosal lining of the rectum with sodium hyaluronate might be a potential alternative treatment in distal active UC. This was a prospective uncontrolled open-label trial. Adult patients with defined active distal UC (UCDAI $\geq$ 4 and sigmoidoscopy score $\geq$ 1) were included and evaluated for clinical and endoscopic activity at day 0 and day 28. All subjects received IBD98E enema once a day (containing Na-HA 60 ml with xantham gum) during the study period. The primary endpoint was clinical response rate, defined as a decrease in UCDAI of at least 2 points, and/or at least 30% reduction from baseline, with a decrease in the sub-score for rectal bleeding of at least 1 point. Secondary endpoints included clinical remission (total UCDAI score $\leq$3), with no individual sub-score $>$1. Endoscopic remission was defined as a sub-score for sigmoidoscopy $\leq$1. A descriptive evaluation was performed, and a paired Student's t test was performed to assess statistically significant differences in subjects between baseline and D28.
RESULTS: From June to December 2012, 21 subjects (10 males) completed the study and were included in the final analysis. Average time of entry to the study from first UC diagnosis was 77.9 months (3.7-204). At D28, 9 subjects (42.9%) were clinical responders, 10 subjects (47.6%) had endoscopic response, defined as a reduction of endoscopic subscore from baseline. Eight patients (38.1%) achieved clinical remission, and ten subjects (47.6%) achieved endoscopic remission. Average UCDAI score decreased on average from 6.10 to 3.81 at D28 (p=0.001), and average endoscopic score decreased from 1.57 to 1.10 (p=0.004). A decrease in the mean PGA e PGS scores was also observed (p=0.02 and 0.04). Safety profile was generally good, no serious adverse events were recorded.
CONCLUSION: IBD98E was effective and safe to induce clinical and endoscopic remission in about half of subjects with active distal UC. Sodium hyaluronate might be a potential new treatment due to its mucosal healing properties. Placebo-controlled studies are warranted.

P326 TIME TO REMISSION AND RESPONSE IN ADALIMUMAB-TREATED PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS FROM ULTRA 2

J.-F. Colombel[1,*], S. Plevy[2], W. Sandborn[3], G. D'Haens[4,5], A. Robinson[6], J. Petersson[7], B. Huang[6], A. Lazar[8], R. Thakkar[6]. [1]*Icahn School of Medicine at Mt Sinai, NY,* [2]*UNC School of Medicine, Chapel Hill,* [3]*UCSD, La Jolla, United States,* [4]*Imelda GI Clinical Research Center, Bonheiden, Belgium,* [5]*Academic Medical Center, Amsterdam, Netherlands,* [6]*AbbVie, N. Chicago, United States,* [7]*AbbVie, Rungis, France,* [8]*AbbVie, Ludwigshafen, Germany*

INTRODUCTION: Objective: To determine the time to achieve remission and response per partial Mayo score (PMS) in patients (pts) with moderately to severely active ulcerative colitis (UC) treated with adalimumab (ADA) enrolled in ULTRA 2[1].
AIMS&METHODS: In the 52-week (wk) trial ULTRA 2, pts with moderately to severely active UC (Mayo score 6-12; endoscopy subscore 2-3) received double blind (DB) ADA 160/80mg at wks 0/2, followed by ADA 40mg every other week (eow) or placebo (PBO). Pts with inadequate response could receive open-label (OL) ADA 40mg eow beginning at wk 12 followed by 40mg weekly. Prior anti-TNF use was allowed. Remission (PMS $\leq$2 with no subscore $>$1) and response (decrease in PMS $\geq$2 points and decrease $\geq$30% from baseline plus a decrease in rectal bleeding subscore [RBS] $\geq$1 or an absolute RBS of 0 or 1) up to wk 52 were analyzed for the ITT population. Subgroup analyses by prior anti-TNF use were also performed. The time to remission or response (number of days from study day 1 to the date of the first occurrence of remission or response, respectively) was determined using Kaplan-Meier curves and tested between treatment groups using weighted log-rank test. Pts were analysed "as randomized" and were not censored at time of moving to OL ADA.
RESULTS: The median time to remission was significantly shorter for ADA-treated than PBO-treated pts (20 wks vs 29 wks, respectively, p=0.015). Similar results were observed for median time to response (4 wks ADA-treated vs 10 wks PBO-treated, p$<$0.001). In subgroup analyses, ADA-treated pts, naïve to prior anti-TNF therapy, achieved remission and response significantly faster than PBO pts (Table). In anti-TNF-experienced pts, median time to response was similar for both treatment groups (8 wks ADA-treated vs 12 wks PBO-treated).
Table. Median wks to clinical remission and response per PMS in ULTRA 2

	All Patients - ITT		Anti-TNF-naive		Anti-TNF-experienced	
	PBO N=246	ADA N=248	PBO N=145	ADA N=150	PBO N=101	ADA N=98
Time to remission (wks)	29	20*	20	12*	44	NR
Time to response (wks)	10	4†	8	4†	12	8

NR: not reached; *p$<$0.05, †p$<$0.001 vs PBO, weighted log-rank test
CONCLUSION: In ULTRA 2, pts with moderately to severely active UC randomized to ADA had shorter times to remission and response than pts randomized to PBO, even though the latter included pts that moved from PBO to OL ADA. Pts naïve to anti-TNF therapy derived the greatest treatment benefit.

P327 HOSPITALIZATION RATES IN PATIENTS WITH CROHN'S DISEASE AND DEEP REMISSION: DATA FROM THE 56-WEEK CHARM TRIAL

J.-F. Colombel[1,*], R. Panaccione[2], E. Louis[3], M. Yang[4], M. Skup[4], R. Thakkar[4], P. Mulani[4], J. Chao[4], W. J. Sandborn[5]. [1]*Mount Sinai School of Medicine, New York, United States,* [2]*University of Calgary, Calgary, Canada,* [3]*University of Liège and CHU Liège, Liège, Belgium,* [4]*AbbVie Inc., North Chicago,* [5]*University of California, San Diego, La Jolla, United States*

INTRODUCTION: Deep remission (DR), an emerging treatment goal in Crohn's disease (CD), may be associated with improved patient outcomes.
AIMS&METHODS: We assessed all-cause and CD-related hospitalization rates among patients (both ADA- and PBO- treated) in the 56-week CHARM trial (NCT00077779) who achieved predicted DR vs. those who did not. Predicted DR was defined as having both predicted mucosal healing (using an index comprised of non-invasive biomarkers and symptomatology[1]) and clinical remission (Crohn's Disease Activity Index [CDAI] total score <150) at Week 12 in CHARM. Hospitalization rates were compared in predicted DR achievers vs. non-achievers from Week 12 to Week 56 using chi-square tests. Logistic regression was used to compare the odds of being hospitalized from Week 12 to Week 56, adjusting for adalimumab treatment and CD disease duration at Week 12. Analyses were performed as observed and with non-responder imputation (NRI) for patients with missing predicted DR data.
RESULTS: At Week 12 in CHARM, 193 of 686 patients achieved predicted DR at Week 12 in CHARM. From Week 12 to Week 56, hospitalizations for any reason (11% vs. 18%; OR=0.59, 95% CI: 0.36, 0.98; *P*=.04) as well as those specifically related to CD (6% vs. 13%; OR=0.43, 95% CI: 0.23, 0.83; *P*=.01) were significantly less among predicted DR achievers vs. non-achievers (**table**; as observed). In the NRI analysis, CD-related hospitalizations were significantly less in DR achievers vs. non-achievers (6% vs. 12%; OR=0.68, 95% CI: 0.25, 0.93; *P*=.03).

Hospitalization Rates in predicted DR Achievers vs. Non-achievers

	As-Observed			NRI		
	Achievers	Non-achievers	*P*-Value	Achievers	Non-achievers	*P*-Value
Week 12 to Week 56	N=193	N=493		N=193	N=585	
All-cause, n (%)	22 (11)	91 (18)	<.05	22 (11)	96 (16)	.12
CD-related, n (%)	12 (6)	66 (13)	<.05	12 (6)	70 (12)	<.05

CONCLUSION: Hospitalizations for any reason or specifically related to CD were fewer in patients with CD who achieved predicted DR compared with those who did not.

P328 INTRAVENOUS CORTICOSTEROIDS IN MODERATE ACTIVE ULCERATIVE COLITIS NOT RESPONDING TO ORAL CORTICOSTEROIDS

J. Llaó[1,*], J. Naves[2], A. Ruiz-Cerulla[3], L. Marin[1], M. Mañosa[2], L. Rodríguez-Alonso[3], E. Cabré[2], E. Garcia-Planella[1], J. Guardiola[3], E. Domènech[2]. [1]*Hospital de la Santa Creu i Sant Pau,* [2]*Hospital Universitari Germans Trias i Pujol,* [3]*Hospital Universitari de Bellvitge, Barcelona, Spain*

INTRODUCTION: Oral corticosteroids remain the mainstay of conventional therapy for moderate flares of ulcerative colitis. In patients who fail to respond to oral CS, it is recommended to attempt the intravenous route before starting rescue therapies, although no evidence supports this strategy.
AIMS&METHODS: To evaluate the efficacy of i.v. CS in moderate attacks of UC according to previous failure to oral CS or not, and to identify differences in long-term outcomes. All UC patients admitted to three University hospitals between 2005 and 2011 were identified. Disease severity was defined according to the Montreal classification, and only patients with moderate active UC treated with i.v. CS were included. Patients were grouped depending on previous treatment with oral CS for the index flare. Main end-points were: *initial efficacy* (defined as mild severity or inactive disease according to Montreal classification at day 7 after starting i.v. CS without a rescue therapy) and the long term clinical outcome.
RESULTS: A total of 110 attacks were included (89 patients),45% of the attacks were initially treated with oral CS without response, with a median dose of 60mg/d and during a median time of 10 days. No differences in clinical features and biological parameters between both groups, except for a younger age and lower C-reactive protein levels at the beginning of i.v. CS in the group of patients initially treated with oral CS. The i.v. CS dose was 60mg/d and the median concentration of C-reactive protein at the beginning of i.v. treatment was 44mg/L. Initial response was achieved in 75%, without differences between the both study groups (78% vs. 75%). Rescue therapy during the admission was required in 26% of cases, with a colectomy rate of 3%. No predictive factors to initial response to i.v. CS were found. After a median follow-up of 12 months (IQR, 4-24), 35% of initial responders developed steroid-dependency and up to 13% required colectomy. The unsuccessful response to oral CS was the only factor associated to steroid-dependence in the long-term (54% vs. 18%, P=0.001).
CONCLUSION: Intravenous CS are efficient for inducing remission in moderately active UC not responding to oral CS, but almost half of the patients develop steroid-dependency later on. Alternative therapeutic strategies should be assessed in this clinical setting.

P329 MANAGEMENT AND OUTCOME OF SEVERE ATTACKS OF ULCERATIVE COLITIS IN THE ERA OF BIOLOGICALS

J. Llaó[1,*], J. naves[2], A. Ruiz-Cerulla[3], J. Gordillo[1], M. Mañosa[2], S. Maisterra[3], E. Cabré[2], E. Garcia-Planella[1], J. Guardiola[3], E. Domènech[2]. [1]*Hospital de la Santa Creu i Sant Pau,* [2]*Hospital Universitari Germans Trias i Pujol,* [3]*Hospital Universitari de Bellvitge, Barcelona, Spain*

INTRODUCTION: The availability of predictors of response to corticosteroids (CS) and the use of cyclosporine and infliximab as rescue therapies should have modified the management and outcome of severe ulcerative colitis (SUC).
AIMS&METHODS: To describe the current need of rescue therapies and colectomy in CS-treated SUC.All UC patients admitted to three University hospitals between January 2005 and December 2011 were identified from electronic databases. Disease severity was defined according to the Montreal classification, and only patients with SUC treated with intravenous CS were included. Main endpoints were: initial CS efficacy (defined as mild or inactive UC activity assessed by Montreal Classification at day 7 after starting intravenous CS without a rescue therapy), medical rescue therapy requirements, colectomy rate, and long-term clinical outcome (steroid dependency, colectomy).
RESULTS: A total of 62 flares were included (57 patients), 18% in active smokers, 70% extensive disease, 33% while on azathioprine maintenance therapy, and 22% previously treated for the same flare with oral GCS. Median C-reactive protein concentration at the beginning of intravenous CS was 99.5 mg/L (IQR, 55.5-163). Initial response of CS was achieved in 50% and 43% of flares required medical rescue therapies (12 cyclosporine, 15 infliximab) and one patient needed colectomy. Median time between the beginning of intravenous CS and rescue therapy was 7 days (IQR, 4-9), without differences between cyclosporine and infliximab-treated patients. The initial treatment with oral CS was the only risk factor (P= 0.017) and to be a former smoker the only protective factor (P= 0.003) for needing rescue therapies. During follow-up, 38% of those patients responding to CS developed steroid-dependency and 4 patients who needed a rescue treatment during admission underwent colectomy. The initial treatment with oral GCS for the index flare, the failure of intravenous CS and the need of rescue therapy were associated with colectomy, but the initial treatment with oral CS was the only independent predictive factor of colectomy in the multivariate analysis (P<0.0001).
CONCLUSION: The efficacy of intravenous CS in SUC is 50%, but the colectomy rate is <10% in the short and long-term. Patients worsening after oral CS are at a higher risk for needing rescue therapies and colectomy.

P330 EFFECTS OF AZATHIOPRINE ON OUTCOME OF PREGNANCY IN INFLAMMATORY BOWEL DISEASE PATIENTS . A PROSPECTIVE STUDY

L. Kecili[1,*], N. Bounab[1], A. Balamane[1], M. Nakmouche[1], N. Debzi[1], K. Belhocine[1], L. Gamar[1], N. Kaddache[1], K. Layaida[1], N. Afredj[1], N. Guessab[1], T. Boucekkine[1]. [1]*Faculty of Medicine, Algiers, Algeria*

INTRODUCTION: It is generally believed that Azathioprine (AZT) is harmless in pregnancy(P)of inflammatory Bowel Disease patients(IBD) both for the pregnant women and fetus .Nevertheless studies are rare,frequently retrospective and concern generally small cohorts .
AIMS&METHODS: To assess in a prospective study influence of AZT on fetal prognosis and natural history of the disease in IBD pregnant patients,we have enrolled 261 consecutive IBD patients in a prospective long term follow-up study from 1/1/2005 to 31/12/2009 of whom 244 (Group I;GI) were pregnant during the study or have had pregnancies;37 had no P (Group II;GII). 37 patients (19 Ulcerative colitis :UC and 18 Crohn's disease :CD) received AZT (2,5 mg/kg/day),(GI:n=30;GII:n=7) during 29 to 36 months.Evaluation was based on

characteristics of the last P with AZT and its outcome. Statistical analysis : Student Fisher's t test and Mann Withney's U test.
RESULTS: Comparison of IBD GI patients who received AZT (IBD/GI/AZT+) and GI patients who did not received AZT (IBD/GI/AZT-) did not show any significant statistical difference (SSD) as regards to demographic and anatomoclinical characteristics,gestational statute and outcome of disease.The same results were found when comparing UC/GI/AZT+ patients and UC/GI/AZT- patients. In return,CD/GI/AZT+ patients differ from CD/GI/AZT– patients by a greater number of anoperineal(27,7% vs 17,5%;p<0,4818) and proximal (11,1% Vs 0%;p=0,0109) locations.Caesareans (13,3% Vs 8,7%;p<0,629),stillbirths (3,3% Vs 1,5%;p=0,9613) and congenital abnormalities (3,3% Vs 0,5%;p=0,6318) were more frequent in IBD /GI /AZT+ than in IBD/GI/AZT- but didn't reach SSD whereas abortions (6,6% Vs 5,2%),premature births (6,6% Vs 5,2%),low weight birth (10% Vs 8,2%) where found at the same rates UC/GI/AZT+ patients didn't differ from UC/GI/AZT-patients as regards to gestational complications.Caesareans(21,4% Vs 10,2%;p=0,4366),low weight births (14,2% Vs 8,2%;p=0,814) and congenital abnormalities (7,1% Vs 0%;p=0,26) were more frequent in CD/GI/AZT+ than in CD/GI/AZT- patients .Long term outcome of the disease,was evaluated according to 4 heading: unchanged, improved,worsened, need for surgery.We found no SSD between IBD/GI/AZT+ and IBD/GI/AZT-patients and between IBD/GI/AZT+ and IBD/ GII/AZT+ patients.
CONCLUSION: Use of AZT in IBD pregnant women is associated with a slight increase in fetal risk mainly in CD.This pejorative effect cannot be entirely imputable to AZT as this drug is prescribed in severe IBD;in this instance, fetal outcome may be due at least in part to the disease activity.

P331 HYPOGONADAL MEN WITH INFLAMMATORY BOWEL DISEASES (M. CROHN AND COLITIS ULCEROSA) BENEFIT FROM LONG-TERM TREATMENT WITH INJECTABLE TESTOSTERONE UNDECANOATE

M. Nasser[1,*], A. Haider[2], W. Kurtz[3], G. Doros[4], F. Saad[5,6]. [1]*Gastroenterology, University of Aleppo, Aleppo, Syrian Arab Republic,* [2]*Private Urology Practice,* [3]*Internal Medicine, Klinikum Bremerhaven, Bremerhaven, Germany,* [4]*Epidemiology and Statistics, Boston University School of Public Health, Boston, United States,* [5]*Research, Gulf Medical University School of Medicine, Ajman, United Arab Emirates,* [6]*Global Medical Affairs, Bayer Pharma AG, Berlin, Germany*

INTRODUCTION: Testosterone (T) has anti-inflammatory effects. T treatment has been found to be beneficial in rheumatoid arthritis and chronic obstructive pulmonary disease. We had reported effects of two years of T treatment in a small group of hypogonadal men with Crohn's disease (Haider A et al., Horm Mol Biol Clin Invest 2010; 2(3): 287–292).
AIMS&METHODS: In a prospective, cumulative, observational registry study, 71 hypogonadal men with Crohn's disease and 2 men with Colitis ulcerosa with T ≤ 12 nmol/L from 2 centers in Bremerhaven, Germany and Aleppo, Syria received treatment with parenteral testosterone undecanoate on day 1, after 6 weeks and thereafter every 12 weeks for up to 75 months. 12 hypogonadal men of similar age with Crohn's disease who did not receive T served as an untreated control group. In total, 73 men received T and 12 hypogonadal men remained untreated. The Crohn's Disease Activity Index (CADI) was assessed as an indicator of the severity of the disease every 3 months. In addition, highly sensitive C-reactive protein (hsCRP) and leukocyte count as markers of inflammatory activity were measured. The Aging Males' Symptoms Scale (AMS) was used as a self-administered quality of life (QoL) questionnaire.
RESULTS: T levels at baseline were 9.37 ± 1.08 nmol/l in the T group and 10.75 ± 0.36 in the control group. During treatment, T increased to 15. 72 ± 0.53 and slightly declined in the control group. The CADI decreased from 231.3 ± 35.96 to 75.0 in the treated group and increased from 196.25 ± 7.11 to 210.0 in the control group. hsCRP (mg/dL) levels at baseline were 14.13 ± 9.18 in the T group vs 7. 3 ± 0.98 in the control group. They decreased to 2.63 ± 1.91 after 72 months in the T group and increased to 13.7 in the control group. Leukocyte count decreased from 12.52 ± 2.76 to 5.97 ± 0.51 in the treated group and remained unchanged in the control group (from 11.38 ± 1.29 to 12.7). The AMS improved from 49.74 ± 8.37 in the T group to 17.33 ± 0.58. In the control group, AMS remained unchanged from 47.17 ± 1.03 at baseline to 48 at the end of the observation period.
CONCLUSION: Normalization of T in hypogonadal men with Crohn's disease led to improvements of the CADI, hsCRP, a reduction of leukocytes and an improvement of QoL. The mechanism of this improvement may be through anti-inflammatory and immunosuppressive effects of testosterone, reducing chronic inflammation of the intestinal wall in Crohn's disease.

P332 EFFICACY AND SAFETY OF ADALIMUMAB IN CHILDREN WITH CROHN'S DISEASE PREVIOUSLY TREATED WITH INFLIXIMAB.

A. Jacob[1], M. Fumery[2,*], J. Salleron[3], L. Michaud[1], F. Vasseur[3], C. Spyckerelle[4], J.-F. Colombel[5], C. Gower-Rousseau[6], D. Turck[1]. [1]*Paediatrics, UNIVERSITY AND HOSPITAL LILLE, Lille,* [2]*Gastroenterology, University Hospital, Amiens,* [3]*Biostatistics EA2694, UNIVERSITY AND HOSPITAL LILLE,* [4]*Paediatrics, St Antoine Hospital, Catholic University, Lille, France,* [5]*Gastroenterology, Henry D.Janowitz Division of Gastroenterology, New-York, United States,* [6]*Epidemiology, UNIVERSITY AND HOSPITAL LILLE, Lille, France*

INTRODUCTION: Adalimumab (ADA) is effective in the treatment of Crohn's disease (CD) in children naive to infliximab (IFX) (1)
AIMS&METHODS: The objective of this study was to evaluate the effectiveness and safety of ADA in children with CD refractory or intolerant to IFX.This retrospective study included all children with CD from a paediatric-onset population-based cohort who received ADA before the age of 18 years because of failure or intolerance to IFX. Response to ADA was evaluated with the Physical Global Assessment (PGA). The effectiveness of ADA was defined as clinical remission (PGA=1) or clinical response defined by a decrease of at least 2 points of PGA 6 mos after the ADA induction.The following parameters were recorded from ADA initiation to maximal follow-up: growth (height/age Z-score); nutritional status (BMI/age Z-score);and inflammatory biomarkers (CRP, orosomucoid). Adverse effects due to ADA were detailed.
RESULTS: 27 CD patients diagnosed from 2001 to 2010 were included.Median age at diagnosis and at ADA initiation were 11 yrs [Q1=10-Q3=12] and 15 yrs [13-15], respectively.Indication of ADA was primary failure to IFX in 4 patients (14%), loss of response to IFX in 16 (60%) and intolerance to IFX in 7 (26%).At ADA induction 5 patients received systemic steroids and 2 azathioprine. Median duration of ADA treatment was 10 months [6-18]. After a follow-up of 9 months, ADA was effective in 19 patients (70%).13 patients had ADA failure including: 8 primary; (30%) and 5 secondary. Optimizing therapy (increase of ADA dose and/or decrease of intervals between ADA injections) was required in 14 patients. Eleven patients (40%) had a total of 19 adverse effects. The main adverse events were: 1) cutaneous (xerosis; n=6, depigmentation; n=3, acne; n-2 and psoriasis: n=1); 2) local reactions (pain, inflammatory reaction) at the injection site (n=3); and 3) transient arthralgia and/or myalgia (n=4). None adverse effects resulted in ADA discontinuation. There was no significant change in growth and nutritional status over the study period but there was a significant decrease of median CRP from ADA initiation to maximal follow-up (18 mg/L [5-39] *vs* 7 [3-19]; p=0.026) and median orosomucoid (1.64 g/L [1.50- 2.56] *vs.* 1.17 [0.88-1.89]; p<0.001).
CONCLUSION: In this cohort of paediatric-onset CD patients previously treated with IFX, treatment with ADA was safe and effective in 70% after a median follow-up of 9 months. Controlled trials are needed.

P333 EXPOSURE-EFFICACY RELATIONSHIP (ER) FOR ADALIMUMAB DURING INDUCTION PHASE OF TREATMENT OF ADULT PATIENTS WITH MODERATE TO SEVERE ULCERATIVE COLITIS (UC)

N. M. Mostafa[1,*], D. Eckert[2], R. S. Pradhan[3], S. Mensing[2], A. M. Robinson[1], W. J. Sandborn[4], S. B. Hanauer[5], J.-F. Colombel[6], R. Thakkar[1], W. M. Awni[1]. [1]*AbbVie Inc., North Chicago, United States,* [2]*Abbott GmbH & Co KG, Ludwigshafen, Germany,* [3]*Former Employee, AbbVie Inc., North Chicago,* [4]*Inflammatory Bowel Disease Center, Division of Gastroenterology, University of California San Diego Health System, La Jolla,* [5]*Section of Gastroenterology, Hepatology and Nutrition, University of Chicago Medicine, Chicago,* [6]*Mount Sinai Medical Center, New York, United States*

INTRODUCTION: The efficacy and pharmacokinetics (PK) of adalimumab in patients (pts) with moderate to severe UC was studied in a Phase 3 trial (ULTRA 2). The purpose of this exposure-response (ER) analysis was to characterize the relationship between serum adalimumab trough concentration (C_{trough}) and clinical remission and response per Mayo Score.
AIMS&METHODS: Adult pts with moderate to severe UC (N=518) were enrolled, where 260 pts received placebo and 258 received adalimumab (160/80 mg at Wks 0/2, and 40 mg every other wk). C_{trough} was measured immediately prior to dosing at Wk 0, 2, 4 and 8 and remission/response was assessed at Wk 8. The relationship between Wk 8 remission/response and C_{trough} was explored by grouping pts C_{trough} into quartiles and plotting C_{trough} vs remission/response rates. Only pts with available C_{trough} at Wk 8 were included in the analysis. The ER was also assessed using logistic regression. Models (linear and E_{max}) were fit to the individual ER data for remission/response at Wk 8. In the E_{max} model, the upper 95% limit of the observed remission/response was used for E_{max}.
RESULTS: The ranges of adalimumab C_{trough} quartiles were <5, 5-8.7, 8.7-11.7 and >11.7 μg/mL. C_{trough} vs remission quartile plots showed a clear ER at Wk 8. Higher C_{trough} values were associated with higher rates of remission. Quartile plots for response showed that the % of pts with Wk 8 response was higher for the 2nd and 3rd C_{trough} quartiles compared with the 1st quartile. The % of pts with Wk 8 response did not increase beyond the 3rd quartile. Logistic regression ER models for remission showed a statistically significant relationship between the % of pts with remission at Wk 8 and C_{trough} (p<0.001 for linear and p=0.011 for E_{max}). Goodness-of-fit plots showed that both models describe the data adequately. For response, the logistic regression models also showed a statistically significant relationship (p<0.001 for for linear and p=0.032 for E_{max}), but the ER observed with response was flatter compared to remission.

CONCLUSION: A statistically significant ER was identified between C_{trough} and remission during the induction phase. The ER for response appeared to be shallower compared to that for remission. This indicates that dosing regimens that result in higher exposures could provide greater efficacy in some pts.

P334 EFFICACY OF CONCOMITANT ENTERAL NUTRITION DURING ADALIMUMAB MAINTENANCE THERAPY IN CROHN'S DISEASE

N. Yoshimura[1,*], T. Kawaguchi[1], M. Sako[1], A. R. Saniabadi[1], M. Takazoe[1]. [1]*Department of Internal Medicine, Social Insurance Central General Hospital, Tokyo, Japan*

INTRODUCTION: Adalimumab (ADA), a fully human anti-tumour necrosis factor (TNF) monoclonal antibody, is effective for inducing and maintaining remission in patients with active Crohn's disease (CD). Currently, loss of response to ADA during maintenance therapy in the clinical management of CD is a major therapeutic challenge. In Japan, until now, enteral nutrition (EN) has been associated with efficacy for inducing and maintaining remission in patients with CD. However, no study has investigated the efficacy of concomitant EN for sustaining response to ADA in patients with quiescent CD during maintenance therapy.
AIMS&METHODS: The aim of this study was to assess the efficacy of concomitant EN in patients with CD during ADA remission induction and maintenance therapy. In this endeavour, a cohort of 78 consecutive patients with moderate to severe CD; CD activity index (CDAI) ≥150 who had received subcutaneous ADA, 160mg, 80mg at weeks 0, 2 as remission induction therapy were retrospectively evaluated. Of 78 patients, 44 had received concomitant EN (≥300kcal/day, EN group) and 34 had received ADA without EN (control group). At week 4, clinical remission (CDAI < 150) rates were compared between the two arms. Patients who had successful ADA induction therapy received ADA maintenance therapy at 40mg, every two weeks. Loss of response to ADA was defined as CDAI≥150 and an increase of >70 points in the CDAI score. All patients were followed for at least 24 weeks. Long-term outcomes in both arms were evaluated by the Kaplan-Meier survival analysis.
RESULTS: Of 78 patients, 44 were in the EN arm (522±260kcal/day), and 34 were in the control arm. In the EN arm, 26 of 44 patients (59.1%) achieved remission vs 24 of 34 (70.6%) in the control arm. There was no significant difference in remission rates between the two arms. Fifty patients who achieved remission during ADA induction therapy received maintenance ADA. Three of 26 patients (11.5%) in the EN arm showed loss of response to ADA vs 8 of 24 (33.3%) in the control arm ($P < 0.01$). The Kaplan-Meier survival analysis showed significantly lower loss of response in favour of the EN arm ($P < 0.05$).
CONCLUSION: This is the first study which has investigated the clinical efficacy of concomitant EN therapy in patients with the loss of response to ADA. Based on the outcomes of the present investigation, concomitant EN should be considered in the management of CD during ADA maintenance therapy.

P335 THE COMBINATION OF MESENCHYMAL STROMAL CELLS AND INFLIXIMAB INCREASES THE ANTI-INFLAMMATORY EFFECT OF THE TREATMENT OF ULCERATIVE COLITIS

O. Knyazev[1,*], I. Ruchkina[1], A. Parfenov[1]. [1]*Central Research Institute of Gastroenterology, Moscow, Russian Federation*

INTRODUCTION: Mesenchymal stromal cells (MSCs) have a high potential for differentiation and immunosuppressive properties. Concentration of azathioprine, methotrexate, 6-mercaptopurine, infliximab no effect on the viability, differentiation, phenotype MSC and ability to suppress proliferation of peripheral blood mononuclear cells [1].
AIMS&METHODS: Assess the clinical and endoscopic efficacy of combination therapy with concurrent use of UC MSC and infliximab (IFX). According to the method of therapy 3 groups of patients with UC with chronic continuous and chronic relapsing severe and moderate severity: 1 group patients (n=28) who were administered MSCs, 2 group patients with UC (n=26) received IFN, the introduction of which was carried out according to the standard treatment regimen of patients with UC. 3-d group of patients with UC (n=10) received MSC and IFX. Duration of disease from 3 to 15 years (Me-8 years), follow-up was 24 months. According to the results of clinical and endoscopic studies of the colonic mucosa we conducted a comparative analysis of the effectiveness of different biologic therapy of patients with UC after 2, 6 and 12 months of therapy. Initial level clinical activity index before treatment was in 1-st group - 8,98±0,38 points, 2-nd - 9,1±0,4, and 3-rd - 9,1±0,6. The level of endoscopic activity index was in the 1-st group 7,46±0,2 points, 2-nd - 7,62±0,16, 3-rd - 7,6±0,4. Statistical difference in groups according to the initial indexes was not ($p > 0,05$).
RESULTS: After 2 months of clinical activity index decreased significantly from baseline in group 1 - 1,53±0,24 points, in the 2nd - to 1,27±0,12, in the 3-rd to 1,1±0.17 points ($p > 0,05$). After 6 months of clinical activity index was in 1-st group 1,64±0,24 points in the 2-nd - 1,35±0,14 points, 3-rd - 0,7±0,15 points, which was significantly lower than in the 1-st and 2-nd groups ($p < 0,05$). After 12 months of clinical activity index was in 1-st group - 1,68±0,8 points in the 2-nd - 1,62±0,16 points, 3-rd - 0,5±0,16 points, which was significantly lower than in the 1st and 2nd groups ($p < 0.05$). Endoscopic activity index Mayo 2 months decreased significantly from baseline in the 1-st, 2-nd and 3-rd groups of up to 1,57±0,24, 1,65±0,25, 1,22±0,2 scores ($p < 0,05$). After 6 months the index Mayo; 1-st - 1,6±0,24 points, 2-nd - 1,65±0,19, 3-rd - 1,1±0,2. After 12 months, the index of Mayo 3-rd group was 0,8±0,2 points, which was significantly lower ($p < 0,05$) than in 1-st group - 1,46±0,22 points and 2-nd - 1,43±0,1 groups.
CONCLUSION: Combined biological therapy of inflammatory bowel disease contributes to more stable clinical and endoscopic remission compared to monotherapy with biological agents.

P336 PREDICTING THE OUTCOME AFTER DISCONTINUATION OF TNFA –BLOCKING AGENTS IN INFLAMMATORY BOWEL DISEASE PATIENTS WITH DEEP REMISSION

P. Molander[1,2,*], J. Haapamäki[3], K. Salminen[4], H. Kemppainen[4], H. Rautiainen[5], U. Nieminen[3], P. Arkkila[3], T. Blomster[6], R. Koskela[6], M. Nissinen[7], A. Jussila[8], J. Kuisma[9], J. Punkkinen[10], K.-L. Kolho[11], H. Mustonen[12], M. Färkkilä[3], T. Sipponen[3]. [1]*Maria Helsinki City Hospital,* [2]*University of Helsinki,* [3]*Helsinki University Central Hospital, Helsinki,* [4]*Turku University Central Hospital, Turku,* [5]*Helsinki University Central Hospital, Jorvi Hospital, Espoo,* [6]*Oulu University Central Hospital, Oulu,* [7]*Helsinki University Central Hospital, Peijas Hospital, Vantaa,* [8]*Department of Gastroenterology and Alimentary Tract Surgery, Tampere University Central Hospital, Tampere,* [9]*Hyvinkää Hospital, Hyvinkää,* [10]*Porvoo Hospital, Porvoo,* [11]*Children's Hospital, Helsinki University Central Hospital,* [12]*Helsinki University Central Hospital, Biomedicum, Helsinki, Finland*

INTRODUCTION: Only few data exist of prognosis of patients with inflammatory bowel disease (IBD) after stopping TNFα- blocking therapy in deep remission. In this prospective multicenter study we evaluated the risk of relapse, predicting factors and the response to re-treatment after discontinuation of TNFα- blocking therapy.
AIMS&METHODS: We prospectively recruited fifty-two patients (18 Crohn's disease [CD], 30 ulcerative colitis [UC] and 4 inflammatory bowel disease type unclassified [IBDU]) in clinical, endoscopic and faecal calprotectin-based ($< 100\mu g/g$) remission after at minimum one year of TNFα- blocking therapy. Patients had been in corticosteroid free remission for at least six months. They were followed up to approximately one year after the discontinuation of TNFα-blocking therapy. Endoscopy was performed at 4 and 12 months after stopping therapy. Clinical relapse in CD was defined as Harvey Bradshaw Index (HBI) ≥8 or an increase of HBI >3 points from baseline to at least 5 points. Clinical relapse in UC or IBDU was defined as partial Mayo score ≥3. Severe endoscopic relapse was defined as the simple endoscopic score for Crohn's disease (SES-CD) ≥16 or Mayo endoscopic subscore ≥2 in UC/IBDU. In case of a clinical relapse or severe endoscopic relapse, TNFα- blocking therapy was restarted.
RESULTS: 16 (31%) patients relapsed after a median follow-up time of 24 months (range 10-37). 5/18 (28%) CD, 10/30 (30%) UC, and 1/4 (25%) IBDU patients relapsed. Re-treatment of TNFα-blocking agents was effective in 94% (15/16) of patients with relapse. No specific factor such as age, gender, disease duration, localization, or behavior, smoking, previous surgery, the TNFα-blocking therapy used, concomitant medications, or duration of the medication based on univariate analysis was associated with the relapse.
CONCLUSION: Of IBD patients in deep remission at the time of cessation of TNFα-blocking therapy, up to 70% sustained their remission during 10 months follow-up. The response to re-induction of TNFα antagonists seems to be effective and well tolerated.

P337 DISEASE CONTROL AMONG ULCERATIVE COLITIS PATIENTS TREATED WITH CONVENTIONAL THERAPIES AND BIOLOGICS NAÏVE IN EUROPE: ULCERATIVE COLITIS CONDITION, ATTITUDE, RESOURCES AND EDUCATIONAL STUDY (UC CARES)-AN INTERIM ANALYSIS

G. Van Assche[1], A. Sturm[2], L. Peyrin-Biroulet[3], **T. Fan**[4,*], M. Lynam[5], S. Rojas Farreras[5], L. Stokes[4], Q. Ding[4]. [1]*Mount Sinai Hospital, Toronto, Canada,* [2]*Charité-Universitätsmedizin Berlin, Berlin, Germany,* [3]*Nancy University Hospital, Vandoeuvre-lès-Nancy, France,* [4]*Merck & Co., Inc, Whitehouse Station, United States,* [5]*IMS Health, Barcelona, Spain*

INTRODUCTION: Thiopurine immunomodulators are recommended for moderate to severe ulcerative colitis (UC) patients. However, use of UC therapies among bio-naïve patients varies considerably in clinical practice, and it is unknown whether disease is well controlled.
AIMS&METHODS: The aim is to describe disease control and treatment satisfaction of biologics-naïve UC patients receiving conventional treatment (5-ASA, steroids and/or thiopurine).
Patients with moderate to severe active UC (Mayo score ≥ 6), aged 18 years or older who received thiopurines during the 12 months prior to the index date were recruited from 46 hospitals across the following 11 European countries: Belgium,

France, Germany, Greece, Italy, The Netherlands, Spain, Sweden, Switzerland, Turkey, and The United Kingdom. Patients who had received biologic therapies, colectomy procedure or ileo-anal J-pouch reconstruction were excluded. Disease control was defined as 1) maintaining remission status, 2) partial Mayo score ≤2 and 3) no corticosteroid use in the past 2 months. Patient surveys and medical charts were reviewed to provide data for analysis. Since November 2012, inclusion criteria were amended by removing the requirements of thiopurines to facilitate more rapid patient enrollment.

RESULTS: By March 20th, 2013, 90 patients were enrolled for an interim analysis. Patients' mean age was 43 (SD =15) and 62% were male. The median duration of UC was 5 years (IQR 2-13). Extent of UC included 20% proctitis, 13% left-sided, and 67% extensive. At the index date, 75 (83%) patients were treated with thiopurines, 65 (72%) were treated with aminosalicylates, 25 (28%) were on corticosteroids, and 3 patients were treated with other types of immunosuppressants. 82% of patients did not have controlled disease. Mean full Mayo score was 4.5 (SD=2.9). In addition, 21% of patients were in remission while 28% of patients received corticosteroids in the past 2 months. Specifically, 27% of patients had Mayo score ≤2, 36% had Mayo score 3-5 and 38% had Mayo score ≥6. Based on a patient satisfaction survey, 57% of patients were satisfied with current UC therapies.

CONCLUSION: The vast majority of biologics naïve UC patients treated with conventional therapies (majority on 5-ASA and thiopurines) were not well controlled and half of patients were unsatisfied with their UC treatment.

P338 SAFETY AND EFFICACY OF HIGH DOSE INTRAVENOUS CORTICOSTEROIDS IN ACUTE ULCERATIVE COLITIS

R. Vora[1,*], H. Finnamore[1], K. Crook[1], E. Whittle[1], M. Dalzell[1], B. Krishnamurthy[1], V. Krishnappa[1], M. Auth[1]. [1]*Paediatric Gastroenterology, Alder Hey Children's Hospital, Liverpool, United Kingdom*

INTRODUCTION: Acute severe ulcerative colitis in children is associated with a high morbidity and it has a colectomy rate of 61% before and 19% even after introduction of biologics. Due to reported steroid unresponsiveness in up to 46% of children treated with a dose of 1.0-1.5 mg/kg/d methylprednisolone, salvage therapy is recommended by ECCO and ESPGHAN. Although the short-time response with CsA (80%), tacrolimus (68%) or infliximab (75%) is limited, there is profound lack of data to define the efficacy and safety of high dose intravenous methylprednisolone.

AIMS&METHODS: To evaluate the efficacy and safety of high dose Methylprednisolone in Acute severe Ulcerative Colitis

Methods:We compared two dosage regimens for the treatment of acute severe and moderate-severe UC using either low dose (LDMP) intravenous Methylprednisolone(< or = 2mg/kg/d) or high dose (>15mg/kg/d, max. 1g) IV Methylprednisolone(HDMP) without randomisation in comparable cohorts. We did a Retrospective case note review on children (n=34) admitted for moderate- or acute-severe UC requiring ivMP over 8 years, by analysis of the one year follow-up data. Disease activity was correlated using actual or retrospective PUCAI score, applying two-tailed student's t-test.

RESULTS: Patient Characteristics

The baseline characteristics of patients in the high dose and low dose MP group were similar with 75-80% of patients in each of the groups having pancolitis. The steroid, azathioprine and salicylate use in the 2 groups was also comparable($p > 0.05$).

Response to treatment

Median PUCAI score	High dose MP	Low dose MP	p-value
Day 1 of iv MP	60	55	p=0.58
Day 3 of iv MP	25	20	p=0.85
Day of Discharge (5-8 days)	6	7	p=0.85
Median Length of Stay in Hospital	7 days	6days	p=0.87

Salvage therapy-

4 out of 14 patients from the LDMP group required Colectomy and none from the HDMP group. The number of patients requiring Inflixmab and ciclosporin in the 2 groups were similar.

Side effects-

Side effects of iv MP were only minor, temporary and comparable in both groups.

CONCLUSION: Our results demonstrate a very low overall colectomy rate (11.7%), and high remission rate (85.2%) for children with acute or moderate severe UC treated with ivMP. Notably, patients with high dose steroids required no colectomy, and their requirement for salvage therapy was not more frequent than in those with low dose steroids. With a median stay of 6.5 days, patients treated with ivMP had no persistent or severe side effects from this medication.

P339 IMPROVEMENT IN PATIENT QUALITY OF LIFE DURING TREATMENT WITH INFLIXIMAB, AZATHIOPRINE, OR COMBINATION INFLIXIMAB+AZATHIOPRINE FOR MODERATE TO SEVERE ULCERATIVE COLITIS

R. Panaccione[1,*], S. Ghosh[1], S. Middleton[2], J. R. Márquez[3], L. Flint[4], H. J. F. van Hoogstraten[4], A. C. Chen[4], H. Zheng[4], S. Danese[5], P. Rutgeerts[6]. [1]*University of Calgary, Alberta, Canada,* [2]*Addenbrookes Hospital, University of Cambridge, Cambridge, United Kingdom,* [3]*Clínica Las Américas, Medellín, Colombia,* [4]*Merck Sharp & Dohme Corporation, Whitehouse Station, United States,* [5]*Istituto Clinico Humanitas, Milan, Italy,* [6]*University of Leuven, Leuven, Belgium*

INTRODUCTION: Improvement in quality of life (QoL) is an important treatment goal for patients with ulcerative colitis (UC). We evaluated QoL in patients with UC who were treated with azathioprine (AZA), infliximab (IFX), or a combination of the 2 therapies.

AIMS&METHODS: UC SUCCESS was a 16-week, double-blind, controlled trial of patients with moderate to severe UC (baseline total Mayo score 6–12). All patients had failed corticosteroids, were biologic-naïve, and were AZA/6-mercaptopurine-naïve or had stopped AZA ≥3 months prior. Patients were randomised to treatment for 16 weeks: AZA 2.5 mg/kg + placebo; IFX 5 mg/kg + placebo; or IFX 5 mg/kg + AZA 2.5 mg/kg. Week 8 nonresponders in the AZA group were eligible for IFX rescue added to AZA. QoL was assessed with the Inflammatory Bowel Disease Questionnaire (IBDQ) and 36-item Short Form Health Survey (SF-36). Treatment group differences were analysed with Mann-Whitney U tests.

RESULTS: 239 patients were enrolled. Of 231 patients eligible for efficacy analyses, 75–80% completed the QoL assessments. Improvements in all IBDQ scores were greater in the combination group than either monotherapy group ($P < .05$, all comparisons; Table). SF-36 physical and mental summary scores (Table) and all 8 component scores showed the same pattern of greater improvement in the combination group than either monotherapy group, although not all of these comparisons were statistically significant. Overall, adverse events were similar across treatment arms.

Table. Mean Change in IBDQ and SF-36 Scores from Baseline to Week 16

		IFX+AZA n=57	IFX n=58	AZA[a] n=53
IBDQ	**Total score**	57.70[bc]	38.55	32.51
	Bowel symptoms	19.40[bc]	12.78	11.30
	Emotional health	18.56[bc]	13.33	10.79
	Systemic function	8.81[bc]	5.14	4.09
	Social function	10.93[bc]	7.31	6.32
		n=59	n=59	n=54
SF-36	**Physical summary**	7.95[b]	4.18	5.28
	Mental summary	11.57	7.55	6.6

[a]26 were week-8 nonresponders and received rescue IFX; their data were imputed by last observation carried forward from week 8; [b]$P < .05$ versus IFX; [c]$P < .05$ versus AZA.

CONCLUSION: Combination treatment with IFX+AZA resulted in greater improvement in QoL than monotherapy with either IFX or AZA. These data are consistent with previous UC SUCCESS reports indicating that clinical responses (steroid-free remission, mucosal healing, and Mayo scores) were better with combination IFX+AZA treatment.

P340 EFFICACY OF INFLIXIMAB AND ADALIMUMAB FOR THE TREATMENT OF ULCERATIVE COLITIS – AN INDIRECT COMPARISON OF RCT EVIDENCE.

M. Chen[1], S. Gurunath[1], C. M. Black[2,3], T. Fan[2,*], M. A. Chaudhary[2], J. P. Jansen[1]. [1]*MAPI CONSULTANCY, Boston,* [2]*Merck, Sharp & Dohme, Whitehouse Station,* [3]*St. John's University, Queens, United States*

INTRODUCTION: Biologics have been demonstrated to be effective in the treatment of patients with moderate to severe ulcerative colitis (UC).
AIMS&METHODS: The objective of this study was to compare the efficacy of adalimumab (ADA) and infliximab (IFX) for the treatment of moderate to severe UC through a network meta-analysis of randomized controlled trials. A systematic literature review identified 5 randomized controlled trials (RCTs) assessing the efficacy of IFX and ADA as induction and/or maintenance treatment for moderate to severe UC. Clinical response was defined as a decrease in Mayo score of ≥30% and ≥3 points, accompanied by a decrease in rectal bleeding score of ≥1 point or a rectal bleeding score of 0 or 1. Clinical remission was defined as a total Mayo score of 2 points or lower, with no individual subscore exceeding 1 point. Mucosal healing was defined as absolute subscore for endoscopy of 0 or 1. Results regarding response, remission, and mucosal healing following induction and maintenance up to 1 year as reported in the individual RCTs were synthesized with network meta-analyses within the Bayesian framework to allow for indirect comparisons.
RESULTS: As induction treatment, IFX 5mg showed greater response (odds ratio= 2.13; 95% Credible Interval, 1.26, 3.61) and remission (OR =2.28; 95%CrI, 1.12, 4.67) than ADA160/80/40mg. This also holds for IFX 10mg (response: OR, 1.98; 95% CrI, 1.17, 3.34; remission: OR=1.76; 95% CI, 0.85, 3.64). Sustained response (OR=1.75; 95%Crl 0.80, 3.93; P(better)=92%) and remission (OR=1.68; 95%CrI 0.53, 5.49, P(better)=81%) at 52 weeks follow-up was more likely with IFX 5mg than with ADA. IFX 10mg showed similar results. IFX 5mg and 10mg showed greater improvement in mucosal healing after induction than adalimumab. (5mg OR=2.20, 95% Crl 1.30, 3.71, P(better)>99%; 10mg OR= 2.12, 95%Crl 1.26, 3.57, P(better)>99%). This remained the case for sustained mucosal healing at week 52 (5mg OR=1.51, 95% Crl 0.69, 3.31, P(better)=85%; 10mg OR= 1.54, 95%Crl 0.70, 3.35, P(better)=86%).
CONCLUSION: Based on indirect comparison of RCT evidence, IFX seems more efficacious to induce and maintain long term response than ADA among moderate to severe UC patients.

P341 REPEATED TREATMENT WITH THE TOLL-LIKE RECEPTOR 9 AGONIST DIMS0150 REINDUCES REMISSION AND LOW LONG TERM COLECTOMY RATES IN TREATMENT REFRACTORY ULCERATIVE COLITIS PATIENTS

E. Musch[1], T. Knittel[2,*], P. von Stein[2], T. Lutfi[3], M. Malek[1], A. Zargari[2], O. von Stein[2]. [1]*Marienhospital, Bottrop, Germany,* [2]*Index Pharmaceuticals, Stockholm, Sweden,* [3]*Department of Surgery, Marienhospital, Bottrop, Germany*

INTRODUCTION: DIMS0150 is a DNA based immunomodulatory oligonucleotide that targets the Toll-like receptor 9 (TLR9) and has shown positive effects in patients with treatment refractory, chronic active ulcerative colitis. The aim of this open label program was to determine the long term colectomy rate and potential treatment regimens after repeated DIMS0150 therapy in treatment refractory ulcerative colitis patients.
AIMS&METHODS: We treated a total of 14 ulcerative colitis patients classed as treatment failures who were elected for colectomy with DIMS0150 as add on to their current therapies. Within the first three months 11 patients received a single topical dose of 30 mg/50mL via endoscopy to or proximal to the inflamed area. Three patients received three doses with four weeks between dosing within the initial 12 week period. 6/14 patients received additional doses beyond the 12 week period. Patients were followed up in average for approximately 27 months and colectomy rates were monitored.
RESULTS: Following an intracolonic dose of DIMS0150 the clinical remission rates at week 12 were 73% for single treatments (8/11) and 100% in the multidose group (3/3) illustrating that DIMS0150 was a very effective short term treatment. Beyond 3 months 6/14 patients were treated with an additional dose of DIMS0150 due to a flare or upcoming relapse of the disease. Interestingly all 6 patients responded to this additional treatment either with a clear response or with an induction of remission.
The follow-up period of 27 months in average indicated that 71% (10/14) of the overall treated patients had avoided colectomy with the longest patient being in symptom free remission for over 48 months. The first year colectomy rate was determined to be 8%, the total cumulative colectomy rate over 2.25 patient years in average was 28% and the annual average colectomy rate was calculated to be 12 %.
Based on the data of 11 patients with longer term follow up data the dosing regimen ranged from a single DIMS0150 application resulting in years in remission up to biannual dosing in some patients. In the repeated dose group (6 patients) an additional dose was given in average at 18 months after initial dosing.
CONCLUSION: DIMS0150 has the potential to be an effective agent for treatment refractory, chronic active ulcerative colitis patients with the prospect to avoid colectomy on a long term basis. A repeated dosing due to relapse resulted in induction of remission and was performed in average 18 months after the initial treatment course.

P342 DETAILED ANALYSIS OF FACTORS DETERMINING PATIENTS ADHERENCE TO THERAPY IN ULCERATIVE COLITIS

W. Kruis[1,*], T. Klugmann[2], M. Düffelmeyer[3], S. Ceplis-Kastner[4], B. Reimers[4], the MUKOSA Study Group. [1]*Evangelisches Krankenhaus Kalk, University of Cologne, Köln,* [2]*Internistische Gemeinschaftspraxis, Leipzig,* [3]*IOMTech GmbH, Berlin,* [4]*Ferring Arzneimittel GmbH, Kiel, Germany*

INTRODUCTION: Improvement of patients' adherence to therapy in IBD is challenging. Detailed knowledge of determining factors may help to improve compliance and lead to lower flare rates.
AIMS&METHODS: 343 patients with ulcerative colitis (UC) were included into a non-interventional prospective study which was conducted in 113 IBD-focused gastroenterology practices in Germany. Oral mesalazine was prescribed either as granules or tablets using doses at the discretion of the physician. Compliance with mesalazine therapy as part of adherence was rated by patients using questionnaires. Severity of UC was rated according to UCDAI. Patients are followed up to 12 months. Interim results on compliance rating at inclusion visit are presented. Results are given as mean±SD and differences were calculated using chi^2-testing.
RESULTS: At inclusion patients preferred granules (77 %) to tablets (13 %) or had no preference (10 %). The prescription was driven by physicians' decision in 76 %, by patients' preference in 24 % only. Patients rated their general compliance on a scale from 1 (very good) to 10 (very bad) as 1.95±2.62. General compliance did not differ significantly between females (1.88±2.45) and males (2.02±2.77), between initial therapy (1.82±2.51) and re-therapy (2.17±2.69) or between high doses (1.91±2.63) and low doses (2.19±2.75). There was a significant difference ($p<0.05$) in compliance in favour of granules (1.77±2.51) vs. tablets (2.68±2.97). In general, compliance was better when the prescribed formulation was based on patients' preference (1.64±2.13) vs. physicians' decision (2.01±2.75). This effect was more pronounced in patients initially treated (1.07±1.87 vs1.89±2.55) than in patients with mesalazine re-therapy (2.08±2.35 vs. 2.21±2.85).
Patients with a short disease course (≤ 2 years) rated their compliance better than those with longstanding disease (> 2 years), irrespective of severity of the disease or mesalazine dosage (1.78±2.54 vs. 2.08±2.69).
CONCLUSION: Detailed analyses of factors determining compliance revealed significant effects of patients' preference and participation in decision making while disease characteristics showed no or less influence on compliance.

P343 HEPATITIS B VIRUS INFECTION IN INFLAMMATORY BOWEL DISEASE

Y. He[1,*], P. Xu[1], Y. Chen[2], R. Yang[3], K. Chao[1], B. Chen[1], R. Mao[1], Z. Zhu[1], Z. Zeng[1], M. Chen[1]. [1]*Gastroenterology, The First Affiliated Hospital of SunYat-Sen University,* [2]*chatfish020@sina.com, Medical Ultrasonics, guangzhou,* [3]*Gastroenterology, Shenzhen Nanshan District people's Hospital, shenzhen, China*

INTRODUCTION: Hepatitis B virus (HBV) infection and inflammatory bowel disease (IBD) can exist in the same patients. Considering the pathogenesis of both diseases belongs to T lymphocyte immune anomaly, we proposed that there might be interaction between HBV infection and IBD in IBD patients infected with HBV.
AIMS&METHODS: Retrospective study was performed on 675 consecutive IBD patients (449 CD and 226 UC). Clinical features, therapeutic approaches and laboratory results were collected from the database established by IBD center in the First Affiliated Hospital of Sun Yat- Sen University.
RESULTS: The prevalence rates of HBV infection were 13.6%,16.8% and 13.8% in CD,UC patients and general population,respectively (P=0.418). No significant difference in clinical characters was found between HBsAg-positve and –negative IBD patients. Liver function was not affected by the use of immunosuppressants in HBV infected IBD patients. Inflammatory parameters, ESR(P=0.026), HsCRP(P=0.026) and platelet count(P=0.000) were significantly lower in HBsAg-positive CD patients compared to HBsAg-negative CD patients. Infliximab was used less often in HBsAg-positive than -negative CD patients (P=0.010). Further multivariate analysis showed that only lower platelet count (OR 0.992,*P*=0.000) and less common use of infliximab therapy (OR 0.1271,*P*=0.127) were independent related factors for CD patients infected with HBV.
CONCLUSION: The prevalence of HBV infection in IBD patients was similar to that in general population in South China. HBV infection didn't affect the clinical characters and medicine choices in either CD or UC. HBV-postive CD patients have lower PLT count and less common use of infliximab compared with HBV-negative CD patients.

P344 PREVENTION OF POSTOPERATIVE RECURRENCE OF CROHN'S DISEASE BY INFLIXIMAB: A META-ANALYSIS OF PROSPECTIVE STUDIES

Y. Qiu[1,*], M.-H. Chen[2]. [1]*Department of Gastroenterology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou,* [2]*Department of Gastroenterology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou,, China*

INTRODUCTION: Although promising, the evidence supporting the use of infliximab (IFX) in the post-operative (PO) setting of Crohn's disease (CD) is still based on limited experience.
AIMS&METHODS: To conduct a meta-analysis of prospective studies evaluating the efficacy of IFX for prevention of PO recurrence of CD.
Selection of studies: Evaluating infliximab for prevention of PO recurrence of CD. **Study quality**: Independently assessed by two reviewers. **Data synthesis**: by "intention-to-treat".
RESULTS: Four prospective clinical trials met criteria were included.
(ii) **Clinical remission: short-term (1 yr PO)** was observed in 90% (18/20) of the IFX group vs. 38% (8/21) in the placebo group (OR 9.32; 95% CI 2.14∼40.59; RD 0.53; 95% CI 0.29∼0.78; NNT=2, $P<0.0001$). **Long-term (≥2 yr PO)** was observed in 100% (20/20) of the IFX group vs. 48%(13/27) in the placebo group (OR 18.51; 95% CI 2.18∼156.87; RD 0.44; 95% CI 0.24∼0. 64; NNT=2, $P<0.0001$), the overall clinical remission was achieved in 95% (38/40) of the IFX group vs. 44%(21/48) in the placebo group (OR 12.05; 95% CI 3.60∼40.37; RD 0.48; 95% CI 0.33∼0. 64; NNT=2, $P<0.0001$)
(ii) Post-operative clinical recurrence **(PO-CR)** was observed in 5% (2/38) of patients in the IFX group vs. 40% (20/50) in the placebo group (OR 0.13; 95%CI 0.04 to 0.47; RD 0.34; 95%CI 0.18∼0.51; NNT=3, $P<0.0001$).
(iii) Post-operative endoscopic recurrence **(PO-ER)** was observed in 31% (12/39) of the IFX group vs. 88% (44/50) of the placebo group (OR 0.03; 95%CI 0.01∼0.14; RD 0.61; 95% CI 0.46∼0.77; NNT=2, $P<0.0001$).
CONCLUSION: IFX may be effective for maintaining both short-term and long-term **clinical remission** in PO CD, reducing both PO-CR and PO-ER with no serious adverse events reported.

P345 EFFICACY OF ADIPOSE-DERIVED STEM CELLS FOR THE TREATMENT OF COMPLEX PERIANAL FISTULAS

Y. Qiu[1,*], M.-H. Chen[1]. [1]*Department of Gastroenterology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

INTRODUCTION: To conduct a meta-analysis of randomized clinical trials (RCTs) evaluating the efficacy of Adipose-Derived Stem Cells (ASCs) for the induction complex perianal fistula healing.
AIMS&METHODS: Search strategy: MEDLINE (PubMmed), The Cochrane Central Register of Controlled Trials, the IBD/FBD review group specialized register and the ISI-Research Institute were searched (1997∼2013) to identify relevant studies all randomized trials. **Selection of studies:** Evaluating ASCs for induction clinical fistula closure. Randomized-controlled-trials comparing ASC with placebo were included in the meta-analysis. **Study quality:** Independently assessed by two reviewers. **Data synthesis:** By "intention-to-treat".
RESULTS: Two RCT studies were included in the meta-analysis.
Induction of fistula healing (Healing was predefined as the absence of drainage through the external openings (whether occurring spontaneously or under externally applied pressure) and complete reepithelialization of external openings, assessed by a blinded evaluation committee.):
two studies (148 ASC-treated patients) showed mean efficacy of 39% vs. 15% in controls (OR =3.87; 95% CI=1.95∼7.71, RD 0.14; 95% CI 0.05∼0.24; NNT = 7, P=0.0003). We further analysis if more dosages will achieve better efficacy, three studies were included, showing no significant difference between more than one dose vs. single dose in introducing complete closure of fistula closure, with the rate of 38% and 44%, respectively (OR =0.74; 95% CI 0.33∼1.67).
CONCLUSION: ASCs are more effective than placebo for the the induction fistula healing, with an odds ratio 3.87 (95% CI=1.95∼7.71) with an NNT of 7 and an absolute risk reduction of 24%.

P346 TACROLIMUS (FK506) FOR INDUCTION OF REMISSION IN REFRACTORY ULCERATIVE COLITIS: A META-ANALYSIS

Y. Qiu[1,*], M.-H. Chen[1]. [1]*Department of Gastroenterology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

INTRODUCTION: To conduct a meta-analysis of randomized controlled trials (RCTs) evaluating the efficacy and safety of tacrolimus (FK506) for corticosteroid refractory ulcerative colitis (UC).
AIMS&METHODS: Selection of studies: Evaluating FK506 for induction of remission in refractory UC. **Study quality**: Independently assessed by two reviewers. **Data synthesis**: by "intention-to-treat".
RESULTS: Two RCTs met criteria were included.
Efficacy
(i) **Clinical remission** was observed in 19% (9/11) of patients in the FK506 group and in 5% (1/47) in the placebo group (OR 4.13; 95% CI 0.71∼24.01, P=0.11).
(ii) **Clinical response** was observed in 51% (37/72) of patients in the FK506 group,

and in 12% (6/50) in the placebo group (OR 7.81; 95%CI 2.92∼30.89; RD 0.23; 95%CI 0.11∼0.35; NNT=4, $P<0.0001$). (iii) **Mucosal healing** was achieved in 54% (37/69) of patients in the FK506 group, and 13% (6/46) of the placebo group (OR 7.07; 95%CI 2.64∼18.95; RD 0.23; 95% CI 0.11∼0.36; NNT=4, $P=0.0001$).

Safety

Patients in the FK506 group (45%, 34/75) were significantly more likely than placebo patients (26%, 13/50) to experience adverse events related to treatment (OR 2.97; 95%CI 1.29∼ 6.80, $P=0.01$). Moreover, there were 2 cases of serious adverse events happened in the FK506 group while none in the placebo patients. However, when taking account all the adverse events, there were no significantly difference between two groups (OR 2.0; 95% CI 0.9∼4.47, $P=0.09$).

CONCLUSION: FK506 may be effective for both clinical improvement and mucosal healing in patients with refractory UC. The use of tacrolimus in the clinical setting requires careful consideration of risks versus benefits and close monitoring for adverse events.

P347 SURGERY AT PRESENTATION OF ILEAL CROHN'S DISEASE: WHAT IS THE PROGNOSIS?

A. T. Oliveira[1,1,*], P. Freire[1], S. Campos[1], S. Mendes[1], M. Ferreira[1], F. Portela[1], C. Sofia[1]. [1]*Gastroenterology, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal*

INTRODUCTION: Crohn's disease (CD) is a heterogeneous entity with unpredictable behavior. Bowel resection is common during the course of the disease, and although it is not often curative, it induces prolonged remission.

AIMS&METHODS: The aim of this work is to compare the clinical course of patients with CD who underwent ileocecal resection at diagnosis with the others who were not.

Retrospective study of patients diagnosed with ileal CD (L1 of Montreal Classification) in the period of 2000-2007, with a minimal follow-up of 5 years. They were divided into two groups: Group A - Diagnosis in the surgical specimen after resection for acute abdomen and Group B - Diagnosis by conventional clinical and laboratory tests. Were assessed personal history, clinical parameters and medical/surgical treatment during the follow-up.

RESULTS: We included 139 patients (Group A-20, Group B-119) over a mean follow-up of 8 years. There was no statistical difference ($p>0.05$) between the two groups in sex (female: A-70,0%, B-58,8%), family history of inflammatory bowl disease, smoking or extra intestinal manifestations. According to the Montreal classification, the category *Behavior* was predominantly penetrating in group A (60%) and non-penetrating non-stricturing in B (49,6%) ($p<0.05$), but no statistical difference was seen in *Age* category (Group A-A2 55,0%, Group B-A2 74,8%) or perianal disease (A-0%, B-13,4%). Group A required less corticosteroids (A-30,0%; B-86,6%; OR 0,067: 0,02-0,19), less immunosuppressive drugs (A-25,0%; B-73,9%; OR 0,117: 0,04-0,35) and less biologic therapy (A-5,0%; B-28,6%; OR 0,132: 0,02-1,02) - $p<0.05$. In group B, 37% of patients required surgery, and the average time between diagnosis and surgery was 26 months. There was no difference ($p>0.05$) in the rate of re-intervention (A-5%, B-10%) or the time until the same (A-5,0 and B-6,1 years).

CONCLUSION: Patients with the diagnosis of Crohn's disease established after intestinal resection for acute abdomen have less need for medical therapy.

P348 TERMINAL ILEITIS IN ADULT PATIENTS WITH CROHN'S DISEASE: IS SURGERY POSSIBLE AS FIRST-LINE THERAPY?

F. Soufflet[1,*], O. Maillard[1], C. Trang[1], G. Meurette[2], S. Bruley des Varannes[1], A. Bourreille[1], M. Flamant[1]. [1]*IMAD - Gastroenterology - Inserm U913,* [2]*IMAD - Digestive and endocrine surgery, UNIVERSITY HOSPITAL, Nantes, France*

INTRODUCTION: Although uncomplicated terminal ileitis is usually managed medically, limited resection could represent a relevant alternative. It was demonstrated in a pediatric population that early surgery was associated with a reduced need of immunosupressors (IS) and biologics (1). The aim of this case-control retrospective study was to compare the course of the disease according to the carried treatment (medical or surgical) in adult patients

AIMS&METHODS: Each patient with an uncomplicated and limited terminal ileitis treated by intestinal resection was matched with two controls treated medically. Matching was performed according to three major criteria i.e. length of ileitis, disease duration, history of intestinal resection and three minor criteria (smoking status, sex and age). The need for IS, biologics, steroids, hospitalization, surgery and the rate of relapses or recurrences were assessed and compared during a two years follow-up. Univariate analyses (Student t-test or Mann-Whitney and Fischer or Mantel-Haenszel test) were performed and the most informative variables ($P < 0.2$) were introduced in a logistic regression model to assess the OR [CI95]

RESULTS: Fifty one patients were identified (17 cases and 34 controls). The clinical, demographic and radiological characteristics were similar between cases and controls excepted the B3 phenotype more frequent in the cases (P=0.01). During the follow-up, the patients treated surgically received less corticosteroids, IS and biologics as compared to the controls (P= 0.03, P= 0.05 and P=0.003 respectively). The number of hospitalization days was similar in the two groups (23 vs 15 dys; $P = 0.1$). Fourty two % of the patients initially treated medically needed a surgery during the two years of follow-up and 13 % of the cases were re-operated

CONCLUSION: In selected patients, surgery appears to be an attractive alternative to the medical management leading to a diminished use of steroids, IS and biologics but prospective studies are needed to define more precisely the best candidates to this strategy

P349 THE CUMULATIVE 30-YEAR BURDEN OF ABDOMINAL AND PERIANAL SURGERIES IN A MEDITERRANEAN IBD REFERRAL CENTER.

K. Katsanos[1,*], V. Tsianos[1], A. Tatsioni[2,3], M. Adamidou[1], E. Saraidari[1], E. Ignatiadou[4], G. Baltoyiannis[4], E. Tsimogiannis[5], D. Sygounas[1], I. Mitselos[1], D. Christodoulou[1], E. Tsianos[1], Northwest Greece, IBD Study Group. [1]*Gastroenterology,* [2]*Family Medicine, Medical School of Ioannina, Ioannina, Greece,* [3]*Tufts University, New England Medical Center, Boston, MA, United States,* [4]*Surgery, Medical School of Ioannina,* [5]*Surgery, 'G. Hatzikosta'' General Hospital, Ioannina, Greece*

INTRODUCTION: The surgical burden of inflammatory bowel disease (IBD) represents a major determinant of IBD related quality of life, disease severity and health care costs. The aim of the study was to assess the cumulative burden of surgical therapies in patients with ulcerative colitis (UC) and Crohn's disease (CD) in a well-defined geographically Mediterranean area.

AIMS&METHODS: Tertiary referral center 30-year (1981-2010) retrospective study. All serial general records for abdominal and perianal surgeries were reviewed and all operated patients with IBD (UC, CD) were recorded on a separate file including demographics, IBD characteristics as well as indication, type and number of surgeries. In parallel, our 652 IBD patient database was reviewed for abdominal and perianal surgical events.

RESULTS: 1469 abdominal and perianal surgeries were reviewed and 71 surgeries (71/1469, 4.8%) in 69 (47 males) IBD patients (38 UC, 31 CD, aged 39.1 ± 7.2) were recorded. Two patients were operated twice for perianal fistula. The indications for IBD abdominal surgeries included acute bowel obstruction or sub-obstruction in 15 patients (7 UC, 8CD), refractory disease (10UC, 3CD), bleeding (2UC, 2CD), perforation (2UC, 6CD), intussusceptions (1CD, 1UC) and internal fistula (4CD).The indications for perianal surgeries in 23/71 (31%) IBD (16UC, 7CD) patients included perianal fistulas (7CD, 4UC) perianal abscesses (8CD, 3UC) and Fournier's gangrene (1UC).

CONCLUSION: In this 30-year retrospective study the cumulative burden of abdominal and perianal surgeries affects 10.5% (69/652) of our IBD patients reflecting also a corresponding 4.8% in the general abdominal and perianal surgery population. One third of IBD surgeries were performed for perianal disease and equally affected CD and UC patients.

P350 POST-OPERATIVE COMPLICATIONS ARE NOT DECREASED BY A PROLONGED NUTRITIONAL SUPPORT IN PATIENTS WITH IBD OPERATED FOR A PERFORATING DISEASE

M. Charvin[1,*], M. Flamant[2], G. Meurette[1], C. Trang[2], E. Duchalais[1], P.-A. Lehur[1], S. Bruley des Varannes[3], A. Bourreille[3]. [1]*IMAD - endocrine and digestive surgery,* [2]*IMAD - Gastroenterology,* [3]*IMAD - Gastroenterology - Inserm U913 - CIC Inserm 04, UNIVERSITY HOSPITAL, Nantes, France*

INTRODUCTION: Perforating CD are often treated by resection with a high rate of morbidity and fecal diversion. Recently, it was suggested that a pre-operative nutritional therapy could decreased the occurrence of post-operative complications (1). However, the benefit was demonstrated in a cohort mixing patients with a perforating and/or a fibrostenotic disease. The aims of our study were 1) to evaluate the benefit of a pre-operative nutritional therapy, and 2) to determine the risk factors of post-operative complications in a cohort of patients operated for an abcess and/or a fistula excluding stenosis.

AIMS&METHODS: All the medical charts of the patients with a CD operated for an abcess or a fistula between 2000 and 2010 were retrospectively reviewed. The pre-operative nutritional therapy was defined by a bowel rest and an enteral or parenteral feeding during more than 2 weeks. The post-operative complications were defined according to the classification of Dindo. Quantitative data were expressed as mean ± SD and compared by a student t test ; the relative risk (RR) and the confidence interval [CI95] were calculated by the Fischer exact test

RESULTS: 72 patients (41 females), mean age 38yrs were operated for an abcess in 47 cases (65 %) and a fistula in 25 cases (35 %). 33 patients (46 %) had a pre-operative nutritional support ;they were not statistically different from the others. A complication occurred in 19 patients (26 %), classified as minor in 10 and major in 9 patients. A diverting stoma was performed in 32 patients (44 %). The pre-operative nutritional support did not decreased the rate of post-op complications (RR 0.3 [0.3 – 1.6]). The delay between the diagnosis and the surgery was not significantly increased by the nutrition: 47 ± 11 vs 34 ± 8 days. Among all the clinical and

demographic factors tested i.e. sex, age, BMI, tobacco, IS, anti-TNF, location and size of the abcess, only steroids and a past history of abcess increased the rate of post-op complications with a RR of 2.0 [1.0 – 3.9] and 3.2 [1.5 – 6.8] respectively

CONCLUSION: Our results confirm the deleterious effect of corticosteroids on the risk of post-op complications; the benefit of pre-op nutritional therapy was not confirmed in this cohort of patients with a perforating disease. Interestingly, IS and anti-TNF had no impact on the risk of complications

P351 EFFECT OF INFLIXIMAB ON SHORT - TERM SURGICAL COMPLICATIONS IN PATIENTS UNDERGOING PROCTOCOLECTOMY WITH ILEAL - POUCH ANAL ANASTOMOSIS

M. Kostrejova[1,*], R. Sequens[1,2]. [1]*Department of gastroenterology,* [2]*Center of gastroenterology and surgery, Hospital of Merciful Sisters of St.Charles Borromeo, Prague, Czech Republic*

INTRODUCTION: Infliximab treatment may increase the risk of subsequent postoperative complications of patiens with chronic ulcerative colitis (CUC). Patiens who are on combination immunosuppressive therapy that includes Infliximab may benefit from a three stage ileal-pouch anal anastomosis (IPAA).

AIMS&METHODS: The aim of this study was to asses the association between preoperative IFX use and short-term surgical complications in a refractory CUC in a single-surgeon cohort at The Centre of colorectal surgery.

A prospectively collected database of pts with a diagnosis of CUC was retrospectively reviuwed for short - term surgical complications after IPAA between January 2006 and December 2012. Of the 112 pts, 51 were treated by IFX until less than 12 weeks of the first stage of their surgery. 61 of pts remained as IFX naive controls, they were indentified from the same database.

Short-term complications were defined as these between the first stage IPAA surgery until up to within 30 days after the last stage IPAA. These complications between the two groups were compared. The pts in both groups were similar with respect to distribution on gender, age and concomitant medication with Azathioprine and corticosteroids. Median time between last infusion and the first operation was 56 (days) IQR 38 (32-70). IPAA was stapled. All pts were operated by one surgeon.

RESULTS: 108 out of all 112 pts a restorative proctocolectomies were perfomed. 12.8% of pts IFX group vs control 24.6% ($p = 0.13$) the procedure was perfomed under urgent conditions.

Overall short-term surgical complications statistically were similar in the IFX and control group 7/47 vs 13/61 (14.9 % vs 21.3 %,Odds ratio /OR/ 0.65, 95 % Confidence Interval /CI/ 0.24 - 1.77 $p = 0.397$).

There was no difference in the rate of infectious complications (10.6 % vs 16.4%, 0R:0.61, $p = 0.394$). In the case of pelvic sepsis there were no differences between groups 2/47 vs 3/61 (4.3 % vs 4.9 %, p=0.79). The occurrence of the wound infection have been the same in both groups (6.4% vs 11.5%, p=0.37) although a trend towards lover rate of overall infectious complications in the IFX group was observed 5/47 vs 10/61. Except slightly more pouch bleeding (6,4% vs 4.9%, OR 1.32 p =0.74),pouch anastomotic leak 2/47 vs 1/61 (4.2% vs 1.6%). Finally, adjusted Odds ratios with respect to age and duration of disease no revealed significant differences between treatment groups for overall (OR 0.72 $p = 0.529$, for infectious OR = 0.63, $p = 0.44$, hemorragic complications 0R 1.83,$p = 0.497$).

CONCLUSION: Preoperative use IFX was not associated with an increased risk of short-term complications after a three stage IPAA.

P352 SURGICAL RATES AND CHARACTERISTICS OF THE FIRST INTESTINAL RESECTION IN CROHN'S DISEASE – A LONG TERM PROSPECTIVE STUDY-

N. Bounab[1,1,*], L. Kecili[1], A. Balamane[1], A. Bousseloub[1], M. Nakmouche[1], K. Belhocine[1], N. Kaddache[1], L. Gamar[1], K. Layaida[1], N. Debzi[1], N. Afredj[1], N. Guessab[1], T. Boucekkine[1]. [1]*Faculty of Medicine, Algiers, Algeria*

INTRODUCTION: Surgical resection rates in Crohn's disease (CD) are high ranging from 25 to 61% at 5 years .Need for surgery remains impredictable.Identifying of predictors for surgery may be of interest for medical therapeutic strategies.

AIMS&METHODS: To determine surgical rates,characteristics and predictive factors of the first intestinal resection in CD,we have studied the outcome of 226 CD patients (103 males:M ;123 females:F),included in a prospective follow-up from 1/1/2005 for at least 5 years or until surgical resection.Mean age at inclusion was 30,6 ± 6,5 y .41 patients (18,1%) were smokers.Disease was located in both colon and small intestine (CSI; n=116;51,4%),small intestine alone (SI;n= 67;29,6%) or colon alone (C;n=43;19%).Lesions were of inflammatory (I),stricturing (S) or penetrating (P) type in 92 (40,7%),76 (33,6%),58(25,7%) cases respectively .Medical treatment of flares was a conventional one;relapses were prevented by 5ASA (n=125;65,3%) or immunosuppressive drugs(n=32 ;14,1%);69 patients (30,5%) received no maintenance treatment .All patients underwent at least 2 annual clinical controls and complete investigation including endoscopy when necessary.Statistical analysis :Student Fisher's t test and Mann Whitney's U test.

RESULTS: The 5-year intestinal resection rate was 29,6%(n=67/226). Annual rate of surgery increased according to duration of disease and varied from 4% between the first and second year to 7% between the forth and the fifth year of follow-up.Emergent surgery was needed in 24 patients (10,6%) and elective one in 19%(n=43) of all the cases.During the follow-up surgical resection was more frequent:1/when disease begun before 20 y (13/29 ;44,8%) comparatively to patients aged between 20 and 40 y (46/160 ;28,7%; $p < 0,001$) or over 40 y (8/ 37;21,6%):$p < 0,1103.2$/ in patients with SI (35/116;37,5%) or CSI (25/67; 30,4%) location compared to patients with C disease (7/43;16,3%) :p=0,06 ;3/in patients with S(38/76 ;50%) or P disease (23/53 ;43,4%)comparatively to I type lesions at inclusion (6/92;6,5%):p=0,0019. In return, rate of surgical resection was not influenced by :1/Gender (F:37/123=30%,M:30/103 =29,1%; $p > 0,05$);2/ Smoking statute of patients :smokers (10/33;30,3%), previous smokers (5/ 15;33,3%) and non smokers (52/170; 30,5%);$p > 0,05$.

CONCLUSION: In this prospective study, the 5-year surgical rate of the first intestinal resection in Crohn's disease was 29,6%. The need for surgery was more frequent when disease begun before 20 years in stenosing and penetrating disease and in SI or CSI location.

P353 EXPERIMENTAL MODEL REPRODUCING PERIANAL CD FISTULAS AND EXPERIMENTAL VERIFYING OF THE TREATMENT BY AUTOLOGOUS ADIPOSE TISSUE DERIVED STEM CELLS

O. Ryska[1,*], Z. Serclova[1], O. Mestak[2], E. Matouskova[3], P. Vesely[2]. [1]*Department of Surgery 2nd Medical Faculty and Central Military Hospital, Central Military Hospital,* [2]*Department of Plastic Surgery, Hospital Bulovka,* [3]*Department of Burns Medicine, 3rd Medical Faculty Charles University, Prague, Czech Republic*

INTRODUCTION: Conservative and surgical treatment of perianal fistulas in patients with Crohn's disease (CD) is effective in about 40-60% (1). Local administration of Adipose Tissue Derived Stem Cells (ADSCs) represents new approach in human fistula treatment with mixed results (2). Clinical relevant experimental model of intestinal fistula is essential for preclinical evaluation of this promising method. Creation of caecostomy was presented previously as a possible technique of fistula simulation in small animal (3).

AIMS&METHODS: The aim of the study was to evaluate experimental model reproducing fistulazing perianal CD suitable for investigation of treatment methods and performation of ADSCs application by various techniques.

Model: Caecostomy with 2-3 cm long subcutaneous canal was used as a model of intestinal fistula in 23 Whistar rats. Attempts to close fistula after its maturation were performed 4 weeks after index surgery by suture of the external opening (4 animals) or ligation of the fistula track (4 animals).

ADSCs therapy: The adipose tissue from inguinal region was harvested and ADSCs were isolated using collagenase technique and cultured in H-MEM medium. Acellular xenodermis (Xe-Derma) as a layer was settled by ADSCs. The Xe-Derma plug was applied into the fistula followed by injection with ADSCs in the peri-fistular tissue (group A). ADSC mixed with fibrin glue (Tissucol) was injected into the fistula (group B). Suspension of pure ADSCs was injected into the fistula tract and peri-fistular region and the external opening was sutured (group C). The fistula tract was evaluated on the 7th, 14th and 30th postoperative day.

RESULTS: All fistulas remained open 4 weeks after caecostomy creation confirmed by fistulography. Suture of the external opening did not lead to permanent fistula closure. After ligation only 1/4 fistula was closed. Application of ADSCs was technically successful without morbidity and mortality. The healing rate was 0/9 in group A and 0/2 in group B and 3/4 in group C within 30 days follow-up.

CONCLUSION: The model of intestinal fistula which persisted despite the surgical treatment was introduced. Simple application of ADSCs using acellular xenodermis did not lead to fistula closure. Combination of external opening closure and ADSCc application could be more effective. Further investigation will be performed.

P354 APPENDICECTOMY AND CLINICAL COURSE OF PATIENTS WITH ULCERATIVE COLITIS

T. Masser[1,*], E. Krones[2], C. Hoegenauer[1], H. Wenzl[1], R. Stauber[2], F. Durchschein[2], V. Stadlbauer-Köllner[2], W. Spindelböck[2], C. Putz-Bankutti[2], G. Zollner[2], P. Fickert[2], W. Petritsch[1], P. K. Kump[1]. [1]*Clinical Department of Gastroenterology,* [2]*Clinical Department of Hepatology, UNIVERSITY HOSPITAL GRAZ, Graz, Austria*

INTRODUCTION: In the pathogenesis of ulcerative colitis (UC) the appendix is thought to be a risk factor for onset and severity of disease. Recent studies even show a prognostic benefit of appendicectomy (AE) in chronic active UC. The objective of this study was to evaluate the rate of AE in patients with UC

compared to controls as well as a potential influence of AE on the course of an existing UC.
AIMS&METHODS: 322 patients with UC (mean age 45±15) out of the IBD clinics of the university hospital in Graz, Austria, were compared in respect to AE with 277 controls (mean age 53±15) out of the clinics for liver diseases. Various therapy regimens since onset of disease served as a surrogate marker of the clinical course of UC. The acquisition of data was performed via questionnaire and retrospective out of the patients' files.
RESULTS: The rate of AE performed before the onset of ulcerative colitis in patients with this IBD was significantly lower compared to controls. [9% (22/237) vs. 42% (115/277) $p < 0{,}001$]. In regard to the demand of medical therapy (5-ASA, corticosteroids, immunosuppressants, biologics) since onset of disease, there was no significant difference in UC patients with and without AE (Tab.1).
Tab.1: percentage of medical therapy according since onset of disease in UC patients with and without appendicectomy (AE)

	5-ASA	Steroids	Immunosuppressants	Biologicals
UC − AE (n=205)	**99%** (n=202)	**72%** (n=171)	**46%** (n=94)	**18%** (n=36)
UC + AE (n=22)	**100%** (n=22)	**82%** (n=18)	**36%** (n=8)	**14%** (n=3)

CONCLUSION: In this study patients with UC presented with significant lower AE rates than controls. However, there was no significant difference of medical therapies in patients with or without AE before disease onset, suggesting a minor role of the appendix in the course of UC. Surprisingly, both, the rate of AE in our patients (9%) and controls (42%), were far higher compared to literature (1% > 8% for patients; 10% > 24% for controls).

P355 MANAGEMENT OF POUCH STRICTURES AFTER TOTAL COLECTOMY WITH ILEO-ANAL POUCH ANASTOMOSIS (IPAA)

T. Emmanouil[1,*], S. Gabriel[2], N. Kontorabdis[2], E. Nikou E[2], P. Evangelides[3], S. Baratsis[2]. *[1]Gastroenterology, [2]General Surgery, [3]Anaestesiology, Iaso General Hospital, Athens, Greece*

INTRODUCTION: Strictures are one of the most common complications after IPAA (3-17%). There may be at the site of ileo-anal anastomosis or at the pouch inlet due to fibrosis or local ischemia. They may result in evacuation problems, pouch dilatation and bacterial overgrowth. Most of them are webs that can be treated by finger dilation or the use of dilators.
AIMS&METHODS: We present clinical outcome and treatment strategy of patients with IPAA who developed post surgery pouch strictures of variable severity. In a total series of 670 patients with IPAA we investigated 65 patients with anastomotic strictures (9, 7%) and 6 patients with pouch inlet strictures (1,08%). Based on patients symptoms and digital examination we ordered pouchography, pouchoscopy and in selected cases CT/MRI enterography. Finally, different treatment modalities were applied.
RESULTS: 65 patients with anastomotic strictures presented with symptoms like increased frequency (95%), incontinence (84%), urgency (73%) and perianal irritation (58%). 55 were treated with digital dilatation under endoscopic view (mean 2,1 times). In 10 patients hegar/savary dilators were applied (mean 3,2 times) to achieve satisfactory dilatation. In 2 tight stricture cases corticoid injection and kneedle knife cutting of circular fibrotic tissue was used and in 2 other cases endoscopic dilatation was possible after intubation of the efferent loop (rendez-vous). In most cases there was no need of hospitalization or systemic use of major analgesics. 6 patients with pouch inlet stricture presented mainly with abdominal pain (80%) and increased frequency (22%). All were treated surgically by local excision and anastomosis or by stricture by-pass. Crohn 's disease was diagnosed in 2 patients.
CONCLUSION: Anastomotic strictures after IPAA are relatively common but usually can be treated safely by digital dilatation on ambulatory basis. In difficult cases endoscopic methods are valuable. Pouch inlet strictures are rare and surgical treatment is needed.

P356 THE ROLE OF SERUM INTERLEUKIN 17 LEVELS IN EVALUATING DISEASE ACTIVITY AND GASTROINTESTINAL INVOLVEMENT IN BEHÇET'S DISEASE

B. Özşeker[1,*], T. Kav[2], Ö. Harmancı[3], Y. Bayraktar[2]. *[1]Gastroenterology, Muga University Department of Gastroenterology, Muğla, [2]Gastroenterology, Hacettepe University Medical School, [3]Gastroenterology, Başkent University Medical School, Ankara, Turkey*

INTRODUCTION: Behçet's disease (BD) is a systemic inflammatory vasculitis of unknown etiology, characterized by relapsing episodes of oral aphthous ulcers, genital ulcers, cutaneous and ocular lesions and other manifestations, including vascular, neurological and gastrointestinal involvements.
AIMS&METHODS: The aim of this study was to evaluate the potential role of serum interleukin 17 (IL-17) in the pathogenesis and GIS manifestations of BD and to compare their value in determining the disease activity with the conventional markers like, erythrocyte sedimentation rate (ESR) and C- Reactive protein (CRP).
RESULTS: Thirty-five adult patients with a confirmed diagnosis of BD and 25 age and sex matched healthy individuals were approached for inclusion in this study. Participants with an acute/chronic infection or inflammatory bowel disease, other systemic disorders, transplant recipients and those with a suspicion of pregnancy were excluded. After a detailed history and physical examination, the patients' laboratory findings and endoscopic procedures, performed within 3 months, were noted. Comparisons were made between both groups with regards to demographic, clinical and laboratory (complete blood count, liver enzymes, ESR, CRP and serum IL-17) findings. The mean hemoglobin and mean corpuscular volume values were significantly lower while RDW values was significantly higher in BD group ($p=0{,}039$, $p=0{,}048$ and $p= 0{,}001$, respectively). Among the markers evaluated, mean ESR levels were significantly higher in BD group than in control group ($p=0{,}000$). But, the difference between groups, regarding CRP and serum IL-17 levels, were not statistically significant. When a subgroup analysis on BD patients was performed only CRP levels were significantly higher in active BD group ($p=0{,}012$). When the endoscopic examinations evaluated, it is found that 28 of 35 patients had an upper GIS endoscopy and 30 of 35 patients had a colonoscopic examination. Colonoscopies performed were normal in 24 patients while one patient had ileitis and 5 patients had ileal ulcers larger than 1 cm, in diameter. Regarding endoscopic findings, serum IL-17 levels were not significantly higher in the group with positive colonoscopic findings ($p=0{,}05$).
CONCLUSION: Even studies with more patients are needed, we concluded that serum IL-17 levels are not a good marker for disease activity and probable gastrointestinal involvement.

P357 ACTIVATION OF HUMAN VISCERAL AFFERENTS BY BRADYKININ VIA B2 RECEPTORS, BUT NOT B1 RECEPTORS

C. McGuire[1,*], G. Boundouki[1], J. Hockley[1], C. Evagora[2], C. Knowles[1], D. Bulmer[1]. *[1]Neurogastroenterology, [2]Pathology, QUEEN MARY, London, United Kingdom*

INTRODUCTION: We have recently developed *in vitro* electrophysiological recordings of human visceral afferent (HVA) fibre activity from isolated human intestine as a translational model of visceral pain. These HVAs respond to chemical mediators, including bradykinin (BK), known to be involved in pain signalling in the viscera. The aim of the present study was to examine the receptor pharmacology underlying BK activation of HVAs.
AIMS&METHODS: All experiments were performed in accordance with UK human ethics regulations [NREC 09/H0704/2]. Surgically resected human colon, ileum and appendix were obtained from consenting patients undergoing bowel resections. Tissue was pinned in a tissue bath, or cannulated (appendix), and superfused with carbogenated Krebs buffer (7ml/min, 32-34°C), containing nifedipine and atropine (10 μM). Mesenteric nerve bundles were carefully dissected and few fibre activity were recorded using suction electrodes. To test the reproducibility of BK responses, three individual applications of BK (20ml, 10μM) were superfused into the bath, each separated by a 60 minute washout period (n=4). To evaluate the contribution of B1 and B2 receptors to the BK response, the preparation was pre-treated with either the B1 antagonist, R715 or the B2 antagonist, HOE140 (100ml, 300nM) before the second application of BK. In addition, to examine the functional presence of B1 receptors on HVAs, the B1 agonist, Sar [D-phe^8]-des-Arg^9-BK (20ml, 1μM) was applied to the tissue (n=2)
RESULTS: Few fibre recordings were made from 15 tissues (8 colon, 2 ileum, 1 rectum, 4 appendix). Responses to repeat applications of BK were reproducible, especially the second and third applications: Application 1, 26.5±20.2 to peak 57.8±36.0 spikes/20s; Application 2 baseline 28.3±23.7 to peak 50.75±32.5 spikes/20s; Application 3 baseline 28.5±18.8 to peak 45±25.9 spikes/20s. B2 antagonism reduced the HVA peak firing rate to BK application: Pretreated baseline 60.6±29.1 to peak 100.0±42.1 spikes/20s vs. Control: baseline 63.0±31.6 to peak 141.0±56.7 spikes/20s (n=6). In contrast, B1 antagonism had no effect on HVA response to BK: Pre-treated baseline 71.6±18.6 to peak 102.5±12.5 spikes/20s vs. Control: baseline 54.0±21.8 to peak 78.5±23.5 spikes/20s (n=2). Furthermore, the application of the B1 agonist had no effect on HVA firing rate baseline 54.0±21.8 to peak 78.5±23.5 spikes/20s ($p > 0.05$).
CONCLUSION: Reproducible HVA responses to BK can be attained, allowing for pharmacological manipulation studies. HVA responses to BK are predominantly through the B2 receptor. This has relevance in intestinal sensory physiology and future strategies for therapeutic intervention.

P358 ASSESSMENT AND TOPOGRAPHICAL ANALYSIS OF THE TOTAL HISTAMINE DEGRADATION CAPACITY (THDC) AT THE LOWER GI-TRACT

C. Reiser[1,*], A. Missbichler[1], A. F. Hagel[1], G. Frost[1], G. Manz[1], R. Rieker[2], J. Kressel[1], A. Carstensen[1], M. F. Neurath[1], M. Raithel[1]. *[1]Medicine 1, [2]Pathology, University Erlangen, Erlangen, Germany*

INTRODUCTION: Irritable bowel syndrome (IBS) may cause various symptoms including abdominal pain, diarrhoea, constipation and is often associated with food intolerances.
AIMS&METHODS: To further evaluate the biological capacity of the GI-mucosa to degradate histamine 96 samples from the lower GI tract were homogenized and quantitative histamine degradation followed at different time points (0,8,12,20 min). Samples were taken from 24 patients with either IBS symptoms or known food allergy from ileum, cecum, colon ascendens and sigmoid. Histamine was measured by ELISA, THDC given as median (25-75%) ng histamine/mg protein x ml x min or % degradation.
RESULTS: Endogenous histamine released from homogenized tissue was quantitatively catabolized within 20 min. The degradation kinetics showed a 50 + 10% degradation rate already after 8 min and was two-staged. Interestingly, repeated experiments showed the THDC for terminal ileum 47,95 (22,07-74,70), followed by cecum 24,67 (16,63-37,70)) and colon ascendens median 23,73 (14,47-45,17)) respectively), while sigmoid had always the lowest histamine catabolization median 24,92 (13,71-35,40)). THDC was positively correlated to the number of lymphoid follicles at the lower gi tract.
CONCLUSION: Measurement of the biological histamine degradation along the lower GI tract exhibited a topographical gradient for histamine catabolization with higher levels at the terminal ileum and cecum, followed by, to distal parts, decreasing values. Future studies will clarify whether disturbances of the histamine degradation in ileum or cecum may be associated with intestinal swelling, induction of inflammation or IBS symptoms.

P359 IMMUNE COMPARTMENTALIZATION IN THE GASTROINTESTINAL TRACT: DIFFERENCES BETWEEN ASCENDING AND DESCENDING HUMAN COLON.

D. Bernardo[1,*], E. Montalvillo[2], F. Bayiroglu[3], E. R. Mann[4], H. O. Al-Hassi[4], N. R. English[4], R. Man[5], L. Fernandez-Salazar[6], S. T. C. Peake[5], J. Landy[5], J. A. Garrote[7], A. L. Hart[5], E. Arranz[8], S. C. Knight[4]. *[1]A.P.R.G., Imperial college London, Harrow, United Kingdom, [2]IBGM. Universidad de Valladolid-CSIC, Valladolid, Spain, [3]University of Yuzuncu Yil, Van, Turkey, [4]Imperial college London, [5]St Mark's Hospital, Harrow, United Kingdom, [6]Hospital Clinico Universitario Valladolid, valladoli, [7]Hospital Universitario Rio Hortega, [8]IBGM. University of Valladolid-CSIC, Valladolid, Spain*

INTRODUCTION: The gastrointestinal tract is in contact with a wide variety of commensal microbiota and diverse pathogens so a balance between immunity and tolerance is required. Dendritic cells (DC), the most potent antigen presenting cells, determine the type and location of immune responses. Most studies of gut immunity are performed in mouse which may not constitute appropriate models for human immunity. Ascending and descending colon have different embryological origins, blood supply, enzymatic activities and gene expression profiles which may affect local DC. We hypothesise that human ascending and descending colon are independent immunological entities.
AIMS&METHODS: Paired colonic samples from ascending and descending colon were obtained from healthy controls and cells characterized by flow cytometry and electron microscopy.
RESULTS: The human ascending colon had higher numbers of total intraepithelial lymphocytes ($CD45^+CD3^+CD103^+$) than the descending colon, most of them with a cytotoxic ($CD8^+$) profile. Electron microscopy revealed higher densities of plasma cells and DC in the ascending colon. The latter was also confirmed by flow cytometry and DC identified as $HLA\text{-}DR^+CD3^-CD14^-CD16^-CD19^-CD34^-$. No difference was found in the type of DC between compartments when determined as myeloid DC ($CD11c^+$) or as CD1c (BDCA1) or CD141 (BDCA3) within $CD11c^+$ DC. However, DC from the ascending colon had significantly decreased expression of innate immunity receptors TLR2 and TLR4. Gut-homing markers $\beta7$, CCR9 and CD103 (restricted to $\beta7^+$ DC) were also decreased on DC from the ascending colon. Finally, ascending colon DC were more mature as determined by increased CD40, CD80 and CD86 expression, increased ongoing production of IL-12 (but not IL-10), decreased phagocytic capacity and ILT3 expression, and increased stimulatory capacity for allogeneic T-cells.
CONCLUSION: The human ascending colon appeared more immunologically active than the descending colon which was also indicated in the different phenotype and function of the DC. Therefore ascending and descending colon should not be considered as a single immune entity but, on the contrary, the human immune system is compartmentalized in different areas of the gastrointestinal tract.

P360 INTESTINAL MICROBIOME AND THE RISK OF CHEMOTHERAPY-INDUCED DIARRHEA IN CANCER PATIENTS

E. Montassier[1,*], E. Batard[1], T. Gastinne[2], T. Carton[3], J. Caillon[1], P. Moreau[2], G. Potel[1], S. Bruley des Varannes[4], F. Le Vacon[3], M.-F. de La Cochetière[5]. *[1]Université de Nantes, Faculté de Médecine, Thérapeutiques Cliniques et Expérimentales des Infections, EA 3826, [2]Hematology department, University Hospital, [3]Biofortis, Mérieux Nutrisciences, [4]Institut des Maladies de l'Appareil Digestif, University Hospital, [5]INSERM, Université de Nantes, Faculté de Médecine, Thérapeutiques Cliniques et Expérimentales des Infections, EA 3826, Nantes, France*

INTRODUCTION: A common side effect of chemotherapy treatment is diarrhea. The underlying mechanisms of chemotherapy-induced diarrhea (CID) are poorly understood and it is unclear whether changes in the intestinal microbiota during chemotherapy contribute to the development of CID. We aim to determine if intestinal microbiota changes precede and predispose to CID.
AIMS&METHODS: 36 patients with Non-Hodgkin lymphoma were included. All of them underwent the same chemotherapy regimen, from Day 1 to Day 6, conditioning for Hematopoietic Stem Cell Transplantation (HSCT). Fecal samples were collected on Day 7 and analyzed using 454 high throughput pyrosequencing spanning the V5-V6 hypervariable regions of the 16S rRNA gene.
RESULTS: 8 patients (22.2%) developed a severe CID (median delay: 13 days [11-15]). By studying fecal metagenomes, principal component analysis and heatmap with hierarchical clustering identified 2 robust clusters, differencing patients who will develop CID and patients who will not develop CID. The main contributors of the clusters were *Bacteroides* for patients who will develop CID and *Escherichia* for patients who will not develop CID. Co-occurrence network demonstrated that the 2 clusters are in fact driven by a group of species contributing to the two different community compositions.
CONCLUSION: Our study demonstrates that intestinal microbiota changes precede CID by a median of 6 days and that the determination of the fecal microbiota composition can identify patients at high risk for severe CID. We demonstrate how high-throughput sequencing technologies can have relevance in clinical disease and can guide the treatment of pertinent populations such as HSCT recipients.

P361 EXPRESSION OF MUCOSAL TOLL-LIKE RECEPTORS AND GRANINS IN IRRITABLE BOWEL SYNDROME

F. V. Rusu[1,2,*], M. Simrén[2], S. Isaksson[2], H. Törnblom[2], L. Öhman[2]. *[1]Dept of Internal Medicine, Emergency County Hospital Cluj, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania, [2]Dept of Internal Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

INTRODUCTION: The pathogenesis of irritable bowel syndrome (IBS) is not completely understood. Recent studies suggest that low-grade mucosal immune activation may contribute to the pathogenesis of IBS. Toll-like receptors (TLR), recognising danger signals, play a key role in the innate immune system. Chromogranins (Cg) and secretogranins (Sg) are secretory proteins ubiquitous in cells of the endocrine, enteric and immune systems.
AIMS&METHODS: The aim of this study was to evaluate the mucosal expression of TLRs, Cg and Sg in IBS patients. Thirty-four patients with IBS (IBS-A=8, IBS-C=10, IBS-D=11, IBS-U=5)(19 females, median age 35 (26-47) years, BMI 22.8 (20.9-24.4)), defined according to Rome III Criteria were included. Ten patients reported a post-infectious onset of IBS. Also, 17 healthy controls (12 females, age 27 (24.3-38.3) years, BMI 23 (20.5-24.5)) were included in the study. Total RNA was prepared from biopsies obtained from the sigmoid colon during unprepared sigmoidoscopy. The levels of mRNA for TLR2, TLR6, TLR9, CgA, CgB, SgIII and the house-keeping gene HPRT were assessed by quantitative real-time PCR. Results were normalized to the expression level of HPRT and expressed as $2^{-\hat{}\ \text{target-HPRT}}$.
RESULTS: The mucosal expression of CgA was lower in IBS patients compared to healthy controls (19.8 (14.5-29.8) vs. 25.6 (17.8-37.9) (median (25-75) percentile); p=0.03). The expression of CgB (0.4 (0.2-0.7) vs. 0.5(0.3-0.7); n.s.) and SgIII (0.07 (0.06-0.1) vs. 0.09(0.07-0.1); n.s.) was comparable in patients and controls. Moreover, the mucosal expression of TLR9 tended to be lower in patients relative to controls (0.06 (0.05-0.2) vs. 0.1(0.1-0.2) p=0.1), whereas the expression of TLR2 (0.13 (0.09-0.16) vs. 0.12(0.08-0.14) n.s.) and TLR6 (0.14 (0.1-0.17) vs. 0.13(0.1-0.16) n.s.) was similar in patients and controls.
CONCLUSION: The reduced mucosal CgA levels might reflect an increased release of the protein from CgA expressing cells in IBS patients. The tendency of reduced TLR9 levels indicates that IBS patients have an altered innate immune response to TLR9 ligands, i.e. unmethylated CpG oligonucleotides. Thus, we conclude that an altered expression pattern or activity of CgA and TLR9 expressing cells may be of importance for the pathogenesis of IBS

P362 MYOPENIA AND THE SYSTEMIC INFLAMMATORY RESPONSE IN PATIENTS WITH OPERABLE COLORECTAL CANCER

G. Malietzis[1,2,*], N. Johns[3], M. Giacometti[1], R. H. Kennedy[1], O. D. Faiz[1], O. Aziz[1], K. Fearon[3], J. T. Jenkins[1]. *[1]Department of Colorectal Surgery, St Mark's Hospital, [2]Department of Medicine, Imperial College, London, [3]Department of Clinical and Surgical Sciences, University of Edinburgh, Royal Infirmary, Edinburgh, United Kingdom*

INTRODUCTION: Neutrophil to lymphocyte ratio (NLR) reflects a systemic inflammatory response, suggesting that elevation preoperatively is associated with poorer survival in colorectal cancer patients. Body composition may be influenced by the host inflammatory response and alterations in muscle mass have been linked to poorer outcomes in cancer patients. The aim of the present study was to examine the relationship between myopenia (clinically relevant muscle wasting) and the systemic inflammatory response expressed as NLR in patients with primary operable colorectal cancer [1].
AIMS&METHODS: Data from 306 consecutive patients diagnosed with colorectal adenocarcinoma undergoing elective curative surgical resection between 2006 and 2011 were included. Cut-offs for low muscularity normalised for stature were based on a CT-based sarcopenic obesity study of cancer patients by Prado et al (L3 skeletal muscle index (cm^2/m^2): ≤38.5 for women and ≤52.4 for men) [2]. Patients were stratified into two groups: low NLR (≦3), high NLR (>3). The relationship between myopenia, NLR and other clinicopathological parameters was assessed using non-parametric statistics for the univariate and binary logistic regression for the multivariate analysis. Analysis considered predictive factors of "association" with myopenia, including age, sex, preoperative albumin levels, BMI, stage and site of the tumour, Charlson comorbidity index and deprivation score (IMD).
RESULTS: 306 patients included in the analysis with median age of 69 years [IQR, 61-75]. 187 patients (61%) were males, 76 (24.9%) and 135 (43.5%) were obese or overweight respectively. The majority of the study's population had reduced muscle mass (n=191, 62.4%). Multivariate regression analysis identified age >75 years (OR 3.736, (95% CI 1.873-7.453) P<0.001), male gender (OR 2.850(1.629-4.988) P<0.001), BMI<25 kg/m^2 (OR 6.907 (3.447-13.839) P<0.001) and NLR>3 (OR 1.812 (95% CI 1.063-3.091) P=0.029) as an independent prognostic factors for being myopenic.
CONCLUSION: The present study highlights a direct and independent relationship between myopenia in patients with primary operable colorectal cancer and age, sex, BMI, and altered systemic inflammatory response. Understanding what factors contribute to these body composition changes may lead to novel and more effective interventions that support optimal body composition and metabolism, ultimately improving clinical and metabolic outcomes in cancer patients both in the perioperative period and in the long term. Whether attempts to reverse myopenia can alter the host immune response remain to be established.

P363 THE EFFECT OF INOS INHIBITORS AND HYPERBARIC OXYGEN TREATMENT IN AN EXPERIMENTAL MODEL FOR RADIATION COLITIS IN RATS

H. Demirci[1], Z. Polat[1,*], O. Sager[2], A. Uygun[1], H. Ergun[1], M. Ozel[3], S. Bagci[1]. *[1]Gastroenterology, [2]Radiation Oncology, Gulhane Military Medical Academy, Ankara, [3]Gastroenterology, Maltepe University, İstanbul, Turkey*

INTRODUCTION: Radiation-induced enterocolitis comprises an important concern in patients treated with radiotherapy for abdominal or pelvic malignancies. Exposure of normal tissues in the radiotherapeutic management of these malignancies is almost inevitable, and consequent deleterious effects of therapeutic radiation on small intestine and colon may be observed as acute or chronic complications in the form of radiation enteritis or radiation colitis.
AIMS&METHODS: We aimed to investigate the effect of S-Methlyisothiourea (SMT), hyperbaric oxygen (HBO), and the combination of both in an experimental acute radiation-induced enterocolitis model. Sixty Sprague-Dawley rats were randomly divided into 5 groups (12 animals per group) of sham group, control group, HBO-only group, SMT-only group and SMT + HBO group. Anesthetized rats were delivered a single dose of gamma irradiation (25 Gy) through the colorectal region. After irradiation, each animal was monitored daily for changes in weight and in the appearance of the anal region. In the control group, we applied 2 ml saline solution intraperitoneally for 5 days. In the HBO group, 100% oxygen at 2.5 atm pressure was applied for 5 days. In the SMT group, 10 mg/kg/day SMT was applied intraperitoneally for 5 days. In the HBO + SMT group, HBO and SMT were applied, respectively. At the end of 5 days, rats were sacrificed and colon samples were collected for histological grading. Blood samples were collected for tumor necrosis factor (TNF)-α, interleukin (IL)-10, IL-1β, transforming growth factor (TGF)-β, intercellular adhesion molecule (ICAM)-1 mRNA assays.
RESULTS: TNF-α, IL-1β, IL-10, TGF-β, ICAM-1 mRNA levels were reduced by SMT, HBO, and HBO + SMT application ($p<0.05$). The microscopic scores differed significantly between SMT, HBO, HBO + SMT groups and control group. There was histologically significant improvement, especially in the HBO + SMT group. When we compared the weight of the rats before and after the study, weight loss was significantly lower in the SMT, HBO and HBO + SMT groups compared with the control group ($p<0.05$).
CONCLUSION: Both HBO and SMT were significantly effective in preventing weight loss and in reducing the inflammatory activities and severity of colitis histology, when comparing with HBO and SMT separately.

P364 INTRAPERITONEALLY INJECTED MESENCHYMAL STROMAL CELLS IN EXPERIMENTAL COLITIS HOME AS STRUCTURED SPHERES IN THE SEROSAL FAT SURROUNDING THE INTESTINES.

I. Molendijk[1,*], J. M. Perez Galarza[2], E. S. de Jonge-Muller[1], A. E. van der Meulen-de Jong[1], W. E. Fibbe[2], D. W. Hommes[3], M. van Pel[2], H. W. Verspaget[1]. *[1]Gastroenterology and Hepatology, [2]Immunohematology and Blood transfusion, Leiden University Medical Center, Leiden, Netherlands, [3]Digestive Diseases, University of California Los Angeles, Los Angeles, United States*

INTRODUCTION: Mesenchymal stromal cells (MSCs) are multipotent cells with immunomodulatory and tissue regenerative properties. Therefore, they may be useful in the treatment of inflammatory bowel disease (IBD). Whether or not MSCs need to home to and engraft at the site of inflammation to exert their beneficial effect in colitis needs to be elucidated. We compared the homing and engraftment capacity of MSCs and prestimulated MSCs in experimental colitis.
AIMS&METHODS: MSCs were isolated from bone marrow of wild type BALB/c mice and transduced with a firefly-luciferase and GFP construct. The week before infusion, some MSCs were prestimulated with interferon-gamma to give iMSCs. TNBS-colitis was induced in BALB/c mice and 2x10^6 transduced (i)MSCs were injected intraperitoneally. (i)MSCs were visualized in vivo by bioluminescence imaging (BLI). At sacrifice, 3 days after injection of the cells, inguinal lymph nodes (ILNs), mesenteric lymph nodes (MLNs), spleen, small intestine (SI) and colon were also imaged by BLI. Organs were imbedded in paraffin for immunohistochemistry.
RESULTS: A 5,5 fold higher amount of injected MSCs and 4,9 fold higher amount of injected iMSCs was traceable by BLI in the abdomen of mice with colitis compared to control mice without colitis 2 days after infusion of the cells (P<0,0001 and P=0,0029). A similar difference was observed a day later (P=0,0005 (MSCs); p=0,0048 (iMSCs)). BLI at sacrifice 3 days after (i)MSC injection showed the same trend in colon, SI and MLN. Nineteen days after infusion of the (i)MSCs BLI-signal was completely disappeared in the mice that were not sacrificed at day 3. Colons and SI stained for GFP showed spherical (i)MSC formations situated in the fat surrounding the serosal site of the intestines. In these spheres macrophage were found close to (i)MSCs. No (regulatory) lymphocytes were observed inside the spheres, whereas in the surrounding area some CD3 and FoxP3 positivity was found. Furthermore, collagen deposition and some proliferation was observed in these (i)MSC-spheres.
CONCLUSION: The amount of traceable injected (i)MSCs in the abdomen was significantly higher in mice with colitis compared to healthy controls. (i)MSCs were more likely to cluster around the intestines when colitis was present. No difference in homing or engraftment was observed between MSCs and iMSCs.

P365 GENOMIC DNA FROM HEALTHY AND TUMOROUS COLONIC EPITHELIAL CELLS HAS AUTOCRINE AND PARACRINE ACTIVATING EFFECT ON HT-29 COLON CARCINOMA CELLS, HDF-ALPHA FIBROBLASTS AND PERIPHERAL MONONUCLEAR BLOOD CELLS

I. Fűri[1,*], F. Sipos[1], S. Spisák[2], Á. V. Patai[1], B. Wichmann[2], G. Műzes[1], O. Galamb[2], V. Gábor[1], A. Kalmár[1], K. Leiszter[1], K. Tóth[1], B. K. Barták[1], Z. B. Nagy[1], B. Molnár[1], Z. Tulassay[1]. *[1]2nd Department of Internal Medicine, Semmelweis University, [2]Molecular Medicine Research Unit, Hungarian Academy of Sciences, Budapest, Hungary*

INTRODUCTION: The methylation pattern of genomic DNA fragments may represent its organ origin. In case of tumorous and inflammatory conditions, the amount of self-DNA is elevated in the serum. The Toll-like receptor 9(TLR9)-mediated immunobiologic effect of self-DNA of normal and tumorous origin may be different.
AIMS&METHODS: We aimed to compare the TLR9- and pro-inflammatory cytokine-associated effects of self-DNA originated from normal and colorectal cancer on different cell types and ex vivo peripheral mononuclear cells (PBMCs). $5x10^5$ HT-29 colon cancer cells, $2x10^5$ HDF-alpha fibroblasts, and $2x10^6$ PBMCs were incubated with 15-15μg of normal or tumorous epithelial genomic self-DNA for 6 hours. Expression levels of TLR9-signaling and pro-inflammatory cytokine related genes were measured by qPCR. Activation of 84 genes in PBMCs was determined by qPCR-based Qiagen T and B cell activation arrays.
RESULTS: Regarding TLR9 pathway, IL-1β expression altered after incubation with both DNA types (dct in control vs. tumorous vs. normal DNA treated samples were: 25.87 ± 0.1627 vs. 23.54 ± 0.2613 vs. 24.28 ± 0.2253). In case of HDF-alpha cells, only normal self-DNA activated the elements of TLR9-signaling pathway (IRAK2: average dct at the treatment with normal DNA was 18.73 vs. 21.31 in control samples; MYD88A dct was: 17.18 vs. 19.16; MYD88B dct was: 16.75 vs. 19.32; NFκB dct was: 17.55 vs. 19.76; IL-8 dct was: 14.22 vs. 18.14; IL-1β dct was: 23.1 vs. 27.24; $p<0.05$ in all cases). PBMCs showed higher IL-2 mRNA expression after the incubation with

normal self-DNA (dct of control sample: 11.74 ± 0.1650; dct of tumorous self-DNA treated sample: 10.18, ± 0.1900; dct of normal self-DNA treated sample: 9.45 ± 0.2900).
CONCLUSION: DNA from tumorous colonic epithelium could act as an endogenous pro-inflammatory ligand in HT29 cells. DNA from normal colonic epithelium may promote fibrogenesis through TLR9 activation. In normal PBMCs normal and tumorous DNA induced IL-2 mRNA overexpression, which was higher in the sample treated with normal DNA. Genomial DNA can act on the different cell types as a paracrine and autocrine regulatory signal factor depending on its methylation grade.

P366 MELATONIN EXHIBITS ANTI-INFLAMMATORY EFFECT IN LPS-INDUCED MURINE MACROPHAGES VIA NFKB SUPPRESSION AND NRF-2 AND HO-1 INDUCTION.

M. Aparicio-Soto[1,*], C. Alarcon de la Lastra[1], A. Cardeno[1], S. Sanchez-Fidalgo[1], M. Sanchez-Hidalgo[1]. [1]*Pharmacology, University of Seville, Seville, Spain*

INTRODUCTION: Melatonin is an indolamine involved in the regulation of multiple functions, including the control of the gastrointestinal system under physiological and pathophysiological conditions. Melatonin exerts its physiological effects through specific membrane receptors which can be found in the gut, regulating gastrointestinal motility, inflammation and pain. Nevertheless, the immunomodulatory molecular mechanisms of melatonin under inflammatory conditions still remain unclear. Since macrophages play a key role in the immunopathogenesis of inflammatory based diseases, the current study was designed to investigate the cellular mechanisms underlying the redox modulation in lipopolysaccharide (LPS)-stimulated inflammatory response by melatonin (12.5, 25, 50 and 100 μM), in murine peritoneal macrophages and deep insight into the action mechanisms involved in its anti-inflammatory effect.
AIMS&METHODS: Cell viability was determined using sulforhodamine B (SRB) assay and nitric oxide (NO) production was measured using the Griess reaction. Changes in the protein expression of the proinflammatory enzymes cyclooxygenase (COX)-2, inducible nitric oxide synthase (iNOS), microsomal prostaglandin E synthase-1 (mPGES-1), heme oxygenase 1 (HO-1) and p38 phosphorylation were determined by western blot. Finally, the role of the nuclear transcription factor kappa B (NFκB) and nuclear factor-E2-related factor-2 (Nrf2) signalling pathways were also analyzed by immunoblotting.
RESULTS: LPS-induced inflammatory response in peritoneal macrophages characterized by an increase in NO production, an upregulation of COX-2, iNOS and mPGES-1 protein expressions and p38 MAPK phosphorylation, a decrease in HO-1 protein expression as well as Nrf2 activation, followed by an increase in nuclear p65 protein expression, as a parameter for NFκB activation.On the contrary, melatonin treatment was found to reduce significantly the levels of nitrites without affecting cell viability. Similarly, melatonin induced a significant decrease in COX-2, iNOS and mPGES-1 protein expressions, an important decrease of p38 phosphorylation and a remarkable increase in antioxidant enzymes(HO-1 and Nrf2) expression levels, which were accompanied by an IκBα protein degradation prevention and a reduced nuclear p65 protein expression.
CONCLUSION: Melatonin reduces inflammatory mediators and enhances the expression of HO-1 via NFκB, p38 MAPK and Nrf2 cascade signalling pathways in LPS-induced macrophages. Thus, melatonin might be a promising target for diseases associated with overactivation of macrophages.

P367 MILK FAT GLOBULE-EPIDERMAL GROWTH FACTOR 8 ACCELERATES ANGIOGENESIS-RELATED GENE EXPRESSION IN COLONIC MUCOSA DURING REGENERATING PHASE OF COLITIS

Y. Tada[1,*], S. Ishihara[1], R. Kusunoki[1], H. Sonoyama[1], A. Oka[1], N. Fukuba[1], N. Oshima[1], I. Moriyama[1], T. Yuki[1], K. Kawashima[1], Y. Kinoshita[1]. [1]*Department of Internal Medicine II, Shimane University School Of Medicin, Izumo-Shi, Japan*

INTRODUCTION: Milk fat globule-epidermal growth factor 8 (MFG-E8), a glycoprotein secreted from different cell types, promotes phagocytic clearance of apoptotic cells to maintain normal tissue homeostasis. In addition to this scavenging function under physiological conditions, we recently found that MFG-E8 ameliorates intestinal inflammation due to its anti-inflammatory function by regulating NF-kB-dependent cellular signaling (J Immunol 2009). However, little is known regarding the role of MFG-E8 in angiogenesis during intestinal inflammation.
AIMS&METHODS: In the present study, we investigated the effects of MFG-E8 on expressions of angiogenesis-related genes in colonic mucosa of MFG-E8 knockout (KO) mice during both active and recovery phases of colitis, and compared those results with the same in wild-type (WT) mice. Experimental colitis was induced in 8-week-old male C57BL/6N WT and MFG-E8 KO mice by administration of dextran sodium sulfate (DSS) for 7 days. To determine the colonic mucosal condition during the recovery phase of colitis, time-course changes of histological score and pro-inflammatory cytokine expression were evaluated for 50 days after stopping DSS administration. Furthermore, to confirm the effects of MFG-E8 on angiogenesis, expressions of 84 angiogenesis-related genes in colonic mucosa of WT and MFG-E8 KO mice during the recovery phase were analyzed using a PCR array profiling system.
RESULTS: The severity of colonic inflammation in the KO mice during the recovery phase was significantly greater, while the regenerating potential of colonic epithelial cells was lower as compared with the WT mice. PCR array results showed that the gene expression profiles of angiogenesis-related genes differed between the WT and KO mice. We also observed markedly decreased expression levels of angiogenesis-accelerating genes including VEGF-A, angiopoietin-2 (ANGPT2), and the endothelial-specific receptor tyrosine kinase (TEK), and increased expression of the anti-angiogenic gene thrombospondin 1 (THBS1) in colonic mucosa of KO mice as compared to WT mice, which was confirmed by real-time PCR findings.
CONCLUSION: MFG-E8 accelerates the expressions of various angiogenesis-related genes in colonic mucosa during the recovery phase of colitis, suggesting its contribution to mucosal repair in the colon when damaged by inflammatory disease.

P368 CIRCULATING TUMOUR CELLS (CTC) IN COLORECTAL CANCER - MESENTERIC VS PERIPHERAL CIRCULATION CELL COUNTS

A. Quyn[1,*], I. Nathke[2], R. Steele[1]. [1]*Surgery and Oncology,* [2]*Cell and Developmental Biology, University of Dundee, Dundee, United Kingdom*

INTRODUCTION: Histopathological examination of colorectal cancer allows an estimate of any occult hepatic metastases at the time of resection, the chance increasing with depth of primary tumour penetration, grade and lymph node status. However in 30% of cases, nodal involvement can skip a tier of glands. In addition, a percentage of patients with node negative disease will develop liver metastasis. Blood borne metastasis is initiated by circulating tumour cells (CTC) that are transported through the circulation from the primary tumour to vital distant organs and is directly responsible for most cancer related deaths. The portal circulation provides a unique method of sampling blood directly from the vein between the primary colorectal tumour and the liver.
AIMS&METHODS: This study aims to compare the number of circulating tumour cells in the mesenteric and peripheral circulation and assess whether the volume of CTCs predict the development of liver metastasis.
Patients presenting to Ninewells Hospital, Dundee for curative resection of a colorectal cancer were considered for the study. Patients with transverse colon and low rectal tumours were excluded from our analysis due to variable venous drainage. Operations were performed by laparoscopic or open technique. 10 ml of blood were collected from the draining mesenteric vein of the resected specimen and from the peripheral circulation intra-operatively into Cyto-Chex cell preservative tubes. Samples were then assessed using Rarecyte, an EpCAM independent CTC isolation technique and number of CTCs quantified. Patients then entered routine intensive folow-up with clinic review, blood check and 6 monthly CT imaging.
RESULTS: Mesenteric and peripheral blood samples were obtained from 27 patients during the study period. 12 patients underwent right hemicolectomy, 4 patients had a left hemicolectomy and 11 patients had an anterior resection. 15 patients underwent laparoscopic resection with the others performed by open technique. The CTC count was higher in mesenteric blood samples compared to peripheral, (6 CTC/ml vs. 0.2CTC/ml respectively; $p=<0.05$). The average number of CTC per ml increased with increasing tumour depth (T1 2CTC/ml; T4 10 CTC/ml; $p<0.05$). There was no correlation between nodal stage and average number of CTC (N0 7 CTC/ml; N2 10 CTC/ml; p=ns). At a median follow-up of 9 months (range 3-13), 3 patients have developed liver metastasis. All three patients had higher CTC counts (range 10-14 CTC/ml).
CONCLUSION: CTC counts are higher in the mesenteric circulation compared to peripheral circulation in patients with colorectal cancer. CTC counts correlate with advanced T-stage and may predict hepatic metastasis.

P369 CONNEXIN 43 EXPRESSION IN PATIENTS WITH COLORECTAL ADENOMATOUS POLYPS

A. Biscanin[1], N. Ljubicic[1], I. Pavic[2], D. Balicevic[2], T. Pavic[1], I. Budimir[1,*], B. Troskot[1]. [1]*Internal medicine,* [2]*Pathology,* "*SESTRE MILOSRDNICE*" *UNIVERSITY HOSPITAL, Zagreb, Croatia*

INTRODUCTION: Connexins are family of transmembrane proteins that build channels in gap junctions. Gradual loss of functional gap junctions and membranous connexin expression during colorectal carcinogenesis has been shown. The aim of this study was to assess the expression of connexin 43 (CX43) in colorectal adenomas and surrounding mucosas, as well as to analyse CX43 correlation with patients' characteristics and pathological features of polyps.
AIMS&METHODS: Forty patients with endoscopically proven colorectal adenomatous polyps were included in the study. Polypectomy was performed in all the patients, and two biopsies from surrounding mucosa were taken. CX43 expression was determined by immunohystochemical staining, both in polyp dysplastic mucosa and surrounding mucosa. The expression of CX43 was analysed in 10 different fields by two independent experienced pathologist, and was assessed according to a 2-point scale : negative, <10% CX43 positive cells; positive, >10% CX43 positive cells. CX43 expression was correlated with patients' clinical data, size and pathohystological characteristics of polyps according to the WHO 2010 classification.

RESULTS: Expression of CX43 was found in mucosa surrounding polyps in 50% of patients (10/20) with low grade adenomatous polyps, and in 85% of patients (17/20) with high grade adenomatous polyps (p=0.009). Statistical analysis showed no significant difference in CX43 expression among low and high grade dysplastic adenomatous polyps. Significant correlation of CX43 expression was neither found with patients' clinical characteristics nor with polyps' characteristics.
CONCLUSION: To our knowledge, this is the first description of CX43 expression characteristics in surrounding mucosa of colorectal adenomatous polyps. We have found no significant difference of CX43 expression in epithelium of low and high grade adenomatous polyps. Despite this fact, frequent CX43 expression in observed surrounding mucosa of adenomatous polyps with high grade dysplasia and frequent lack of CX43 expression in surrounding mucosa of adenomatous polyps with low grade dysplasia, suggests there is a the role of CX43 in the progression of dysplasia in adenomatous polyps as well as in colorectal carcinogenesis.

P370 SERRATED ADENOMAS OF THE COLON. NEW ENTITY OR UNDERDIAGNOSED?

G. Michalopoulos[1], S. Vrakas[1], C. Zeglinas[1], S. Charalampopoulos[1], V. Ntouli[1], S. Lamprinakos[1], C. Tzathas[1,*]. [1]*Gastroenterology, Tzaneion, General Hospital of Piraeus, Piraeus, Greece*

INTRODUCTION: There is recently a great interest for serrated polyps (S.P), mainly due to the identification of the "serrated pathway of carcinogenesis".
AIMS&METHODS: The aim of this retrospective study was to compare the rates of histological diagnosis of S.P with those of "hyperplastic" (H.P) and "mixed polyps" (M.P) over a thirty months period form January 2010 to June 2012. Additionally, demographic characteristics of S.P (age, sex), as well as localization and grade of dysplasia, were also compared to conventional adenomatous polyps (A.P).
From 1100 polypectomies of 643 patients, all S.P, H.P and M.P were recorded and alterations in histology were estimated between the first and the last year of study (x^2 Yates correction). Additionally, the 76 S.P (6.9%) were compared to the 769 A.P (69,9%) with logistic regression analysis regarding age, sex, localization and grade of dysplasia.
RESULTS: The number per year and the percentage of the histological diagnosis of polyps are presented in the Table. A significant increase in the identification of S.P with a parallel decrease of H.P (p=0,001) and M.P (p=0,001) was observed. Additionally, 257 A.P and 39 S.P were recorded in women and 509 and 37 in men respectively. The mean age of patients was 66.2 and 62.8 years for patients with A.P and S.P respectively. 106 A.P but only 1 S.P had high grade dysplasia. 20 S.P were detected in right colon and 56 in left, while 265 and 451 A.P were respectively detected (n.s). An increase of age by 10 years decreased the probability of presence of S.P in comparison to A.P by 22% (p=0.014). S.P showed 52% less probability of occurrence in men in comparison to A.P (p=0.002). Finally S.P showed 91% less probability of expressing high grade dysplasia in comparison to A.P (p=0,013).

Polyps/Year	H.P.	S.P.	M.P.
398 / 2010	82 (20.6%)	9 (2.26%)	47 (11.8%)
394 / 2011	47 (11.9%)	10 (2.5%)	34 (8.6%)
308 / 2012	34 (11%)	57 (18.5%)	11 (3.6%)

CONCLUSION: There is an increase in the histological diagnosis of S.P with a parallel decrease of HP and MP in the last years. This probably correlated to the publication of the WHO classification in 2010 and emphasizes the importance of familiarization with the new classification. In comparison to A.P, S.P seem to have decreased presence probability by age, to be less common in men and to show low probability for high grade dysplasia.

P371 WIF1 METHYLATED GENE TEST AND MICROBIAL CHANGES AS COLORECTAL CANCER (CRC) DIAGNOSIS MARKER.

I. Sobhani[1,*], H. Mansour[1], A. Amiot[1], I. Baumgaertner[2], J. P. Furet[3], F. Canoui-Poitrine[4], CCR Group of Val de Marne. [1]*Gastroenterology & Oncology, [2]Oncology, University Paris Est Creteil UPEC & APHP Hopitaux de Paris, CRETEIL, [3]Instiut Micalis, INRA, Jouy en Josas, [4]Biostatistics, University Paris Est Creteil UPEC & APHP Hopitaux de Paris, CRETEIL, France*

INTRODUCTION: Faecal occult blood test (FOBT) is recommended for CRC screening. However, FOBT had fair sensitivity and specificity as compared to Colonoscopy. Sporadic CRCs result from the environment. Colon microbiota dysbiosis, consequence of environment, is associated with CRC; this may induce mutation(s) and/or hypermethylation in anti oncogenes. The aim was to evaluate FOBT, dysbiosis, mutated and methylated genes in reference to colonoscopy.
AIMS&METHODS: A cross-sectional study included consecutive subjects referred (2003 up to 2007) for colonoscopy screening to endosocpy units. Those with germline mutation, IBD and previous colon or rectal surgery have been excluded. Clinical factors (age, gender, personal and familial history of cancer, BMI, diabetes, and treatments, nutrition behaviours) were recorded. Prior to colonoscopy, effluents (fresh stools, sera-S and urines-U) were harvested and FOBT performed. Seven dominant and subdominant bacterial populations in stools and genes (Wif1, ALX4, and vimentin) methylation levels in stools, S and U were quantified. Mutation gene markers (Kras s, Bat25, Bat 26) have been detected in tissues and stools. Bacteria were quantified (qPCR). Calibration was assessed by Hosmer-Lemeshow chisquare and discrimination by Area Under ROC curve (AUC)
RESULTS: 247 patients were included (mean age 60.8 yrs, extremes 50-75, 52% men). Colonoscopy and pathology identified 90 pts with CRC (n=66) or large adenomas (>10 cm) and remaining cases with normal colonoscopy or adenomatous less than 10 min in diameter. A multivariate model adjusted for age, male gender, and previous personal history of polyps and familial history of cancer leaded to AUC of 81.5% (95%CI: 75.7-87.4). After supplementary adjustment in different models, for dysbiosis, AUC increased to 83.4% (77.9-88.9 with bacteroides and leptum levels being border line; p= 0.08), to 84.9% (79.6-90.3; p=0.02) after adjustment for FOBT, to 90.1% (85.8; 94.4; p<0.001) after adjustment for Wif1 (S or U). When adjusted jointly for clinical parameters, FOBT, dysbiosis and wif1, only FOBT and wif1 remained independently associated with CRC. However, the AUC of the full-adjusted multivariate model did not increase significantly (91.7; 87.8; 95.6; p=0.075).
CONCLUSION: A single qPCR of methylated gene marker in S or U improved diagnosis accuracy compared to FOBT while microbial changes in dominant or subdominant bacteria populations did not improve it. Blood methylated testing can be used in those individuals reluctant to stool testing.

P372 FACTORS INFLUENCING LYMPH NODE HARVEST IN SURGICAL TREATED STAGE I-III RECTAL CANCER.

J. Lykke[1], O. Roikjær[2], P. Jess[3,*]. [1]*Surgical Department,, Roskilde Hospital, [2]Surgical Department,, Roskilde Hospital, [3]Surgical Department,, Roskilde, Roskilde-4000, Denmark*

INTRODUCTION: According to American Joint Committee on Cancer a lymph node (LN) harvest (LNH) of a minimum of 12 LNs is required to ensure LN negative disease in rectal cancer (RC).
Correlations between age, BMI, pT/ypT stage and preoperative chemoradiotherapy (pCRT) and LNH in RC have been proposed. Overall survival (OS) has been related to LNH.
AIMS&METHODS: The aims of this study were in a large nationwide cohort of patients with radical treated RC to evaluate:
LNH in relation to age, BMI, pT/ypT stage and pCRT
OS according to LNH
All patients in The Danish Colorectal Cancer Group's database who had a curative resection of a stage I-III adenocarcinoma (1 Jan 2001 to 31 Dec. 2012) were included. Univariate and multivariate tests were used.
RESULTS: A total of 7950 patients (4832 males and 3118 females) were included. The median LNH was 13 (interquartile range (iqr) 8-19). No difference

between sex was observed. A number of 2302 ptt. had pCRT and a number of 5655 ptt. had surgery alone. A total of 3447 (43.4%) had a LNH < 12 and 4503 (56.6%) had a LNH > =12.
Age: The median LNH according to age (< 60 years; 61-75 years and > 75 years) were: 13 (iqr 9-20); 13 (iqr 8-19) and 12 (iqr 8-18), p < .0001.
BMI: The median LNH according to BMI (BMI < 25; 25 to 29 and ≥30) were: 13(iqr 8-20); 13(8-19) & 13(8-19), N.S.
T-stage: The median LNH according to the T stages were: ypT0: 9(iqr 6-14), p/ypT1: 10(iqr 6-15), p/ypT2: 12(iqr 7-17), p/ypT3: 14(iqr 10-21), & p/ypT4: 16(iqr 10-26), p < .0001.
Preoperative CRT: The median LNH according to +/- pCRT were: 10(iqr 6-14) and 14(iqr 9-20), p < .0001. The percentage of patients having LNH < 12 according to +/- pCRT were 58.7% and 37.1%, p < .0001.
OS: The median OS for LNH < 12/ > =12 were 93/117 months (-pCRT), p < .0001, and 118/114 months (+pCRT), N.S.
In a multivariate analyse with age and year of operation as covariates, T-stage and pCRT had a significant impact on mean LNH with a distribution as follows: ypT0: 6.2, pT1/ypT1: 12.4/9.0, pT2/ypT2: 14.7/10.0, pT3/ypT3: 18.3/12.1 and pT4/ypT4: 21.8/12.9, p < .0001.
CONCLUSION: No relation between sex, BMI and LNH was found.
A minor reduction of LNH with increasing age was observed, p < .0001.
We found a significant relation between T stage and LNH, why T-stage has to be taken into account, when LNH is evaluated.
We also found a significant relation between +/- pCRT and LNH, but no difference in OS for < 12/ > = 12 LN was found in the +pCRT group opposite to the –pCRT group. Therefore, our results do not support a LNH of 12 as a surrogate marker for oncological sufficiency in RC patients treated with pCRT.

INTRODUCTION: Colorectal cancer (CRC) screening programs effect on proximal colorectal neoplasia is limited.
AIMS&METHODS: To compare FIT diagnostic accuracy (one determination, 100ng/ml threshold) and simulated sigmoidoscopy according to UK, SCORE and NORCCAP criteria for proximal advanced colorectal neoplasia (CRC, advanced adenoma) in a cohort of asymptomatic individuals undergoing screening colonoscopy.1292 individuals (mean age 56.4 ± 7.9 years, 53% women, at least one first-degree relative with CRC 45.1%) with complete colonoscopy included in two prospective multicenter, blind diagnostic tests studies to determine FIT (OC-sensor ^{TM}) diagnostic accuracy were analyzed. Sigmoidoscopy diagnostic yield was simulated according to UK, SCORE and NORCCAP criteria to complete colonic examination. We compared diagnostic accuracy with ROC curves, area under the curve and the homogeneity area test. Sensitivity, specificity, positive and negative predictive value and the number needed to scope (NNS) were also determined and sensitivity and specificity were compared with McNemar test.
RESULTS: Distal and proximal advanced neoplasms were detected in 115 (8.9%) and 47 (3.6%) individuals, respectively. FIT ≥ 100ng/ml was determined in 6.6% of the subjects included and 10.1, 12.7 and 23.5% met UK, SCORE and NORCCAP criteria to complete colonoscopy respectively. No statistically significant differences in AUC for proximal advanced neoplasia detection between FIT(0.56, 95% CI 0.5 to 0.61) and UK (0.56, 95% CI 0, 5 to 0.62, P = 0.88), SCORE (0.56, 95% CI 0.49 to 0.62, P = 0.88) and NORCCAP criteria (0.6, 95% CI 0.53 - 0.68, p = 0.21). In the table below data regarding sensitivity, specificity, predictive values and NNS are shown. FIT was significantly more specific than sigmoidoscopy (p < 0.001) but significantly less sensitive than NORCCAP criteria (P = 0.004).

Diagnostic test	FIT ≥100ng/ml	UK criteria	SCORE criteria	NORCCAP criteria
Sensitivity (%)	17	21,3	23,4	42,6
Specificity (%)	93,8	90,4	87,7	77,2
Positive predictive value (%)	9,4	7,7	6,7	6,6
Negative predictive value (%)	96,8	96,8	96,8	97,3
Number needed to scope	10,62	13	14,9	15,2

CONCLUSION: FIT and sigmoidoscopy diagnostic yield for proximal advanced colorectal neoplasia is low. FIT is more specific than sigmoidoscopy but less sensitive than sigmoidoscopy according to NORCCAP criteria.

P374 DIAGNOSIS OF COLORECTAL POLYPS USING OPTICAL PROJECTION TOMOGRAPHY– HOW WELL DO PATHOLOGISTS AGREE?

M. V. Coats[1,*], S. Wedden[2], R. Keogh[3], R. Steele[1], F. A. Carey[4]. *[1]Cancer Division, University of Dundee, Dundee, [2]MRCT, Edinburgh, [3]London School of Hygiene and Tropical Medicine, London, [4]Pathology, NHS Tayside, Dundee, United Kingdom*

INTRODUCTION: Optical Projection Tomography (OPT) is a non-destructive, in vitro 2D and 3D imaging technology, which is being evaluated as a diagnostic tool for colorectal polyps. Colonic polypoid cancers are the earliest detectable form of colorectal cancer (CRC) and if completely excised, can offer a potential cure. However, their diagnosis using conventional 2D histopathology gives rise to marked inter-observer variation due to features such as epithelial misplacement but also due to the lack of clarity in differentiating between areas of dysplastic change.
AIMS&METHODS: Our aim was to identify how well OPT compares to conventional methods and to evaluate agreement among specialist pathologists. Polyps from the UK screening population were scanned using OPT and their corresponding H&E glass and digital slides reviewed. Images were analysed by 5 gastrointestinal pathologists blinded to the specimen diagnosis in each of the three imaging modalities. Observers classified each specimen as low grade dysplasia (LGD), high grade dysplasia (HGD) or invasive cancer (ICA)and the surface morphology as tubular, tubulovillous or villous. Inter and intra observer variation analyses were made and the glass slide diagnosis taken as the current gold standard (GS).
RESULTS: 59 (39 LGD; 8 HGD; 12 ICA) specimens were reviewed. Inter-observer analysis showed that no pathologist agreed with the GS for all specimens when reviewing glass slides alone. Intra-observer analysis of dysplasia diagnoses showed substantial agreement when comparing glass and digital slides (k 0.68-0.74; specificity 93.6-100%) and fair to moderate agreement between glass and OPT images (k0.27-0.47; specificity 86.3-97.6%). Evaluation of surface morphology demonstrated a similar pattern of agreement between glass and digital slides (k0.31-0.71 specificity 50-73.7%) and OPT images (k0.23-0.45; specificity 21.1-72.7%) but a much lower specificity. The pathologist with the most OPT experience had the best agreement. Inter-observer analysis of ICA polyps showed that all 5 pathologists gave this same diagnosis on glass slides in 66.7%, digital slides in 58.3% but 0% on OPT images.
CONCLUSION: Inter-observer variation remains a significant problem when making a qualitative pathological assessment of colorectal polyps. Introducing a new technology, such as OPT, creates more variation in those with limited experience and highlights the growing need for a robust semi-automated or quantitative diagnostic tool to aid pathologists in making an accurate diagnosis.

P375 IS ECTOPIC CRYPT FORMATION SPECIFIC FOR TRADITIONAL SERRATED ADENOMAS?

M.-J. Kim[1,*], E.-J. Lee[2], D. S. Kim[2], D. H. Lee[2], S. H. Lee[1], E. G. Youk[2]. *[1]Pathology, [2]Surgery, Daehang hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Ectopic crypts, defined as abnormally positioned crypts that have lost orientation toward the muscularis mucosae, are suggested to be a pathognomonic finding of traditional serrated adenomas (TSAs). However, the significance of the ectopic crypt formation (ECF) in the distinction between TSAs and conventional adenomas (CAs) has rarely been studied.
AIMS&METHODS: We designed this study to determine whether ECF can be found in CAs and its presence is pathognomonic of TSAs. We studied 107 TSAs and 191 CAs including 106 tubular adenomas (TAs), 66 tubulovillous adenomas (TVAs), and 19 villous adenomas (VAs).
RESULTS: ECF was identified in most (79.4%) but not all TSAs. ECF was not infrequent in CAs (62 of 191, 32.5%) and its presence correlated with the presence of a villous component and larger tumor size ($P < .001$, each). Focal serration of crypts was noted in 20 (10.5%) cases of CAs. Abundant eosinophilic cytoplasm was noted in 10 (5.2%) of CAs and its presence was significantly associated with the presence of ECF ($P < .001$).
CONCLUSION: Based on its strong association with the presence of a villous component and larger tumor size, ECF appears to be involved in the villous or protuberant growth of colorectal adenomas. The identification of ECF is very helpful in the diagnosis of TSAs, however, ECF can be found in CAs, particularly in cases with a villous component. Therefore, a possibility of CA should be considered before making a diagnosis of TSA if we encounter colorectal adenomas with ECF because ECF is not uncommon in CAs.

P376 THE YIELD OF FECAL IMMUNOCHEMICAL TEST IN SCREENING INDIVIDUALS WITH A FAMILY HISTORY OF COLORECTAL CANCER

S. C. Ng[1,*], J. Ching[1], V. Chan[1], M. C. Wong[2], B. Y. Suen[1], H. Hirai[1], J. Y. Lau[3], F. K. Chan[1], J. J. Sung[1]. *[1]Medicine and Therapeutics, [2]The Jockey Club School of Public Health and Primary Care, [3]Surgery, Chinese University Of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: The role of fecal immunochemical test (FIT) in screening individuals with a positive family history of colorectal cancer (CRC) is not clear.
AIMS&METHODS: We assessed the diagnostic accuracy of FIT using colonoscopy findings as gold standard in identifying colorectal neoplasms. We analyzed data from 4,539 asymptomatic subjects aged 50-70 years who had both colonoscopy and FIT at our bowel cancer screening center between 2008 and 2012. We assessed sensitivity of FIT in detecting advanced neoplasms and cancers in subjects with a family history of CRC. Advanced neoplasm was defined as lesions with one of the following: size $\geq$10 mm, have villous or tubulovillous component, high-grade dysplasia or carcinoma-in-situ
RESULTS: Advanced neoplasms and cancers were found at screening colonoscopy in 219 (4.8%) and 22 (0.5%) individuals, respectively. The mean age was 57.68 $\pm$ standard deviation (SD) 4.86 and 44% were male. 572 subjects (12.6%) had a family history of CRC. FIT was positive in 59 (10.3%) subjects. The sensitivity of FIT in detecting adenoma, advanced neoplasm, and cancer in subjects with a family history of CRC was 9.5% (95% confidence interval [CI], 5.7%>15.3%), 35.1% (95% CI, 20.7%>52.6%), and 25.0% (95% CI, 1.3%>78.1%), respectively. Among FIT negative subjects, adenoma was found in 152 (29.6%), advanced neoplasm in 24 (4.7%) and invasive cancer in 3 (0.6%) individuals who have a family history of CRC.
Table 1: Diagnostic performance of FIT in subjects with a family history of CRC

Colonoscopy findings	FIT positive (N=59)	FIT negative (N=513)	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)
All neoplasms	28 (8%)	302 (92%)	8.5 (5.8-12.2)	87.2 (82.2-91.0)	47.5 (34.5-60.8)	41.1 (36.9-45.5)
Hyperplastic polyps	1 (3%)	32 (97%)	3.0 (0.2-17.5)	89.2 (86.2-91.7)	1.7 (0.1-10.3)	93.8 (91.2-95.6)
Adenomas	16 (10%)	152 (90%)	9.5 (5.7-15.3)	89.4 (85.8-92.1)	27.1 (16.7-40.5)	70.4 (66.2-74.3)
Advanced neoplasms	13 (35%)	24 (65%)	35.1 (20.7-52.6)	91.4 (88.6-93.6)	22.0 (12.7-35.1)	95.3 (93.0-96.9)
Invasive cancers	1 (25%)	3 (75%)	25.0 (1.3-78.1)	89.8 (86.9-92.1)	1.7 (0.1-10.3)	99.4 (98.2-99.8)

CONCLUSION: Compared with colonoscopy, FIT is more likely to miss advanced neoplasms or cancer in individuals with a family history of CRC.

P377 A COMPUTATIONAL MODEL FOR EARLY DETECTION OF COLORECTAL CANCER BASED ON COMPLETE BLOOD COUNTS, DERIVED FROM AN ISRAELI POPULATION, PERFORMS EQUALLY WELL ON A UK POPULATION

Y. Kinar[1], N. Kalkstein[1], P. Akiva[1], E. E. Half[2], I. Goldshtein[3], G. Chodick[3], V. Shalev[3,*]. *[1]Medial Research, Ramot Hashavim, [2]Gastroenterology Department, Rambam Health Care Campus, Haifa, [3]Medical Division, Maccabi Healthcare Services, Tel Aviv, Israel*

INTRODUCTION: Compliance with colorectal cancer
(CRC) screening programs is sub-optimal. Recently, we developed an automated model that analyzes existing clinical data (complete blood counts- CBCs, age and gender) and produces a personal score for stratifying the probability of having CRC. Our model was developed and validated on an Israeli population of 860,000 individuals, and is able to accurately identify (specificity 90%) more than half of the CRC patients (sensitivity 50.4%). Notably, our model can potentially double the number of CRC cases detected by current Israeli screening program. Although externally validated, our model was not validated in non-Israeli populations.
AIMS&METHODS: Here we aim to validate our model on a UK population to determine its applicability to other populations. To achieve this we applied our model to 77,550 primary care UK patients (age 40+) using the health information network (THIN) database, including 5,977 CRC cases. The CBCs were analyzed at different points in time prior to cancer diagnosis date. The model performance was evaluated by standard area under the receiver operating curve (AUC) (with value approaching 1 for perfect identification and 0.5 for random scoring) and the portion of CRC cases detected (sensitivity) at a given accuracy (specificity).
RESULTS: Compared to the Israeli population, the UK population has fewer CBC records (average of 4 CBCs during 8 years, vs 8 in Israelis), and these CBCs were lacking information, such as RDW. In spite of these differences, the model performed very well, achieving similar performance for both populations. When considering CBCs 3-6 months prior to the CRC diagnosis date, the AUC is 0.81 and the model detected 55.6% of the UK CRC cases at 90% specificity. When considering CBCs taken up to one month before the diagnosis date, performance is even more impressive (AUC 0.84, 60.4% of UK CRC cases at 90% specificity).
CONCLUSION: We developed a computational method based on age, gender and CBCs that efficiently detects CRC. Importantly, compared to the existing screening program, the wide availability of CBCs allows us to cover a much larger proportion of the population and to greatly increase the number of CRC cases detected potentially at an earlier stage. Here we applied our model on a UK population, which is very different from our original dataset in terms of ethnicity, age composition, health care practices, and more. Remarkably, we were able to achieve similar performances in both populations, suggesting that our model is applicable to other populations.

P378 EICOSAPENTAENOIC ACID-FREE FATTY ACID PREVENTS AND SUPPRESSES COLONIC TUMOURS IN COLITIS-ASSOCIATED COLORECTAL CANCER.

G. Piazzi[1], A. Prossomariti[1,*], G. D'Argenio[2], V. Lembo[2], G. Mazzone[2], P. Vitaglione[3], V. Fogliano[3], A. Munarini[1], C. Ceccarelli[4], C. Fazio[1], L. D'Angelo[1], A. Belluzzi[5], P. Chieco[6], M. A. Hull[7], M. Romano[8], F. Bazzoli[1], L. Ricciardiello[1]. *[1]Department of Medical and Surgical Sciences, University of Bologna, Bologna, [2]Department of Experimental and Clinical Medicine, University of Naples "Federico II", Naples, [3]Department of Food Science, University of Naples "Federico II", Portici (Naples), [4]Clinical Department of Radiological and Histopathological Sciences, [5]Gastroenterology Unit, [6]Center for Applied Biomedical Research (CRBA), S.Orsola-Malpighi Hospital, Bologna, Italy, [7]Section of Molecular Gastroenterology, Leeds Institute of Molecular Medicine, St James's University Hospital, Leeds, United Kingdom, [8]Division of Hepato-Gastroenterology, Second University of Naples, Naples, Italy*

INTRODUCTION: Inflammation plays a critical role on colorectal cancer (CRC) development. The consumption of n-3 polyunsaturated fatty acids (n-3 PUFAs) reduces the risk of sporadic CRC but its effect on colitis-associated cancer (CAC) has yielded conflicting results. The Notch pathway is critical for colon carcinogenesis, with opposite activity between sporadic CRC and CAC.
AIMS&METHODS: We evaluated the effectiveness of eicosapentaenoic acid as free fatty acid (EPA-FFA; SLA Pharma UK) in preventing tumours in murine models of CAC. C57BL/6 mice treated with AOM-DSS were randomized into three groups (n=20 each) to be fed either standard (Ctrl) or EPA-FFA 1%>containing diets and the effects were evaluated on both initiation (Init) and promotion (Prom) of carcinogenesis. Blood was collected for cytokine levels, lipid peroxidation and antioxidant activity. Urine was obtained for PGE2 levels, and tissues were collected for macroscopic and microscopic analysis and mucosal fatty acids composition. Expression of Notch1 targets (Nrarp, Hath1 and Hes1) and ligands, were tested by Real time PCR.
RESULTS: EPA-FFA strongly decreased tumour multiplicity in the Prom (76.4%) and Init (67.2%; $p<0.01$ for each group vs. Ctrl). EPA-FFA reduced the incidence in the Prom (70.5%) and Init (50.8%; $p<0.01$ for each group vs. Ctrl), and reduced max tumour size in the Prom (72.7%) and Init (60.9%; $p<0.05$ for each group vs. Ctrl). The combined content of mucosal arachidonic and linoleic acids decreased with EPA-FFA ($p<0.001$ for each group vs. Ctrl) while combination of EPA, DPA, DHA increased ($p<0.001$ for each group vs. Ctrl). EPA-FFA reduced interleukin-1β by 49.2% (Prom), and interferon-γ by 40.7% (Init) ($p<0.05$). EPA-FFA decreased PGE2 excretion, parcicularly in the Init (Init vs. Ctrl $p<0.05$). No changes in lipid peroxidation and antioxidant activity were observed. Concordant with previous reports, the Ctrl arm showed low Notch1 activity. A trend toward increased Hes1 and downregulated Hath1 was found in treated arms, while a significant increase of Nrarp was observed in the Init arm ($p<0.001$).
CONCLUSION: Our data suggest that EPA-FFA could be an excellent candidate for chemoprevention in colitis-associated colorectal cancer.

P379 PREOPERATIVE NEUTROPHIL TO LYMPHOCYTE RATIO >3 AS A PREDICTOR FOR DISEASE-FREE SURVIVAL AFTER CURATIVE COLORECTAL CANCER SURGERY.

G. Malietzis[1,2,*], M. Giacometti[1], A. Askari[1], S. Nachiappan[1], R. H. Kennedy[1], O. D. Faiz[1], O. Aziz[1], J. T. Jenkins[1]. *[1]Department of Colorectal Surgery, St Mark's Hospital, [2]Department of Medicine, Imperial College, London, United Kingdom*

INTRODUCTION: Neutrophil to lymphocyte ratio (NLR) reflects a systematic inflammatory response, with some evidence suggesting that an elevated preoperative NLR >5.0 is associated with poorer survival in colorectal cancer patients [1-4]. This study aims to determine the role of the NLR as a prognostic marker for colorectal cancer patients with non-metastatic disease undergoing curative resections.

AIMS&METHODS: Data from 506 consecutive patients diagnosed with non-metastatic colorectal adenocarcinoma undergoing surgical resection between 2006 and 2011 were included. Receiver Operating Characteristics (ROC) curve analysis was used to identify the optimal value for NLR in relation to disease-free and overall survival. Univariate and multivariate Cox regression models were used to determine the role of NLR after stratification by several clinicopathological factors. Patients were followed by a standardised protocol until February 2013.

RESULTS: Median follow-up was 44.57 months [IQR, 20.97-65.16]. Multivariate Cox regression analysis identified NLR > 3 as an independent prognostic factor for disease free survival (OR 2.41, (95% CI 1.12-5.15) P= 0.024,) but not for overall survival (OR 1.23, (95% CI 0.80-1.90) P=0.347). A high NLR was significantly associated with older age, higher T and N stage, presence of micro vascular invasion, low pre-operative albumin levels and ASA status of the patients.

CONCLUSION: For patients diagnosed with CRC, a pre-operative NLR > 3 is an independent prognostic factor for disease free survival. Considering this in addition to well-established prognostic variables may improve the processes of identifying patients at higher risk of recurrence who would benefit from adjuvant therapies, thereby providing more personalised care.

P380 PROTON PUMP INHIBITOR CAN INDUCE APOPTOSIS IN CACO2 CANCER CELL LINES

H. S. Lee[1,*], S. H. Kim[1], H. S. Choi[1], E. S. Kim[1], B. Keum[1], Y. T. Jeen[1], H. J. Chun[1], S. H. Um[1], C. D. Kim[1], H. S. Ryu[1], Department of Internal Medicine, Division of Gastroenterology and Hepatology, : , Korea University Anam Hospital. [1]*Department of Internal Medicine, Division of Gastroenterology and Hepatology, Korea University Anam Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Recent studies suggested that proton pump inhibitors induced selective apoptosis of cancer cell and concept for anti-tumor effect due to changes of intracellular acidity in tumor cells was emerged. Until now, whether proton pump inhibitors induce apoptosis of CaCO2 (human intestinal cancer cell line) is not known, where as the effects of proton pump inhibitor on gastric cancer, pancreatic cancer, B-cell lymphoma were studied before. The aim of this study is to evaluate the effect of proton pump inhibitor (omeprazole) on apoptosis of human CaCO2 cells.

AIMS&METHODS: For MTT assay, human intestinal CaCO2 cells were incubated with each concentrations of omeprazole for 24 hours in 37°C incubator and concentrations showed 25% and 50% of cell viability were selected. Apoptosis of human CaCO2 cells were measured by performing TUNEL assay with the concentrations decided by MTT assay. We measured apoptosis related signals such as caspase-3, caspase-8, Bcl-2, Bax, PARP using western blot analysis.

RESULTS: TUNEL assay showed that omeprazole induced the apoptosis of human CaCO2. The expression of major signals related apoptosis such as caspase-3, caspase-8, Bax, PARP were significantly increased and anti-apoptosis signal, Bcl-2 was decreased.

CONCLUSION: Proton pump inhibitor induces apoptosis of human CaCO2 cells and expression of important signals related to apoptosis. Further studies about anti-tumor effect of proton pump inhibitors are needed.

INTRODUCTION: Tumor environment contributes to tumor progression, chemoresistnance and metastatic feature. It is well known that medium surrounding tumor is acidic and cytosolic pH is alkaline. Acid pump antagonist is the reversible inhibitor of gastric H^+/K^+-ATPase by competing with K^+ onthe surface of the enzyme so that is independent of secretory status and results rapid onset. Recent studies suggested that proton pump inhibitors induced selective apoptosis of cancer cells due to changes of intracellular and extracellular acidity in tumor cells. However, effect of acid pump antagonist to tumor cells has not been studied. The aim of this study is to evaluate the effect of acid pump antagonist (YH-1885) on apoptosis of human colorectal adenocarcinoma cell lines (CaCO2).

AIMS&METHODS: For MTT assay, human CaCO2 cell lines were incubated with each concentrations of YH 1885 for 24 hours in 37°C incubator and concentrations showed 25% and 50% of cell viability were selected. Apoptosis of human CaCO2 cell lines was measured by performing TUNEL assay with the concentrations decided by MTT assay. We measured apoptosis related signals such as Bax, Bcl-2, cleaved PARP, caspase-3, caspase-8 using western blot analysis.

RESULTS: TUNEL assay showed that YH-1885 induced the apoptosis of human CaCO2 cells. The expression of major signals related apoptosis such as Bax, cleaved PARP, caspase-3, caspase-8 were significantly increased and anti-apoptosis signal, Bcl-2 was decreased.

CONCLUSION: Acid pump antagonist may have an effect to microenvironment of tumor cells and induces apoptosis of human CaCO2 cell lines. Further studies are needed to evaluate the apoptotic effect of acid pump antagonist for tumor cells.

P382 AGE AND FIVE-YEAR SURVIVAL IN OPERATED PATIENTS FOR COLORECTAL CANCER

J. J. Arenal[1,*], C. Tinoco[1], C. Benito[1], M. Á. Citores[1], L. Sancho[2], R. Ruiz-Zorrilla[3]. [1]*Surgery,* [2]*Gastroenterology,* [3]*University Hospital Río Hortega, Valladolid, Spain*

INTRODUCTION: Colorectal carcinoma in elderly patients is increasing. There is a tendency to offer a sub-standard treatment for these patients because of their chronologic age.

AIMS&METHODS: To analyse the influence of patients age in the survival for colorectal cancer**.** Cohort of 1779 patients diagnosed of colorectal cancer in a 21 years period (1985- 2006), divided in four groups of age: < 65 years (482 cases), 65-74 years (553 cases), 76-84 years (547 cases) and ≥ 85years (193 cases). Measurements: demographic data, peri-anaesthetic risk (American Society of Anaesthesiologists (ASA) grade), character (elective or non-elective) and curability of surgery, pathological data, mortality, and survival. The cancer was staged using the TNM cancer staging system. Statistics: The chi-squared test was performed to determine significance in nonparametric variables. Kaplan-Meier curves were used in survival and comparisons made with Log-rank test. Logistic regression was used to estimate crude and specific survival risk including the follow variables: sex age, ASA grade, curative or palliative surgery, tumour differentiation, starved nodes, invaded nodes, venous invasion, and TNM stage. For all tests is has been considered a level of signification P ≤ 0,01.

RESULTS: Perioperative risk increases with age increase (P=0.0001). Rate of curative surgery decreases from 73% in the group under 65 years of age to 48% in patients aged 85 years of age and older (p=0.0001). Non-elective surgery and postoperative mortality have increased with the age (p=0.0001). No differences have been observed in pathological data between groups. Crude five-years survival in operated patients with curative intent has been 72% for those under 65 years of age, 68% for the group 65-74 years, 57% for the group 75-84 years and 33% for those aged ≥ 85 years (p=0.0001). Nonetheless, cancer specific five-years survival has been 74%, 73%, 66% y 59%, respectively. By logistic regression analyses, crude five-year survival of operated patients is related to age (p=0.0001), ASA grade (p=0.0001), curative surgery (p=0.0001), starved nodes (p=0.004), tumour differentiation (p=0.001) and tumour stage (p=0.0001). By regression analyses of specific five-year survival in operated patients, age disappear as a related factor. Only curative surgery (p=0.0001), starved nodes (p=0.007), tumour differentiation (p=0.002), and tumour stage (p=0.0001) are related factors to specific five-year survival in operated patients.

CONCLUSION: The age of operated patients for colorectal cancer is not a factor related to specific five-year survival

P383 A NATIONAL SURVEY OF HEREDITARY COLORECTAL CANCER SERVICES IN THE UNITED KINGDOM

K. J. Monahan[1,*], S. K. Clark[2], British Society of Gastroenterology (, BSG) Cancer Group. [1]*Gastroenterology, West Middlesex University Hospital,* [2]*Polyposis Registry, St Mark's Hospital, London, United Kingdom*

INTRODUCTION: The appropriate management of genetic susceptability is an essential tool for the prevention of colorectal cancer. Heritable factors contribute about 35% of all colorectal cancer risk which has a significant impact on clinical activity in centres managing colorectal cancer. The British Society of Gastroenterology (BSG) and Association of Coloproctologists of Great Britain and Ireland (ACPGBI), released updated guidelines in 2010 for the management of patients with a family history of colorectal cancer in the United Kingdom(1). There is evidence that adherence to these guidelines is highly variable both for endoscopic screening and testing individuals for inherited conditions such as Lynch Syndrome and the Polyposis Syndromes.

AIMS&METHODS: The aim of this survey was therefore to facilitate understanding of how services for patients with inherited colorectal cancer risk can be improved, and to raise awareness of this issue amongst clinicians. This survey was designed by members of the BSG Cancer Group. Gastroenterologists, Colorectal Surgeons, and Oncologists were invited to complete a short 10 point questionnaire. This was cascaded by email to 1,793 members of the Royal College of Radiologists (RCR), Association of Cancer Physicians (ACP), the BSG and ACPGBI. We sought their opinion and perception of local hereditary colorectal cancer services, also their adherence to and understanding of current national guidelines.

RESULTS: Three hundred and eighty-two members responded to the survey, an overall response rate of 21.3%. Although 69% of respondents felt there was an adequate service for these patients, 64% also believed that another clinician was undertaking this work. There was no apparent patient pathway in 52% of centres, and only 33% maintain a register of these patients. Patients rarely receive initial tumour block testing for Lynch Syndrome. When asked what they would like to augment the service they receive many respondents requested 'clear guidelines', 'pathways' and dedicated support networks. Many appeared to be unaware of the BSG/ACPGBI guidelines for the management of these patients.

CONCLUSION: There is wide variability in local management and in subsequent clinical pathways for hereditary colorectal cancer patients. There is a perception that they should be managed by 'another' unspecified clinician. National guidelines are not adhered to, therefore we recommend improved education, well defined pathways and audit in order to improve care of patients with hereditary colorectal cancer risk.

P384 DOWNREGULATION OF MTOR SIGNALLING IN COLORECTAL CANCER CELLS BY A COMBINATION OF EICOSAPENTAENOIC ACID-FREE FATTY ACID, EPIGALLOCATECHIN-3-GALLATE AND PROANTHOCYANIDINS.

L. D'Angelo[1,*], G. Piazzi[1], A. Prossomariti[1], C. Fazio[1], A. Pacilli[2], L. Montanaro[2], G. Graziani[3], V. Fogliano[3], A. Munarini[1], A. Belluzzi[4], F. Bazzoli[1], L. Ricciardiello[1]. INTRODUCTION: The low incidence rates of colorectal cancer (CRC) in Mediterranean countries has been mainly attributed to their dietary habits. In preclinical settings, many natural compounds display potent chemopreventive activities but at high doses. mTOR (mammalian target of rapamycin) signaling is a key regulator of translation initiation and plays a critical role in CRC.

AIMS&METHODS: The aim of the study was to explore the effect of a combination of three natural compounds, eicosapentaenoic acid-free fatty acid (EPA-FFA, SLA Pharma UK), epigallocatechin-3-gallate (EGCG) and proanthocyanidins (grape seeds extract, GS) at low concentrations on HCT116 CRC cells and test their activity on mTOR pathway and on translational regulation through analysis of polysome profiles. MTT assay was employed to evaluate cell viability. Fatty acid incorporation was analyzed by GC-MS. Protein analysis was performed to evaluate the effect on downstream effectors of mTOR. Polysomal RNA was isolated from polyribosomal fractions after treatment. Gene expression analysis was performed by Real-Time PCR.

RESULTS: After establishing their $IC_{50,}$ EPA-FFA, EGCG and GS were employed either as single agents, or in combination at concentrations that at 24h showed: 1) No cell death (comb. #1, EPA-FFA 100μM+EGCG 125μM+GS 5μM); 2) 10% cell death (comb. #2, EPA-FFA125μM+EGCG 150μM+GS 10μM); 3) 30% cell death (comb #3, EPA-FFA150μM+EGCG 175μM+GS 15μM). We found that each single compound differently affected the downstream mTOR targets, pS6K and p4EBP1. The highest effects were found with 4h treatments. Importantly, the combination of three compounds at concentrations lower than IC_{50} resulted in the strongest inhibition, up to 98% for pS6K/S6K (#3), and to 78% for p4EBP1/4EBP1 (#3). The combination #3 led to an inhibition comparable with that obtained using the mTOR inhibitor rapamycin at 20nM for 48h. Importantly, the combination #3 reduced the translation of mRNAs encoding for ribosomal protein (L5, L11, L13), cell cycle regulators (C-Myc, Cyclin D1).

CONCLUSION: The treatment with EPA-FFA, EGCG and GS on HCT116 cells decreased mTOR activity and the translation of its targets when used in triple combination and at concentrations much lower than their IC_{50}. Our results indicate that these natural compounds, when used at non-cytotoxic concentrations, could be very effective chemopreventive agents.

P385 THE RISK OF ADENOMAS AND CARCINOMAS IN THE ILEAL POUCH AND RECTUM AFTER SURGICAL TREATMENT IN PATIENTS WITH FAMILIAL ADENOMATOUS POLYPOSIS

M. Tajika[1,*], T. Tanaka[1], M. Ishihara[1], N. Mizuno[2], K. Hara[2], S. Hijioka[2], H. Imaoka[2], Y. Nagashio[2], M. Sekine[2], T. Fujiyoshi[2], Y. Sakamoto[2], T. Sato[2], T. Yogi[2], H. Tsutsumi[2], V. Bhatia[3], K. Yamao[2], Y. Niwa[1]. [1]*Endoscopy,* [2]*Gastroenterology, AICHI CANCER CENTER HOSPITAL, Nagoya, Japan,* [3]*Medical Hepatology, Institute of Liver and Biliary Sciences, New Delhi, India*

INTRODUCTION: Restorative proctocolectomy has become the most common surgical procedure for patients with familial adenomatous polyposis (FAP). However, over time adenomas and even carcinoma may develop in the ileal pouch.

AIMS&METHODS: We evaluated the incidence and nature of rectal adenomas, and also ileal pouch and non-pouch adenomas and carcinomas in patients with familial adenomatous polyposis. Endoscopic and medical records of all patients with FAP (n=75) treated in Aichi cancer center hospital, Nagoya, between January 1965 and December 2010 were reviewed. Forty patients from 28 families (23 women; median age: 51.7 years; range: 28 to 75 years) were enrolled in endoscopic surveillance, and are the subjects of this retrospective study. These patients had undergone Kock's continent ileostomy (Kock) (n=8), ileorectal anastomosis (IRA) (n=8), and ileal pouch-anal anastomosis (IPAA) (n=24). All patients were followed with a standardized protocol including chromoendoscopy and biopsies of visible polyps in the ileal pouch, non-pouch mucosa, and the rectum.

RESULTS: Median follow-up period was 17.4 years (2.3 to 36.1 years). Twenty of 32 pouch patients (Kock and IPAA) developed adenomas in the ileal pouch mucosa, and all 8 patients with IRA developed adenomas in the rectal mucosa, none in the ileal mucosa. The prevalence of ileal adenomas was significantly higher in pouch patients than in IRA patients ($P<0.01$). Three cases of adenocarcinomas developed in the ileal pouch mucosa. One of them died of ileal cancer. The risk of adenoma development in the ileal pouch was 10%, 45%, and 90% at 5, 10, and 20 years of follow-up, respectively after proctocolectomy with Kock and IPAA. The risk of rectal adenomas after colectomy with IRA was 50%, 75%, and 100% at 5, 10, and 20 years of follow-up, respectively. The overall risk of adenoma development was significantly higher in IRA patients compered to pouch patients ($P<0.05$).

CONCLUSION: Although the overall risk of adenoma development was significantly higher in IRA patients, we also found a high frequency of adenomas in the ileal pouch mucosa, with evolution into carcinoma. Regular endoscopic surveillance of the ileal pouch is recommended in these patients.

P386 IMPACT OF 5-FU ENZYME ON CHEMOTHERAPY FOR PATIENTS WITH RESECTABLE COLORECTAL CANCER

T. Ochiai[1,*], M. Umeki[2], H. Miyake[3], OPRT on behalf of, OPRT collaborative study group, collaborative study group. [1]*Surgery, Tobu Chiiki Hospital Tokyo Metropolitan Health and Medical Treatment Corporation, Tokyo,* [2]*Surgery, Hyogo Prefectural Awaji Hospital, Hyogo,* [3]*Surgery, Kasukabe Municipal Hospital, Saitama, Japan*

INTRODUCTION: Recently, there is a useful biomarker for molecularly targeted drug. However, there has been no useful biomarker yet for 5-FU in spite of being the key drug for colorectal cancer (CRC). 5-FU based chemotherapy has been the key regimen for CRC. Orotate Phosphoribosyl Transferase (OPRT) converted into mostly 5-FU active form in the first step. Dihydropyrimidine dehydrogenase (DPD) is the initial enzyme of 5-FU catabolism. Also Prodrugs of 5FU (ex. TS-1, capecitabine) were initially converted into active or inactive forms by these enzymes. Accordingly, it was important for antitumor activity of 5-FU that these enzymes were evaluated. The correlation between these enzymes and the response of 5FU was suggested. However, the correlation was not yet investigated prospectively.

AIMS&METHODS: The aim of this prospective cohort study is to evaluate these enzymes as a predictive factor of 5-FU for patients with resectable CRC. This study was a multicenter prospective cohort study. 14 centers collaborated in this study. OPRT and DPD activities were assessed in surgical biopsies obtained from patients with resectable CRC. These enzyme activities were assayed for actual kinetic enzyme activity in vivo. We calculated the value of OPRT and DPD activity followed by OPRT, and the DPD activity ratio (OPRT/DPD) and the cut off value of OPRT/DPD were calculated for 5 years disease free survival (DFS) and overall survival (OS). Patients were treated with 5-FU/Leucovorin (LV) regimens (bolus 5-FU on day1 and LV in 2-hour infusion on day1 weekly for 6 consecutive weeks postoperatively). This study's endpoint was the correlation between OPRT/DPD ratio and 5 years DFS and OS. The cut off value of OPRT/DPD ratio was determined by the maximum χ^2 statistic method against 5 years DFS and OS.

RESULTS: 68 patients were eligible (median age 66, male 42pts, female 26pts) from July 2003 to May 2005. Median follow up was 1925 days. Mean OPRT activity was 0.270 nmol/min/mg protein and DPD was 36.5 pmol/min/mg protein. Mean OPRT/DPD ratio was 0.01360. Cut off value of OPRT/DPD ratio for 5 years DFS and OS was 0.01467, 0.01254, respectively. In 5 years DFS, patients with higher cut off had better prognosis than lower (p=0.0280). In 5 years OS, patients with higher cut off had better prognosis than lower (p=0.0208).

CONCLUSION: This result suggested that OPRT/DPD ratio could be a predictive factor for 5-FU /LV adjuvant chemotherapy and FOLFOX therapy was need for the poor responder.

P387 LACK OF EFFECT OF SACRAL NERVE STIMULATION FOR SCLERODERMA FAECAL INCONTINENCE

A. Alam[1,*], S. K. Butt[1], K. Krogh[2], S. Buntzen[2], A. Emmanuel[1].
[1]Gastroenterology, UCL London, London, United Kingdom, [2]Gastroenterology, Aarhus University, Aarhus, Denmark

INTRODUCTION: Scleroderma is a multi-system disorder of unknown aetiology leading to the deposition of excessive connective tissue in the skin, blood vessels and internal organs. GI involvement is present in 90% of cases and the prevalence of faecal incontinence is 38%. The predominant type of faecal incontinence is passive faecal soiling, related to connective tissue deposition and internal anal sphincter (IAS) dysfunction. The only published study of sacral nerve stimulation (SNS) in scleroderma enrolled five patients and reported that temporary SNS was successful in four, all of whom had complete resolution of their incontinence episodes following a permanent implant. The mechanism of SNS in this indication, and others, remains unclear.
AIMS&METHODS: To assess the outcome of SNS in patients with scleroderma faecal incontinence.
This was a retrospective analysis on prospectively collected data performed on all scleroderma patients from our two centres who had undergone SNS for faecal incontinence.
RESULTS: A total of 10 female patients with a mean age of 54 (37-72) had temporary SNS performed. Faecal incontinence symptom duration ranged from 2 to 25 years (mean 13 years, median 12). All had passive faecal incontinence symptoms. Each patient had pre-procedure ano-rectal physiology and endoanal ultrasound documenting internal sphincter atrophy/fragmentation, or reduced anal resting pressure. Overall, there was no statistically significant difference (p=0.567) in the total Wexner incontinence scores obtained before and (mean 15.1 range 11-19) and during temporary SNS procedures (mean 13.1 range 13-18) . Two patients with a significant improvement went on to have permanent SNS with only one patient achieving a favourable outcome at one year.
CONCLUSION: This study shows that SNS in scleroderma passive faecal incontinence did not achieve favourable results in 9 of 10 patients.

P388 PREDICTION PATHWAYS FOR INNATE IMMUNE PATHOLOGY, IBS, ANXIETY AND DEPRESSION IN A GENERAL POPULATION (THE POPCOL STUDY)

A. Andreasson[1,2,*], M. P. Jones[3], M. M. Walker[4], N. J. Talley[5], H. Nyhlin[6], L. Agréus[1]. *[1]Centre for Family Medicine, Karolinska Institutet, Huddinge, [2]Stress Research Institute, Stockholm University, Stockholm, [3]Psychology, Macquarie University, North Ryde, Sweden, [4]Anatomical Pathology, University of Newcastle, Newcastle, Australia, [5]Faculty of Medicine, University of Newcastle, Newcastle, [6]Medicine, Karolinska Institutet, Solna, Sweden*

INTRODUCTION: Irritable bowel syndrome (IBS) is a common diagnosis known to be associated with anxiety and depression. Interaction between innate inflammatory mediators and immune cells may disturb neural pathways in IBS causing dysmotility and pain which could lead to anxiety and depression.
AIMS&METHODS: The aim of this study was to ascertain whether low grade innate inflammation contributes to a pathway of depression and anxiety via IBS. We evaluated immune cell counts in colonic mucosa in normal subjects and those with IBS (Rome III) from a population based study in which 745 randomly selected subjects had a colonoscopy (mean age 51 years;57% women). Intraepithelial lymphocytes (IELs) per 100 enterocytes and eosinophils (eos) per five non-overlapping high power fields (HPF) were counted by light microscopy in 90 controls and 100 cases; immunocytochemistry (CD117) was performed for mast cells per 5HPF in 80 controls and 81 cases. IELs, mast cells and eos were individually summed over 5 sites (terminal ileum, caecum, transverse colon, sigmoid colon and rectum) to give a total cell load. Anxiety and depression scores were calculated from HADS. A causal model path model which hypothesises immune cells being associated with IBS which, in turn, is associated with elevated anxiety and depression was tested using path analysis implemented in the MPlus software. Standardized path coefficients are reported along with two-tailed p-values. The model's fit to the observed variance-covariance structure was assessed in several ways, viz the residual Chi-Square test which is ideally non-significant ($p > 0.05$), the ratio of Chi-Square to degrees of freedom (ideally < 5.0) the comparative fit index (CFI, ideally > 0.95) and the Tucker-Lewis index (TLI, ideally > 0.95).
RESULTS: All hypothesised paths reached statistical significance supporting the individual hypothesized pathways, see table. The overall model fit was not ideal in all respects but also was not indicative of a poorly-fitting model (X^2_4=10.46, p=.03, X^2/df=2.6, CFI=.91, TLI=.83).

IBS	Anxiety	1.734	0.342	0.471	<0.001
IBS	Depression	1.181	0.251	0.390	<0.001

CONCLUSION: In this model there is a significant contribution of innate immune inflammatory load leading to anxiety and depression via IBS. Whether therapy directed to decreasing this inflammatory load also lifts depression and anxiety is an interesting concept which should be further explored.

P389 FEMALE GENDER FAVORS GUT PROINFLAMMATORY RESPONSES TO STRESS

C. Alonso Cotoner[1,*], M. Pigrau[1], M. Vicario[1], B. Lobo[1], C. Frias[1], A. M. González-Castro[1], E. Salvo-Romero[1], C. Sevillano[1], C. Martínez[1], B.-K. Rodiño-Janeiro[1], M. D. Castillo[1], M. Moris[1], F. Azpiroz[1], J. Santos[1]. *[1]Neuro-Immuno-Gastroenterology Group, Digestive Diseases Research Unit, Gastroenterology Department, Hospital General Vall d'Hebron, Vall d' Hebron Research Institute, CIBERehd, Barcelona, Spain*

INTRODUCTION: Irritable bowel syndrome (IBS) is a highly prevalent disorder, linked to intestinal epithelial dysfunction and mucosal microinflammation, with unexplained increased women susceptibility. We have demonstrated that female gender *per se* determines intestinal barrier dysfunction in response to acute experimental stress. This response could represent, in susceptible individuals, an early stage towards the onset of functional digestive diseases.
AIMS&METHODS: We aim to identify gender-dependent molecular biomarkers of intestinal barrier dysfunction in response to acute stress in healthy individuals to understand the mechanistic origin of increased female prevalence in IBS.
METHODS:Twelve men (M) and 12 age-matched females (F) were recruited. In each participant, two consecutive jejunal biopsies were obtained by Watson's capsule: one at baseline and another 90 min after 15 min of intermittent cold pain stress (CPS). Throughout the study, autonomic (blood pressure and heart rate), hormonal (plasma cortisol) and psychological responses (Subjective Stress Rating Scale) to CPS were monitored. Mucosal RNA was isolated and submitted to microarray analysis followed by differential gene expression and biological pathways identification.
RESULTS: CPS induced a significant autonomic response identified by increased heart rate, blood pressure and plasma cortisol, in association with elevated stress perception in all participants. Interestingly, gene expression studies uncovered differential responses to stress between M and F. Particularly, in the female group, CPS induced circadian rhythm regulation ($P < 0.00001$), along with NK and T cell activation (NFIL3: 1.8; MAL: 1.8 fold change vs basal), and changes in epithelial integrity proteins (KRT13: 1.9 fold change vs basal). In the male group, the stress response was associated with urea cycle and aminoacid metabolism activation ($P < 0.005$), and upregulation of antioxidant genes (SOD1: 1.9 fold change vs basal).
CONCLUSION: Acute experimental stress highlights gender-specific molecular responses involving immune activity and regulation of epithelial integrity in healthy gut, responses that may be linked to female predominance in IBS.

P390 MUCOSAL IMMUNE BIOMARKERS IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

C. Cremon[1,*], R. Barbaro[1], M. Fiorentino[2], A. Altimari[2], R. De Giorgio[1], R. Corinaldesi[1], V. Stanghellini[1], G. Barbara[1]. *[1]Department of Medical and Surgical Sciences, [2]Laboratory of Molecular Pathology, Addarii Institute of Oncology, University of Bologna, Bologna, Italy*

INTRODUCTION: At present, a useful biomarker of irritable bowel syndrome (IBS) does not exist. In mechanistic pharmacological studies, immune cells has been proposed as biomarkers both for entry into the study and as an end-point.
AIMS&METHODS: We assessed mucosal biopsies of patients with IBS, ulcerative colitis (UC) and healthy controls (HC) to evaluate if total immune cells, mast cells or immune gene expression may be useful IBS biomarkers. We included in our study a total of 144 patients with IBS, 32 patients with UC, and 68 HC. All subjects underwent colonoscopy and histological examination. Colonic immunocytes were identified with quantitative immunohistochemistry. The expression of toll-like receptor (TLR)-4, pre-haptoglobin-2, nerve growth factor and interferon (INF)-gamma was evaluated in a total of 37 formalin-fixed, paraffin-embedded colonic biopsy samples (10 HC, 20 IBS and 7 CU). Total RNA was extracted, reverse transcribed to cDNA and analyzed using quantitative real-time RT-PCR assays. Sensitivity, specificity, positive and negative predictive value, and diagnostic accuracy (DA) were analyzed.
RESULTS: Total immune cells, mast cells, TLR-4 and INF-gamma expression were significantly increased in patients with IBS compared to HC ($P<0.01$). As expected, the magnitude of this immune activation in IBS was significantly lower than that of UC ($P<0.01$), with the exception of mast cells which were similar in patients with IBS and UC. The best cut-off range between IBS and HC was: 20.2% to 20.3% for total immune cell count (sensitivity: 77.1%; specificity: 87.5%; DA: 80.6%); 4.3% to 4.7% for mast cell count (sensitivity: 93.8%; specificity: 73.5%; DA: 87.3%); 1.063-1.149 2^-DDCt for TLR-4 expression (sensitivity: 80.0%; specificity: 90.0%; DA: 83.3%); and 0.001 to 0.257 2^-DDCt for INF-gamma expression (sensitivity: 85.0%; specificity: 90.0%; DA: 86.7%). The best cut-off range between IBS and UC was: 33.8% to 34.0% for total immune cell count (sensitivity: 87.5%; specificity: 91.7%; DA: 90.0%); 1.536-1.653 2^-DDCt for TLR-4 expression (sensitivity: 85.7%; specificity: 90.0%; DA: 88.9%); and 6.764 to 8.674 2^-DDCt for INF-gamma expression (sensitivity: 100.0%; specificity: 95.0%; DA: 96.3%).
CONCLUSION: Our data suggest that mucosal total immune cells, mast cells and immune gene expression have good sensitivity and specificity in distinguishing patients with IBS not only from HC but also from patients with UC.

P391 DETERMINANTS OF HEALTH RELATED QUALITY OF LIFE IN IRRITABLE BOWEL SYNDROME PATIENTS

G. Hauser[1], P. Sanda[2], D. Stimac[1,*], M. Tkalcic[2]. [1]*Department of Internal Med., Division of Gastroent, CLINICAL HOSPITAL CENTRE, RIJEKA, CROATIA,* [2]*Department of Psychology, Faculty of Humanities and Social Sciences, University of Rijeka,, Rijeka, Croatia*

INTRODUCTION: Irritable bowel syndrome (IBS) is a disorder of the lower gastrointestinal tract, characterized by abdominal pain and discomfort as well as changes in stool frequency and stool consistency. The main psychological characteristics are higher scores on trait neuroticism and trait anxiety. IBS, like other chronic diseases, has a negative impact on the patients' quality of life and affective state.
AIMS&METHODS: The aim of this study was to examine which factors contribute to the patients' health related quality of life (HRQoL). The data was obtained from 31 IBS patients (26 F and 5 M; age range 18 to 69). The patients first completed a set of questionnaires, including Big Five Inventory (BFI), State-Trait Anxiety Inventory (STAI-T), Beck Depression Inventory (BDI) and Short Form-36 Health Survey (SF-36). Following that, the patients filled out a symptom severity scale for 14 days. The symptom severity score was calculated as the average intensity of present symptoms over the period of 14 days. The patients' faecal calprotectin levels were also obtained.
RESULTS: In order to determine which factors contribute to the patients' quality of life, we performed two regression analyses. The dependent variables used were the two composite scores of SF-36 – physical and mental component, while the predictors were neuroticism, anxiety, depression, symptom severity and calprotectin. The results of the analyses showed depression was the only significant predictor of the mental component of HRQoL (β=-,47; p<,05), while the physical component of HRQoL was predicted by anxiety (β=-,49; p<,05), depression (β=-,45; p<,05) and calprotectin (β=-,61; p<,01).
CONCLUSION: We can conclude that higher levels of anxiety and depression are indicative of lower HRQoL in IBS patients. This implies that lowering anxiety and depression through psychological treatment could increase the patients' HRQoL. Also, calprotectin seems to be a good indicator of the physical component of HRQoL, supporting it as an important marker of disease severity in IBS patients.

P392 THE TRANSCRIPTIONAL REGULATION OF SERT BY EGF VIA EGFR CONTRIBUTES TO THE EFFECTS OF EGF ON THE FORMATION OF VISCERAL HYPERSENSITIVITY

H. Zhang[1,*], X. Cui[2], Y. Yang[1]. [1] *Gastroenterology, First Affiliated Hospital of Nanjing Medical University,* [2] *Gastroenterology, First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

INTRODUCTION: Serotonin transporter (SERT) in the colon tissues of the patients with diarrhea-predominant irritable bowel syndrome (D-IBS) was down-regulated. The mechanisms underlying are not fully understood. It was reported that epidermal growth factor(EGF) via EGF receptor(EGFR) regulated the expression of SERT in gut.
AIMS&METHODS: The present study was designed to investigate the role of the modulation of SERT gene expression by EGF in visceral hypersensitivity, and to delineate the mechanisms. Rat models of visceral hypersensitivity were established by intra-colonic infusion of acetic acid in 10-day-old Sprague-Dawley rats. Abdominal withdrawal reflex (AWR) and electromyography (EMG) were used for assessing visceral sensitivity. The levels of EGF in plasma and intestinal tissues were measured by enzyme-linked immunosorbent assay (ELISA). The study was performed to examine the regulation of SERT by EGF using rat intestinal epithelial cell -6(IEC-6) cells. EGFR kinase inhibitor PD153035 was used in this study. The expression of SERT was detected by Real-time PCR and western blot. EGFR
involved.
RESULTS: The EGF levels in colon tissue and plasma are significantly decreased and the EGF levels are positive correlated with SERT expression in the model rats with chronic visceral hypersensitivity. The expression of SERT in IEC-6 cells treated with EGF was significantly increased in dose-dependent and time–dependent manner, compared with control. Inhibition of EGFR tyrosine kinase activity by PD153035 blocked the stimulatory effects of EGF on SERT expression. These results suggest EGF via EGFR can up-regulate the SERT expression.
CONCLUSION: These findings suggest that transcriptional regulation of SERT by EGF via EGFR may contribute to the formation of visceral hypersensitivity.

P393 A POTENT AND SELECTIVE 5-HT4 RECEPTOR AGONIST, YH12852 EXHIBITS ROBUST IN VIVO EFFICACY FOR STIMULATING GASTROINTESTINAL MOTILITY WITH EFFECTIVE SUPPRESSION OF VISCERAL HYPERSENSITIVITY

J. Y. Sim[1,*], M. H. Cha[1], E. J. Jeong[1], S. W. Lim[1], H. S. Seo[1], S. Y. Chung[1], H. N. Hong[1], S. W. Oh[1], K. K. Ahn[1], S. Y. Nam[1]. [1]*Yuhan Corporation, Seoul, Korea, Republic Of*

INTRODUCTION: YH12852, a novel 5-hydroxytryptamine 4 (5-HT_4) receptor agonist, is being investigated for the next generation therapeutics of functional gastrointestinal (GI) disorders.
AIMS&METHODS: The pharmacological properties of YH12852 were examined in a variety of *in vitro* and *in vivo* experiments. *In vitro* profile of YH12852 was evaluated with binding affinity, agonistic activity, and selectivity for 5-HT_4 receptor. *Ex vivo* contractile activity was studied in isolated guinea pig colon. *In vivo* GI motility activities were evaluated by measuring fecal pellet output in guinea pigs, colonic motility in dogs, and gastric emptying rate in rats. The antinociceptive property of YH12852 was tested in an acute acetic acid-induced visceral hypersensitivity rat models.
RESULTS: In *in vitro* assays, YH12852 had high affinity (pKi=10.3) and selectivity for human recombinant $5\text{-HT}_{4(a)}$ receptor over other 5-HT family subtypes and other non-related receptors. In addition, YH12852 (pEC_{50}=11.3) showed 3.4 times more potent agonistic activity than tegaserod (pEC_{50}=10.8). YH12852 (pEC_{50}=9.1) had 17 times more potent intrinsic contractile activity than 5-HT (pEC_{50}=7.9) using the isolated guinea pig colon. Moreover, intraluminal administration of YH12852 increased the rate of propulsive motility by 43 ± 14% at 1 nM from the baseline. Oral administration of YH12852 at 0.1-10 mg/kg significantly increased the fecal pellet output (FPO) in guinea pigs. In this test, YH12852 induced 90% increase in FPO at 0.3 mg/kg while prucalopride induced 71% increase in FPO at the maximum response dose, 3 mg/kg. The maximum response of YH12852 was shown at 10 mg/kg where it increased the fecal pellet output (FPO) by 149%. In conscious beagle dogs, intravenous administration of YH12852 at 10 μg/kg increased the colonic motility. In gastric emptying study in rats, YH12852 at 3 mg/kg significantly increased gastric emptying rate which is comparable to mosapride. Following oral administration of YH12852 at 10 mg/kg, visceromotor response was significantly suppressed, inhibiting visceral hyprsensitivity induced by acetic acid in rats.
CONCLUSION: The strong *in vitro* potency and high selectivity for 5-HT_4 receptor of YH12852 were well translated into robust *in vivo* activity. YH12852 significantly increased GI motility and effectively inhibited visceral hypersensitivity in animal models indicating that YH12852 would be the next generation therapeutics to fulfill the unmet needs in patients with IBS-C and other GI motility disorders.

P394 MECHANOTRANSDUCTION IN MOUSE VISCERAL AFFERENT FIBRES IS MODULATED BY VOLTAGE-GATED SODIUM CHANNEL SUBTYPE 1.9 (NAV1.9)

J. Hockley[1,2,*], V. Cibert-Goton[2], C. Knowles[2], M. Baker[3], W. Winchester[4], D. Bulmer[1]. [1]*Wingate Institute of Neurogastroenterology,* [2]*National Centre for Bowel Research and Surgical Innovation,* [3]*Neuroscience and Trauma, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London,* [4]*Neusentis (Pfizer) Ltd, Cambridge, United Kingdom*

INTRODUCTION: Mechanical stimulation of the bowel either by obstruction or distension is a principle cause of pain in functional and inflammatory bowel conditions, particularly in combination with visceral hypersensitivity. The voltage gated sodium channel subtype 1.9 (Nav1.9) has been implicated in the generation of mechanical hyperalgesia in models of inflammatory pain;

however the role of Nav1.9 in visceral afferent sensitivity to mechanical distension in the gut has not been studied in great detail. Using Nav1.9 -/- mice we show that Nav1.9 has an important role in determining afferent activity to distension *ex vivo*.

AIMS&METHODS: The distal colon and mesentery from C57BL6, Nav1.9 +/+ or Nav1.9 -/- mice were removed from mice euthanized by rising concentration of CO_2, and placed in a recording chamber superfused with carbogenated Krebs buffer at 32-34°C supplemented with nifedipine (10μM), atropine (10μM) and indomethacin (3μM). The lumbar splanchnic nerve bundles were dissected free and nerve activity was recorded using a suction electrode. The tissue was luminally perfused (0.1mL/min) and the afferent response to ramp distensions (0-80mmHg or 0-145mmHg) determined. In separate preparations the afferent response to repeated (10min interval) phasic 80mmHg distensions (60secs duration) were examined. Data is expressed as mean ± S.E.M. and statistically compared using a 2-way ANOVA or t-test, where appropriate.

RESULTS: In Nav1.9 +/+ mice ramp distensions of 80mmHg evoked pressure-dependent increases in colonic afferent firing producing a maximum response of 13.3 ± 3.7Hz (n=6) at 80mmHg which was greatly attenuated in recordings from Nav1.9 -/- mice (1.4 ± 0.6Hz n=6; $P<0.05$). By contrast no significant difference was seen in the maximum response to ramp distensions of 145mmHg between tissue from Nav1.9 +/+ mice (34.6 ± 7.3Hz n=6) compared with Nav1.9 -/- mice (25.4 ± 7.8Hz n=5). Similarly afferent responses to the first 80mmHg phasic distension were comparable in tissue from Nav1.9 +/+ and Nav1.9 -/- (n=6) mice. In Nav1.9 +/+ mice, further phasic distensions (2^{nd} – 3^{rd}), led to a decrease in magnitude of the afferent response, reaching a stable response during the 4^{th} - 6^{th} distensions (6^{th}, 36.3 ± 5.0Hz). The decrease in afferent response to repeat distensions was more rapid in Nav1.9 -/- mice (6^{th}; 8.0 ± 1.3Hz; $P<0.05$) and failed to reach a stable response.

CONCLUSION: Together these data demonstrate that Nav1.9 significantly contributes to colonic afferent mechanosensitivity dependent on the magnitude, frequency and dynamics of the stimulus.

P395 LIFE STRESS DETERMINES DIFFERENTIAL CELLULAR AND MOLECULAR PROFILES IN HEALTHY GUT IN RESPONSE TO ACUTE STRESS

M. Pigrau[1,*], M. Vicario[1], B. Lobo[1], A. González-Castro[1], C. Alonso[1], C. Frías[1], E. Salvo-Romero[1], C. Sevillano-Aguilera[1], B. K. Rodriño-Janeiro[1], C. Martínez[1], M. Moris[1], M. D. Castillo[1], P. Rodríguez[1], F. Azpiroz[1], J. Santos[1]. [1]*Neuro-Immuno-Gastroenterology Group, Digestive Diseases Research Unit, Gastroenterology Department, Hospital General Vall d'Hebron, Vall d' Hebron Research Institute, CIBERehd, Barcelona, Spain*

INTRODUCTION: The body response against stressful events is an essential physiologic mechanism to ensure energy input and to guarantee survival. Functional gastrointestinal disorders (FGID) are associated with chronic psychosocial stress, although the stress-derived mechanisms leading to gut dysfunction remain unsettled.

AIMS&METHODS: To determine whether grade of life stress *per se* leads to altered systemic and local response to incoming acute experimental stimuli.

METHODS: Twenty four healthy volunteers were recruited and stratified by levels of psychosocial stress (Holmes-Rahe questionnaire) in 2 groups: low stress (LS, n=18; 9 men) and moderate-high stress (MS, n=6; 3 men). In each participant, two consecutive jejunal biopsies were obtained by Watson's capsule: one at baseline (pre-CP) and another 90 min after (post-CP) 15 min of intermittent cold pain stress (CP). Throughout the study, autonomic (blood pressure and heart rate), hormonal (plasma cortisol) and psychological responses (Subjective Stress Rating Scale) to CP were monitored. Mucosal eosinophils, mast cells, and intraepitheal lymphocytes were quantified. RNA from pre-CP and post-CP biopsies was isolated and submitted to microarray analysis followed by differential gene expression and biological pathways identification.

RESULTS: CP induced a strong and reproducible clinical and biological response in all participants, but MS subjects showed higher stress perception (MS: 6.2 (5.0-8.5); LS: 4.4 (2.9-5.5); $P<0.05$) and increased eosinophilic infiltrate (pre-CP: 1.2 vs. post-CP: 3.7 cells/HPF; $P<0.05$), respect to LS participants. Gene expression analysis revealed distinctive biological functions in response to acute stress: LS group displayed altered migration of antigen presenting cells, lipid oxidation and circadian rhythm ($P<0.0001$) associated with CCL20 and HSP71 up-regulation (1.9; 2.2 fold-change; $P<0.0001$); and MS group showed cytokines expression, apoptosis, inflammatory response, and chemotactic activity ($P<0.001$), associated with HSP71 and Aldolase-B up-regulation (1.9; 1.8 fold-change; $P<0.001$) and IL-18 and SLC26A3 down-regulation (-1.7; -1.6 fold-change; $P<0.001$).

CONCLUSION: Life stress acts as a relevant factor determining intestinal responses to acute experimental challenge in healthy subjects. Whether this altered response represents a step of progression between healthy gut and disordered "functional gut" remains to be explored.

P396 ASSOCIATION BETWEEN ABDOMINAL PAIN AND EATING IN PATIENTS WITH IRRITABLE BOWEL SYNDROME. ROLE OF SOMATISATION

E. Arsiè[1], M. Coletta[1,*], B. M. Cesana[2], G. Basilisco[3]. [1]*Gastroenterology, Università degli Studi di Milano, Milano,* [2]*Medical Statistics and Biometry Unit, Università di Brescia, Brescia,* [3]*Gastroenterology, IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy*

INTRODUCTION: It has been reported that abdominal pain worsens after eating in about half of the patients with irritable bowel syndrome (IBS), but it has not yet been established whether this is due to chance. Somatisation might increase the strength of the association as it enhances the intensity of symptoms after a meal, but an opposite effect might be expected from an unspecific increase in the frequency of reported symptoms.

AIMS&METHODS: To assess the strength of the association between meals and abdominal pain in IBS patients using a validated statistical method, and whether it is influenced by somatisation. Sixty-two IBS patients according to Rome III criteria (age 37±12 years; 61% female) recorded meal times (MTs) and the occurrence and intensity (0-10) of abdominal pain (AP) on a 10-day diary card divided into 30-minute intervals, and completed the IBS Symptom Severity Scale (IBS-SS), the SCL90-R for psychological symptoms and the SF36 for the quality of life. Fisher's exact test was used to calculate the probability (P) that MT and AP were unrelated in a time window of 90 minutes; the symptom-association probability (SAP) was calculated as (1-P) x 100%, and the discordance of the association between AP and MT was calculated using the frequency of false positives (AP+,MT-) - false negatives (AP-,MT+)/$\sqrt{}$(AP+,MT-) + (AP-,MT+). Normalized SCL90-R values were calculated for the somatisation, anxiety and depression scores, with a t score of ≥63 indicating a positive case. The Mann-Whitney U test was used to make the statistical comparisons. The data are given as mean values±SD.

RESULTS: A SAP of ≥95% ($P \leq 0.05$) was observed in 27 patients (44%) and ≥99% ($P \leq 0.01$) in 20 patients (32%). Age, gender, bowel habit, the frequency and intensity of pain, the scores of somatisation and the quality of life were not significantly different between the patients with and without a significant SAP (data not reported). The somatisation score was ≥63 in 30 patients (48%), who were younger (32±9 *vs* 40±12 years; $P=0.006$), more anxious (61±8 *vs* 54±9; $P=0.004$), and had more severe IBS (327±73 *vs* 262±80; $P=0.003$) and a poorer quality of life (physical 41±8 *vs* 46±9, $P=0.016$; mental 35±11 *vs* 47±11, $P=0.0007$). SAP was not significantly different between patients with somatisation scores of ≥63 or <63 (64%±38% *vs* 53% ±39%; $P=0.49$) nor was the discordance of the association (-0.30±4.13 *vs* 0.17±4.35; $P=0.80$).

CONCLUSION: Meals and abdominal pain are significantly associated in more than one-third of patients with IBS. Somatisation significantly influences the severity of IBS and the patients' quality of life, but does not seem to affect the strength of this association.

P397 MOLECULAR MIMICRY AND AUTOIMMUNITY TO VINCULIN IN HUMANS: THE MISSING LINK IN THE PATHOPHYSIOLOGY OF IBS

M. Pimentel[1,*], C. Brikos[1], V. Pokkunuri[1], W. Morales[1], S. Weitsman[1], S. Srinivasan[2], P. Guerry[3], G. Barlow[1], Z. Marsh[1], E. Rooks[1], G. Kim[1], C. Chang[1]. [1]*Cedars-Sinai Medical Center, Los Angeles,* [2]*Digestive Diseases, Emory University, Atlanta,* [3]*Enteric Diseases, Naval Medical Research Center, Silver Spring, United States*

INTRODUCTION: In a *C. jejuni* rat model of post-infectious IBS, rats develop altered bowel habits, small intestinal bacterial overgrowth (SIBO) and reduction of interstitial cells of Cajal (ICC). After infection with mutant *C. jejuni* lacking cytolethal distending toxin B (CdtB), rat sequelae were mitigated. Later experiments determined that antibodies to CdtB predict SIBO and through molecular mimicry have affinity for ICC and enteric ganglia. In this translational study, we investigate the human antigen to which anti-CdtB binds.

AIMS&METHODS: First, non-IBS human full thickness ileal tissue (from right hemicolectomy) was obtained. Ileal sections were incubated with purified rabbit antibodies to CdtB, washed and incubated with fluorescent secondary antibodies. Colocalization studies were performed with anti-c-kit (specific for ICC), S-100 (specific for neurons) and PGP 9.5 (specific for ganglia). Next, immunoprecipitation was performed by generating a column with anti-CdtB through which a lysate of human enteric neuronal cells (Emory University) was passed. Anti-CdtB adherent protein was eluted and western blots performed with anti-CdtB and the other with anti-CdtB pre-incubated with CdtB protein (blocking peptide). A band was identified at 117kDa, purified and identified by mass spectroscopy as human vinculin. An aliquot of 0.4 ug of commercial vinculin was coated per well in 96 well plates. Anti-CdtB was added to one series of wells, and anti-CdtB mixed with whole CdtB protein (blocking peptide) to another.

RESULTS: Using full-thickness human ileal tissue, anti-CdtB was specific for ICC and ganglia. This was based on colocalization of anti-CdtB with anti-c-kit, PGP 9.5 and S-100 (see figure). Thus anti-CdtB appeared to be interacting with a human protein on ICCs and ganglia. Based on immunoprecipitation, a protein band was identified at 117kDa. Using mass spectroscopy this protein was identified as human vinculin. Subsequently, human vinculin was obtained commercially and by ELISA, anti-CdtB had a high affinity for human vinculin but not the control peptide. Binding to vinculin was blocked by the CdtB peptide.

CONCLUSION: In the pathophysiology of post-infectious IBS, subjects develop antibodies to CdtB which cross react through molecular mimicry to vinculin, a cell membrane cytoskeletal protein important in neural migration and adherence. Given emerging data of reduced vinculin levels in post-infectious rats, molecular

mimicry to vinculin may be important to the cause of SIBO and IBS through effects on ICC and ganglia.

P398 DENDRITIC CELLS IN THE COLON OF RATS WITH VISCERAL HYPERSENSITIVITY EXPRESS HIGH LEVEL OF PROTEIN DISULFIDE ISOMERASE A3

M. Li[1,*], B. Lu[1]. [1]*Department of Gastroenterology, Department of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou310006, P R China, HANGZHOU, China*

INTRODUCTION: Although visceral hypersensitivity is a major pathophysiological feature of irritable bowel syndrome (IBS), its molecular mechanisms are still poorly understood. We had already proved that antigen presenting dendritic cells(DCs) mediated abnormal immune response play a cardinal role in the formation of visceral hypersensitivity in rats. Protein disulfide isomerase A3 (PDIA3) is involved in the processe of antigen presentation. Therefore, in the present study, we established a rat model with visceral hypersensitivity and try to identified the relationship between PDIA3 and dentritic cells.
AIMS&METHODS: Twenty male rats were chosen to established a IBS model by using colorectal distention and restraint stress, later all rats underwent abdominal withdrawal reflex (AWR) to evaluate visceral sensitivity. Western blotting was used to determine the protein expression of PDIA3 in colonic mucosa, and DCs were numbered by double labeling immunofluorescent staining of either CD11c (marker of dendritic cells) and PDIA3 .
RESULTS: In comparison to controls, All rats in the IBS group manifested higher visceral sensitivity ($p<0.05$). Western blotting showed that protein expression of PDIA3 was up-regulated in colonic mucosa in IBS rats ($P<0.05$), both CD11c-positive dendritic cells and PDIA3-positive cells observed under fluorescence microscopy were significantly increased in the IBS group compared with the control group ($P<0.05$). The number of CD11c/PDIA3-positive cells in the IBS group was statistically more than in the control group ($P<0.05$).
CONCLUSION: High level of protein disulfide isomerase A3 observed in dendritic cells could enhance the antigen presentation, which may lead to the dendritic cells mediated abnormal immune response, and contribute to the generation of visceral hypersensitivity in IBS rats.

P399 ANTIBIOTIC-INDUCED INTESTINAL DYSBIOSIS ATTENUATED VISCERAL PAIN-RELATED RESPONSES IN MICE

M. Aguilera[1,*], P. Vergara[1], V. Martínez[1]. [1]*Dept. of Cell Biology, Physiology and Immunology, Universitat Autònoma de Barcelona, Bellaterra - Barcelona, Spain*

INTRODUCTION: Visceral pain and intestinal dysmotility are common symptoms of functional gastrointestinal disorders (FGDs). It has been suggested that dysbiotic states of the gut commensal microbiota (GCM) might contribute to the pathophysiology of FGDs.
AIMS&METHODS: To determine if a dysbiosis of the GCM results in changes in visceral pain-related responses and colonic contractility. CD1 mice were treated with non-absorbable/broad spectrum antibiotics (bacitracin/neomycin, 0.4 mg/mouse/day, 14 days, PO). Visceral pain-related responses were assessed *in vivo* after intraperitoneal acetic acid (0.6%, 10 ml/kg; Writhing test) or intracolonic capsaicin (50 μg/mouse, 0.05 ml). Colonic contractility was assessed *in vitro* (organ bath). Luminal microbiota was characterized using fluorescence *in* situ hybridization. Colonic gene expression of pain-related markers [cannabinoid receptors (CB1/CB2), μ-opioid receptor (MOR), vanilloid receptors (TRPV1/3), tryptophan hydroxylase (TPH1/2) and serotonin transporter (SERT)] and anti- (IL10) and pro-inflammatory cytokines (IL6, IL12p40 and TNFα) were assessed by RT-qPCR.
RESULTS: Antibiotics reduced by 2.5-fold total bacterial counts ($x10^8$ cells/ml; vehicle: 434±28; antibiotic: 174±11; $P<0.05$, n=6 each) and induced a specific dysbiosis, lowering Clostridia and increasing *Lactobacillus* spp./Enterobacteria counts. Abdominal contractions in response to acetic acid were reduced by 33% in antibiotic-treated mice (contractions/30 min: 40.9±7.6, $P<0.001$ vs. vehicle: 61.4±4.0; n=6 each). Similarly, capsaicin-induced pain-related behaviors were reduced by 48% in antibiotic-treated mice (behaviors/30 min: 12.9±4.2, $P<0.05$ vs. vehicle: 25.1±2.3; n=6 each). Spontaneous colonic contractility was similar in both groups. However, contractile responses to carbachol were higher in antibiotic-treated animals (2-fold reduction in the EC_{50}: $5.2x10^{-7}$ M vs. vehicle: $1.0x10^{-6}$ M, n=6 each). Response to the NO-synthase inhibitor L-NNA were higher in antibiotic-treated mice (56±8 g vs. vehicle: 28±17 g; P=0.07, n=6 each). In dysbiotic mice, expression of CB2 was up-regulated, while CB1 and MOR were down-regulated. Neither histological nor molecular signs of colitis were observed.
CONCLUSION: Intestinal dysbiosis was associated to a reduction in visceral pain-related responses and a selective modulation of pain-related markers. Altered colonic contractility to cholinergic stimulation or NO inhibition was also noted. These data indicate that GCM is able to modulate gut sensory and motor systems, leading to functional changes. Similar mechanisms might explain the beneficial effects of antibiotics in the treatment of FGDs.

P400 SPINAL CORD STIMULATION IN THE IRRITABLE BOWEL SYNDROME – A RANDOMIZED CROSS-OVER TRIAL

P. M. Hellström[1,*], G. Lind[2], B. Linderoth[2]. [1]*Department of Medical Sciences, Uppsala University, Uppsala,* [2]*Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden*

INTRODUCTION: Irritable bowel syndrome (IBS) is a common disorder of multifactorial origin. Presently existing therapies are often ineffective. Spinal cord stimulation (SCS) has long been used for treatment of certain forms of chronic pain. In animal studies, SCS has been shown to reduce the reaction to colonic balloon dilatation, known to be increased also in IBS patients. Beneficial results of SCS in a single IBS patient have been reported as well as for other forms of abdominal pain.
AIMS&METHODS: To elucidate the potential for SCS as a treatment for IBS a limited clinical trial has been performed. Ten patients with IBS, mean age 39 (26-56) were recruited. A SCS system with a 4-polar electrode at the T5-8 level was implanted. In a randomized, cross-over study, stimulation was tested and compared to a period without stimulation, with an ensuing stimulation period, twice as long. At the end of the study patients could choose to retain their stimulating system or have it removed. Patients recorded average pain level, pain attacks and diarrheas as well as global quality of life evaluations in a diary.
RESULTS: A total of 18 IBS patients were selected by the gastroenterologist according to the Rome II criteria and referred to the neurosurgical team. Ten patients were successfully implanted, 9 of which completed the whole trial period. Implantation was made percutaneously at T11/12 and advanced to a position yielding adequate paresthesias. During the stimulation periods median pain scores were significantly lower as compared to non-stimulating periods (6.3±1.1 vs 4.7±1.3, $p<0.05$). The number of pain attacks was also reduced (4.5±1.5 vs 2.5±1.3).
Individual patients also reported diminished number of diarrheas. After study termination six patients chose to retain their stimulating system.
CONCLUSION: The outcome of the present trial suggests that SCS may be a useful treatment IBS as a majority of patients submitted to neurostimulation responded favorable. To further evaluate the clinical usefulness of SCS on this indication larger, multi-centre, studies are warranted.

P401 ALTERED RECTAL STRUCTURE AND SENSITIVITY IN THE GENESIS OF FAECAL INCONTINENCE AFTER DIFFERENT ANORECTAL SURGERY PROCEDURES

R. A. Awad[1,*], S. Camacho[1], F. Flores[2], M. García[2]. [1]*Experimental Medicine and Motility Unit U107,* [2]*Surgery Service, Mexico City general Hospital, Mexico City, Mexico*

INTRODUCTION: To investigate the anal sphincter and rectal factors that determines faecal incontinence after anorectal surgery (FIAS).
AIMS&METHODS: Twenty-seven patients with faecal incontinence after different anorectal surgery procedures were studied [rectosigmoidoscopy, manometry and barostat (sensitivity, tone, compliance and capacity) and compared with asymptomatic healthy subjects (HS). Time since surgery was at least two years. All patients suffered from 10±15 incontinence episodes per week. The postoperative continence score was 13.6±2 (St Mark's faecal incontinence grading system).
RESULTS: (Table: All data represent the mean (95% CI). *$p<0.05$ Vs. HS) Rectal structure: Vs. HS, rectal tone was increased in patients who had undergone sphincterotomy or fistulotomy (p=0.005). Rectal compliance decreased after fistulotomy (p=0.021) and rectal capacity lessened after rectal prolapsed procedures (p=0.037). Rectal sensitivity: FIAS patients at similar pressures as HS reported the noxious stimulus of pain. In sphincterotomy patients, the thresholds for non-noxious stimuli of the sensations of gas (p=0.016) and urge to-defecate (p=0.043) were reported at higher pressures compared with HS. Internal anal sphincter function: Only patients with sphincterotomy showed greater anal resting and squeeze pressures (p=0.014) and a higher amplitude of relaxation in their rectoanal Inhibitory reflex (p=0.0006) than HS.

	Sphincterotomy (n=8)	Fistulotomy (n=8)	Rectal prolapse (n=6)	Healthy subjects (n=10)
Tone (ml)	50.7 (16-85)*	37.8 (16-59.5)*	53 (15.8-90.5)	103.5 (71.8-135)
Compliance (v/p)	6 (1.8-10.7)	4.7 (2-7.5)*	6.7 (1.9-11)	11.7 (7-16)
Rectal capacity (ml)	342.6 (304-380.7)	347.5 (306-388)	207 (145.6-268.9)*	302.8 (251.8-353.9)
First sensation (mmHg)	18 (15.8-20.9)	15 (13-17.6)	15 (11.7-19)	14 (10.9-17)
Gas sensation (mmHg)	24.9 (21.7-28)*	21.6 (19-24)	21 (14-28)	17.9 (14-21.6)
Urge defecate (mmHg)	31 (24-38)*	28.7 (23-34)	24 (12-35.9)	22 (17.9-26.9)
Pain sensation (mmHg)	35.8 (32-39)	39 (36-42)	26 (15.7-36.9)	35.9 (30-41)
Anal resting pressure (mmHg)	62 (48.8-75)*	43 (26.5-61)	22 (7-38)	34 (21-48)
Anal squeeze pressure (mmHg)	113 (67.5-158)*	69 (19.8-118.6)	66 (24.6-108)	43 (28.4-57.9)

CONCLUSION: Most FIAS patients preserve internal anal sphincter function but present with impaired rectal tone, compliance, capacity and rectal hyposensitivity for non-noxious stimuli. It seems that an impaired afferent nerve pathway and abnormal rectal structure and function are involved in the genesis of FIAS. The rectum seems to be more involved than the internal anal sphincter in the genesis of FIAS; therefore, surgeons should preserve the rectal anatomy and neural networks as much as possible.

P402 COLONOSCOPIC FEATURE OF 293 IRRITABLE BOWEL SYNDROME (IBS) PATIENTS IN JAPAN

T. Mizukami[1,*]. [1]*internal medicine, NHO KURIHAMA MEDICAL AND ADDICTION CENTER, Yokosuka-city Kanagawa, Japan*

INTRODUCTION: As there is no pathognomonic diagnostic measurement for IBS, the diagnosis relies on the clinical symptoms, and is only made after exclusion of organic diseases.

We have reported a non-sedative painless colonoscopy, "WATER NAVIGATION COLONOSCOPY (Mizukami T. Dig Endosc 2007 19: 43-48.)". When colonoscopies are done only with spasmolytic, persistent colonic movements are observed in approximately 10% of the patients, and most of them have IBS symptom (Mizukami T. Gastroenterology 2010; 138: S-233.).

On the other hand, there are some IBS patients without persistent colon movement and most of them have abnormal colon morphology, these are difficult cases for cecal intubation.

AIMS&METHODS: The present study was designed to evaluate colon motility and morphology of IBS by colonoscopy, and assess its pathophysiology. 293 IBS patients and 50 asymptomatic subjects were recruited. Diagnosis of IBS was based on ROME III. Colonoscopy was performed according to "WATER NAVIGATION COLONOSCOPY" only with 20 mg scopolamine butylbromide IM and cecal intubation time was recorded. Duration time and the patterns of colon movement persisting after spasmolytic IM were recorded.

RESULTS: Persistent colon movement after scopolamine butylbromide IM was significantly frequently observed in IBS (24.9% vs 2.0%, $p<0.001$). It was significantly frequently observed in IBS-D more than IBS-C and IBS-M group (IBS-C 23.1% vs IBS-D 52% vs IBS-M 6.2%, $p<0.001$). Peristalsis was frequently observed in IBS-D, which causes incontinent passing of gas during colonoscopy and probably causes diarrhea. Segmental movement was observed in IBS-C, which makes it difficult to intubate colonoscope and probably causes constipation. IBS patients with persistent colon motility had experienced stress related to the symptoms.

Abnormal colon morphology such as mesocolon descendens and sigmoidcolon malrotation was frequently observed in IBS group (82.5% vs 24.0%, $p<0.001$). This was more frequently observed in IBS- M and IBS- C more than IBS- D (IBS-C 81.8% vs IBS-D 61.3% vs IBS-M 100%, $p<0.001$). IBS patients only with persistent abnormal colon morphology had not experienced stress related to the symptoms.

Cecal intubation time was significantly longer in IBS group (12.1+6.9min vs 4.6+1.9min, $p<0.001$). There were no significant difference in cecal intubation time among IBS subgroups (IBS-C 12.2+7.2 vs IBS-D 9.5+5.4 vs IBS-M 11.7+5.4, ns).

CONCLUSION: Non-sedative colonoscopy reveals that there are 2 types of IBS "Abnormal colon motility type" and "Abnormal colon morphology type". "Abnormal colon morphology type" is very common in Japan, and is very difficult for cecal intubation. Classification based on non-sedative colonoscopy will improve understanding of the pathophysiology in IBS.

P403 ADVANCED AGE LEADS TO REDUCED SENSITIVITY OF MOUSE INTESTINAL AFFERENT NEURONS TO BRADYKININ

V. Cibert-Goton[1,*], R. Greene-Diniz[1], V. W. Kung[1], C. H. Knowles[1], J. Broad[1], G. J. Sanger[1], D. C. Bulmer[1]. [1]*Blizard Institute, Barts & The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom*

INTRODUCTION: The ability to sense visceral pain or respond to acute GI inflammation during peritonitis is often impaired in the elderly, leading to difficulties in diagnosis (*Hall 2002, Am J Physiol 283 G827-32*).

AIMS&METHODS: To explore the possibility that the sensitivities of visceral nociceptors and myenteric neurons to inflammatory stimuli are reduced with age we examined the effects of noxious inflammatory mediators on intestinal mesenteric nerves and neuromuscular functions in adult and aged C57B6 mice. (1) Nerve recordings: Intestine with attached mesentery were removed, cannulated and perfused externally (7ml/min) and internally (0.1ml/min) with carbogenated Krebs' supplemented with nifedipine, atropine (10μM each) and indomethacin (3μM). A mesenteric nerve bundle was isolated and on-going nerve discharge recorded using suction electrodes. Changes in nerve discharge were determined following bath perfusion with 20ml bradykinin (BK; 1μM) or adenosine (1mM); a maximum of 2 stimuli separated by at least 60 min were studied in each preparation and peak changes in nerve discharge from baseline determined. (2) Neuromuscular experiments: Mucosa-intact loops, cut parallel to the circular muscle of the colon from 3 month mice, were suspended in Krebs solution in tissue baths for electrical field stimulation (EFS; 5 Hz, 0.5ms, 50V for 30s every 120s) and isometric recording of muscle tension. Data are expressed as means ± sem and compared between ages using a one way ANOVA vs. the 3 month group.

RESULTS: Robust afferent responses were observed with each stimulus in tissue from 3 month mice (BK: 54.6±8.3 Hz; Adenosine: 14.3±3.5 Hz, n=4 each). In aged mice the response to BK was greatly reduced (18.9±5.9 and 18.3±2.2 Hz, respectively, for the 18 and 24 month mice; $P<0.01$ each; n=5 and 10). In contrast the response to adenosine remained unchanged (9.9±2.7 and 18.0±4.5 Hz, respectively; n=5 and 6). In the muscle loops, EFS evoked relaxations followed by after-contractions (abolished by TTX 1μM; n=5); the relaxations and after-contraction were separately abolished by L-NAME 300μM and atropine 1μM (n=3, 4). BK 1μM reduced the amplitude of the after-contractions by 28.7±8.0% and decreased baseline muscle tension (by 2.8±1.0% of the maximum contraction to carbachol; $P<0.05$ each; one sample t test; n=5).

CONCLUSION: Afferent responses to the algogenic inflammatory mediator BK were impaired in aged mice. By contrast the response to adenosine was unchanged, suggesting some specificity in age-related changes of afferent sensitivity to inflammatory mediators. Studies into age-related changes in neuromuscular functions of BK are on-going.

P404 INCIDENCE OF NEW ORGANIC GASTROINTESTINAL DISEASE IN IRRITABLE BOWEL SYNDROME (IBS) REMAINS HIGH EVEN 10 YEARS FOLLOWING IBS DIAGNOSIS

C. Canavan[1,*], T. Card[1], J. West[1]. [1]*Division of Epidemiology and Public Health, University of Nottingham, Nottingham, United Kingdom*

INTRODUCTION: Symptoms of Irritable bowel syndrome (IBS) are common and are also seen in coeliac disease, colorectal cancer (CRC) and inflammatory bowel disease (IBD). Clinicians are often keen to exclude these diseases before diagnosing IBS. In those diagnosed with IBS there is little evidence about rates of these other diseases, changes over time, or if years after a diagnosis of IBS they still require consideration.

AIMS&METHODS: A cohort of 189826 incident IBS patients was constructed from the Clinical Practice Research Dataset. All prevalent coeliac disease (398), CRC (142) and IBD (1536) was excluded. A Poisson model determined incidence of each disease at different intervals following IBS diagnosis, stratified by age at IBS diagnosis. Rate ratios (IRR) were derived, with 5 years after IBS diagnosis as baseline.

RESULTS: Initially high rates of IBD and coeliac disease fall over the first 5 years then plateaux. For IBD in particular, they remain higher than might be expected in the general population, especially in the young. Rates of CRC in patients diagnosed with IBS are high in all ages groups at all time periods. Rates of new diagnosis significantly increase after 5 years following IBS diagnosis.

CONCLUSION: It is currently unclear if the rates seen are due to initial misdiagnosis or to associations between IBS and the other conditions, nor whether increasing CRC rates after 5 years can be fully explained by advancing age. It is important to remain mindful of these organic conditions when treating patients with existing IBS diagnoses.

P405 A PROSPECTIVE SURVEY OF FUNCTIONAL GASTROINTESTINAL DISORDERS IN U.K. GASTROENTEROLOGY CLINICS: WORKLOAD AND ITS MANAGEMENT

C. Shekhar[1,*], Z. Syed[2], N. Patodi[3], M. R. Anderson[4], L. A. Houghton[5,6]. [1]*Gastroenterology, UNIVERSITY HOSPITAL OF NORTH STAFFORDSHIRE, Stoke on Trent,* [2]*General Practice Trainee, North West Deanery, Manchester,* [3]*Gastroenterology, South Warwickshire General Hospital, Warwick,* [4]*Gastroenterology, Birmingham City Hospital, Birmingham,* [5]*Institute of Inflammation and Repair, University of Manchester, Manchester, United Kingdom,* [6]*Division of Gastroenterology and Hepatology, Mayo Clinic, Jacksonville, United States*

INTRODUCTION: Functional gastrointestinal disorders (FGIDs) are extremely common constituting up to 5% of all and 50% of GI primary care patient visits, and up to 50% of secondary care visits[1]. Diagnosis however, can sometimes be challenging leading to testing, despite well established guidelines encouraging a positive diagnosis based on the Rome III criteria in the absence of alarm features alone[2].

AIMS&METHODS: To determine the work load that FGIDs present to UK secondary care, reasons for referral from primary care, and whether clinicians embrace a positive diagnosis rather than one by exclusion.

Prospective data was collected from 45 general gastroenterology out-patient clinics in 28 hospitals between 2010 and 2011. For every new and follow-up patient a questionnaire was completed by the clinician or trainee gastroenterologist.

RESULTS: Of a total of 439 patients seen, 81(18.5%) were diagnosed with a FGID of which 20%(16/81) were male and 80%(65/81) female. 62%(50/81) had symptoms consistent with a FGID for less than 2 years. 50%(40/81) had received a diagnosis of FGID by the primary care physician at the time of referral, with 9% (7/81) been referred because of associated alarm symptoms and 41%(33/81) because of uncontrolled symptoms. Despite hospital clinicians reporting reasonable confidence in their FGID diagnosis in 86%(70/81) patients, 73%(59/81) of patients were still scheduled for endoscopy and 43%(35/81) for ultrasound or CT scanning. Only 37%(30/81) of hospital clinicians used formal diagnostic criteria (eg Manning, Rome etc) with even less using the current Rome III criteria (6%(5/81)).

CONCLUSION: Secondary care FGID workload was lower than expected maybe because of increased awareness (NICE and BSG guidelines)[3] and confidence in diagnosing FGIDs in primary care. Positive FGID diagnosis however remains low with little use, in particular, of the Rome III criteria. Thus there is a need for better implementation of these and forthcoming guidelines to improve the cost-effectiveness of care.

P406 PREDICTIVE FACTORS FOR A CLINICAL DIAGNOSIS OF IRRITABLE BOWEL SYNDROME IN A COHORT OF 440,822 YOUNG ADULTS.

D. Carter[1,*], M. Beer-Gabel[1], A. Afek[2]. [1]*Department of gastroenterology , Sheba medical center,Israel, Ramat Gan,* [2]*Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel*

INTRODUCTION: The prevalence of irritable bowel syndrome (IBS) in the community has been reported in numerous cross-sectional surveys. However, less is known about the incidence and predictive factors for the clinical diagnosis of IBS.

AIMS&METHODS: We examined the association of socioeconomic, anthropometric and occupational factors with the incidence of IBS in a cohort of 440,822 young Israeli adults aged 18-39 who served in active military service during the years 2005-2011.

RESULTS: During follow-up of 1,925,003 person years, IBS was diagnosed de novo in 926 and worsened in 50, giving an incidence rate of 0.2% (221:100,000) for the diagnosis or worsening of IBS. On multivariable Cox analysis, higher socioeconomic state (HR 1.629 95%CI 1.328-1.999, $p<0.0001$), Israeli birth (HR 1.362, 95%CI 1.084-1.712, p=0.008), Jewish ethnicity (HR = 2.089, 95%CI 1.344-3.248, p=0.001), education of more than 11 years (HR 1.674, 95%CI 1.019-2.751,p=0.042) and a non-combative military position (HR 1.196, 95%CI 1.024-1.397, p=0.024) were found to be risk factors for the diagnosis or for the worsening of IBS. Overweight (HR 0. 0.744, 95%CI 0.589-0.941, p=0.014), obesity (HR 0.698, 95% CI 0.510-0.95, p=0.025), living in a rural settlement (HR 0.705, 95%CI 0.561-0.886, p=0.003), and Asian (HR 0.739, 95%CI 0.617-0.884, p=0.001,) or African origin (HR 0.702, 95%CI 0585-0.842, $p<0.001$) were found to be protective for the diagnosis or the worsening of IBS.

CONCLUSION: The incidence of IBS in our cohort was similar to that reported in the western countries. Specific socioeconomic, anthropometric and occupational factors were associated with the occurrence of IBS.

P407 DIENTAMOEBA FRAGILIS AND BLASTOCYSTIS: TWO PARASITES THE IRRITABLE BOWEL MIGHT BE MISSING. A POPULATION-BASED CASE-CONTROL STUDY OF SUBJECTS WITH AND WITHOUT GASTROINTESTINAL (GI) SYMPTOMS

L. Rindom Krogsgaard[1,*], A. L. Engsbro[2], C. R. Stensvold[3], H. V. Nielsen[3], P. Bytzer[1]. [1]*Medicine, Køge Sygehus, Køge,* [2]*Microbiology, Hvidovre hospital,* [3]*Parasitology, Statens Serum Institut, Copenhagen, Denmark*

INTRODUCTION: Several studies have demonstrated that the parasites *D. fragilis* and *Blastocystis* are frequently found in patients with irritable bowel syndrome (IBS) and suggest that these may be involved in the pathogenesis of IBS. However, previous studies have all lacked a well-defined asymptomatic control group. We hypothesised that intestinal parasites may be associated with symptoms of IBS.

AIMS&METHODS: In 2010, members of a web-panel (n=19.567), representative of the Danish population aged 18-49 years (females 50%), were invited by e-mail to fill out a questionnaire. 6.112 responded to screening questions on age, sex and GI symptoms. Those reporting of GI symptoms were linked to a questionnaire based on the Rome III criteria for IBS. Stool samples were requested from 200 subjects with IBS symptoms and 300 asymptomatic controls. Two consecutive stool samples were tested for parasites (microscopy, culture for *Blastocystis* and real-time PCR for *D. fragilis, Cryptosporidium spp., Entamoeba histolytica and dispar* and *G. intestinalis*). The questionnaire and stool sampling was repeated after 1 year in responders from the first survey.

RESULTS: In 2010, stool samples were analyzed from 328 subjects (124 had IBS symptoms; 204 controls). Intestinal parasites were found in 44.5% (n=146) of all. Subjects with IBS were significantly *less* likely to harbor parasites than the asymptomatic background population (35.5% *vs.* 50%, p=0.01). Harboring parasites was not associated with gender. *D. fragilis* was found in 30.1% of all subjects; significantly more prevalent in controls compared to IBS subjects (34.8% *vs.* 23.4%, p=0.03). *Blastocystis* was found in 18.9% of all subjects and more often in controls (22% *vs.* 14.5%, p=0.09).

In 2011, follow-up was completed in 275/328 (83.8%) subjects, who gave stool samples in 2010 (106 IBS subjects and 169 controls). In both IBS subjects and controls there were no significant differences in development of GI symptoms over 1 year between those with and without parasites ($p>0.1$), nor when analyzed for *D. fragilis* or *Blastocystis* separately.

CONCLUSION: In an asymptomatic adult background population 50% harbor intestinal parasites, this is significantly more compared to subjects with IBS symptoms. Harboring intestinal parasites does not influence the development or disappearance of IBS symptoms over 1 year.

P408 EPIDEMIOLOGY OF IRRITABLE BOWEL SYNDROME (IBS) A POPULATION- BASED SURVEY IN DENMARK.

L. Rindom Krogsgaard[1,*], A. L. Engsbro[2], P. Bytzer[3]. [1]*Medicine, Køge Sygehus, Køge,* [2]*Microbiology, Hvidovre hospital,* [3]*Medicine, Køge Sygehus, Copenhagen, Denmark*

INTRODUCTION: IBS is a common gastrointestinal GI disorder, varying in prevalence between countries and according to diagnostic criteria. Patients with IBS pose a significant health burden partly because IBS is often considered a diagnosis of exclusion.
AIMS&METHODS: We aimed to investigate the epidemiology of IBS in the Danish adult population according to Rome III criteria. An internet-based survey was conducted in 2010 with a 1 year follow-up in 2011. In 2010, members of a web-panel (n=19.567) representative of the Danish adult population aged 18-49 years (mean age 35,3 yr, females 49,5%) were invited by email to fill out a questionnaire. Responders (n=7.827, 40%) were linked to screening questions on sex, age and GI symptoms. 6.112 subjects completed the screening, and those reporting of GI symptoms within the past 3 months (n=2.928, 48%) were linked to the Rome III questionnaire for IBS. Responders were further asked about healthcare seeking and details of diagnosis likely to explain their symptoms. In 2011, 6.112 initial responders were invited to fill out the same questionnaire. A total of 3.784 (62%) (mean age 36,8 yr, females 60%) completed screening. 2.026 reported GI symptoms within the past 3 months and were linked to the Rome III questionnaire.
RESULTS: In 2010, a total 979/6.112 (16%; 95% CI: 15.1-16.9%) had symptoms compatible with IBS and no organic diagnosis (72% women, mean age 34.9 yr). The prevalence of IBS in 2011 was 672/3.784 (17.6%).
The incidence of IBS was 9% (95 % CI: 8.1-9.9%) (339/3.784) of these 128 were asymptomatic in 2010 and 211 had GI symptoms not fulfilling criteria for IBS (non-IBS) in 2010.
Table 1 shows transition in symptom-status from 2010 to 2011, n (%).

Table 1	IBS	Asymptomatic	Non-IBS	Missing
IBS (n=979)	319 (32,6)	114 (11,6)	198 (20,2)	348 (35,5)
Aymptomatic (n=3184)	128 (4)	1255 (39,4)	558 (17,5)	1243 (39)
Non-IBS (n=1800)	211 (11,7)	364 (20,2)	533 (30,7)	692 (38,4)

In 2010, 18.4% (180/979) had consulted a doctor for their symptoms within the past 3 months but only 7.9% (77/979) were diagnosed with IBS. Of the incident IBS-cases, 14.7% (50/339) had consulted a doctor within the past three months for their symptoms and 4.4% (15/339) had the diagnosis.
CONCLUSION: IBS defined by the Rome III criteria is very prevalent in the Danish adult population and furthermore there is a high incidence of 9%. The high prevalence and high consultation-rate emphasizes that IBS is associated with significant healthcare cost. At the 1 year follow up most IBS subjects continuously reported of GI symptoms with a minority becoming asymptomatic.

P409 FREQUENCY AND EPIDEMIOLOGICAL PROFILE OF FUNCTIONAL BOWEL DISORDERS: AMONG 4850 ILEOCOLONOSCOPY

S. Ouahou[1,*], N. Kabbaj[1], M. Salihoun[1], L. Amrani[1], M. Acharki[1], M. Guedira[1], Z. Chaoui[1], M. Nya[1], N. Amrani[1]. [1]*EFD-Hepatogastroenterology unit, Ibn Sina Hospital, Mohamed 5 Souissi University, rabat, Morocco*

INTRODUCTION: Clinical manifestations of functional bowel disorders (FBD) are not specific. Diagnosis is assessed after elimination of organic causes by ileocolonoscopy.
AIMS&METHODS: The aim is to study the frequency and the epidemiological characteristics of these disorders in a Hepato-gastroenterology Unit in Morocco. Patients were selected from subjects with present or past symptoms of FBD (abdominal pain, transit disorders and abdominal bloating) who underwent ileocolonoscopy in our Unit during 4 years. Patients with alarm signs (rectal bleeding, melena, anemia, and weight loss) or with incomplete ileocolonoscopy were excluded. Therefore, the diagnosis of FBD is based on criteria of Rome III (characteristic symptoms for at least 12 weeks during the last 12 months) and in the absence of endoscopic or biochemical abnormalities.
RESULTS: Out of 4850 ileocolonoscopies performed during this period, 1218 (25%) are indicated for symptoms of FBD without alarm signs. Mean age is 47 years (16-89 years) with a female predominance (67%). Frequency of symptoms is as follows: abdominal pain in 64.3% of cases, chronic diarrhea in 33%, chronic constipation in 30.8%, alternating diarrhea-constipation in 18% and abdominal bloating in 10.7%. 611 patients (50.1%) have a normal ileocolonoscopy while it is abnormal in 607 patients (49.9%) of cases. The endoscopic lesions are colonic polyps in 47 %, diverticula in 19 %, congestive or ulcerated aspect of ileal and/or colonic mucosa in 18.8% related to Inflammatory Bowel Disease (IBD), colorectal tumor in 7%, colonic lipoma in 4.7% and melanosis coli in 3.5%.
CONCLUSION: Ileocolonoscopy is mandatory to exclude organic causes of functional bowel disorders. Indeed, half of our patients with these symptoms have organic lesion dominated by colonic polyps, diverticula and IBD.

P410 PATIENTS' EXPERIENCE OF LIVING WITH IRRITABLE BOWEL SYNDROME (IBS) FROM A GENDER PERSPECTIVE- AN INTERVIEW STUDY

I. Björkman[1,2,*], L. Dellenborg[1,3], G. Ringström[1,2], M. Simrén[1,2], E. Jakobsson-Ung[1,3]. [1]*University of Gothenburg Centre for Person-Centered Care (GPCC),* [2]*Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg,* [3]*Institute of Health and Care Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

INTRODUCTION: There is limited knowledge of how patients experience living with IBS, particularly from the male perspective. In general, a sex rather than a gender perspective has been used in research on men, women and IBS. Such a perspective refers to the biological maleness or femaleness of an individual as opposed to a gender perspective that investigates cultural and social constructs associated with biological sex. Such cultural constructs are likely to influence experience of ill-health so to truly understand patient experience of IBS means being sensitive to gender issues.
AIMS&METHODS: Aim: The aim of the study was to explore the impact of IBS on daily life from a gender perspective.
Methods: A qualitative, hermeneutic method was applied (Gadamer 1989). Interviews were conducted with 19 (10 men) patients in 2011. Interviews were analysed within a constructionist gender framework based on the work of Butler (2006).
RESULTS: The main theme to emerge from the interviews was: *A normative framework of femaleness and maleness leads to suffering for persons with IBS*. This consists of three interwoven themes: *Being forced to abandon gender illusions; Being forced to transcend taboos and Reinforced suffering in healthcare encounters*. Both men and women suffer from that IBS is invisible to others and how this negatively affects that amount of support one receives. They also feel that the unpredictability of symptoms restricts life. Men demonstrated masculinity in their narratives by stressing the importance of being solid family providers and felt that IBS made them feel weak and not in control. Women demonstrated femininity through speaking of their nurturing and relational responsibilities and also stated that IBS severely impaired their performance at work.
CONCLUSION: The experience of living with IBS differs between men and women due to differing societal expectations, their life situation and the everyday construction of gender identities. Gender stereotyping by healthcare professionals perpetuates rather than alleviates the suffering experienced by men and women with IBS. In healthcare encounters, women risk being trivialised and men risk being overlooked due to the 'female health concern' label applied to IBS.

P411 IS LYMPHOCYTIC DUODENOSIS A MARKER FOR IRRITABLE BOWEL SYNDROME?

I. Aziz[1,*], D. M. Smillie[1], D. S. Sanders[1]. [1]*Department of Gastroenterology, Sheffield Teaching Hospitals, Sheffield, United Kingdom*

INTRODUCTION: Lymphocytic duodenosis (LD) is defined by normal villous architecture and intraepithelial lymphocytes (IELs) >25 per 100 enterocytes. Such patients should not be diagnosed with coeliac disease (CD), solely by histology, as recent studies have suggested other associations with LD. Despite a paucity of data, previous investigators have suggested that LD may also be associated with irritable bowel syndrome (IBS).
AIMS&METHODS: We aimed to prospectively assess the associations between LD and IBS.
Two hundred patients with LD were investigated for associated LD conditions, by means of revisiting the patient's history and recent investigations including the initial coeliac serology, followed by a combination of gluten challenge, HLA typing, repeat duodenal biopsies, and exclusion of infection/inflammatory bowel disease.
A diagnosis of CD was based on the persistence or progression of LD on a gluten-containing diet, the presence of HLA DQ2 or DQ8, and a clinical response to a gluten free diet.
In the absence of an alternative cause, a diagnosis of IBS was made on the presence of the ROME III criteria.
RESULTS: 150 female, 50 male, mean age 49, SD 16, age range 17-83
An identifiable association was found in 70% of patients with CD (20%), NSAIDs (17%) and H,pylori (16%) accounting for the majority. Other causes included gastrointestinal infections (7%), autoimmune disorders (6%), inflammatory bowel disease (2%), TB or HIV (1.5%), and IgA deficiency (1%).
In 60 cases (30%) no cause was found, although reassuringly two-thirds normalised their histology. In just over half of those without an identifiable cause, symptoms were consistent with IBS (35/60). IBS, therefore, accounted for 17% of all LD cases.
Whereas all patients with CD were HLA positive, only 55% of those with alternative causes or IBS were HLA positive ($p < 0.0001$).
CONCLUSION: 17% of LD is associated with the Rome III criteria for IBS. LD may, therefore, be a disease marker for IBS and a reflection of low grade inflammatory response although no clues to the triggering mechanism were elucidated.

P412 GASTROINTESTINAL MANIFESTATIONS OF EHLERS-DANLOS SYNDROMES: RESULTS OF A NATIONAL COHORT STUDY ON 134 PATIENTS

J.-D. Zeitoun[1,*], J. H. Lefevre[2], V. de Parades[3], C. Séjourné[4], I. Sobhani[5], C. Hamonet[6]. *[1]Gastroenterology, [2]Digestive and General Surgery, Saint-Antoine Hospital, [3]Proctology, Saint-Joseph Hospital, Paris, [4]Private Office, Marolles en Hurepoix, [5]Gastroenterology, Henri Mondor Hospital, Créteil, [6]Physical and Rehabilitation Medicine, Hôtel Dieu Hospital, Paris, France*

INTRODUCTION: Ehlers-Danlos syndromes (EDS) are a heterogeneous group of connective tissue disorders. Gastrointestinal manifestations in EDS have been described but their frequency, typology and impact are poorly known.
AIMS&METHODS: We aimed to assess digestive features in a national cohort of EDS patients. A questionnaire has been sent to 212 EDS patients through the French patient support group, all of which had been formally diagnosed according to the Villefranche criteria. The questionnaire included questions about digestive symptoms, the GIQLI (Gastrointestinal Quality of Life Index), KESS scoring system and the Rome III criteria.
RESULTS: Overall, 135 patients (64% response rate) have sent the questionnaire and 134 were analyzable (123 women; 91%). Mean age and Body Mass Index were respectively 35±14.7 and 24.3±6.1 kg/m^2. The most common subtype was hypermobility form (n=108; 80.6%). GIQLI and KESS median values were respectively 63.5 (27-117) and 19 [13.5-22] and 84% of patients had functional bowel disorders (FBD) according to the Rome III criteria. An irritable bowel syndrome according to the same criteria was observed in 64 patients (48%) and 48 patients (36%) reported functional constipation. A gastro-esophageal reflux disease (GERD) was reported in 90 patients (68.7%), significantly associated with a poorer GIQLI (60.5±16.8 *versus* 75.9±20.3; $p<0.0001$). There was a significant correlation between FBD and GERD.
CONCLUSION: Natural frequency of gastrointestinal manifestations in EDS seems higher than previously assessed. FBD and GERD are very common in our study population, the largest ever published until now. Their impact is herein shown to be important. A systematic clinical assessment of digestive features should be recommended in EDS.

P413 A POSSIBLE ASSOCIATION BETWEEN IRRITABLE BOWEL SYNDROME AND SEPARATION ANXIETY DISORDER

E. Shadach[1], Y. Ben-Israel[1], Y. Niv[2], A. Sperber[3], R. Dickman[2,*]. *[1]School of Behavioral Scienes, Tel Aviv-Yaffo Academic College, Tel Aviv, [2]Gastroenterology, Rabin Medical Center, Petach Tikva, [3]Gastroenterology, Tel Aviv Medical Center, Tel Aviv, Israel*

INTRODUCTION: Irritable bowel syndrome (IBS) in adults, as well as early separation anxiety disorder (SAD) and recurrent abdominal pain (RAP) in childhood are associated with anxiety and somatization.
AIMS&METHODS: The aim of this study was to examine possible associations between IBS in adulthood and SAD in childhood.
Forty adults with IBS and 40 healthy controls completed a demographic questionnaire, the Separation Anxiety Symptom Inventory (SASI), the somatization subscale of SCL-90-R, the Attachment Style Questionnaire (ASQ), and a retrospective self-report questionnaire regarding RAP. A regression model was constructed for the prediction of IBS in adulthood by retrospective SAD symptoms, somatization score, and attachment style.
RESULTS: Groups were similar for mean age and gender distribution. Compared to controls, IBS patients scored higher on the SCL-90-R scale of somatization (25.35 ± 7.47 vs.16.50 ± 4.40, $p<0.001$), and more IBS patients (25% vs.7.5%) reported RAP in childhood. The multiple logistic regression model for predicting the presence of IBS in adulthood was statistically significant with a total (omnibus) significance: chi-square (df=10, n=80) = 80.568, $p<0.0001$. The accuracy of the prediction was 63.5% (Cox and Snell's $R^2 = 0.635$). However, retrospective recall of SAD symptoms in childhood was lower in IBS patients than in controls (20.98 ± 5.07 vs. 25.33 ± 6.80, $p<0.005$).
CONCLUSION: The results of this study suggests that children with a tendency for somatization, SAD and with an avoidant attachment style are more likely to develop IBS in adulthood but less likely to retrospectively report symptoms of SAD in childhood.

P414 PREVALENCE OF ORGANIC DISORDERS IN CONSECUTIVE NEW PATIENTS MEETING CRITERIA FOR IBS IN A GASTROENTEROLOGY CLINIC

U. Shivaji[1,*], D. J. Gracie[1], A. Sainsbury[1], A. C. Ford[1]. *[1]Gastroenterology, Leeds Teaching Hospitals NHS Trust,Leeds, Leeds, United Kingdom*

INTRODUCTION: A positive diagnosis of irritable bowel syndrome (IBS), without the need for recourse to investigation, is encouraged. Patients meeting symptom-based diagnostic criteria for IBS are often given reassurance that there is no serious underlying pathology, and treated symptomatically. However, some studies have suggested that an organic diagnosis, such as coeliac disease or pancreatic insufficiency, may be missed if this approach is adopted. We aimed to examine the yield of investigation in patients meeting criteria for IBS in real-life clinical practice.
AIMS&METHODS: Review of consecutive unselected new patient referrals to a single Gastroenterologist's outpatient clinic during a 3-year period, from January 2010 to December 2012. All clinic letters were reviewed retrospectively, and symptoms reported by the patient at the initial consultation were recorded. Those who described lower abdominal pain associated with a change in bowel habit, in the absence of alarm features such as rectal bleeding, anaemia, or weight loss, were classified as meeting criteria for IBS at presentation. IBS subtype was classified as diarrhoea-predominant (IBS-D), constipation-predominant (IBS-C), or mixed (IBS-M), according to stool pattern. Radiology, endoscopy, chemical pathology, and histopathology databases were then cross-examined in order to ascertain the final diagnosis following full investigation, to the level deemed appropriate by the consulting physician.
RESULTS: There were 613 consecutive unselected new patient referrals to a single Gastroenterologist between January 2010 and December 2012. Of these, 49 (8.0%) (mean age 42.8 years, 31 (63.3%) female) reported symptoms compatible with IBS, (31 (63.2%) IBS-D, 11 (22.4%) IBS-C, and 7 (14.3%) IBS-M). In total, 10 (20.4%) patients were found to have an organic explanation for their symptoms after investigation. The commonest organic diagnosis among patients meeting criteria for IBS was bile acid malabsorption, occurring in 5 (10.2%). Other organic diagnoses detected included coeliac disease (2 patients), Crohn's disease (1 patient), inflammatory bowel disease-unclassified (1 patient), and pancreatic insufficiency (1 patient). Organic diagnoses were commonest among those meeting criteria for IBS-D, occurring in 9 (29.0%) patients.
CONCLUSION: Our data suggest that organic diagnoses may occur in up to one in five patients meeting criteria for IBS without alarm features. Bile acid malabsorption occurred in more than 10%. The yield of investigations in IBS-C was low, suggesting these individuals can be labelled confidently as having IBS without the need for further investigation.
Disclosure of Interest: None Declared
Keywords: Bile acid malabsorption, Coeliac disease, IBS, Irritable bowel syndrome, Organic disease

P415 DIAGNOSTIC APPROACHES TO INFLAMMATORY BOWEL DISEASE, IRRITABLE BOWEL SYNDROME AND CHRONIC CONSTIPATION: A SURVEY AMONG GENERAL PRACTITIONERS, GASTROENTEROLOGISTS AND EXPERTS IN FIVE EUROPEAN COUNTRIES

V. Andresen[1,*], P. Whorwell[2], J. Fortea[3], J. Milce[4]. *[1]Israelitisches Krankenhaus Orchideenstieg, Hamburg, Germany, [2]Wythenshawe Hospital, Manchester, United Kingdom, [3]Almirall, Barcelona, Spain, [4]Kantar Health, Paris, France*

INTRODUCTION: The confident diagnosis of chronic abdominal conditions can often be challenging and this study aimed to assess the diagnostic process in irritable bowel syndrome with constipation (IBS-C), irritable bowel syndrome with diarrhoea (IBS-D), inflammatory bowel disease (IBD) and chronic constipation (CC).
AIMS&METHODS: 25 experts, 100 gastroenterologists (GEs) and 104 general practitioners (GPs) from Germany, Spain, France, Italy and the United Kingdom were interviewed online. Following an exploration of their perception, attitude and diagnostic approach to IBS, participants were shown a patient vignette demonstrating a typical case of IBS-C, IBS-D, IBD and CC. For each vignette they were asked to make a diagnosis and answer questions on the investigation and further management of each case.
RESULTS: Ability to make a diagnosis for each patient vignette

	IBS-C			**IBS-D**		
Type of physician	**Experts**	**GEs**	**GPs**	**Experts**	**GEs**	**GPs**
Correct diagnosis	**88%**	**56%**	**31%**	**92%**	**72%**	**64%**
Incorrect diagnosis	4%	4%	5%	8%	12%	14%
Don't know	8%	40%	64%	-	16%	22%
	IBD			**CC**		
Type of physician	**Experts**	**GEs**	**GPs**	**Experts**	**GEs**	**GPs**
Correct diagnosis	**92%**	**87%**	**85%**	**60%**	**60%**	**67%**
Incorrect diagnosis	4%	13%	14%	40%	40%	32%
Don't know	4%	-	1%	-	-	1%

CC and IBS-C caused the greatest diagnostic difficulty. For the IBS-C patient, the majority of GEs and GPs who did not make a correct diagnosis said they did not know what the diagnosis should be. In contrast, an incorrect diagnosis in the CC patient was because they considered the patient to have IBS-C.

The physicians' level of confidence in making the diagnosis was 7.0/9 for IBS-D, 6.8/9 for IBS-C, 6.7/9 for CC and 6.3/9 for IBD. The low score for IBD was because most physicians said they would wait for the result of investigation before making a diagnosis.
Experts were more likely than GEs and GPs to endorse a positive approach to the diagnosis of IBS, IBD or CC, whereas GEs and GPs would rather adopt a diagnosis by exclusion approach. For IBS and CC patients, the physicians' next action would be to prescribe a treatment, whereas for the IBD patient, the next action would be to conduct tests. A good knowledge of the Rome III diagnostic criteria was claimed by 96% of experts and 73% of GEs but only 15% of GPs.
CONCLUSION: The study highlights the difficulty experienced by GPs, GEs and experts in confidently diagnosing conditions such as IBS. Differentiating between IBS-C and CC is particularly challenging and diagnostic criteria designed for research purposes may not necessarily be applicable in the normal clinical setting.

P416 APREPITANT USE IN CHILDREN WITH CYCLICAL VOMITING SYNDROME

F. Cristofori[1], N. Kumaraguru[1], E. Saliakellis[1,*], V. Giorgio[1], M. Elawad[1], N. Thapar[1], F. Kiparissi[1], K. Lindley[1], O. Borrelli[1]. [1]*GREAT ORMOND STREET HOSPITAL NHS FOUNDATION TRUST, LONDON, United Kingdom*

INTRODUCTION: Cyclic vomiting syndrome (CVS) is a chronic disorder characterized by recurrent, stereotypical episodes of nausea and vomiting interspersed with symptom-free periods. In a subgroup of children, both acute and prophylactic standard treatments remain unsatisfactory. Aprepitant, a neurokinin-1 receptor antagonist, is efficacious in preventing chemotherapy-induced nausea and vomiting in adults and older children; its role in other disorders remains to be defined. In this study we assessed the efficacy of aprepitant as a prophylactic/acute treatment in CVS children refractory to standard therapies.
AIMS&METHODS: Thirty-eight children (16 males; median age 11 years) fulfilling Rome III criteria for CVS and treated acutely or prophylactically with aprepitant were identified through retrospective chart review. The prophylactic schedule (Regimen A, RA) was: 40 mg twice/week in children <40 kg, 80 mg in children $>40<60$ kg, 125 mg in children >60 kg. The acute schedule (Regimen B, RB) was: 125 mg at day 1 (prodromic phase), followed by 80 mg at day 2 and 3 in children >20 kg, 80 mg for 3 consecutive days for those <20 kg, 80 mg at day 1, 40 mg at day 2 and 3 for those <15 kg. Primary outcome was defined as: 1. complete response, no attacks; 2. partial response, $\geq 50\%$ decrease in attack frequency and intensity; 3. no response, $<50\%$ decrease. Secondary outcomes were: no. of episodes/year, episode length (days), symptom-free interval length (days), and % of school attendance.
RESULTS: During a follow-up period ranging between 12 and 58 months, 37 children were still on treatment. One child discontinued the treatment due to headache. Thirteen children were on RA, while 24 on RB. 30 children (81%) had response to the treatment. Among them, 6 (16%) showed a complete response, while 24 (65%) a partial response. At follow-up there was a significant decrease in no. of episodes/year [6 (2.8-12) vs 12.9 (10-20), $p<0.001$] and in episode length (days) [2.5 (0.5-4) vs 5 (4-5), $p<0.001$], as well as a significant increase in symptom-free interval length (days), [60 (30-127.5) vs 28 (18.5-36.2), $p<0.001$] and % of school attendance [80 (80-100) vs 63 (50-67.5), $p<0.001$]. In the subgroup analysis, no difference was found between RA and RB in the proportion of children showing either complete response (3/13 vs 3/24 respectively, NS) and partial response (8/13 vs 16/24 respectively, NS) as well as for all secondary outcomes. No other side effects were recorded.
CONCLUSION: Aprepitant is effective and well tolerated for acute and prophylactic management of CVS refractory to standard therapies. However, larger randomized studies are needed to confirm our findings.

P417 THE FREQUENCY AND THE RISK FACTORS OF FUNCTIONAL CONSTIPATION IN XI'AN CHILDREN OF SCHOOLAGE

W. Yan[1,*], Z. Jun[2]. [1]*Xi'an Jiaotong University, Xi'an, China,* [2]*Division of Gastroenterology, Xi'an Jiaotong University, Xi'an, China*

INTRODUCTION: Data regarding the prevalence of constipation in Xi'an children of schoolage using internationally standardized definitions are scarce.
AIMS&METHODS: The aim of this study was to investigate the prevalence rate of FC in Xi'an children of schoolage using pediatric Rome III criteria, and to find out the factors surrounding their daily life which will encourage postponement of defecation and hinder the development of regular bowel habits.
A cross-sectional questionnaire survey with stratified cluster and random sampling was performed in December, 2012.2846 children from 5 primary schools was invited to participate in the survey. The questionnaire is made up of two parts, Part1 is the Questionnaire on pediatric Gastrointestinal Symptoms; Part2 is about risk fators. Functional constipation was defined by pediatric Rome III criteria. A small number of children who met the criteria were further selected to undergo a detailed physical examination to exclude organic disease .
RESULTS: 1. 2846 children was invited to participate in the survey,2131 questionnaires were returned , the response rate is 74.88%. 1997 (70.17% effective response rate)were qualified for analysis.
2. The range of age is 6-12 years , mean age was 8.99 ± 1.80 years, 55.3% (1105/1997)were girls. eighty-four children (4.21%, 95% confidence interval [CI] 3.33%–5.09%) were found to have functional constipation. The prevalence rates of the age groups 6y∼, 7y∼, 8y∼, 9y∼, 10y∼, 11y∼, 12y∼were 8.4%(16/191), 5.6%(17/301), 2.9%(10/341), 2.9%10/342), 3.1% (10/326, 4.1%(13/319), 4.5%(8/177), respectively. A higher prevalence rate of FC was seen in the 6y∼group than in other groups ($P < 0.008$) . There was no difference in prevalence between boys(4.15%,37/892) and girls(4.25%,47/1105) ($P > 0.05$).
3. In this survey, Logisit regression analysis shows that functional constipation was found to be significantly more prevalent among those children who had at least 3 times fast food one week, formula-fed during infant period, lived with niether parent or only father $>50\%$ of time, never been taught by parent about how to defecate correctly, slept less than 7 hours, done exercise less than half an hour, static activities in addition to school hours more than 3 hours, refused to pass bowel movements in school($P<0.05$, $OR>1$).
CONCLUSION: Children functional constipation is a common problem, the highest prevalence of constipation was in age of 6 years. The factors surrounding their daily life have an influence on constipation, paying attention to these risk factors may help prevent or stop the progression of childhood constipation at its early stages.

P418 CLINICAL BENEFIT AND PROTECTIVE ROLE AGAINST ACUTE DIVERTICULITIS OF NON-ABSORBABLE ANTIBIOTICS WITH CYCLIC ADMINISTRATION IN DIVERTICULAR COLONIC DISEASE

A.-M. Singeap[1,2,*], A. Trifan[1,2], C. Cojocariu[1,2], I. Girleanu[1,2], C. Sfarti[1,2], C. Stanciu[1,3]. [1]*Center of Gastroenterology and Hepatology ,* [2]*University of Medicine and Pharmacy "Gr. T. Popa",* [3]*Romanian Academy, Iasi, Romania*

INTRODUCTION: Colonic diverticular disease is a relatively frequent disease, with wide clinical spectrum: lack of symptomatology/transit troubles, meteorism, abdominal disconfort or pain/complications as acute diverticulitis.
AIMS&METHODS: AIM: to evaluate the clinical benefit and the protective effect against acute diverticulitis of non-absorbable antibiotics, in cyclic long-term administration, in patients with colonic diverticular disease. PATIENTS AND METHODS: we prospectively studied all patients diagnosed during one year in the Center of Gastroenterology and Hepatology with colonic diverticular disease, by colonoscopy or barium enema, with lower intestinal tract symptoms and to whom major colonic lesions were excluded. All patients received specific medication for irritable bowel syndrome and different supplementary treatment: group A-fiber-rich diet, B-fiber-rich diet and rifaximin 7 days/month, 400 mgx2/day, for 1 year. We analyzed after one year of treatment the clinical benefit on the lower intestinal tract symptoms (by questionning the patients) and the percent of patients which developped acute diverticulitis.
RESULTS: 84 patients diagnosed with colonic diverticular disease were followed. In the group A (42 patients), clinical benefit was obtained in 29 patients (69%) and 1 case of acute diverticulitis (2.3%) was noted. In the group B (42 patients), clinical benefit was obtained in 32 patients (76%) and 1 case of acute diverticulitis (2.3%) was noted.
CONCLUSION: Non-absorbable antibiotics with cyclic administration could bring clinical benefit to symptomatic patients with colonic diverticular disease, but not in a significant manner, while prevention of acute diverticulitis was not demonstrated. More studies with longer follow-up and with cost-efficiency analysis would be useful.

INTRODUCTION: With the westernization of diets, incidence of acute colonic diverticulitis has been increasing in Japan. Recently, several studies have shown a

relationship between obesity and complication of diverticulitis such as abscess or perforation. However, the relationship between obesity and complicated diverticulitis: (CD) remains a matter of debate.

AIMS&METHODS: The aim of this retrospective study was to assess the relationship between obesity and CD in large retrospective multicenter Study in Japan. This retrospective study included 1110 patients (654 males, 456 females, mean age 51.8 ±16.6 years) diagnosed with acute colonic diverticulitis between May 2006 and January 2011 at 20 flagship hospitals with diverticular disease study groups in Japan. Complication case was defined as abscess or perforation case. We divided the patient into four groups based on WHO criteria of obesity. The four groups were Underweight group (BMI < 18.5kg/m^2), Normal group (18.5kg/m^2≦BMI < 25 kg/m^2), Overweight group (25 kg/m^2≦BMI < 30kg/m^2) and Obesity group (30kg/m^2≦BMI). Then, we compared normal group and other groups with respect to complication rate.

RESULTS: In male patient, complication rate in each group was below, Underweight group (36.0%: 10/29), Normal group (15.2%: 62/411), Overweight group (12.7%: 24/189) and Obesity group (8.0%: 2/25). In female patient, complication rate in each group was below, Underweight group (7.1%: 4/56), Normal group (10.9%: 35/321), Overweight group (11.1%: 7/63) and Obesity group (6.3%: 1/16). Complication rate revealed no significant differences between Normal group and Obesity group both male (15.2% *vs.* 8.0%: P=0.3317) and female (10.9% *vs.* 6.3%: P=0.8422). On the other hand, in male patient, complication rate was significantly higher in Underweight group compared to Normal group (36.0% *vs.* 15.2%: P=0.0064). However, this trend was not seen in female patient (7.1% *vs.* 10.9%: P=0.3945).

CONCLUSION: Obesity wasn't a risk factor for CD both male and female in Japan. On the other hand, underweight was a risk factor for CD in male. We need to pay attention to underweight male patients to prevent complicated diverticulitis.

P420 IMMUNE AND EXTRACELLULAR MATRIX REMODELLING ALTERATIONS IN PERIDIVERTICULAR INFLAMED MUCOSA OF PATIENTS WITH DIVERTICULITIS

P. Biancheri[1,2,*], A. Di Sabatino[2], P. Giuffrida[1,2], S. L. Pender[3], T. T. MacDonald[1], G. R. Corazza[2]. [1]*Centre for Immunology and Infectious Disease, Barts and the London School of Medicine and Dentistry, London, United Kingdom,* [2]*Department of Internal Medicine, S. Matteo Hospital, University of Pavia, Pavia, Italy,* [3]*Division of Infection, Inflammation and Immunity, University of Southampton, Southampton, United Kingdom*

INTRODUCTION: Increased mucosal expression of pro-fibrogenic mediators such as collagen has been reported in diverticulitis and, to a lesser extent, in diverticulosis. While tumor necrosis factor (TNF)-α is overexpressed in diverticulitis, no information exists on other innate and adaptive pro-inflammatory cytokines in diverticulitis and diverticulosis. We therefore investigated the mucosal immunologic changes and the pro-fibrogenic response occurring next to inflamed diverticula.

AIMS&METHODS: Intestinal biopsies were collected from peridiverticular areas of 15 patients with diverticulitis and 15 with diverticulosis, from inflamed areas of 14 inflammatory bowel disease (IBD) patients, from strictured areas of 10 Crohn's disease (CD) patients and from normal mucosa of 15 control subjects. After isolation, lamina propria mononuclear cells (LPMCs) were stimulated with pokeweed mitogen (PWM) or with anti-CD3/CD28 antibodies, whereas myofibroblasts were cultured with medium alone. Interleukin (IL)-1β, IL-6, IL-12, TNF-α, IL-17A, interferon (IFN)-γ and collagen were measured in culture supernatants. Mucosal transforming growth factor (TGF)-β1 transcripts were measured by quantitative RT-PCR and immunohistochemistry for smooth muscle actin (SMA) was performed on biopsy sections.

RESULTS: PWM- and anti-CD3/CD28-stimulated LPMCs from diverticulitis and IBD patients produced significantly higher concentrations of IL-1β, IL-6, IL-12 and TNF-α, and IFN-γ and IL-17A, respectively, than uninflamed diverticula and control mucosa, with no difference between control and diverticulosis patients. Myofibroblasts from diverticulitis and strictured CD patients released significantly higher amounts of collagen than diverticulosis patients and controls. Raised transcripts of mucosal TGF-β1 were found in diverticulitis and strictured CD patients. SMA was overexpressed in the mucosa of diverticulitis compared to diverticulosis patients and controls.

CONCLUSION: Mucosa from peridiverticular inflamed areas is characterized by a marked pro-inflammatory immune activation and by an enhanced pro-fibrogenic response. The abnormal innate and adaptive immune response observed in diverticulitis is likely to amplify the aberrant process of fibrogenesis intrinsically associated to diverticulum formation.

P421 CHALLENGING A DOGMA - NECESSITY OF ROUTINE COLONOSCOPY AFTER COMPUTED TOMOGRAPHY-DIAGNOSED ACUTE DIVERTICULITIS

V. Sallinen[1,*], P. Mentula[1], A. Leppäniemi[1]. [1]*Department of Abdominal Surgery, Helsinki University Central Hospital, Helsinki, Finland*

INTRODUCTION: Current guidelines recommend computed tomography (CT) to diagnose acute diverticulitis, and a colonoscopy after 6 weeks to confirm the diagnosis and rule out cancer mimicking diverticulitis (1-2). Coloscopy is an invasive method assosiated with 0.04 - 0.07% risk of bowel perforation (3-4). On the other hand only 0.5 - 2 % of CT-diagnosed acute diverticulitis turn out to be colon cancers instead (5-8). Based on recent meta-analysis, scientific data to support routine colonoscopy after CT-diagnosed acute diverticulitis is limited (9).

AIMS&METHODS: The aim of the study was to evalute the risk of colon cancer mimicking diverticulitis, and the need of colonoscopy after CT-diagnosed acute diverticulitis.

This was a retrospective cohort study. Patients treated during 2006-2010 were identified based on ICD-10 code K57. Data was manually obtained from electronic patient records and analyzed for age, sex, laboratory parameters, prior diverticulitis, surgical operations, pathology reports, CT reports and images, and colonoscopy charts. CT-diagnosis of acute diverticulitis was defined as primary diagnosis given by an expert consultant radiologist. All patient records were manually searched for colorectal cancer diagnosis in patients that had not been evaluated by colonoscopy or the colonoscopy had been incomplete. As it is mandotory by law to report all cancer cases to national registry, similar search was performed for Finnish Cancer Registry. Minimum interval between the searches for cancer and index diverticulitis was two years.

RESULTS: Six-hundred and thirty-three patients with CT-diagnosed acute colonic diverticulitis were included. Ninety-seven underwent emergency resection during index hospital admission, whereas 536 were treated conservatively. Three-hundred and ninety-four conservatively treated patients underwent colonoscopy in the follow-up. Seventeen cancers (2.7%) were identified in patients initially treated as having an acute diverticulitis. Sixteen cases (94%) had abscess in the CT-scan, whereas one case had pericolic extraluminal air, but no abscess. 11.4% of patients treated as having a diverticular abscess had cancer instead. No cancer were found in patients treated for uncomplicated acute diverticulitis. In addition to absess, independent risk factors for cancer mimicking diverticulitis included suspicion of cancer by radiologist, thickness of bowel wall over 15 mm, no diverticula seen on CT-scan, and previously undiagnosed metastases in CT-scan.

CONCLUSION: Routine colonoscopy after uncomplicated acute diverticulitis does not seem necessary, while colonoscopy should be performed in all patients treated for diverticular abscess.

P422 COULD UPPER GI CANCER EXPLAIN 'FALSE POSITIVE' FAECAL OCCULT BLOOD TEST (FOBT) RESULTS IN THE BOWEL CANCER SCREENING PROGRAMME?

G. M. Clifford[1], J. Shenfine[2], H. Jaretzke[2], C. J. Rees[3,4,*]. [1]*South of Tyne Screening Centre, GATESHEAD HEALTH NHS FOUNDATION TRUST, GATESHEAD,* [2]*Northern Oesophago-Gastric Unit, Royal Victoria Infirmary, Newcastle,* [3]*South of Tyne Screening Centre, SOUTH TYNESIDE NHS FOUNDATION TRUST, South Shields,* [4]*School of Medicine Pharmacy & Health, Durham University, Durham, United Kingdom*

INTRODUCTION: The Bowel Cancer Screening Programme (BCSP) commenced in England in 2006 using the Hemoccult guaiac faecal occult blood test (FOBt). The study aimed to evaluate if significant numbers of upper GI cancers were being diagnosed in patients with a positive FOBt in the absence of colonic pathology.

AIMS&METHODS: A quantitative data analysis of all BCSP patients with a negative colonoscopy cross referenced with all patients within screening age (60yrs>) diagnosed with upper GI cancer in the North East of England, comprising of South of Tyne, North of Tyne, Teesside, Durham and Darlington.

RESULTS: Collectively the North East Bowel Cancer Screening centres carried out 5176 colonoscopies from 2008-2011, resulting in 1108 (21.4%) normal investigations.

In the same time period 589 patients were diagnosed with upper GI cancer. 243 were invited to participate in BCSP and 109 (45%) took part. 33/109 (30%) patients were diagnosed with upper GI cancer prior to submitting FOBt, leaving 76 (70%) presumably undiagnosed.
72/76 (94.8%) returned a negative FOBt, 2 (2.6%) returned an unclear subsequently followed by 2 negative FOBt kits according to BCSP practice, leaving 2 (2.6%) patients with a positive FOBt who subsequently had a normal colonoscopy. At the time of screening both patients were symptomatic with upper GI symptoms, and diagnosed with upper GI cancer within 3 months of screening.
CONCLUSION: These data suggest that carrying out an upper GI investigation in FOBt positive and colonoscopy negative patients is not justified. Consideration to investigate maybe given in the presence of upper GI symptoms; however, further work is needed to evaluate the prevalence of upper GI symptoms in this population.

P423 RESULTS AND RISK FACTORS OF COLORECTAL NEOPLASMS IN SCREENING COLONOSCOPY IN PERSONS 40 TO 49 YEARS OF AGE

J. E. Koo[1,*], K.-J. Kim[2], H. W. Park[1], J.-W. Choe[1], S.-K. Yang[2], J. H. Kim[2]. [1]*Health Promotion Center,* [2]*Gastroenterology, University of Ulsan College of Medicine, Asan medical center, Seoul, Korea, Republic Of*

INTRODUCTION: Screening guidelines for colorectal cancer include colonoscopy starting at age 50 years based on the prevalence of adenomas and the incidence of colon cancer at that age. However, there is a paucity of data on colonoscopic screening in asymptomatic individuals aged 40 – 49 years. The aim of this study is to investigate the prevalence and risk factors for colorectal neoplasms in persons 40 to 49 years of age.
AIMS&METHODS: Of 4,783 individuals aged 40-49 who underwent colonoscopy for health check up, 2,531 adults received screening colonoscopy for the first time. We analyzed questionnaire information, anthropometric, laboratory and radiologic measurements, and colonoscopic findings for 2,531 adults, based on prospectively collected data.
RESULTS: The prevalence of overall adenoma, high-risk adenoma, and advanced adenoma was 27.2%, 4.4%, 2.1% respectively in 40-49 years aged subjects. Five patients (0.2%) had an adenocarcinoma detected. About half of overall colorectal neoplasms as well as advanced adenoma were showed proximal location. Older age (≥ 45 years), male sex, current smoking, heavy alcohol drinking were associated with an increased risk of overall colorectal adenoma. Metabolic syndrome was also associated with an increased risk of overall adenoma (OR=1.29, 95% CI=1.03-1.63) and high-risk adenoma (OR=1.99, 95% CI=1.30-3.04). Among the individual components of metabolic syndrome, high TG levels and low HDL levels were associated with an increased risk of high-risk adenoma (OR=1.61, 95% CI=1.06-2.45; OR=1.63, 95% CI=1.01-2.64, respectively).
CONCLUSION: We found that metabolic syndrome increased the risk of colorectal adenoma and adenomas were equally distributed proximally and distally in 40-49 aged adults.. Five colorectal cancer were also found. Thus, consideration should be given for age based colonoscopic screening beginning at age 40, especially for individuals with metabolic syndrome.

P424 GECCO 2012: EPIDEMIOLOGY OF CHRONIC CONSTIPATION IN GERMANY

P. Enck[1,*], J. Schwille-Kiuntke[1], A. Joseph[2], P. Hodgkins[3], J. Leinert[4], T. Köhler[4]. [1]*Psychosomatic Medicine, University Hospital, Tuebingen, Germany,* [2]*Global HEOR, Shire, Eysins, Switzerland,* [3]*Global Health Economics, Shire, Wayne, PA, United States,* [4]*INFAS, Bonn, Germany*

INTRODUCTION: Prevalence of chronic constipation in Germany has been reported to be 5%. This number is substantially lower than in other European countries and worldwide, but reliable data are unavailable.
AIMS&METHODS: We ran a data-sampling frame using a RDD approach (Random Digit Dialing), and conducted a telephone interview (CATI; Computer assisted telephone interview) with individuals who acknowledged the presence of constipation symptoms during the preceding 12 months. Constipation symptoms for more than 6 months were regarded as chronic. Individuals willing to provide their postal address were sent a questionnaire asking about the presence of other diagnoses, and current regular medication for constipation and co-morbid conditions.
RESULTS: Based on response rates during a test trial with 1005 individuals, we interviewed 15 002 individuals age 18 or older (mean age: 49.5 yrs; 51.4% females) who agreed to participate in CATI. Of these, 2193 (14.6%) acknowledged having experienced constipation during the last 12 months, 864 (5.8%) reported constipation during the last 4 weeks, and 380 (2.5%) having current constipation symptoms. Of the latter, 307 (80.8%) had constipation for more than 6 months. A total of 1037 individuals (46.3% of all constipated participants) agreed to be sent the questionnaire, and 642 questionnaires (61.9%) were returned. More than one third (38%) of all constipated respondents reported 1 or more chronic medical conditions that could account for the constipation (e.g. hypothyroidism, neurological diseases). This was further supported by the fact that many of the constipated respondents regularly took medication that may have induced or exacerbated constipation (e.g. calcium antagonists, L-Thyroxin, pain medication). Sixty-two percent of the 642 respondents had constipation of putative functional origin. Medication use for constipation was different between functional and secondary constipation: Patients with secondary constipation more often used conventional laxatives (bisacodyl, senna, lactulose, macrogol) while patients with functional constipation more often used either nutrition-based measures (psyllium) or novel drugs (prucalopride).
CONCLUSION: Up to 15% of the general German population may report symptoms of constipation. More than 1/3 of them may have constipation secondary to another clinical condition while 2/3 may have functional constipation.

P425 AN INEQUALITIES ANALYSIS OF INDIVIDUALS INVITED FOR COLORECTAL CANCER SCREENING

R. Steele[1,*], P. McClements[2], D. Brewster[2]. [1]*Surgery, UNIVERSITY OF DUNDEE, Dundee,* [2]*Population Health, NHS National Services Scotland, Edinburgh, United Kingdom*

INTRODUCTION: The Scottish Colorectal Cancer Screening Programme commenced a phased roll out in June 2007 (1) with all NHS Boards participating in the Programme by December 2009. By December 2011 everyone within the eligible age range (50-74 years) had been invited to participate in at least one round of screening. Screening uptake is an important performance indicator for population screening, and has been shown to be affected by deprivation and gender, although not in a fully rolled-out national programme.
AIMS&METHODS: In this study we have examined uptake, positive predictive value (PPV) and stage distribution by deprivation and gender in the National Screening Programme. Data on all eligible individuals during the first five years of the Programme were analysed by gender and deprivation quintile. Comparative information was obtained from the National Cancer Registry. The main outcome measures were uptake, cancer and adenoma detection and Dukes' stage.
RESULTS: The expected gradient in uptake was seen with lower uptake in disadvantaged groups and males. Uptake in males ranged from 38% in the most deprived quintile to 58% in the least deprived quintile; for females from 44% to 66%. 80% of those screening once did so again on next invitation and here the deprivation gradient was very small. PPV for both cancers and adenomas was worse in the disadvantaged and women; the PPV for cancer ranged from 3.5% in the most deprived quintile to 6% in the least deprived quintile for females and from 5% to 8% in males. Screen detected cancers are generally diagnosed at an earlier stage. The proportion of cancers which were screen detected increased steadily to round 25% in 2011 and have increased within each deprivation quintile.

CONCLUSION: The recognised differentials by sex and social group are seen. However once engaged in screening the vast majority of individuals in all social groups continue participating. Thus, there are implications for encouraging uptake and targeting funding and resources to traditionally disengaged groups. However, improving screening uptake in disadvantaged groups increases the proportion of false positive investigations.

P426 THE EFFECT OF A MULTISPECIES PROBIOTIC ON THE INTESTINAL MICROBIOTA DURING ANTIBIOTIC THERAPY

Y. Fominykh[1], S. Zakharenko[2,*], C. Koning[3], Y. Uspenskiy[1]. [1]*SPSMU n.a. I.P. Pavlov,* [2]*VMA n.a. S.M. Kirov, SPb, Russian Federation,* [3]*Winclove b.v., Amsterdam, Netherlands*

INTRODUCTION: Antibiotic intake causes a marked and sustained disturbance of the intestinal microbiota resulting in long-term health consequences. Probiotics have shown to be able to prevent these disturbances. However, different probiotics (both mono- and multispecies) and treatment strategies (during or after antibiotic therapy (ABT)) are used. The aim of this study was to investigate the efficacy and safety of a multispecies probiotic "Rioflora®Balance" during and directly after ABT.

AIMS&METHODS: Patients treated with ABT for focal pneumonia were randomized into three groups. Group 1 received 2 capsules Rioflora®Balance twice daily (10^{10}cfu/day) for 14 days in parallel with ABT; group 2 received 2 capsules Rioflora®Balance twice daily (10^{10}cfu/day) for 14 days directly after cessation of ABT; group 3 received ABT only. At the start and end of ABT/multispecies probiotic supplementation complaints were assed by the treating physician. Moreover, gas chromatography was applied to investigate the dynamics of the small intestinal microbiota and quantitative PCR was used to determine changes in the colonic microbiota (*Bacteriodes fragilis, Bacteriodes thetaiataomicron,* lactobacilli, bifidobacteria, *Clostridium difficile, Eschericia coli* and *Faecalibacterium prausnizii*).

RESULTS: 120 patients completed the study (40 in each group, mean age 33.7±9.4 years; 47 men, 73 women). ABT had a profound influence on the small and large microbiota (increase in small intestinal *C. difficile* and Candida, decrease in both small intestinal and colonic bifidobacteria and lactobacilli, decrease in small intestinal *B. fragilis* and an increase in colonic *E.coli*). Multispecies probiotic supplementation was able to completely counteract these antibiotic induced disturbances of the microbiota. Moreover, an increase of both small intestinal and colonic bifidobacteria and lactobacilli was observed. Supplementation of the multispecies probiotic in parallel with ABT was characterized by a more pronounced effect than supplementation after cessation of ABT. No adverse events were reported. No antibiotic associated diarrhea was observed in any of the patients.

CONCLUSION: The intestinal microbiota was markedly affected by ABT. Although the exact long-term consequences of this disturbance need to be fully elucidated it is strongly associated with a negative impact on health. Supplementation with the multispecies probiotic Rioflora®Balance is safe and effective in preventing antibiotic induced disturbances of the intestinal microbiota. Moreover, multispecies probiotic supplementation appears to be more effective if started at the start of ABT than after cessation.

OESOPHAGEAL, GASTRIC AND DUODENAL DISORDERS I – Poster Area

P427 PREVALENCE OF SEVERE ATROPHIC BODY GASTRITIS IN DYSPEPTIC PATIENTS SEEN AT THE ENDOSCOPY UNIT OF A BRAZILIAN GENERAL HOSPITAL

A. J. A. Barbosa[1,*], C. G. Miranda[1]. [1]*Anatomia Patológica, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil*

INTRODUCTION: For many dyspeptic patients the diagnosis of atrophic body gastritis (ABG) is the first step indicating the presence of autoimmune gastritis, associated or not with pernicious anemia.

AIMS&METHODS: The aim of this study was to investigate the prevalence of cases of severe ABG among dyspeptic patients undergoing endoscopy in a Brazilian general hospital. We surveyed all cases of upper gastrointestinal endoscopy with biopsy sampling of gastric antropyloric region and gastric body performed from 2007 to 2009 at a general hospital in the city of Belo Horizonte. A total of 6,005 consecutive gastroesophageal endoscopies with gastric biopsies of the antropyloric and body mucosa were reviewed. Among these cases 2,564 (42.7%) had the diagnosis of chronic gastritis as the main pathological condition of the gastric mucosa. Among them, all the cases of gastritis reporting glandular atrophy or intestinal metaplasia were reassessed by an expert GI pathologist (AJAB). When necessary the paraffin blocks of these patients were retrieved for obtaining new histological sections. Immunohistochemical staining of ghrelin-producing cells was used to differentiate atrophic body mucosa with pseudopyloric metaplasia from true antropyloric mucosa. Ghrelin-producing cells are usually numerous in pseudopyloric metaplasia of the corpus and rare in mucous glands of the antropyloric region [1, 2].

RESULTS: Among the 2,564 cases of chronic gastritis 141 (5.5%) patients had the diagnosis of severe atrophic body gastritis in the original reports. After reviewing all the cases other 55 patients were added, making up 196 (7.6%) patients with severe ABG. The 196 patients ranged in age from 11 to 94 years, with a significant predominance of females (76.0%) over males (24.0%). Fifty patients were in relatively young age range (31 to 50 years) with an even more significant predominance of females, i. e., 83.3% *vs.* 16.7%.

CONCLUSION: The present results show that severe ABG seems to be a common pathological condition among Brazilian dyspeptic patients equivalent to 7.6% of patients with chronic gastritis seen at a general hospital. Furthermore, it appears that about 24% of these patients leave the hospital without receiving the correct diagnosis of gastric disease which may delay the final diagnosis of autoimmune gastritis.

P428 REGULATION OF OESOPHAGEAL KERATINOCYTE PROGENITOR CELLS FUNCTION BY THE COX2/ PROSTAGLANDIN E/C-AMP/PKA PATHWAY AND BY KGF. IMPLICATIONS FOR OESOPHAGEAL EPITHELIAL RENEWAL, HEALING AND THE THERAPEUTIC ACTIONS OF HYDROTALCITE

A. S. Tarnawski[1,*], A. Ahluwalia[1], M. K. Jones[1], H. Gergely[1]. [1]*Gastroenterology , University of California, Irvine; VALBHS & SCIRE, Long Beach, United States*

INTRODUCTION: Oesophageal progenitor cells (OPC) are critical for maintenance, renewal and healing of oesophageal epithelium. The mechanisms regulating OPC function, survival and proliferation remain unknown.

AIMS&METHODS: We tested hypotheses that: 1) Prostaglandin E (PGE) EP receptors, cycloogygenase2 (Cox2) and keratinocyte growth factor (KGF) receptors (KGFR) are expressed in OPC and regulate their survival and proliferation; 2) upregulation of Cox2 (generating PGE) and KGFR by hydrotalcite (HTL, a newest generation antacid) is the basis for protective and healing actions of this drug. METHODS: We used: 1) normal rat oesophageal tissues, 2) organ cultures of rat oesophageal explants, and 3) human oesophageal epithelial HET-1A cell line, which has many features of OPC. Organ cultures and HET-1A cells were treated with placebo or HTL (1-5 mg/ml) for 1-4 hrs; HET-1A cells were also treated with: 1 μg/ml misoprostol (PGE1 analog); 1 μg/ml 16,16 dmPGE2; 0.4 mM protein kinase A (PKA) inhibitor, Rp-cAMP; or 50 ng/ml KGF. *Studies*: 1) epithelial integrity with confocal microscopy; 2) expression of Cox2, EP1-4 receptors, KGF and KGFR using immunostaining and western blotting; 3) In HET-1A cells we quantified: **a)** expression of Cox2, EP receptors1-4, KGF and KGFR and **b)** [i]cAMP (using Biotrack EIA), cAMP response element-binding protein (CREB) and cell proliferation (BrdU assay) prior to and after treatment with PGEs or KGF.

RESULTS: In normal oesophagus, OPC expressed Cox2, EP receptor2 and KGFR; stromal cells expressed KGF. In oesophageal explants, HTL treatment increased Cox2 and KGFR expression in OPC by 69±5 and 72±6% (both $p < 0.01$ vs. placebo). In HET-1A cells, HTL increased Cox2 and KGFR expression by >50% (both $p < 0.01$). PGEs treatment increased in HET-1A cells: c-AMP by >163-fold, P-CREB and cell proliferation by ~64% (all $p < 0.01$). These effects were abolished by pretreatment with PKA inhibitor. KGF stimulated HET-1A cell proliferation by 68% ($p < 0.01$).

CONCLUSION:) This is the first demonstration that Cox2 and EP-2 receptor are expressed and co-localized in oesophageal OPC indicating that Cox2 generated PGEs play an autocrine regulatory role in OPC proliferation and survival via the c-AMP/CREB/PKA signalling pathway. 2) KGFR are expressed in OPC while KGF is expressed in stromal cells reflecting mesenchymal-OPC interactions. 3) HTL treatment significantly upregulates expression of Cox2 and KGFR in OPC. 4) These findings provide new mechanisms regulating OPC, oesophageal mucosal defense and new insight into the protective and healing actions of hydrotalcite.

P429 IN VIVO, REAL TIME, NON-INVASIVE ASSESSMENT OF GASTRIC MUCOSAL INJURY AND PROTECTION USING CONFOCAL LASER ENDOMICROSCOPY: FOCUS ON MUCOSAL MICROVESSELS AND PROGENITOR CELLS. COMPARISON WITH HISTOLOGY AND EM

A. S. Tarnawski[1,*], A. Ahluwalia[1], E. Zhu[1], M. K. Jones[1]. [1]*Gastroenterology , University of California, Irvine; VALBHS & SCIRE, Long Beach, United States*

INTRODUCTION: The mechanisms and cellular targets of gastric mucosal injury are not fully defined. Histological assessment of fixed specimens may not fully reflect *in vivo* events. Confocal laser endomicroscopy (CLE), a novel cutting edge technology, enables *in vivo* real-time visualization of mucosal structures at a subcellular resolution – ''virtual biopsy''. This study was aimed to assess using CLE *in vivo* acute gastric injury with a focus on mucosal microvessels and progenitor cells.
AIMS&METHODS: Fischer F344 rats received 1 ml 0.5% fluorescein i.v. followed by ethanol (ETOH, 1 ml 50%) or placebo intragastrically (i.g.). In some rats, either 1 ml of placebo or hydrotalcite (HTL-newest generation antacid) was given i.g. 30 min prior to ETOH. We used CellvizioLAB LSU F400 and Z ProFlex probe, which was inserted i.g. and CLE images were monitored for 20 min before and after ETOH. **Studies** using CLE: 1) glandular epithelium and microvasculature imaging; 2) vascular permeability measurements; 3) mucosal blood flow dynamics; 4) epithelial progenitor zone integrity; 5) VEGFR2 molecular imaging using labeled antibody; 6) detection of labeled bone marrow-derived stem cells (BMDSC) in gastric mucosa after i.v. injection. For comparison we performed quantitative histology and electron microscopy (EM).
RESULTS: At baseline, CLE demonstrated a normal gastric gland pattern, lamina propria and microvasculature, microvascular blood flow and low vascular permeability. ETOH induced exfoliation of surface epithelium within 2-3 min followed by a 550% increase in vascular permeability ($p < 0.001$) at 3-5 min, microvessel rupture within 5-10 min, extensive extravasation of plasma and erythrocytes and vascular stasis. Progenitor zone cells were severely damaged. Histology and EM confirmed these changes. VEGFR2 was visualized in endothelial cells of microvessels. BMDSC were visualized in gastric mucosal microcirculation. Pretreatment with HTL reduced ETOH-induced vascular permeability by $> 55\%$ ($p < 0.01$), preserved mucosal blood flow and reduced extent and severity of injury (all $p < 0.01$), reflecting mucosal protection.
CONCLUSION: 1) CLE enables precise *in vivo*, real time, sequential analysis of events during gastric injury and evaluation of mucosal protection. 2) Microvascular injury and increased vascular permeability occur early and precede progenitor cell damage and deep hemorrhagic erosions. 3) CLE provides a significant advantage over histologic and EM assessment, by allowing real time monitoring of *in vivo* mucosal structure and function, e.g. vascular permeability, and molecular imaging.

P430 OXIDATIVE-ANTIOXIDATIVE BALANCE IN DUODENAL EPITHELIAL CELLS UPON LONG-TERM GASTRIC HYPOCHLORHYDRIA AND ITS CORRECTION WITH MULTIPROBIOTIC "SYMBITER"

K. Dvorshchenko[1], U. Savko[1], L. Ostapchenko[1,*]. [1]*Educational and Scientific Centre "Institute of Biology", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine*

INTRODUCTION: Hypoacidic states of stomach occupy an important place among disorders of gastrointestinal tract (GIT). Long-term gastric hypochlorhydria (LTGH) can lead to digestive disorders, development of dysbiosis and inflammatory processes in GIT [1]. Probiotics are usually used in order to correct structural and functional damages in GIT, since they possess restoration of homeostasis due to normalization of GIT microbiota.
AIMS&METHODS: The purpose of work was to investigate the oxidative-antioxidative balance in rat duodenal epitheliocytes upon LTGH and administration of multiprobiotic ''Symbiter''.
Experiments were performed on white non-strain male rats. Hypoacidic state was reached by abdominal injection of omeprazole (14 mg/kg) once a day during 28 days. The second group simultaneously with omeprazole was treated with multiprobiotic ''Symbiter'' (0,14 ml/kg orally). Duodenal cells were isolated by low-temperature method. The rate of superoxide anion and hydrogen peroxide generation was assessed spectrophotometrically with XTT and xylenol orange, respectively. The content of diene conjugates were determined in heptane-izopropanol extract spectrophotometrically, Schiff bases – by fluorimetric assay. The content of TBA-reactive compounds was determined by reaction with thiobarbituric acid. Statistical processing of experimental data was performed with conventional analysis of variance.
RESULTS: It was shown that upon LTGH the levels of superoxide radical and hydrogen peroxide in duodenal epitheliocytes were increased: in 1.6 and 1.5 times in villus cells, and in 2.8 and 1.4 times in crypt cells as compared to the control, respectively. The level of lipid peroxidation products (diene conjugates, TBA-reactive substances, schiff bases) was elevated upon LTGH: in 1.7, 1.6, 1.5 times in villus epitheliocytes, and in 2.1, 2.3, 1.8 times in crypt epithelial cells in relation to control, respectively. Administration of multiprobiotic ''Symbiter'' to the rats with hypoacidity was associated with normalization of investigated parameters in duodenal cells.
CONCLUSION: Activation of free radical processes in duodenum upon LTGH was observed, thus indicating oxidative stress development in epithelial cells. Multiprobiotic ''Symbiter''contributed to the amelioration of free radical processes activity in duodenal cells of rats with hypoacidity, which can be explained by multifunctional nature of multiprobiotics (antimicrobial, antioxidant, immune-stimulating and other properties).

P431 PERITUMORAL ADIPOSE TISSUE MICROENVIRONMENT IN ESOPHAGEAL CANCER.

E. Trevellin[1], M. Scarpa[2,*], A. Carraro[3], F. Calabrese[4], F. Lunardi[4], M. Cagol[2], R. Alfieri[2], C. Castoro[2], R. Vettor[1]. [1]*Dept. of Medicine, University of Padova,* [2]*Veneto Oncological Institute (IOV-IRCCS), Padova,* [3]*Dept. of General Surgery and Odontoiatrics, University of Verona, Verona,* [4]*Dept. of Cardiothoracic and Vascular Sciences, University of Padova, Padova, Italy*

INTRODUCTION: Obesity is strictly associated with chronic inflammation of adipose tissue and may influence cancer development, growth and/or invasion. In particular peritumoral adipose tissue may play a role in cancer pathophysiology, affecting tumor behaviour by altering the local microenvironment.
AIMS&METHODS: The peritumoral adipose tissue has been analyzed in patients with esophageal cancer in terms of adipocyte size and inflammation (CD45, CD68), angiogenesis (CD31) and lymphangiogenesis (podoplanin) markers expression. Adipose tissue samples were obtained from peritumoral and omental depots of 50 patients with esophagogastric junction adenocarcinoma or esophageal squamous cell carcinoma undergoing surgical resection. Complete anthropometric data were retrieved. Adipocytes diameter and immunohistochemical expression of CD45, CD68, CD31 and podoplanin was evaluated in haematoxylin and eosin stained sections. Non-parametric statistics were used.
RESULTS: Adipocyte size was directly correlated with CD45, CD68, CD31 and podoplanin expression in both peritumoral and omental adipose tissue. However adipocytes size directly and significantly correlated ($R=0.37$; $p < 0.01$) with positive lymph node involvement only in peritumoral but not omental adipose tissue.
CONCLUSION: Our results suggest that an increased adipocyte size may be related with inflammation and angiogenesis/lymphangiogenesis processes in adipose tissue. Moreover, peritumoral adipose tissue may play a role in alterating tumor microenvironment thus promoting invasiveness in esophageal cancer.

P432 DETERMINATION OF CXCR7 EXPRESSION IN ESOPHAGEAL CANCER

M. Tachezy[1,*], H. Zander[1], F. Gebauer[1], K. von Loga[2], J. R. Izbicki[1], M. Bockhorn[1], m.tachezy@uke.de. [1]*General, Visceral and Thoracic Surgery,* [2]*Dept. of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

INTRODUCTION: The chemokine CXCL12 and its receptor CXCR4 play a major role in tumor invasion, proliferation and metastasis of different malignant diseases, amongst others esophageal carcinoma. CXCR7 was recently identified as a novel alternate receptor for CXCL12. Aim of this study was to evaluate the prognostic impact of the expression of chemokine receptor CXCR7 in patients with esophageal carcinoma (EC).
AIMS&METHODS: Expression of CXCR7 in primary tumors, lymph node and distant metastases of 299 patients with EC was evaluated by immunohistochemistry on a tissue micro array and correlated with clinical and histopathological data.
RESULTS: In esophageal cancer sections CXCR7-specific reactivity was apparent in 45% ($N = 72$) of the squamous cell carcinoma (ESCC), but only occasionally in adenocarcinoma (EAC) (2%, $N = 3$). No correlation between CXCR4 and CXCR7 expression was evident (0.128). We correlated CXCR7 expression with clinical and histopathological characteristics (pT, pN, UICC stage bone marrow metastasis), but could not find any association.
CONCLUSION: In contrast to the other known CXCL12 receptor CXCR4, CXCR7 is expressed in ESCC only, underlining the divergent mechanisms and backgrounds of EAC and ESCC. The results of the study do not indicate a significant functional role of CXCR7 in EAC or ESCC of the esophagus. However, the variable expression in the main two cell types of EC needs to be further investigated.

P433 COMPARATIVE STUDY OF OLGA AND OLGIM STAGING SYSTEM AND RELATIONSHIP WITH CLINICOPATHOLOGICAL CHARACTERISTICS, GASTRITIS STAGE AND INTEROBSERVER AGREEMENT

S. Isajevs[1,2,*], I. Liepniece-Karele[1,3], D. Janciauskas[4], G. Moisejevs[5,6], K. Funka[7,8], I. Kikuste[9], A. Vanags[9], I. Tolmanis[9], M. Leja[6,8]. [1]*Department of Pathology, Faculty of Medicine, University of Latvia,* [2]*Center of Pathology, Riga East University Hospital,* [3]*Academic Histology Laboratory, Riga, Latvia,* [4]*Faculty of Medicine, 3Lithuanian University of Health Sciences, Kaunas, Lithuania,* [5]*Faculty of Medicine, University of Latvia,* [6]*Riga East University Hospital, Riga, Latvia,* [7]*Department of Gastroenterology, Riga East University Hospital,* [8]*Faculty of Medicine, University of Latvia,* [9]*Digestive Disease Center GASTRO, Riga, Latvia*

INTRODUCTION: Atrophic gastritic remains a difficult histopathologic diagnosis with low interobserver agreement. The Operative Link for Gastritis Assessment [OLGA]) has proposed a system for reporting gastritis in terms of stage, which arranges the histological phenotypes of gastritis along a scale of progressively increasing gastric cancer risk [1]. A recently-proposed OLGIM system basically incorporates the same staging frame, but replaces the atrophy with the histological assessment of intestinal metaplasia (IM) alone [2].
AIMS&METHODS: The aim of our study was to compare gastritis staging, clinicopathological characteristic and interobserver agreement in the assessement of gastritis by OLGA and OLGIM systems.
RESULTS: 837 patients were enrolled in the study. Overall, 280 (33.4%) and 167 (19.9%) patients were classified as stage I-IV according to OLGA and OLGIM, respectively. In addition, the stage III-IV was observed in 25 patients staged by OLGA, but in 24 patients staged by OLGIM. Interobserver agreement for atrophic gastritis was moderate in antrum and incisura angularis (respectively, kappa=0.53 and 0.57, $p<0.0001$), but fair for atrophic gastritis assessement in corpus (kappa = 0.38). However, interobserver agreement was almost perfect for intestinal metaplasia assessement both in antrum, incisura angularis and corpus (respectively, kappa=0.82, 0.80 and 0.81, $p<0.0001$).
There was a significant positive correlation between the patient age and gastritis OLGA and OLGIM stage (Rho=+0.34; $p<0.0001$). In addition, there was a weak negative correlation between the serum pepsinogen-1 level, patients's BMI and gastritis OLGA and OLGIM stage.
CONCLUSION: OLGA and OLGIM staging systems correlated with clinicopathological characteristics such serum pepsinogen-1, patient age and BMI. OLGIM staging system characterized with a highest interobserver agreement, however, substantial proportion of potentially high-risk individuals would have been missed if OLGIM staging is applied only. Therefore we recommend to use a combination of OLGA and OLGIM stages in routine clinical reports.

P434 LONG-TERM THREE-DIMENSIONAL PRIMARY GASTRIC CULTURE UNDER AN AIR-LIQUID INTERFACE ENVIRONMENT

T. Katano[1,*], T. Mizoshita[1], T. Joh[1]. [1]*Department of Gastroenterology and Metabolism, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

INTRODUCTION: With advances in stem cell research, molecular markers of stem and early progenitor cells have been discovered in the small intestine and colon. On the other hand, little is known about stem cells in the stomach because of a lack of specific stem cell markers and an in vitro system that allows long-term culture.
AIMS&METHODS: The aim was to produce a culture system that mimics normal gastric epithelial growth and differentiation. Glandular stomach cells from postnatal day 2 C57BL/6J mice were cultured in our three-dimensional (3D) primary culture system. This culture system maintains the cultured cells that are embedded in a collagen gel under an air-liquid interface environment.
RESULTS: Cultured stomach cells showed outer spindle cells and yielded expanding sphere structures, which grew for three months. The wall of cultured gastric spheres consisted of a monolayer of tall columnar cells with round nuclei at the base and mucus cytoplasm. Immunohistochemistry revealed cells that were positive for MUC5AC, demonstrating differentiation into gastric surface mucous cells. Fewer than 1% of the epithelial cells were positive for enteroendocrine cell marker chromogranin A. Ultrastructural examination revealed fully differentiated microstructures in cultured gastric epithelial cells such as microvilli, junctional complexes, and glycogen and secretory granules. Real-time PCR of cultured gastric spheres revealed mRNA expression of MUC5AC and did not show expression of MUC2 and CDX2. These results showed that cultured cells in our 3D primary gastric culture system maintained the characteristics of the stomach without transformation to the intestinal phenotype.
CONCLUSION: In conclusion, we established a 3D culture system to allow long-term culture of primary stomach cells within the stem cell niche. This culture method should be useful for stem cell research and elucidating the cause of gastric diseases.

P435 TELOMERE LENGTH IN NON-NEOPLASTIC GASTRIC MUCOSA CORRELATES WITH H. PYLORI INFECTION, DEGREE OF GASTRITIS AND NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS) USE

T. Tahara[1,*], T. Shibata[1], M. Okubo[1], T. Ishizuka[1], Y. Ichikawa[1], M. Miyata[1], K. Sumi[1], T. Kawamura[1], M. Nakamura[2], M. Nagasaka[1], Y. Nakagawa[1], N. Ohmiya[1], T. Arisawa[2], I. Hirata[1]. [1]*Gastroenterology, Fujita Health University School of Medicine, Toyoake,* [2]*Gastroenterology, Kanazawa Medical University, Ishikawa, Japan*

INTRODUCTION: Telomere shortening occurs with human aging in many organs and tissues and is accelerated by rapid cell turnover and oxidative injury.
AIMS&METHODS: To clarify the clinical importance of telomere shortening in gastric mucosa, we measured average telomere length using quantitative real-time PCR in non-neoplastic gastric mucosa and assessed its relationship to *H. pylori* related gastritis, ulcer disease, and non-steroidal anti-inflammatory drugs (NSAIDs) usageGastric biopsies were obtained from 150 cancer free subjects including 48 chronic NSAIDs users and 102 non-users. Relative telomere length in genomic DNA was measured by determining the ratio of telomere repeat copy number (T) to single copy gene (S) copy number(T/S ratio) in individual samples relative to a reference pooled DNA from healthy blood samples. *H. pylori* infection status, histological severity of gastritis, and serum pepsinogens (PGs) were also investigated**.** E-cadherin (CDH1) methylation status was determined by methylation-specific PCR (MSP)
RESULTS: Average relative T/S ratios of *H. pylori* infected subjects were significantly reduced when compared to *H. pylori* negative subjects (4.03+/-1.96 *vs.* 2.82+/-1.62 mean+/-SD, $p=0.002$). Reduction of relative T/S ratio was closely associated with all histological parameter of gastritis (acute inflammation: $p=0.004$, chronic inflammation: $p=0.0003$, atrophy: $p=0.0002$, and metaplasia: $p=0.002$) and CDH1 methylation ($p=0.0002$). In *H. pylori* negative subjects, NSAIDs users presented significantly reduced relative T/S ratio than non-users ($p=0.028$). Reduction of relative T/S ratio was also associated with gastric ulcer occurrence in all subjects ($p=0.01$) and NSAIDs user ($p=0.009$)
CONCLUSION: Telomere shortening is closely associated with severity of *H. pylori* induced gastritis and CDH1 methylation status. Also, telomere shortening is accelerated by NSAIDs usage especially in *H. pylori* negative subjects.

P436 CORRELATION BETWEEN THE LEVEL OF SYSTEMIC AND ESOPHAGEAL CD4+ T LYMPHOCYTES IN HIV-INFECTED PATIENTS WITH CANDIDA ESOPHAGITIS

A. L. Werneck-Silva[1,2,*], C. Pagliari[2], R. A. Patzina[3], W. L. F. da Silva[2], L. Kanashiro-Galo[2], M. I. S. Duarte[2]. [1]*Casa da AIDS-Infectious Disease Division, University of Sao Paulo,* [2]*Laboratório da Disciplina de Patologia de Moléstias Transmissíveis,* [3]*Pathology, Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil*

INTRODUCTION: Several studies have shown that HIV infection is associated with depletion of intestinal CD4+ T cells. However, the esophagus mucosal immune dysfunction has not been described yet. It is known that *Candida* esophagitis rises in incidence in HIV-infected patients with blood CD4+T cells count <200 cells/mm^3. It is not known if this correlation is also seen in the level of CD4+ T cells present in the esophageal mucosa.
AIMS&METHODS: Aim: To conduct a comparative analysis of how *Candida* infection affects CD4+ T cells in the esophageal mucosa and to investigate whether this event correlates with the level of CD4+ T cell depletion as measured in the peripheral blood.
Methods: Immunohistochemistry to CD4+ T cells were performed in histological samples obtained from esophageal endoscopic biopsies in a total of 26 HIV-infected patients including 14 HIV-infected patients with *Candida* esophagitis (5 female and 9 male, mean age 44.6 years) and 12 HIV-infected controls (8 female and 4 male, mean age 51 years) with normal esophagus. Immunostained cells were quantified by counting the number of positive cells for each specimen at X400 magnification using a square grid of 0.0625mm^2. The number of positive cells was compared between the two groups using Graph Pad Prism version 5.00 for Windows (Graph Pad software, San Diego, CA, USA) to perform a Mann-Whitney test with the level for significance set at 95%. The blood CD4 lymphocyte count obtained at the time of endoscopy was also analyzed by flow cytometry. The study conformed to the principles of Declaration of Helsinki and Brazilian governement requirements.
RESULTS: Esophageal CD4+ T cell was lower in the group with *Candida* esophagitis (mean 52.96) compared to the control group (mean 74.53). Mean peripheral blood CD4+ T cell count in HIV-infected patients with *Candida* esophagitis was 96.07 (range 9-180) and in the control group was 359.08 (range 165-577). The difference between the level of CD4+ T cell in the blood was statistically significant ($p<0.0001$). However, this difference was not maintained in the CD4+ T cell count in esophageal mucosa ($p=0.6069$)
CONCLUSION: The level of CD4+ T cell in blood was not directly correlated with the severity of CD4+ T cell depletion in esophageal mucosa. Our results did not show a significant difference in the level of esophageal CD4+ T cells between the *Candida* infection and control group. Therefore, CD4+ T cells could not have a decisive role in the immunopathogenesis of *Candida* esophagitis in HIV-infected patients.

P437 PREVALENCE OF AUTOIMMUNE GASTRITIS IN PATIENTS WITH AUTOIMMUNE DISEASE

E. Losik[1,*], K. Ivashkin, A. Serova, T. Lapina, E. Shirokova, V. Ivashkin. [1]*Gastroenterology, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation, Moscow, Russian Federation*

INTRODUCTION: Autoimmune gastritis involves the fundus and corpus of the stomach and characterized by the presence of antiparietal cell antibodies (APCA), leading to mucosal atrophy. Earlier reports have shown high prevalence of *autoimmune gastritis in patients with other autoimmune disease*. We aimed to study the prevalence of autoimmune gastritis in different groups of patients with *autoimmune disorders such as autoimmune thyroiditis and* autoimmune hepatitis 1 type, primary biliary cirrhosis, primary sclerosing cholangitis and overlap syndrome, comparing to control group.
AIMS&METHODS: 104 patients with autoimmune thyroiditis (males/females: 14/90, mean age 59, 79) and 23 patients with autoimmune liver disease (males/females: 6/17, mean age 49, 71) were included in this study. 39 patients without autoimmune disease (males/females: 10/29, mean age 48, 09) were in control group. APCA status was evaluated by enzyme-linked immunosorbent assay (ELISA).
RESULTS: This study demonstrated significant difference in APCA status between these three groups of patients. The highest prevalence (52,9%) of autoimmune gastritis was in patients with autoimmune thyroiditis. In patients with autoimmune liver disease, APCA was positive in 30,4% patients, comparing to 23% in control group ($p<0,01$).
CONCLUSION: This study shows significantly higher prevalence of autoimmune gastritis in patients with autoimmune thyroiditis and autoimmune liver disease, comparing to control group. Results of our study sustaining the hypothesis of an overall association between autoimmune diseases, including GI disorders. Apparently, affected by some autoimmune disease, patients have a higher probability of being affected by a second or several autoimmune disorders.

P438 THE EFFECT OF PROTON PUMP INHIBITORS ON THE FUNCTION OF NEUTROPHILS AND MONONUCLEAR CELLS

M. Kostrzewska[1,*], E. Jablonska[2], M. Garley[2], W. Ratajczak[2], A. Dabrowski[1]. [1]*Department of Gastroenterology and Internal Medicine,* [2]*Department of Immunology, Medical University of Bialystok, Bialystok, Poland*

INTRODUCTION: Proton pump inhibitors (PPIs) are popular and relatively safe drugs. Apart from inhibition of gastric acid secretion potential anti-inflammatory properties of proton pump inhibitors have been suggested. This effect could probably have therapeutic implications but may also predispose to infectious diseases.
AIMS&METHODS: The aim of this study was evaluation of PPIs effect on function of human neutrophils *in vivo*. Thirty patients without accompanying immunodeficiency were enrolled. A proton pump inhibitor was administered orally for 7 days: 15 patients were treated with omeprazole 20 mg per day and 15 patients with pantoprazole 40 mg per day. Total nitric oxide (NO) in the serum and supernatants obtained from polymorponuclear neutrophils (PMN) and peripheal blood mononuclear cells (PBMC) were measured. The expression of inducible nitric oxide synthase (iNOS) and phospho-p38 mitogen-activated protein kinase (MAPK) were estimated by Western blotting. The generation of superoxide anion radicals by the cells was measured using the cytochrome-c reduction test. The cyclic guanosine monophosphate (cGMP) level in the cell supernatant and plasma was assessed using an enzyme-linked immunosorbent assay kit. Reduction test of spontaneous and reduced of nitrotetralizate blue test (NBT) were performed according to the Park method.
RESULTS: Treatment with omeprazole or pantoprazole did not significant changes in serum NO level. A statistically significant increase in the percentages of activated phagocytes (NBT) was found in the group with omeprazole treatment (16.0 *vs* 27.0%; p=0,04), but not in the group with pantoprazole (21.0 *vs* 16.%; ns). No significant differences were observed in neutrophil supernatant NO and cGMP concentration in both groups. We found significant decrease of mononuclear cell supernatant NO concentration after pantoprazole (30.68 *vs* 19.89 mmol/5x10^6 PBMC/ml; p=0,04), but not after omeprazole treatment (17.05 *vs* 19.32 mmol/5x10^6 PBMC/ml; ns). Treatment with PPI's had no effect on neutrophil iNOS, phospho-p38 expression as well as on generation of superoxide anion radical.
CONCLUSION: Treatment with omeprazole but not pantoprazole stimulates reactivity of neutrophils. However, it is not accompanied by activation of cell inflammatory machinery and may indicate neutrophil malfunctioning. On the other hand, treatment with pantoprazole may decrease antimicrobial and cytotoxic capability of mononuclear cells.

P439 GASTRIC MUCOSAL LYMPHOCYTE SUBPOPULATIONS IN SOME VARIANTS OF THE COURSE AND OUTCOME OF CHRONIC INFLAMMATION OF UPPER GASTROINTESTINAL TRACT

M. Kobiashvili[1,*], N. Davydova[2], N. Bychkova[2], I. Mihaylova[1]. [1]*endoscopy,* [2]*immunology, All-Russian Center of Emergency and Radiation Medicine, Saint-Petersburg, Russian Federation*

INTRODUCTION: Gastric mucosal lymphocyte subpopulations may play significant role in course and outcome of chronic inflammation of upper gastrointestinal tract
AIMS&METHODS: 36 patients chronic gastritis, erosive-ulcerative conditions and neoplasia of the stomach were examined. H. Pylori absence was confirmed by immunocytochemical method. According to the histological analysis the groups were formed: 1 (n = 17) - chronic non-atrophic gastritis, 2 (n = 7) - chronic atrophic gastritis, 3 - gastric cancer (n = 7), 4 (n = 5) - erosive-ulcerative conditions of gastric mucosa (GM). Lymphocyte subpopulations (CD45CD3CD4CD8, CD45CD3CD (16 +56) HLADR, CD45CD19, CD45CD3$\alpha\beta$TCR$\gamma\delta$TCR, CD45CD95, Beckman-Coulter, USA), infiltrating the GM derived from biopsy using mechanical disaggregation (Medimachine, Decton Dickinson, USA) were examined by multicolor flow cytometric analysis (FC-500, Beckman-Coulter, USA). The gastric mucosal cell proliferative activity was investigated by DNA cytometry (FC-500, Beckman-Coulter, USA).
RESULTS: Substantially in all groups except the 4th in GM CD3 + T-lymphocytes dominated, among which cytotoxic CD3 + CD8 + prevailed, that greatly differed from the ratio of the peripheral blood lymphocyte subpopulations. The ratio of T-helper to cytotoxic T-lymphocytes in 1, 2 and Group 4 was 0.05 to 0.7 relatively, and only in the 3rd group reached 1. Among the intraepithelial lymphocytes in the 3rd and 4th groups a high percentage of "double-positive" T-lymphocytes revealed. The majority of T cells expressed $\alpha\beta$TCR, the number of lymphocytes CD3 + $\gamma\delta$TCR + ranged from 1.5 to 2.5% in the different groups, reliable differences were found between the 2nd and 4th groups. The NK-cell number (CD3-CD (16 +56) +) expressing HLADR was the lowest in group 1 and the maximum in the 3rd and 4th groups. Ratio of B- cells (CD19 +) averaged 7-13%, except group 4, in which it was 5-fold higher. Markers (HLA DR, CD95) were maximal in patients of group 4. The GM cell proliferative activity ranged from 3 to 11% in different groups and was the highest in group 4.
CONCLUSION: The ratio of gastric mucosal lymphocyte subpopulations differs from that in the peripheral blood significantly. Immune responses in all survey groups have particular features, but they are characterized by prevalence of T-cell immune response, with the exception of group 4. In neoplasia disbalance between proliferation and apoptosis was characterized by the highest index of cell proliferation, which combined with the maximum number of lymphocytes expressing the marker of readiness to apoptosis.

P440 EVALUATION OF PSORIASIS TREATMENT WITH ESOMEPRAZOL - A PILOT STUDY

M. Bafutto[1,*], E. O. Chaves[2], S. Zaterca[3], J. Almeida[4]. [1]*Departamento de Medicina da Universidade Federal de Goiás, Instituto Goiano de Gastroenterologia,* [2]*Departamento de Cirurgia da Faculdade de Medicina , Universidade Federal de Goiás, Goiânia,* [3]*Departamento de Medicina da USP, Universidade de São Paulo, São Paulo,* [4]*Faculdade de Medicina, Instituto Goiano de Gastroenterologia, Recife, Brazil*

INTRODUCTION: Psoriasis is an inflammatory skin disease that affects 1–3% of Caucasian populations and may be persistent, disfiguring and stigmatising.Proton pump inhibitors (PPIs) are potent blockers of gastric acid secretion. They are widely regarded as the agents of choice for the treatment of acid-peptic disorders. In addition to anti-secretory effects, however, PPIs have been found to have anti-oxidant properties and direct effects on neutrophils, monocytes, endothelial, and epithelial cells that might prevent inflammation. Also PPIs inhibit the expression of intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) as well as endothelial-dependent neutrophil adhesion. Those anti-inflammatory effects of the PPIs might influence a variety of inflammatory disorders, both peptic and non-peptic, within and outside of the gastrointestinal tract (1,2). There are few reports about PPI treatment in psoriasis
AIMS&METHODS: Aims: To evaluate the treatment of Psoriasis with Esomeprazole. Methods: Adult patients (18 year or more) with Psoriasis were selected. Exclusion criteria included concomitant use of any treatment for Psoriasis, organic diseases, use of other PPI than Esomeprazole. 10 patients were selected and psoriasis was evaluated by Psoriasis Area and Severity Index(PASI). Patients were medicated with Esomeprazole 40mg B.I.D for 90 days. At the 90th Day the patients were again evaluated by PASI. Paired t test was used for statistical analyses
RESULTS: Results:Statisticaly significant results were seen when compared PASI before and at 90Th Day of treatment :(mean +/- SD x mean +/- SD) (5.52 +/- 2,93 x 0.89 +/- 0.74) $p = 0.0002$.At 90th day of treatment most patients presented no erythema, induration or scaling of plaques with >75% fall in the PASI.
CONCLUSION: Conclusion: The use of Esomeprazole for Psoriasis presented excellent clinical results with important reduction of PASI. These preliminary results warrant further larger randomized controlled studies.

P441 BUFFERING AND ANTIREFLUX EFFICACY OF ALGINATE-ANTACID FORMULATION (GAVISCON DOUBLE ACTION LIQUID) IN PATIENTS WITH GERD

O. Yanova[1,*], V. Kim[2], O. Berezina[1]. [1]*upper GI disorders, Central research institute of gastroenterology,* [2]*endoscopy, Central reserach institute of gastroenterology , Moscow, Russian Federation*

INTRODUCTION: A postprandial "acid pocket" has recently been described and in patients with GERD it shows greater extension. It is postulated that antacids or alginate-antacids might raise the pH locally and so provide relief from this acid pocket, although at present clinical data are ambiguous
AIMS&METHODS: to assess and compare buffering and antireflux efficacy of Gaviscon Double Action (alginate-antacid) and antacid postprandially in patients with GERD.
10 patients with non-erosive GERD (female - 7 male - 3, mean age - 44 ±11,1 yrs) underwent upper GI endoscopy and pH-monitoring. 3 electrode pH-probe was disposed in corpus, cardia and 5-7cm above lower esophageal sphincter, the arrangement was controlled by X-ray. The effect was assessed by 34 hour pH-monitoring: basal and postprandial acid secretion, number and period of acid reflux were evaluated during 24h without drug consumption, on the second day pts were given alginate-antacid Gaviscon Double Action (group 1) and antacid (group 2). After the first dose of drugs buffering property was assessed during 4 h, than drugs were given after meal in 20min 3 times, so the monitoring has been lasted for 10h.
RESULTS: Buffering effect of both drugs has been lasted for 2h and slightly decreased to baseline pH (1,6 - 2,2). The increase of gastric secretion after drug effect ("rebound effect") wasn't observed in both groups. In group 1 number of acid reflux significantly decreased from 63,4±14,2 to 5,4±2,7 (p=0,000), index DeMeester also diminished from 17,51±2,82 to 1,66±1,17 (p=0,000), that demonstrated antireflux properties of alginate-antacid. In group 2 reflux number reduced from 61,2±10,8 to 48,4±11,2, index DeMeester decreased from 15,82±1,8 to 11,69±4,8, though the difference wasn't statistically significant (p=0,103).
CONCLUSION: alginate-antacid Gaviscon Double Action demonstrates buffering and antireflux properties that emphasizes benefit of both antacid and alginate in patients with GERD.

P442 UPPER GASTROINTESTINAL EVENT REDUCTION AND CARDIOVASCULAR SAFETY OF ANTIPLATELET THERAPY WITH PA32540, A TABLET WITH ENTERIC-COATED ASPIRIN AND IMMEDIATE-RELEASE OMEPRAZOLE: RESULTS OF TWO 6-MONTH, PHASE 3 STUDIES

A. Lanas[1,*], J. L. Goldstein[2], J. M. Scheiman[3], J. G. Fort[4], Y. Zhang[4]. [1]*University of Zaragoza, Zaragoza, Spain,* [2]*NorthShore University Health System, Evanston,* [3]*University of Michigan Medical Center, Ann Arbor,* [4]*POZEN Inc., Chapel Hill, United States*

INTRODUCTION: PPIs can significantly reduce aspirin (ASA)-associated GI symptoms that impact adherence to long-term antiplatelet therapy. PA32540 is a coordinated-delivery tablet of immediate-release (IR) omeprazole 40 mg and enteric-coated (EC) ASA 325 mg. We hypothesized that PA32540 would have fewer gastric ulcers (GU) and fewer upper GI events compared with EC ASA while maintaining the cardiovascular (CV) benefits of ASA.
AIMS&METHODS: Two identical phase 3 double-blind multicenter studies enrolled 1,049 subjects prescribed daily ASA at 325 mg for ≥3 months before study enrollment for secondary prevention of CV events. Subjects were randomly assigned to once-daily treatment with PA32540 or EC ASA 325 mg. The primary endpoint was the cumulative proportion of subjects with endoscopically-confirmed GU (defined as a mucosal break ≥3 mm in diameter with depth) at any time throughout 6 months. Endoscopic assessments were performed at screening and at 1, 3, and 6 months. Upper GI events were prospectively defined. Major adverse CV (MACE) were adjudicated by an independent blinded endpoint committee.
RESULTS: Baseline characteristics and results are shown below. The incidences of GU and upper GI events leading to study discontinuation were significantly lower following administration of PA32540 vs EC aspirin alone over 6 months ($p < 0.05$). No significant difference in MACE was identified.
Baseline Characteristics and Results

Table: P442

BASELINE CHARACTERISTIC (Intent-to-Treat Population)	PA32540 (N=524)	ASA (N=525)
Age, mean (SD), y	66.3 (7.5)	65.7 (7.2)
Male, n (%)	375 (71.6%)	374 (71.2%)
Race, n (%)		
White	470 (89.7%)	473 (90.1%)
African American	49 (9.4%)	42 (8.0%)
Other	5 (0.9%)	10 (1.9%)
History, n (%)		
Diabetes	213 (40.6%)	188 (35.8%)
Previous MI	214 (40.8%)	199 (37.9%)
CVD	102 (19.5%)	113 (21.5%)
Concomitant lipid-lowering therapy, n (%)	439_(83.8%)	430_(81.9%)
***RESULTS AT STUDY END*(6 months)**	**(N=524)**	**(N=525)**
Endoscopic GU, n (%)*	17 (3.2%)	45 (8.6%)
Discontinuation due to upper GI event, n (%)*	8 (1.5%)	43 (8.2%)
*P<0.05		

MACE (Safety Population)	PA32540 (N=521)	**ASA (N=524)**
CV death	0	1
Nonfatal MI	5	3
Acute coronary syndrome	0	5
TIA	1	4
Congestive heart failure	1	1
CAD	1	0
Planned CABG	1	0
Subjects with any MACE events	9 (1.7%)	13 (2.5%)[1]

[1]One subject had 2 events

CONCLUSION: PA32540 was associated with fewer GUs and fewer upper GI symptoms compared with EC ASA 325 mg alone, with no increase in serious CV events. The findings have important implications for the use of PA32540 in the long-term management of patients requiring ASA for secondary CV prevention.

P443 PREDICTION OF MORTALITY IN PATIENTS WITH IN-HOSPITAL UPPER NON VARICEAL BLEEDING: A PROSPECTIVE MULTICENTER STUDY IN ITALY.

G. Rotondano[1,*], R. Marmo[2], M. Koch[3], L. Cipolletta[4], M. A. Bianco[4], E. Grossi[5], Progetto Nazionale Emorragie Digestive - PNED. [1]*Gastroenterology, Hospital Maresca, Torre del Greco,* [2]*Hospital Curto, Polla,* [3]*ACO San Filippo Neri, rome,* [4]*Hospital Maresca, Torre del Greco,* [5]*Bracco Medical Division, Milano, Italy*

INTRODUCTION: Non variceal upper GI bleeding (NVUGIB) that occurs in patients already hospitalized for another condition is associated with increased mortality, but outcome predictors have not been consistently identified.
AIMS&METHODS: To compare outpatients presenting with NVUGIB to in-hospital bleeders (IHB) and to better identify predictors of mortality from NVUGIB in patients suffering from in-hospital bleeding
Secondary analysis of prospectively collected data from two nationwide multicentric databases (PNED). Descriptive, inferential, and multivariate logistic regression models were carried out in 338 inpatients (68.6±16.4 years, 68% males) and 1,979 outpatients (67.8±17 years, 66% males)
RESULTS: Mortality in patients with in-hospital bleeding was significantly higher than outpatients (8.9% vs. 3.8% - OR 2.44 [95%CI 1.57-3.79], p< 0.0001). Predictors of death were hemodynamic instability on presentation, severe comorbidity, (ASA score 3 or 4), past history of peptic ulcer, recurrent bleeding, failure of endosocpic treatment and low dose aspirin use. The impact of these risk factors was different in the two pooulations of in- and outpatients (see table). As a results the predictive accuracy of the model (AUROC) in IHBs was 85.3% vs.74.0% for outpatients, p<0.02.

Hemodynamic instability	7.31 [2.71 - 19.65]	0.000	2.31 [1.17- 4.59]	0.016
ASA score 3 or 4	6.72 [1.87-24.0]	0.003	3.89 [2.33-6.50]	0.000
Low-dose aspirin's use	0.12 [0.02-0.56]	0.008	0.25 [0.11-0.58]	0.001
Past history of peptic ulcer disease	3.18 1.27-7.95]	0.013	1.54 [0.89-2.64]	0.120
Recurrent bleeding	0.71 0.10-4.94]	0.730	5.22 [2.45-11.10]	<0.000
Failed endoscopic treatment	4.38 [0.69-31.9]	0.145	14.29 [5.22-39.17]	0.000
Gastric + duodenal ulcer at endoscopy	3.72 0.77-17.99]	0.101	0.94 [0.12-7.45]	0.958

CONCLUSION: Patients with in-hospital NVUGIB have a significantly higher risk of death, because they are sicker than outpatients admitted for NVUGIB. There are significant differences in both clinical features and treatment patterns between in-patients and outpatients. Predictors of death have a different impact in the two populations.

P446 COMPARISON BENEFIT OF SECOND-LOOK ENDOSCOPY AFTER INITIAL ENDOSCOPIC HEMOSTASIS IN ACUTE PEPTIC ULCER BLEEDING FACTOR ANALYSIS OF RECURRENT BLEEDING

J. B. Hong[1,*], C. W. Choi[1], D. H. Kang[1], H. W. Kim[1], S. B. Park[1], B. J. Song[1], S. J. Kim[1]. [1]*division of gastroenterology, Pusan National University Yangsan Hospital, Yangsan, Korea, Republic Of*

INTRODUCTION: Endoscopic hemostatic therapy for gastrointestinal bleeding(GIB) is high effectiveness. But rebleeding occurs in 10% to 25% of cases after initial endoscopic hemostasis. Clinical value of a second-look endoscopy after initial endoscopic hemostasis with high-dose proton pump inhibitor(PPI) infusion therapy is controversial.
AIMS&METHODS: We aim to determine whether routine second-look endoscopy is necessary and to assess predictors of rebleeding after initial endoscopic hemostasis and high dose PPI medication. In addition we make a comparison between Rockall score and AIMS65 score.Both endoscopic and clinical data were analyzed in 101 acute peptic ulcer bleeding patients during August 2008 to June 2012. All peptic ulcer bleeding patients were treated with high-dose PPI infusion therapy after initial endoscopic hemostasis. To know the patients who need second-look endoscopy, we analysed predictors of rebleeding in patients with high risk on second-look endoscopy.
RESULTS: The rebleeding rate after first endoscopic hemostasis and high dose PPI infusion was 11.8%(12/101). The preendoscopic predictors of rebleeding were use of NSAIDs(p<0.01), albumin level (p=0.042), complete Rockall score(p=0.043), Forrest type(I,IIa)(p=0.017), transfusion requirements before endoscopic hemostasis(P=0.013). No significant difference was found for the factors of initial hemoglobin, sex, age, systolic blood pressure, diastolic blood pressure, heart rate, INR level, use of antiplatelet drug, anticoagulant drug, diabetes, liver cirrhosis, cardiovascular disease, chronic kidney disease, malignancy ulcer location, ulcer size≥1cm, AIMS65score. In univariated analysis of high risk group (Forrest type I or IIa), liver cirrhosis(p=0.040) and complete Rockall score ≥ 4 point were the risk factors of rebleeding. The Multivariated analysis of high risk group identified complete Rockall score ≥4 as only statistically significant risk factor(odds ratio, 5.123; 95% Cl, 1587-16.542, p=0.006).
CONCLUSION: In this study, complete Rockall score showed higher specificity and AIMS65 score showed higher sensitivity to predict mortality and recurrent bleeding in non-variceal upper gastrointestinal bleeding. However, both scoring system have insufficient predictive power about death and rebleeding(all AUROC < 0.7), so it is necessary to design new scoring system which have far higher sensitivity and specificity in the future.

P447 INDEPENDENT RISK FACTORS OF 30-DAY OUTCOMES IN PEPTIC ULCER BLEEDING (PUB'S) BY MULTIVARIATE ANALYSES: IS ULCER SIZE A PREDICTOR OF WORSE OUTCOMES WITH CURRENT TREATMENTS?

M. Camus[1,*], T. O. Kovacs[2], D. M. Jensen[2], M. E. Jensen[2], D. Markovic[3], J. Gornbein[3], CURE Hemostasis Research Group. [1]*Department of Digestive Disease, LARIBOISIERE UNIVERSITY HOSPITAL APHP, Paris, France,* [2]*CURE Hemostasis Research Group, CURE Digestive Diseases Research Center, Division of Digestive Diseases, Ronald Reagan UCLA Medical Center, David Geffen School of Medicine,* [3]*Biomathematics, UCLA, Los Angeles, United States*

INTRODUCTION: Earlier studies report that large ulcer size is a risk factor for PUB rebleeds. However, with changes in medical therapy (high dose IV PPI's) & newer endoscopic hemostasis – NEH, independent risk factors for rebleeding or other 30 day outcomes have not been reported for PUB's.
AIMS&METHODS: In patients with severe PUB's, our purposes were to determine: 1) independent risk factors of 30-day rebleeding, surgery, & death & 2) whether ulcer size alone or in combination with other risk factors is an independent predictor of major outcomes. A large prospectively studied population of patients hospitalized with severe PUB's between January 1993 & December 2011 at our two tertiary care academic medical centers, stratified by stigmata of recent hemorrhage (SRH) & treated optimally (IV high dose PPI & NEH) were included. Using logistic regression model we analyzed independent risk factors of each outcome up to 30 days.
RESULTS: 1264 patients were included. Major SRH were active arterial bleeding in 126 (10%) patients, oozing in 95 (7.5%), non-bleeding visible vessel in 312 (24.7%), & adherent clot in 155 (12.3%). Minor SRH were spots in 110 (8.7%) & 466 (36.9%) patients had clean ulcers. For ulcers 10 mm or larger, the odds of 30 day rebleeding increased 6% per each 10% increase in ulcer size (OR 1.06, 95%CI 1.02-1.10, p=0.0053). Other risk factors of 30-day rebleeding were major SRH, inpatient start of bleeding, & prior GI bleeding. But female gender, any aspirin use, & endoscopic hemostasis were independent protective factors. Ulcer size was not a predictor of 30-day surgery. Major SRH, prior GI bleeding, & cirrhosis were also predictors of 30-day surgery, whereas aspirin & endoscopic hemostasis were protective factors. Risk factors of 30-day death were major SRH, inpatient bleeding, PTT >35 s & cirrhosis. Combined with major SRH, larger ulcer size was a risk factor for death (OR 1.08 per 10% increase in ulcer size, 95%CI 1.02-1.14, p=0.0095).
CONCLUSION: 1. Increasing ulcer size was an independent risk factor of PUB rebleeding in subset with ulcers 10 mm or larger. 2. Combined with major SRH, increasing ulcer size was also a predictor of death.

P448 LOCAL IMPLANTATION OF ADIPOSE-DERIVED MESENCHYMAL STEM CELLS ENHANCED HEALING OF GASTROTOMY IN AN ANIMAL MODEL

L. Liu[1,*], P. Lam[2], E. K. Ng[2], P. B. Lai[2], P. Chiu[1]. [1]*Department of Surgery, Institute of Digestive Disease, The Chinese University of Hong Kong,* [2]*Department of Surgery, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: Mesenchymal stem cells (MSCs) have high plasticity in differentiation and can secret growth cytokines to accelerate healing. This study aims to investigate the effect of local application of ADMSCs in enhancing healing of gastrotomy.
AIMS&METHODS: MSCs were isolated from the adipose tissue of transgenic-GFP SD rats. A 2-cm incision was created at gastric body and subsequently closed with 5-0 interrupted sutures in wild type SD rats. The animals were divided into four treatment groups, including the control, addition of fibrin glue, fibrin glue with MSCs and MSCs implantation groups. For fibrin glue with MSCs, 5×10^6 MSCs in 70 μl PBS were topically applied on the gastrotomy with a layer of fibrin glue. For MSCs group, MSCs were injected around the gastrotomy. The outcomes assessment included pneumatic bursting pressure, histological analysis, expressions of PCNA, IL-6, TGF-β, Cox-2 and VEGF, and MSCs differentiation.

RESULTS: The gastrostomies in MSCs injection group can withstand significantly higher pneumatic bursting pressure on postoperative day 3 and 5 (P=0.001)(Fig 1 and 2). Histological analysis showed that MSCs injection group had less inflammatory cell infiltration, earlier onset of granulation, epithelialization and more collagen at gastrotomy compared with control and fibrin glue groups. The expression of IL-6 was reduced from day 3 to 7 for MSCs injection group. In contrast, there was a significant increase in IL-6 from day 3 to 7 for the control and fibrin glue groups. Compared with other groups, PCNA and TGF-β expressions were significantly higher in MSCs injection group (MSCs injection vs. control group, PCNA expression: P=0.001 for 3 days, TGF-β expression: P=0.01 and 0.001 for 3 and 5 days, respectively). At 14 and 21 days, MSCs were observed at the gastrotomy with a spindle shape with expression of α-SMA, which indicated the differentiation into muscle cells.
CONCLUSION: : Direct implantation of MSCs can hasten the healing of gastrotomy through enhancing the process of granulation and epithelialization. The results of this study will provide basis for clinical application of MSCs to improve healing of gastrotomy after Natural Orifices Transluminal Endoscopic Surgery.

P449 PREVALANCE AND INVESTIGATIONAL PATHWAYS OF PATIENTS WITH CONSTIPATION PREDOMINANT IRRITABLE BOWEL SYNDROME

M. Kurien[1,*], S. Lin[1], I. Aziz[1], J. S. Leeds[1], D. S. Sanders[1]. [1]*Department of Gastroenterology, ROYAL HALLAMSHIRE HOSPITAL, Sheffield, United Kingdom*

INTRODUCTION: Our group has previously described investigational pathways that occur in patients with diarrhoea predominant irritable bowel syndrome (IBS-D). Currently, there is a paucity of work undertaken in either primary or secondary care evaluating patients with constipation predominant irritable bowel syndrome (IBS-C).This study evaluates the population prevalence of IBS-C, determining also the investigational pathways that occur in these patients.
AIMS&METHODS: We prospectively collected data from 3 groups of patients between April 2005 and November 2012. Group 1 (n= 1002) were healthy volunteers, Group 2 (n=64) were patients fulfilling Rome III criteria for IBS-C, with Group 3 (n=403) being patients fulfilling Rome III criteria for IBS-D. In Group 1 the prevalence of IBS and its differing subtypes (IBS-D, IBS-C, mixed IBS (IBS-M) and unspecified IBS) were determined using the Rome III Diagnostic Questionnaire. In groups 2 and 3, demographic data and diagnostic yield of any investigations undertaken as part of the diagnostic workup were evaluated. Statistical analysis was performed using SPSS version 17.0 (SPSS Inc, Chicago, IL) with Fisher's exact test used to compare categorical data, and an unpaired T-test used to compare continuous data
RESULTS: IBS prevalence in healthy volunteers (Group 1) was 6% (60/1002), with 80% being female ($p<0.0001$).Mixed IBS was the most common IBS subtype (Table 1), with IBS-C patients being significantly older than other patients with IBS (mean age 45 vs 30 years, p=0.027). When comparing Groups 2 and 3, patients with IBS-C underwent a total of 56 additional investigations (including radiological, endoscopic investigations, breath tests, SeHCAT scan, faecal pancreatic elastase), significantly lower than the number of investigations undertaken in the IBS-D group of 885 ($p<0.001$). Whilst further investigations in Group 3 identified an alternative diagnosis to IBS-D in 25%, the 56 additional tests undertaken in Group 2 did not help establish an alternative diagnosis to IBS-C in any of the patients.
Table 1: Prevalence rates of differing types of IBS in Group 1 (n=1002)

Subytype of IBS	Number of Patients	Prevalence (%)	Sex (F:M)	Mean Age	Standard Deviation
IBS-D	14	1.4	7:7	32	18
IBS-C	7	0.7	6:1	45	21
IBS-M	27	2.7	24:3	32	15
Unspecified IBS	12	1.2	11:1	25	7

CONCLUSION: This is the first study to evaluate the population prevalence of differing IBS subtypes within a UK population. Whilst, further investigation of IBS-D patients may lead to an alternative diagnoses and instigation of an appropriate management strategy, the merits of further investigation in IBS-C patients is to be questioned.

P450 ANXIETY IS DRIVING DYSPEPSIA AND GASTROOESOPHAGEAL REFLUX SYMPROMS IN THE GENERAL POPULATION – THE KALIXANDA STUDY 10 YEAR FOLLOW-UP

P. Aro[1,*], N. Talley[2], S.-E. Johansson[1], L. Agréus[1], J. Ronkainen[1,3]. [1]*Centre for Family Medicine, Karolinska Institutet, Stockholm, Sweden,* [2]*University of Newcastle, Newcastle, Australia,* [3]*Center for General Practice, University of Oulu, Oulu, Finland*

INTRODUCTION: Functional dyspepsia (FD) is associated with anxiety but longitudinal follow-up studies in the general population are not available.
AIMS&METHODS: We aimed to define if anxiety and depression are associated with FD (Rome III definition) and gastro-oesophageal reflux symptoms (GORS) in a population based follow-up study.
The participants (n=3000) were randomly selected from the national population register and surveyed by validated abdominal symptom questionnaire and by hospital anxiety and depression scale (HADS) in 1998. 1000 individuals were then randomly selected 1998-2001 for oesophagogastroduodenoscopy. All eligible subjects from the endoscoped cohort (n=887) were invited to a follow-up study in June-August 2010 with the same questionnaires. The data was analyzed by logistic regression for correlated data (GEE) and by logistic regression in longitudinal analysis.
RESULTS: 703 (79.3%) completed the questionnaires at follow-up. FD was reported by 110 (15.6%) at the baseline and by 93 at follow-up (13.3%); 48 were new cases. GORS without organic disease was reported by 185 indivuals (26.3%) at the basic study and by 203 individuals (28.9%) at follow-up. 75 were new cases. Anxiety was associated with FD (OR 3.14; 95% CI 1.38-7.15) and with GORS (OR 2.58; 95% CI 1.19-5.58) in longitudinal analysis. Anxiety at baseline was associated with new onset FD at follow-up (OR 4.33; 95% CI 1.27-14.82) but not with GORS. Low level of anxiety at follow-up was not linked with loss of FD or GORS.
CONCLUSION: Anxiety is linked with ongoing FD and GORS. Anxiety at baseline is associtaed with new onset FD.

P451 CHANGE IN DNA METHYLATION PATTERN OF SLC6A4 IN THE GASTRIC MUCOSA MAY HAVE A ROLE FOR DEVELOPING FUNCTIONAL DYSPEPSIA

T. Tahara[1,*], T. Shibata[1], M. Okubo[1], T. Ishizuka[1], Y. Ichikawa[1], M. Miyata[1], K. Sumi[1], T. Kawamura[1], M. Nakamura[2], M. Nagasaka[1], Y. Nakagawa[1], N. Ohmiya[1], T. Arisawa[2], I. Hirata[1]. [1]*Gastroenterology, Fujita Health University School of Medicine, Toyoake,* [2]*Gastroenterology, Kanazawa Medical University, Ishikawa, Japan*

INTRODUCTION: The neurochemical serotonin (5-HT) is an important signaling molecule in the gastrointestinal motor and sensory functions. A key regulator of 5-HT levels is the transmembrane serotonin transporter (5-HTT; SLC6A4) that governs the reuptake of 5-HT. Recent studies have indicated 5-HTT expression may be regulated by epigenetic mechanisms.
AIMS&METHODS: We investigated DNA methylation status of *SLC6A4* gene in the gastric mucosa from functional dyspepsia (FD) because of their potential role in dyspeptic symptoms. Endoscopic gastric biopsies were obtained from 78 subjects with no upper abdominal symptoms (mean age, 59.8+/-1.64 SE; female / male, 33/45) and 79 patients with FD (mean age, 57.0+/-1.72 SE; female/male, 42/37). The FD patients consisted of 43 patients with EPS, 24 patients with PDS, and 12 patients with having both EPS and PDS according to the Rome III classification. Bisulfite Pyrosequencing was carried out to determine the methylation status of promoter CpG islands (PCGIs), promoter non CpG islands (PNCGIs) and gene body non CpG islands (NPNCGIs) in the *SLC6A4* gene. Gene expression was examined by real-time PCR.
RESULTS: Methylation level of *SLC6A4* in the gastric mucosa was lowest in PCGIs (5.1+/- 0.29%) and highest in NPNCGIs (60.4+/-1.1%), while PNCGIs presented intermediate methylation level (20.9+/-0.64%). Methylation level of PCGIs and PNCGIs were positively correlated (R=0.22, p=0.005), while inverse correlation in methylation level was found between PCGIs and NPNCGIs (R=-0.59, $p<0.0001$). In overall, methylation level of PCGIs was significantly lower in FD compared to control subjects (4.5+/-0.3% vs. 5.7+/-0.5%, p=0.04). Methylation level of PNCGIs was also tended to be lower in FD compared to controls (19.7+/-0.8% vs. 22.0+/-1.0%, p=0.08). On the other hand, methylation level of NPNCGIs was significantly higher in FD compared to control subjects (62.9+/-1.6% vs. 58.0+/-1.6%, p=0.03). Lower methylation level in PNCGIs was highlighted in the patients with PDS (p=0.01), while higher methylation level in NPNCGIs was more prominent in the patients with EPS (p=0.017). Methylation levels of PCGIs and PNCGIs were inversely correlated, while methylation levels of NPNCGIs was positively correlated with *SLC6A4* mRNA levels in the non-neoplastic gastric mucosa and gastric and colorectal cancer cell lines.
CONCLUSION: Our data suggest that change in DNA methylation pattern of *SLC6A4* in the gastric mucosa may have a role for developing FD. A role of epigenetics for developing FD needs do be further evaluated.

P452 EXPRESSION AND FUNCTION OF SLC26A9 MEMBER OF THE SLC26 ANION TRANSPORTER FAMILY IN THE GASTROINTESTINAL TRACT

X. Liu[1,2], T. li[2,*], B. riederer[2], A. singh[2], B. tuo[1], U. seidler[2]. [1]*Gastroenterology, Affilated Hospital of Zunyi Medical College, Zunyi, China,* [2]*Gastroenterology Hepatology and Endokrinology, Hannover Medical School, Hannover, Germany*

INTRODUCTION: We recently identified Slc26a9 as an anion conductance that is upregulated in airway inflammation and prevents bronchial mucus obstruction (Anagnostopoulou et al. JCI 2012). Slc26a9 variants were recently found associated with meconium ileus in cystic fibrosis infants (Sun et al. Nature 2012).
AIMS&METHODS: The association with meconium ileus raises the question where Slc26a9 is expressed in the gastrointestinal tract and what is its function. Acid, HCO_3^-, short circuit current (Isc) measurements were performed in isolated mucosa and acid, HCO_3^- and fluid absorptive and secretory rates were measured by single pass perfusion and back titration in anesthetized Slc26a9 KO and WT mice by inhalation of 2.0% isoflurane. Slc26a9 cellular expression was studied by laser dissection and qPCR, and quantitative morphometry was performed in the different segments of the murine Gastrointestinal tract.

RESULTS: Slc26a9 was found highly expressed in the mucosae of the upper gastrointestinal tract, with abrupt decrease of expression levels to virtually undectable levels beyond the duodenum. As previously reported, Slc26a9 KO mice had completely lost the ability to secrete acid in adulthood. However, Slc26a9 was found highly expressed along the whole gastric gland, even in areas without H^+,K^+-ATPase expression. Proximal duodenal bicarbonate and fluid secretory rates, which are higher in the proximal than the distal duodenum in WT mice, as well as the ability to stimulate these rates with forskolin, were reduced in the absence of Slc26a9 expression. The gastric antrum, as well as the fundus (after omeprazole treatment to rule out any residual acid secretory capacity) was studied to test whether Slc26a9 transports HCO_3^- itself. Gastric antrum, while expressing high Slc26a9 levels in WT mice, had lower basal and forskolin-stimulated HCO_3^- rate as well as lower Isc response in WT than KO mice, arguing against a role of Slc26a9 as a HCO_3^- transporter. Morphometry revealed strongly elongated fundic as well as antral glands, and slightly elongated proximal duodenal villi as well as crypts
CONCLUSION: Slc26a9 expression is necessary for normal gastric acid and proximal duodenal bicarbonate secretion, but it is not expressed in more distal parts of the gastrointestinal mucosa. The increased risk for meconium ileus may be due to loss of digestive function of the stomach and proximal duodenum.

P453 EARLY RESULTS OF PERORAL ENDOSCOPIC MYOTOMY USING HYBRID KNIFE TM VS LAPAROSCOPIC HELLER'S MYOTOMY FOR ACHALASIA CARDIA

A. Maydeo[1,*], N. Joshi[1], S. Bhandari[1], M. Bapat[1], R. Daftary[1], A. Upasani[1], P. Rao[2], B. Thakkar[1], V. Dhir[1]. *[1]Gastroenterology, Baldota Institute of Digestive Sciences, [2]Gastroenterology, Global Hospital, Mumbai, India*

INTRODUCTION: Laparoscopic Hellers's cardiomyotomy (LHM) is an established treatment for achalasia cardia. Recently endoscopic myotomy (POEM) has been described as a promising technique with good short term results. Hybrid knife is supposed to shorten the procedure time of POEM. We compared the technical and early functional results of the POEM and LHM.
AIMS&METHODS: Data was collected prospectively for all patients of achalasia cardia. Endoscopy, high resolution manometry and barium swallow was done in all patients to confirm the diagnosis of achalasia cardia. POEM was performed under general anaesthesia using C02 insuffilation . Both the creation of submucosal tunnel and myotomy was done using hybrid knife (ERBE Elektromedizin, GmbH, Germany) capable of injecting and cutting with the same instrument. LHM was done using 4 ports along with anterior Dorr fundoplication . Technical results of both the procedures are given in table.
RESULTS: There were 12 POEM and 20 LHM procedures done in the period 2009 to 2012. The technical and functional results are shown in the table. There was no significant difference in the technical and functional success rates in the two groups. Two patients in the POEM group developed reflux symptoms while one patient in the LHM group developed severe reflux following removal of wrap (due to dysphagia). Two patients in the LHM group required reintervention, one for severe chest pain and other for severe dysphagia. One patient in the POEM developed pneumoperitomeum and pneumomediastinum after the procedure and was treated conservatively. Procedure time and length of hospital stay were significant longer for LHM group (Table).

	POEM	Hellers Cardiomyotomy	p value
Total No. of patients	**12**	**20**	
Mean Eckardt's dysphagia score	**8.1**	**9.2**	
Pretreatment	**1.8**	**1.6**	
Post treatment.			
Technical success rate	**12/12**	**19/20 (95 %)**	
Functional success rate	**12/12**	**17/20 (85 %)**	**0.274**
LES Pressure mm Hg (Mean)	**50.73**	**52**	
Pretreatment	**16.18**	**18**	
Post treatment			
Length of Myotomy (cms)	**10**	**8**	
Mean procedure time (Min)	**65**	**111.5**	**0.0006**
Complications	**1**	**2**	**1.000**
1. **Mucosal tear**	**0**	**0**	**0.375**
2.**Significant blood loss**	**1**	**0**	
3.**Pneumoperitoneum/ Pneumomediatinum**	**0**	**0**	
4.**Death**			
Mean duration of hospital stay (Days)	**2**	**4**	**0.0004**

CONCLUSION: Both POEM and LHM have excellent short term results. However, the procedure time and length of stay were significantly longer for LHM group in our study. It is possible that the use of Hybrid knife reduces the procedure time of POEM.

P454 A SURVEY OF THE PREVALENCE AND CHARACTERISTICS OF UNINVESTIGATED DYSPEPSIA IN CHINESE COLLEGE STUDENTS

M. Li[1], B. Lu[1,*], L. Chu[1]. *[1]Department of Gastroenterology, Department of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou310006, P R China, HANGZHOU, China*

INTRODUCTION: Dyspeptic symptoms, defined as the presence of symptoms considered to originate from the gastroduodenal region. Epidemiological studies suggest that uninvestigated dyspepsia (UD) is common. However, there is little data on the prevalence of UD and its overlap with other gastrointestinal diseases in the college student population. The aim of this survey was to investigate UD in college students in the Zhejiang province.
AIMS&METHODS: A total of 2520 college students completed a questionnaire. The diagnosis of UD and irritable bowel syndrome (IBS) was based on the Rome-III criteria. Gastroesophageal reflux disease (GERD) was defined as episodes of heartburn and/or acid regurgitation that occurred at least once a week. General items, such as gender, age and body mass index (BMI), were also included in the questionnaire.
RESULTS: A total of 2520 students were interviewed, and 650 students were excluded due to incomplete questionnaire responses. A total of 1870 students (967 males, mean age 21.34 years) completed the questionnaire. The incidence of UD was higher in females and in senior students. The prevalence of UD, IBS, GERD, UD+GERD overlap and UD+IBS overlap was 108 (5.67%), 129 (6.89%), 17(0.91%), 12 (0.64%) and 18 (0.96%), respectively.
CONCLUSION: The prevalence of UD in college students from the Zhejinag province was 5.67% in this study. Symptoms of dyspepsia occurred most frequently in females and in more senior students. The majority of those affected had postprandial distress syndrome. Overlaps were present, not only between UD and IBS, but also between UD and GERD.

P455 CLINICAL RELEVANCE OF INEFFECTIVE OESOPHAGEAL MOTILITY IN SECONDARY PERISTALSIS OF PATIENTS WITH GORD

C.-L. Chen[1,*], C.-H. Yi[1], T.-T. Liu[1]. *[1]Department of Medicine, BUDDHIST TZU CHI GENERAL HOSPITAL AND TZU CHI UNIV, Hualien, Taiwan, Province of China*

INTRODUCTION: Secondary peristalsis contributes to oesophageal clearance for retained food bolus and refluxate. Ineffective oesophageal motility (IOM) is common in patients with gastro-oesophageal reflux disease (GORD). We aimed to investigate the hypothesis whether the presence and severity of IOM would affect the physiological characteristics of secondary peristalsis in patients with GORD.
AIMS&METHODS: We aimed to investigate the hypothesis whether the presence and severity of IOM would affect the physiological characteristics of secondary peristalsis in patients with GORD. Secondary peristalsis was performed with slow and rapid air injections into mid-oesophagus of IOM patients and age matched control subjects. IOM severity was defined according to the presence of oesophageal transit abnormalities by application of combined multichannel intraluminal impedance and manometry (MII-EM) with liquid and viscous swallowing, including those without functional abnormalities (i.e., normal bolus transit for both liquid and viscous, IOM-N), and with functional abnormalities (i.e., abnormal bolus transit for liquid and/or viscous, IOM-A).
RESULTS: Eighteen GORD patients with IOM and 15 control subjects participated in this study. IOM patients were further categorized into those with IOM-N ($n = 11$) and IOM-A ($n= 7$). Secondary peristalsis during slow air distension was triggered less frequently in patients with IOM-A (43%) and IOM-N (75%) when compared with control subjects (100%) (both $P < 0.01$), and the difference also occurred between IOM-A and IOM-N ($P < 0.05$). The frequency of secondary peristalsis induced by rapid air distension was significantly lower in IOM-A patients compared to both control subjects (40% vs. 100%, $P < 0.001$) and IOM-N patients (40% vs. 75%, $P = 0.02$). The threshold volume for inducing secondary peristalsis by slow and rapid air distensions didn't differ between control subjects and IOM patients. There were no differences in pressure wave amplitude and duration of secondary peristalsis between control subjects and IOM patients during slow and rapid air distensions.
CONCLUSION: The data suggest that IOM may predispose to impaired activation of secondary peristalsis, but have no effect on motility characteristics of secondary peristalsis. Increased IOM severity is associated with defective triggering of secondary peristalsis which may further impair osophageal clearance.

P456 PRESERVED PROXIMAL STOMACH RESPONSE TO FOOD IN THE HEALTHY, ASYMPTOMATIC ELDERLY.

L. E. A. Troncon[1,*], M. F. Walter-Ibrahim[1], M. Noccioli de Souza[2], M. Secaf[1]. [1]*Medicine,* [2]*Physics, University of Sao Paulo, Ribeirao Preto, Brazil*

INTRODUCTION: It has been suggested that ageing is associated to reduced proximal stomach relaxation in response to food ingestion and impaired gastric accommodation, which might originate upper gastrointestinal symptoms impairing food ingestion and therefore contribute to malnutrition[1-3]. Nevertheless, studies of the process of gastric accommodation after food ingestion in the healthy elderly are scarce, and the frequency of postprandial slow phasic contractions of the proximal stomach in this particular group has not been studied so far.
AIMS&METHODS: This work aimed at both assessing postprandial gastric accommodation and measuring the frequency characteristics of the phasic contractions of the proximal stomach in healthy, asymptomatic elderly volunteers, in comparison to a control group of younger adults. Nine healthy elderly volunteers (5 female) aged 62-70 years and 14 young healthy adults (7 female) aged 21-33 years were included in the study. After fasting overnight, volunteers ingested a standard liquid nutrient test meal (360 mL; 400 Kcal) labeled with Technetium-phytate. Dynamic acquisitions of anterior and posterior images of the stomach were carried out with a gamma camera during meal ingestion and for 10 min thereafter. The values for the area under the activity *versus* time curve for both the proximal and the total stomach were determined, which allowed the calculation of the proportion of the total intragastric activity retained in the proximal stomach, as a measure of gastric accommodation. The dominant frequency of phasic oscillations of the proximal stomach in the study period was determined using Fast Fourier Transform after digital signal processing (MatLab; Mathworks Inc.).
RESULTS: There were no significant differences between groups concerning proximal stomach postprandial function. Indeed, meal residence in the proximal stomach in proportion to that found in the total stomach were similar in both groups (52 ± 14% vs. 48 ± 7%; $p > 0.90$). Also, there were no differences between groups concerning the dominant frequency of proximal stomach slow phasic contractions (1.18±0.44 versus 1.05±0.28; $p > 0{,}90$).
CONCLUSION: Our data do not provide evidence that ageing significantly influences gastric accommodation. It is therefore unlikely that the effects of ageing on proximal stomach motor response to food ingestion are of substantial physiological or clinical significance.

P457 WHAT IS THE TECHNIQUE FOR MEASURING THE LOWER ESOPHAGEAL SPHINCTER PRESSURE THAT BEST CORRESPONDS WITH THE ESOPHAGEAL SYMPTOMS?

M. I. Delli Quadri[1,*], M. C. Bolino[1], M. Furia[1], G. Iantorno[1], L. Facio[1], F. Espinoza[1], F. Vera[1], H. Vazquez[1], Y. Y. Lien[1]. [1]*motilidad, Hospital de gastroenterologia Bonorino Udaondo, Ciudad autonoma de Buenos aires, Argentina*

INTRODUCTION: Introduction: Esophageal motor patterns recorded in manometry are defined according to pre established criteria for liquid swallowing. However, there are no internationally accepted benchmarks to analyze the variables and the methods for evaluating lower esophageal sphincter (LES) pressure are still controversial.
AIMS&METHODS: Aims:1. Compare five techniques for measuring the pressure of the LES. 2. To evaluate whether any of them is more useful to explain the symptoms. Methods: We included adults patients who underwent esophageal manometry (EM) for dysphagia and/or heartburn at the Gastroenterology Hospital Motility Lab between for one year.Design: Retrospective, observational, comparative and cross sectional study. Dysphagia and heartburn symptoms were collected from medical records. Manometric tracings were evaluated as follows: Stationary measurements (M) during 10 swallows: M1: average of swallows and inter-swallow interval pressures; M 2: average of inter swallows interval pressures. Slow withdrawal measurements: M 3: average pressure of 4 channels. M 4: Average measures 1 + 3; M 5: Average measures 2 + 3. Statistical analysis: Medcalc 11.21.1.0, ANOVA test.
RESULTS: Results: A total of 120 records were reviewed and finally 104 patients were included, 81 were male (67%), mean age: 51 years (range: 18-81). Symptoms recorded were dysphagia: 25% (n=26), heartburn 33%(n=34) and dysphagia and heartburn 42%(n=44). We evaluated patients with a single symptom. Manometric diagnoses no statistically significant differences were found between the five techniques for measuring the LES pressure in patients with dysphagia (pNS). Statistically significant differences were observed between the five techniques in patients with heartburn (<0.0001). 2. M 1 was more accurate and useful to explain heartburn symptoms.
CONCLUSION: Conclusions: In our study the different techniques for measuring the LES pressure showed no differences in patients with dysphagia, but evidenced different values in patients with heartburn. "M 1" technique, as was called by our team, was the more accurate to explain this symptom. This evidence could help to improve patients diagnostic approach. Limitation: the pressure at the end of expiration was not measured according to standard practice in our laboratory as we consider that it has no clinical relevance in the physiology of the studied conditions.

P458 CHARACTERISTICS OF ESOPHAGEAL INVOLVEMENT IN SCLERODERMA

M. Lahcene[1,*], N. Oumnia[1], N. Chiali[1], Y. Saadaoui[1], M. Boudjella[1], A. Tebaibia[1]. [1]*Internal medicine, Hospital of Kouba - Algiers-Algeria, Algiers, Algeria*

INTRODUCTION: Esophageal involvement is frequent in scleroderma.
AIMS&METHODS: Aim: To precise clinical, endoscopic, pH-metric and manometric features of esophageal involvement in systemic sclerosis (SSc).
Methods: This study was prospective and concerned 227 patients with SSc classified by the 1980 American College of Rheumatology criteria and the 2001 Leroy and Medsger criteria. Mean age was 39,7 ± 13,2 years and sex-ratio of 0,13. Gastroesophageal endoscopy and esophageal manometry were performed in all the cases and a 24-hour esophageal pH monitoring in 89 cases.
RESULTS: Esophageal symptoms were present in 121 cases (53.3%) and were signs of GERD or dysphagia respectively in 98 (43.2%) and 93 patients (40.9%). Reflux esophagitis was found in 76 cases (33.4%); it was mild or moderate in 49 cases (A or B of LA classification) (21.6%) and severe (C or D LA) or complicated with stenosis and/or Barrett esophagus in the remaining cases. Esophageal pH-metry revealed a pathologic acid reflux in 59 cases (66.3%), more often in presence of esophagitis than in its absence: 34 (92%) vs 25 (48%): $p < 0.001$. Rate of acid reflux was also more important in cases with reflux esophagitis : mean percentage of time at $pH < 4/24h = 23 \pm 19$ vs 11 ± 14: $p < 0.001$. Esophageal motor disorders (EMD) and lower esophageal sphincter (LES) incompetence were present respectively in 169 cases (74.4%) and 126 (55.5%). Presence of EMD was not related to age, gender or duration of the disease, but to presence of esophageal complaint and/or reflux esophagitis.
CONCLUSION: Esophageal involvement is frequent in scleroderma. It's symptomatic in 50% of cases and is complicated by a reflux esophagitis in more than 1/3 of cases. EMD, frequent in all forms of SSc, are constant in that with reflux esophagitis.

P459 BOTULINUM TOXIN INJECTION FOR SPASTIC AND HYPERTENSIVE ESOPHAGEAL MOTILITY DISORDERS: SAFETY AND EFFICACY

S. Marjoux[1,*], C. Brochard[2], S. Roman[1], R. Gincul[1], V. Lepilliez[1], M. Pagenault[2], T. Ponchon[1], A. Ropert[2], F. Mion[1]. [1]*Digestive diseases, Hopital Edouard Herriot, Lyon,* [2]*Digestive diseases, CHU Rennes, Rennes, France*

INTRODUCTION: Esophageal motor disorders such as spastic or hypertensive peristaltic disorders are a rare cause of dysphagia and chest pain. Medical treatment options are limited. Endoscopic botulinum toxin injection (BTX) has been proposed to treat diffuse esophageal spasm (ref 1). It is known as an easy and safe procedure.
AIMS&METHODS: The purpose of this retrospective study was to evaluate the tolerance and the efficacy of BTX in patients with spastic and hypertensive esophageal motility disorders as classified according to the Chicago classification (ref 2) for high resolution manometry (HRM). All patients with spastic or hypertensive motility disorders in HRM and treated with esophageal BTX at 2 different institutions, were included in the study. HRM recordings were systematically re-analyzed and a patient's phone survey was conducted.
RESULTS: 46 patients (23 men, mean age 66 years, range 28-87) with type III achalasia (n=22), Jackhammer esophagus (n=8), distal esophageal spasm (DES) (n=9), and others (n=7), unresponsive to medical therapy, were included. Patients presented with dysphagia (100%), weight loss (65%, mean 8 kg [2-18]) and chest pain (50%). They underwent one BTX session with 80 to 100 IU of Botox° (Allergan) diluted in 10 mL of saline solution into the lower esophageal sphincter (LES) and/or at the lower third of the esophagus.
Safety. Chest pain was reported in 13 cases (28%), requiring morphine administration in 3 cases, and disappeared in less than 7 days in all cases. Two serious adverse effects occurred (4%): aspiration pneumonia, and death following surgery-requiring mediastinitis 3 weeks after BTX. No complication occurred in the remaining 31 cases (68%).

Efficacy. The efficacy was evaluated in 43 patients (2 lost of follow-up, one death). Thirteen patients (28%) did not exhibit any symptom improvement or it lasted less than 2 months. A significant short-term response (symptom-free for more than 2 months) was obtained in 30 cases (65%): 6 Jackhammer (75%), 7 DES (78%), 13 achalasia (59%), 4 others (57%). Twenty-four (52%) remained asymptomatic for more than 6 months: 5 Jackhammer (62%), 5 DES (55%), 11 achalasia (50%), 3 others (43%). Mean symptom-free period in these patients was 14 months [6-23].

CONCLUSION: BTX into the LES and/or lower third of esophagus appears effective in spastic and hypertensive esophageal motility disorders with symptom improvement in 65% of patients. However, severe adverse effects might occur. Prospective randomized trials are required to identify which disorders are likely to benefit the most from BTX treatment, and how safety may be improved.

P460 UNDERSTANDING THE CAUSE OF PERSISTENT GERD SYMPTOMS DESPITE PROTON PUMP INHIBITOR THERAPY: IMPEDANCE-PH MONITORING REVISITED.

D. Ang[1,*], C. H. Poh[1], K. M. Fock[1]. [1]*Gastroenterology, Changi General Hospital, Singapore, Singapore*

INTRODUCTION: Patients with persistent reflux symptoms despite proton pump inhibitors (PPIs) and a normal gastroscopy pose a challenge. Impedance-pH (MII-pH) clarifies the symptom profile and evaluates patients objectively for acid-reflux (AR) and non-acid reflux (NAR).

AIMS&METHODS: ***Aim***: Evaluate MII-pH characteristics in PPI non-responders. ***Methods:*** Between January 2009-December 2012, consecutive patients with persistent typical reflux symptoms (group 1); atypical symptoms(group 2) and non-cardiac chest pain (NCCP, group 3) underwent 24 hour MII-pH study after PPI washout for 2 weeks. Abnormal MII-pH study was defined by (1)esophageal acid exposure time (AET)>4.2%; bolus exposure (BE>1.4%), high reflux numbers (RE>73) and/or a positive symptom index (SI ≥50%) and/or symptom association probability (SAP ≥95%). The prevalence of abnormal AET and MII-pH parameters between groups was compared by chi-square and student t-test.

RESULTS: 150 patients (60M, mean age 45.5± 12.8) were studied (Table 1). Group 1 patients had significantly more symptomatic AR and NAR events ($p<0.05$) compared to groups 2 and 3 and increased proximal RE compared to group 3 ($p<0.05$). Patients with a positive symptom association for AR events were more likely to have abnormal BE (p=0.01) and abnormal reflux numbers($p<0.05$).

	Group 1 Typical (N=24M,24F)	Group 2 Atypical (N=31M,48F)	Group 3 Non cardiac chest pain (N=5M,18F)
Raised AET	4/48 (8.3%)	11/79(13.9%)	1/23(4.3%)
No. of AR events (mean, SEM)	24.3 ± 3.3	21.4 ± 2.2	18.6 ± 3.2
No. of NAR events (mean, SEM)	30.9 ± 4.8 *p<0.05 compared to groups 2 and 3*	23.8 ± 1.6	18.4 ± 2.4
No of proximal reflux events (mean,SEM)	29.7± 3.9 *p<0.05 compared to group 3*	23.8 ± 1.8	18.4 ± 3.4
Acid Clearance Time (mean, SEM)	70.5 ± 10.1 *p<0.05 compared to group 2*	111.5 ± 18.1	99.8 ± 30.4
Bolus Clearance Time (mean, SEM)	11.0 ± 0.8 *p<0.05 compared to group 2*	13.7 ± 0.7	11.5 ± 1.0
Positive symptom association for acid reflux	22/48(45.8%) *p<0.05 compared to groups 2*	20/79 (25.3%)	7/23(30.4%)
Positive symptom association for non-acid reflux	25/48 (52.1%) *p<0.05 compared to groups 2 and 3*	30/79(38.0%)	0/23 (0.0%)

CONCLUSION: Both AR and NAR events account for persistent symptoms in PPI non-responders, especially patients with typical reflux symptoms. Therapies beyond PPI may be necessary.

P461 IMPEDANCE-PH REFLUX PATTERNS AND POSITIVE SYMPTOM ASSOCIATION PREDICT THE PRESENCE OF MICROSCOPIC ESOPHAGITIS IN NON-EROSIVE REFLUX DISEASE PATIENTS

E. Savarino[1,*], P. Zentilin[2], L. Mastracci[3], N. de Bortoli[4], R. Fiocca[3], V. Savarino[2]. [1]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua,* [2]*Department of Internal Medicine, Division of Gastroenterology,* [3]*DICMI, Pathologic Division, University of Genoa, Genoa,* [4]*Department of Internal Medicine, Division of Gastroenterology, University of Pisa, Pisa, Italy*

INTRODUCTION: Microscopic esophagitis (ME) is frequently encountered in patients with erosive and non-erosive reflux disease (NERD). Recently, this histological finding has been regarded as the potential main mechanism in symptom generation in NERD. Impedance and pH (Imp-pH) testing detects both acid and non-acid reflux and is useful for evaluating symptom-reflux association and overall reflux patterns.

AIMS&METHODS: To determine whether any symptom association or reflux pattern was associated with ME in patients with NERD.

We evaluated 84 (39M/45F; mean age 45) consecutive patients with NERD while off-PPI therapy. During upper endoscopy multiple biopsies were taken at Z-line and 2 cm above it. Basal cell hyperplasia, papillae elongation, dilation of intercellular spaces and eosinophil (Eos) intraepithelial infiltration were measured [0 (absent), 1 (mild or 1=1 Eos), and 2 (marked or 2=>1 eos/HPF)] on hematoxylin–eosin-stained slides by two expert and blinded pathologists. A global score (GS) was calculated by summing up all the scores and dividing by the number of assessed lesions and was considered positive for ME when >0.35. Within 3 days from endoscopy, patients underwent impedance-pH testing. We measured esophageal acid exposure time (AET), mean acid clearance time (MACT), number of impedance-detected reflux episodes (acid, nonacid) and symptom association probability (SAP; positive if ≥95%).

RESULTS: Reflux characteristics are summarized in the Table (univariate analysis). Overall, multivariate analysis showed that the factors associated with the presence of ME were: a positive symptom association probability [OR 3,485 (95%CI 1,045-11,626; p=0,0423], a prolonged MACT [OR 4,322 (95%CI 1,473-12,678; p=0,0077] and an abnormal number of total reflux events [OR 3,485 (95%CI 1,029-8,833; p=0,0443].

Reflux Features (upper limit of normal value)	Median Values (range) **Whole population (n=84)**	Patients with Abnormal Values n (%) **Patients with ME (n=47)**	Patients with Abnormal Values n (%) **Patients without ME (n=37)**	*p value*
Total AET, % (n=4,2%)	2.8 (0.7-5.1)	19 (40%)	6 (17%)	0.0235
MACT total, sec (n=85)	69 (29-125)	27 (57%)	8 (22%)	0.0009
GER total, n (n=54)	51 (35-77)	29 (62%)	9 (24%)	0.0006
Proximal Reflux, n (n=30)	22 (13-47)	23 (49%)	7 (19%)	0.0044
SAP+ all reflux	61	41 (87%)	20 (54%)	0.0007

CONCLUSION: While confirming the importance of acid clearance in favouring the presence of esophageal microscopic damage in patients with NERD, impedance-pH data emphasize the major role of overall reflux episodes in promoting these histological lesions and further support the relevance of ME in symptom generation.

P463 THE PROXIMAL EXTENT OF WEAKLY ACIDIC LIQUID AND MIXED LIQUID-GAS REFLUX IS A MAJOR FACTOR ASSOCIATED WITH REFLUX PERCEPTION IN PATIENTS WITH NERD ON PPI THERAPY IN JAPAN: STUDY USING COMBINED IMPEDANCE-PH MONITORING

K. Nakagawa[1,*], T. Koike[1], K. Iijima[1], T. Shimosegawa[1]. [1]*Division of Gastroenterology, Tohoku University of Graduate School of Medicine, Sendai, Miyagi, Japan*

INTRODUCTION: The pathogenesis of heartburn and acid regurgitation still remains to be fully elucidated in the non-erosive reflux disease (NERD) patients. Few studies have evaluated association between reflux symptoms and reflux episodes including gas reflux in the NERD patients in Japan.

AIMS&METHODS: The aim of this study is to assess the determinants of reflux perception in patients with NERD on proton pump inhibitor (PPI) therapy in Japan. Seventeen patients with persistent symptoms suggestive gastro-esophageal reflux, despite taking rabeprazole 10mg twice daily for at least 8 weeks, were included in this study. Patients' symptoms were assessed using the questionnaire for the diagnosis of reflux disease, the frequency scale for symptoms of gastro-esophageal reflux disease (FSSG), and all patients were performed ambulatory 24-hour combined impedance-pH monitoring. Reflux episodes were identified and classified as liquid (acid, weakly acidic or weakly alkaline) or gas reflux and were considered symptomatic if patients recorded a symptom within 2 minutes after a reflux episode. Symptom index (SI) was considered to be positive if ≧ 50%, and proximal reflux episodes were determined when reflux reaches 15 cm above the proximal margin of the lower esophageal sphincter (LES).

RESULTS: Of 17 patients, 6 were SI-positive, and 11 were SI-negative. The mean FSSG score of SI-negative (27.5±8.1) tended to be higher than that of SI-positive (18.7±9.5) (p=0.059). In the SI-positive patients, a total of 129 liquid reflux episodes was detected. Overall, 18 (14.0%) reflux were symptomatic, including one (5.5%) acid, 14 (77.8%) weakly acidic, and 3 (16.7%) weakly alkaline reflux. Distal reflux episodes were significantly more frequent (75.2%)

than proximal reflux (24.8%, $p<0.001$). On the contrary, occurrence rate of reflux symptoms in proximal reflux episodes was significantly more frequent (67.4%) than in distal reflux (15.6%) ($p<0.001$). A total of 41 mixed liquid-gas reflux episodes were detected, and 4 (9.7%) were symptomatic. Distal reflux episodes were significantly more frequent (68.3%) than proximal reflux (31.7%, $p<0.001$). In contrast, occurrence rate of reflux symptoms in proximal reflux episodes was significantly more frequent (23.1%) than in distal reflux (6.3%, p=0.013). On the other hand, a total of 323 gas reflux episodes were detected, but only 4 (1.2%) were symptomatic.

CONCLUSION: The proximal extent of weakly acidic liquid and mixed liquid-gas reflux is a major factor associated with reflux perception in SI-positive patients with NERD on PPI therapy.

P464 COMPARISON OF ESOPHAGEAL MANOMETRY FEATURES OF WEAKLY ACIDIC REFLUX ASSOCIATED HEARTBURN AND FUNCTIONAL HEARTBURN

K. Wang[1,*], L.-P. Duan[1], Y. Ge[1], Z.-W. Xia[1], Z.-J. Xu[1]. [1]*Department of Gastroenterology, Peking University Third Hospital, Beijing, China*

INTRODUCTION: Whether esophageal motility disorders play roles in the occurrence of heartburn needs to be elucidated.

AIMS&METHODS: The aims of this study were to analyze the esophageal pressure topography (EPT) findings in the weakly acidic reflux (WAR) associated heartburn and compare them with that of acid reflux (AR) and functional heartburn (FH).

The heartburn patients with over 12 months' history were enrolled. All of them underwent gastroscopy to exclude organic diseases and reflux esophagitis, as well as 24 hour impedance-pH monitoring. The patients were divided into three groups: a, AR: patients with acid exposure time (AET) > 4% but without overload of weakly acid or non-acid; b, WAR: patients with weakly acid events > 18 and normal AET and non-acid events; c, FH: patients with normal range of AET, Symptom index, Symptom association probability, weakly and non-acid reflux. The EPT results were analyzed following Chicago classification criteria 2012

RESULTS: Total 103 patients were enrolled. 46 patients were AR, 36 were WAR and 21 were FH. The percentage of esophageal motility disorder in WAR, AR and FH group was 63.9%, 54.3% and 61.9% respectively ($p>0.05$). The features of motility disorder in the three groups presented significantly difference.(table)

Group %	WAR (a) N=36 52±12 yr	AR (b) N=46 52±15 yr	FH (c) N=21 51±11 yr	P value (chi-square test)
Weak peristalsis	61.1 (22/36)	37.0 (17/46)	23.8 (5/21)	a/b, p=0.045; a/c, p=0.028
Large breaks	36.1 (13/36)	23.9(11/46)	19.4(4/21)	NS
Small breaks	25 (9/36)	13.4(6/46)	4.8(1/21)	a/b, p=0.018; a/c, p=0.010
Normal	36.1(13/36)	45.7(21/46)	38.1(8/21)	NS
Rapid contractions	2.8(1/36)	4.3(2/46)	14.3(3/21)	NS
Distal esophageal spasm (DES)	0	6.5(3/46)	14.3(3/21)	a/c, p=0.045
EGJ outflow obstruction	0	4.3(2/46)	9.5(2/21)	NS
Jackhammer	0	2.2(1/46)	0	NS

CONCLUSION: Peristaltic defect was most frequent motility disorder in WAR heartburn patients. It suggests WAR patients present incomplete bolus transit, which may play a role in the development of heartburn by increasing reflux volume and prolonging the time of reflux content contact with the esophageal mucosa. And DES might be a cause of the symptom in FH patients

P465 RELATIONSHIP BETWEEN POSTPRANDIAL GASTRO-ESOPHAGEAL REFLUX PATTERN AND SEVERITY OF MUCOSAL DAMAGE

P. Zentilin[1], M. Furnari[1,*], E. Savarino[2], E. Marabotto[1], N. de Bortoli[3], A. Moscatelli[1], M. Brunacci[1], L. Gemignani[1], G. Sammito[1], V. Savarino[1]. [1]*Di.M.I., Gastroenterology Unit, UNIVERSITY OF GENOA, GENOA, ITALY,, genoa,* [2]*Gastroenterology Unit, University of Padua, Padua,* [3]*Gastroenterology Unit, University of Pisa, Pisa, Italy*

INTRODUCTION: It has been hypothesized that the postprandial increase of gastroesophageal reflux (GER) results from an increase in the rate of transient lower esophageal sphincter relaxations (TLESRs) which occur more frequently after gastric distention. However, few data exist on the characteristics of GER episodes during the post-prandial (PP) period when the amount of acid is reduced (i.e. neutralization of gastric acidity by food) and the acid pocket occurs. Impedance-pH testing, detecting both acid and non-acid GER, can be used in this setting to characterize better than traditional pH-metry PP reflux events.

AIMS&METHODS: To evaluate the PP reflux patterns among healthy volunteers (HVs) and non-erosive reflux disease (NERD), erosive esophagitis (EE) and Barrett esophagus (BE) patients. We studied 30 HVs [8F; median age 25y] and 35 NERD [11F; 49.5y], 35 EE [7F; 43.5y] and 30 BE patients [5F; 59y]. All patients underwent upper endoscopy, esophageal manometry and impedance-pH off-therapy. During the 24-hour study, patients and HVs ate three standard meals.We measured acid exposure time (AET, % time pH < 4), median bolus clearance time (MBCT), mean acid clearance time (MACT), number of acid and non-acid GER events during the first PP hour for each of the three daily meals. Liquid, mixed and gas refluxes were also assessed.

RESULTS: All parameters increased progressively from HVs to BE, with patients with BE and EE having the higher values of AET, number of acid and non-acid GER events, MBCT and MACT compared to HVs and NERD patients ($p<0.05$). Moreover, patients with NERD had higher values of AET, number of acid and non-acid GER events, MACT compared to HVs ($p<0.05$). Finally, a gradual increase in pure liquid and mixed liquid–gas GER episodes was found in the patients with increasing degrees of esophageal damage ($p<0.05$).

	AET	MBCT	MACT	GER ACID	GER non-ACID	Liquid and mixed	Gas
HV	0.8 (0.2-2.4)	12 (9-16)	27 (7.5-49)	6 (3.5-8.5)	9 (4.5-11)	15 (10.5-20)	1 (0-4)
NERD	4.9 (2.4-9)	17 (13-24)	70 (51-105)	11 (6.5-14.5)	6.6 (4-11)	20.5 (14-31)	2 (1-3.5)
EE	10.1 (5.6-16.6)	18.5 (13.5-33)	73 (42-129)	15 (10-24)	7 (3-13)	22.5 (18-36)	2 (1-3)
BE	15.6 (2.8-30.3)	20.5 (15-28)	89 (43-157.5)	18 (5-26)	5.5 (2.5-13.5)	24.5 (18-38)	3.5 (1.5-7)

CONCLUSION: Our findings show that PP impedance-pH parameters increase in parallel with the severity of mucosal damage. We can hypothesize that BE and EE patients may have more TLESRs during the PP period as result of a more impaired gastric accommodation in them. This may favor the backflow of the content of acid pocket into the esophagus and the development of mucosal injuries.

P466 REFRACTORY GERD: INCREASED BODY MASS INDEX IS ASSOCIATED WITH ONGOING ACID REFLUX BUT NOT WITH HYPERSENSITIVE ESOPHAGUS OR FUNCTIONAL HEARTBURN

N. Viazis[1,*], G. P. Karamanolis[2], I. Anastasiou[1], E. Saprikis[1], G. Kechagias[1], G. Tribonias[1], J. Vlachogiannakos[2], S. D. Ladas[2], D. G. Karamanolis[1]. [1]*2nd Department of Gastroenterology, EVANGELISMOS HOSPITAL,* [2]*Academic Gastroenterology Department, LAIKO HOSPITAL, Athens, Greece*

INTRODUCTION: Compare the prevalence of ongoing acid reflux, hypersensitive esophagus and functional heartburn in obese/overweight and normal weight patients referred for multichannel intraluminal impedance and pH monitoring, because of persisting gastroesophageal reflux disease (GERD) symptoms despite therapy with proton pump inhibitors.

AIMS&METHODS: Patients with normal endoscopy and typical GERD symptoms, despite proton pump inhibitor (PPIs) therapy twice daily, underwent 24-hour pH-impedance monitoring. Distal esophageal acid exposure (% time pH < 4) was measured and reflux episodes were classified into acid or non-acid. A positive symptom index (SI) was declared if at least half of symptom events were preceded by reflux episodes. Patients were categorized to those with ongoing acid reflux, those with hypersensitive esophagus and those with functional heartburn. Incidence of ongoing acid reflux, hypersensitive esophagus and functional heartburn between overweight/obese patients (BMI≥25 Kg/m^2) and normal weight patients (BMI < 25 Kg/m^2) was subsequently evaluated.

RESULTS: A total of 246 patients (females: 158, males: 88, increased BMI: 151, normal BMI: 95, mean age 55 - range 18-75 years) were included. Ongoing acid reflux was found in 39 patients (increased BMI: 31, normal BMI: 8), hypersensitive esophagus in 77 patients (increased BMI: 43, normal BMI: 34) and functional heartburn in 118 patients (increased BMI: 69, normal BMI: 49). When comparing BMI among all 3 groups, patients with increased BMI were more likely to have acid reflux than hypersensitive esophagus or functional heartburn (p=0.03).

CONCLUSION: In patients with GERD symptoms refractory to double dose PPI therapy those with increased BMI are more likely to have ongoing acid reflux than hypersensitive esophagus or functional heartburn.

P467 ENHANCED PERCEPTION OF PROXIMAL GASTRO-OESOPHAGEAL REFLUX IN GORD: IMPAIRED MUCOSAL INTEGRITY OR DISTINCT SENSORY INNERVATION?

P. Woodland[1,*], C. Lee[1], R. Aktar[1], E. Mthunzi[1], L. A. Blackshaw[1], S. Preston[1], D. Sifrim[1]. [1]*Barts & The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom*

INTRODUCTION: In patients with GORD, including refractory disease, reflux events reaching the proximal oesophagus are more likely to be perceived than those

only reaching the distal oesophagus. Experimental data suggests an increased sensitivity of the proximal oesophagus relative to the distal. As such, the proximal oesophagus is likely to be significant in the pathogenesis of GORD symptoms. Reasons for this are unclear, but may include reflux volume, impairment in mucosal integrity (i.e. high permeability and/or low transepithelial electrical resistance, TER) or changes in sensory innervation. The mucosal integrity of the proximal oesophagus is untested in GORD, and little is known about differences in mucosal afferent innervation between distal and proximal oesophagus.

AIMS&METHODS: We **aimed** to characterise mucosal integrity and afferent nerve distribution in the proximal and distal oesophageal mucosa in patients with heartburn without oesophagitis.

We took mucosal biopsies from the distal and proximal oesophagus in 15 patients with heartburn but no oesophagitis, and from 10 healthy volunteers. Biopsies were mounted in an Ussing chamber, and basal and dynamic integrity evaluated by measuring baseline TER and change in TER on exposure of the luminal aspect to a ''test'' pH2 solution containing 1mg/ml pepsin and 1mM taurodeoxycholic acid.

In 9 patients and 10 healthy volunteers, proximal and distal biopsies were examined immunohistochemically for presence and location (number of cells from the luminal aspect of the biopsy) of CGRP-immunoreactive nerve fibres.

RESULTS: There was no difference in baseline TER between the proximal and distal oesophagus in patients or healthy volunteers (179.0±18.2Ω vs. 148.6±21.4Ω (patients) vs. 194.3±22.3 vs. 149.4±22.1 (healthy volunteers), $p>0.05$ for all comparisons). Similarly, there was no significant difference in the change in TER on exposure to the ''test'' solution.

Mucosal afferent nerves were located in more superficial location in the proximal compared to distal oesophagus in both patients and healthy volunteers. Furthermore, fibres were located significantly more superficially in the proximal (but not distal) oesophageal mucosa of patients compared to controls (mean 5.7±0.7 vs. 22.2±2.7 cells from lumen in patients, 13.1±1.1 vs. 23.6±1.3 in healthy volunteers).

CONCLUSION: The enhanced sensitivity of the proximal oesophagus in GORD, is not explained by a distinct impairment of proximal mucosal integrity. However, our results suggest that such increased sensitivity might be associated with a more superficial location of mucosal afferent nerves in the proximal oesophagus of patients with GORD.

P468 ASSOCIATIONS BETWEEN SLEEP DISTURBANCES AND REFRACTORY GERD SYMPTOMS IN PATIENTS RECEIVING ONCE-DAILY PPI AND EFFICACY OF TWICE-DAILY RABEPRAZOLE TREATMENT

Y. Fujiwara[1,*], T. Watanabe[1], K. Tominaga[1], Y. Habu[2], K. Ashida[3], M. Kusano[4], K. Higuchi[5], T. Arakawa[1]. [1]*Osaka City University,* [2]*Saiseikai-Noe Hospital,* [3]*Saiseikai Nakatsu Hospital, Osaka,* [4]*Gunma University Hospital, Maebashi,* [5]*Osaka Medical College, Osaka, Japan*

INTRODUCTION: Approximately 20–40% of patients with gastroesophageal reflux disease (GERD) are refractory to the standard regimen of once-daily proton pump inhibitor (PPI) treatment. Nighttime acid reflux that influences refractory symptoms is strongly associated with sleep disturbances.

AIMS&METHODS: The aim of this study was to examine the associations between sleep disturbances and refractory GERD symptoms in patients receiving once daily PPI and the efficacy of twice-daily rabeprazole treatment. In a multicenter survey, 433 GERD patients receiving once-daily PPI treatment completed a self-report questionnaire that included the Frequency Scale for the Symptoms of GERD (FSSG) and questions about sleep disturbances. Study cases were defined as patients with an FSSG score ≥8. Of the 222 study cases, 106 individuals received rabeprazole 10 mg twice daily for 4-8 weeks.

RESULTS: Of the 433 subjects, 222 patients (51.2%) had refractory GERD symptoms. Use of a half dose of PPI (odds ratio [OR], 1.93; 95% confidence intervals [CI], 1.07-3.50), nighttime symptoms (OR, 2.58; 95% CI, 1.78–3.74), arousals during sleep (OR, 2.16; 95% CI, 1.18–3.96), daytime sleepiness (OR, 1.59; 95% CI, 1.00–2.53), and poorer sleep quality (OR, 1.64; 95% CI, 1.25–2.16) were significantly associated with refractory GERD symptoms. Twice-daily rabeprazole treatment significantly improved FSSG scores and sleep disturbances.

CONCLUSION: About 50% of GERD patients receiving once-daily PPI treatment had refractory GERD symptoms. Use of a half dose of PPI and sleep disturbances were significantly associated with refractory GERD symptoms. Twice-daily rabeprazole treatment was effective in such cases.

P470 RELATIONSHIP BETWEEN AIR SWALLOW AND GASTROESOPHAGEAL REFLUX DISEASE

Y.-Q. Zhao[1], L.-P. Duan[1,1,*], Y. Ge[1]. [1]*Department of Gastroenterology, Peking University Third Hospital, Beijing, China*

INTRODUCTION: Air swallow is a normal physiological phenomenon in health. Some researchers believed that patients with gastroesophageal reflux disease (GERD) swallowed air more, but there were some contradictory reports.

AIMS&METHODS: We aimed to investigate the relationship between air swallow and GERD by using the 24h multichannel esophageal pH-impedance monitoring.

GERD patients and health volunteers (controls) underwent 24h multichannel intraluminal impedance and pH monitoring. All of the subjects received gastroendoscopy to exclude abnormalities other than erosive esophagitis or chronic superficial gastritis previously. Impedance data was analyzed to record the numbers of air events and the parameters of gastroesophageal reflux. Correlation between the parameters of air events and gastroesophageal reflux was analyzed. P value less than 0.05 was considered statistically significant.

RESULTS: A total of 30 GERD patients (45±13 yrs., m/f=18/12) and 30 controls (41±13 yrs., m/f=10/20) was enrolled. The numbers of air swallow in GERD patients were higher than that in controls (22.6±20.8 vs. 16.1±12.7, $p<0.05$), especially in female GERD patients (GERD vs. controls: f, 23.4±21.5 vs. 14.3±11.3, $p<0.05$; m, 22.1±20.0 vs. 19.9±15.0, $p>0.05$). Air swallow happened mainly between meals (GERD vs. controls, female: between meals: 21.2±20.5 vs. 10.9±9.0, $p<0.05$; during meal: 2.3±2.0 vs. 3.4±3.2, $p>0.05$). Meanwhile, air swallow events were significant correlated with the total events number of air reflux for 24h (R=0.517, p=0.000) and the total mixed reflux time (R=0.442, p=0.000). Furthermore, air swallow events correlated negatively with the total esophageal clearance time in GERD patients (R=-0.361, p=0.05), but not in controls (R=0.173, p=0.361).

CONCLUSION: Air swallow happens more often in GERD patients, especially in female between meals. Air swallow might be a reason of gastroesophageal air reflux and mixed reflux. On the other hand, air swallow may play an important role for esophageal content clearance in GERD patients.

P471 SYNCHRONOUS EXPRESSION OF CD147, MONOCARBOXYLATE TRANSPORTER 1 AND THEIR ASSOCIATION WITH CD44 IN ESOPHAGEAL SQUAMOUS CELL CARCINOMA

K. Horiba[1,*], M. Miyashita[1], T. Seya[1], T. Nomura[2], N. Sakurazawa[1], S. Yokomuro[1], E. Uchida[2]. [1]*Surgery, NIPPON MEDICAL SCHOOL, Chiba,* [2]*Surgery, NIPPON MEDICAL SCHOOL, Tokyo, Japan*

INTRODUCTION: CD147, extracellular matrix metalloproteinase inducer is a glycosylated transmembrane protein that has been identified as a member of the immunoglobulin superfamily, known to induce matrix metalloproteinases. There are evidence for the upregulation of MCTs in tumors, such as colorectal, cervical and lung carcinomas. Recently, it was demonstrated that the prognostic value of CD147 is associated with monocarboxylate transporter 1 (MCT1) co-expression in gastric cancer. It was suggested that constitutive interactions between hyaluronan and CD44 also contribute to regulation of MCT localization and function in breast carcinoma cells.

AIMS&METHODS: The aim of this study was to investigate the relationship between CD147, MCT1, CD44s, CD44v6, MMP9 expression and clinicopathological factors in esophageal squamous cell carcinoma(ESCC). Immunohistochemical analysis of CD147, MCT1, MMP-9, CD44s and CD44v6 was carried out in paraffin-embedded sections of surgically resected 43 cases of ESCC and paired distal normal esophageal tissues. Sections were scored semi-quantitatively for immunoreaction and intensity of staining.

RESULTS: Immunostaining of CD147 and MCT1 was seen in cancer cell surface. Immunostaining of MMP-9 was seen in tumor cell cytoplasm and stromal elements. Overexpression of CD147 was observed in 29 cases (67.4%) of 43 ESCC. MCT1 overexpression was observed in 30 cases (69.7%) of 43 ESCC. In CD147 positive 29 cases, MCT1 positive case was 25 cases (86.2%), MMP-9 positive case was 23 cases (79.3%) and CD44 positive case was 17 cases (58.6%). Significant correlations were observed between CD147/MCT1 co-expression and depth of tumor invasion (T1 33.3%, T2 60.0%, over T3 71.4%), lymph node metastasis (N0 46.1%, N1 63.3%) and disease stage (stage I 37.5%, stage II 41.6%, stage III, IV 73.9%). Immunostaining of CD44 was seen in cancer cell surface and basal cell layer of epithelial cells. Overexpression of CD44 was observed in 24 cases (55.8%) of 43 ESCC. Significant correlations were observed between CD44 overexpression and depth of tumor invasion (T1 41.6%, T2 60.0%, over T3 61.9%), lymph node metastasis (N0 38.4%, N1 63.3%), disease stage (stage I 50.0%, stage II 33.3%, stage III, IV 69.6%) and histological differentiation (well 25.0%, mod. 66.7, por. 100%).

CONCLUSION: In ESCC, co-expression of CD147/MCT1 correlates with expression of MMP-9. The results of this study suggest that CD147 activity is dependent on MCT1 co-expression. Both CD147/MCT1 co-expression and CD44 upregulation correlates with invasive activity and lymph node metastasis. CD44 upregulation correlates with histological differentiation.

P472 LEUKOTRIENE B4 RECEPTOR-1 (BLT-1) AND CYSTEINYL LEUKOTRIENE RECEPTOR-2 (CYSLT-2) ARE DEREGULATED IN BOTH TRANSFORMED AND NON-TRANSFORMED EPITHELIUM OF PATIENTS WITH ESOPHAGEAL SQUAMOUS CELL CARCINOMA

M. Venerito[1,*], C. Helmke[1], D. Küster[2], T. Wex[1], K. Antweilar[3], J. Weigt[1], P. Malfertheiner[1]. [1]*Dept. of Gastroenterology, Hepatology and Infectious Diseases,* [2]*Institute of Pathology,* [3]*Department of Biometrics and Medical Informatics, OTTO-VON-GUERICKE UNIVERSITY, Magdeburg, Germany*

INTRODUCTION: Leukotriene B4 receptors (BLT-1 and BLT-2) and cysteinyl leukotriene receptors (CysLT-1 and CysLT-2) are suggested to contribute to malignant cell transformation and proliferation. The expression of these receptors in esophageal squamous cell carcinoma (ESCC) has not been investigated.
AIMS&METHODS: We aimed to investigate the expression of BLT-1, BLT-2, CysLT-1 and CysLT-2 in ESCC and adjacent non-transformed squamous epithelium of the esophagus (NTSE), as well as in control biopsy samples from esophageal squamous epithelium (CSE) of patients with functional dyspepsia. Nineteen consecutively diagnosed patients with ESCC were prospectively enrolled between March 2010 and January 2011. UICC stage was calculated based on the 7th AJCC/UICC edition. Furthermore, 9 sex- and age-matched patients with functional dyspepsia were included as controls. Expression levels of BLT-1, BLT-2, CysLT-1 and CysLT-2 were analyzed by immunohistochemistry (IHC) and quantitative reverse transcription-polymerase chain reaction (qRT-PCR) in biopsy samples. Spearman correlation, Friedman test, Wilcoxon rang sum test and Mann-Whitney-U-test (2-sided) were used for statistical analysis.
RESULTS: 11/19 (58%) patients with ESCC were at AJCC/UICC stage IV, 8/19 were in stage I to III. BLT-1, BLT-2, CysLT-1 and CysLT-2 were ubiquitously expressed in all biopsy samples. Protein and transcript levels of BLT-1 were significantly increased in both ESCC and NTSE compared to CSE ($p < 0.05$). ESCC showed a significantly increased BLT-2 protein expression compared to NTSE and CSE ($p < 0.05$), whereas BLT-2 transcript levels did not differ among the three groups. The protein expression of CysLT-1 and CysLT-2 was significantly increased in ESCC compared to NTSE and CSE ($p < 0.05$). CysLT-1 mRNA expression was significantly decreased (3.2 fold) in ESCC compared to CSE ($p < 0.05$), but not to NTSE. A significant decrease of CysLT-2 mRNA expression was observed in both ESCC (17 fold) and NTSE (16.1 fold) compared to CSE ($p < 0.05$). Gene expression levels of BLT-1, BLT-2, CysLT-1 and CysLT-2 were not correlated with AJCC/UICC stage.
CONCLUSION: The expression of LT receptors is deregulated in ESCC. Up-regulation of BLT-1 and down-regulation of CysLT-2 gene expression occur already in NTSE of patients with ESCC suggesting a potential role of these receptors in early steps of esophageal carcinogenesis.

P473 IMPACT OF HDAC-1 AND MTA-1 EXPRESSION FOR ESOPHAGEAL CARCINOGENESIS

T. Miyashita[1,*], D. Matsui[1], S. Nakanuma[1], S. Sakai[1], I. Makino[1], H. Hayashi[1], H. Nakagawara[1], H. Tajima[1], H. Takamura[1], H. Kitagawa[1], T. Ohta[1]. [1]*Department of Gastroenterological Surgery, KANAZAWA UNIVERSITY HOSPITAL, Kanazawa, Japan*

INTRODUCTION: Animal models are important in the development of novel therapies for esophageal cancer. While the relationship between reflux and esophageal carcinoma has been explored in a number of studies, the molecular mechanisms underlying esophageal carcinogenesis are still not well understood. HDAC1/MTA1 complexes are known to inhibit p53 acetylation, and thus inhibit p53-induced apoptosis.
AIMS&METHODS: The aim of this study is to investigate the role of HDAC1 and MTA1 expression on esophageal carcinogenesis in rats.
Rats underwent a total gastrectomy followed by esophago-jejunostomy to induce chronic duodenal content reflux esophagitis. The animals were sacrificed sequentially at 20, 30, 40 and 50 weeks post-surgery and esophagi were examined. Immuno-histochemical analysis was used to assess the expression and localization of HDAC1 and MTA1.
RESULTS: At 20 weeks post-surgery, squamous proliferative hyperplasia and Barrett's metaplasia were observed. Adenocarcinoma associated Barrett's metaplasia and squamous cell carcinoma were observed 30-50 weeks post-surgery. Nuclear expression of HDAC1 and MTA1 were seen in all stages of squamous cell carcinogenesis and adenocarcinogenesis, but not in normal esophageal epithelium.
CONCLUSION: The expression of HDAC1 and MTA1 may play a role in duodeno-esophageal reflux induced neoplastic transformation of esophageal mucosa to cancer cells with squamous differentiation and adeno differentiation.

P474 A COMPARATIVE STUDY OF NARROW-BAND IMAGING AND LUGOL IODINE STAINING IN THE DIAGNOSIS OF EARLY ESOPHAGEAL CANCER AND PRECANCEROUS LESION

C. Yin[1,*], L. Yu[1]. [1]*Jiangsu Province Hospital, Nanjing, China*

INTRODUCTION: Esophageal (esophageal cancer, EC) is the eighth most common cancers and the sixth most common cause of death from cancer. Surgical resection is the treatment of early esophageal cancer, and esophageal cancers carry a high mortality mainly due to its late diagnosis, with a five-year survival of less than 10%.More than 70% of diagnosis are made in patients presenting with dysphagia and weight loss, clinical findings frequently observed in patients in at least stage II.
AIMS&METHODS: Objective: To observe the esophageal through the narrow-band imaging techniques (NBI) and Lugol iodine staining, and then compare the efficacies of two methods in the diagnosis of early esophageal cancer and precancerous lesion.
Method: 103 patients were enrolled from January 2010 to January 2013. Conventional endoscopic white light imaging (WLI) with NBI and Lugol iodine staining were consecutively performed, and the discovered lesions were confirmed by pathologic diagnosis as the gold standard, NBI and iodine staining scale was compared with pathologic diagnosis. Then compared the value of WLI, NBI and Lugol iodine staining.
RESULTS: (1) 125 lesions were found in 103 patients. 96 lesions were detected with WLI, 120 lesions were detected with NBI endoscopy, 125 lesions were detected with iodine staining. There was no significant difference between NBI and iodine staining in detecting rate ($p > 0.05$). The detection rate of WLI was lower than NBI and iodine staining.($p < 0.01, p < 0.01$).
(2)The sensitivity for severe dysplasia and early esophageal of NBI and iodine staining was 100%, 100% ($p > 0.05$), which were higher than WLI ($p < 0.05$). There was no significant difference in detecting mild and moderate dysplasia between NBI and iodine staining (94.20% vs 100%, $p > 0.05$); which were higher than WLI (73.91%, $p < 0.01, p < 0.01$).
(3) The NBI classification for Severe dysplasia and early esophageal cancer was,I,90% (36/40);II and III, 10%(4/40); for mild and moderate dysplasia,I, 2.90%(2/69); II andIII, 94.20% (65/69); The iodine staining grading for Severe dysplasia and early esophageal cancer was,I, 95%(38/40);II and III, 5%(2/40); for mild and moderate dysplasia,I, 5.80%(4/69); II and III, 94.20%(65/69).
CONCLUSION: NBI appears as effective as Lugol iodine staining to detect early esophageal cancer and precancerous lesions. Although NBI is more technically easy to perform, less time-consuming, and Lugol iodine staining is cheaper, especially for the screening for early esophageal cancer and precancerous lesions in the undeveloped areas. Therefore, these two methods can't replace each other, and still be ideal complementary diagnostic tool.

P475 H.PYLORI INFECTION IN PATIENTS WITH ESOPHAGEAL SQUAMOUS CELL CARCINOMA

A. C. Dülger[1,*], E. Aytemiz[1], M. Beyazal[2], B. Gültepe[3], E. Gönültaş[1]. [1]*Gastroenterology,* [2]*Radiology,* [3]*Microbiology, Yuzuncuyil University School of Medicine, Van, Turkey*

INTRODUCTION: H.Pylori is a gram negative, spiral shaped, multiple unipolar flagellated and urease producing bacteria. Esophageal squamous cell carcinoma (ESCC) is one of the most agressive digestive system tumour in rural areas of Asia. A clear association has been showed between Helicobacter pylori infection and gastric cancer (1,2). However, there are conflicting reports the relationship between ESCC and *H.pylori* (3). The aim of this study examined the prevalence of *H.pylori* in patients with esophageal squamous cell carcinoma.
AIMS&METHODS: 65 ESCC patients (43 women, aged 32-92 years) were evaluated in our clinic from April 2010 to April 2013. All of the patients were diagnosed by esophagogastroscopy and histopathological examination. 26 of them had esophagectomy. Esophagogastroscopy with antral biopsy was performed for each patient. Gastric biopsy samples are tested for urease activity by using a commercial hp fast test, which has an urea containing medium and a pH reagent. The control group comprised 100 dyspeptic subjects (60 women and 40 men, aged 30-85 years) Antrum biopsies with normal endoscopic evaluation were examined for *H.pylori* by the same method. Comparisions between two groups were performed by the Mann- Whitney U-test.
RESULTS: The mean age was 45.96 ±1.61 in control (dyspeptic) group and was 59.43±1.90 in ESCC group. *H.pylori* infection was observed in 49 of 65 (75.3%) ESCC patients. In dyspeptic group, *H.pylori* infection was found in 53 of 100 (53%) patients. We found significantly higher infection with *H.pylori* in patients with ESCC compared to the dyspeptic population (p=0.002).

CONCLUSION: These results suggested that *H.pylori* infection could be an ethiological factor in patients with ESCC.

P476 USEFULNESS OF ORAL PREDNISOLONE IN THE TREATMENT OF ESOPHAGEAL STRICTURE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA.

A. Ishiyama[1,*], M. Okuno[1], A. Tomita[1], H. Osumi[1], K. Morishige[1], N. Yoshizawa[1], Y. Horiuchi[1], H. Ishikawa[1], M. Omae[1], T. Hirasawa[1], Y. Yamamoto[1], T. Tsuchida[1], J. Fujisaki[1], K. Chin[1], M. Igarashi[1], S. Mine[2], K. Yamada[2], N. Yamamoto[3]. [1]*Gastroenterology,* [2]*Surgery,* [3]*Pathology, CANCER INSTITUTE HOSPITAL, Tokyo, Japan*

INTRODUCTION: Endoscopic subumucosal dissection (ESD) permits en bloc removal of superficial esophageal squamous cell carcinoma. A circumferential mucosal defect involving over three fourths the circumference of the esophagus after ESD was significantly associated with the subsequent development of esophageal stenosis. So, it is necessary to prevent postprocedure stricture after ESD. We analyzed that frequent endoscopic balloon dilation (EBD) was required in the treatment of the stenosis after semicircular ESD, treated with pre-emptive EBD. The number of EBD required was 5.3(4-8) in the pre-emptive group. 50% of them had complications, perforation and deep laceration of the muscular layer, related to EBD itself.

AIMS&METHODS: To evaluate the effectiveness of oral prednisolone in controlling postprocedure esophageal stricture. Design: Retrospective study. Setting: Endoscopy department in our hospital. 22 superficial esophageal lesions in 21 patients who underwent semicircular ESD for esophageal squamous cell carcinoma involving over three fourths defect of the lumen from November 2011 to January 2013 were retrospectively studied. Intervention: Pre-emptive EBD was not started until stenosis occurs. Esophageal stenosis was defined when a standard endoscope (9.8mm in diameter) failed to pass through the stenosis. Oral prednisolone was started at 30 mg/day on the first day post-ESD. The prednisolone gradually tapered off and then was canceled eight weeks. The quantity of drug and schedules referred to an existing report.

RESULTS: 8 of 22 lesions (38.4%) was occurred stricture. The number of EBD required was 3.6(0-16) on these lesions. The number of EBD sessions tended to be greater (5.3 v.s.3.6) in the pre-emptive EBD group than in the oral prednisolone group (Table2). The risk factor of stricture was ''cervical esophagus'', ''chemoradiotherapy or systemic chemotherapy history''. There was one perforation related to EBD itself in 21 patients. And an attempted suicide occurred, could not deny related to oral prednisolone.

CONCLUSION: Oral prednisolone may therefore potentially reduce the overall cost and complications associated with mechanical luminal dilation and may offer a useful preventive option for post-ESD esophageal stricture.

P477 THE VALUE OF AIR INSUFFLATION CT ON DIAGNOSIS OF ESOPHAGEAL SUBMUCOSAL TUMORS

B. Liu[1,*]. [1]*THE SECOND HOSPITAL OF HARBIN MEDICAL UNIVERSITY, Harbin, China*

INTRODUCTION: with the advantage of both endoscopy and ultrasound, EUS has emerged as a reliable detection method for evaluating these lesions under both direct vision and satisfactory ultrasonic field .

However, the limitations of EUS include not only poor observation of the anatomic features of the adjacent structures but also the demand of special instruments and experienced endoscopists.

Esophageal lumen is closed during conventional CT scan and it is difficult to distinguish SMTs clearly from esophageal wall and surrounding tissue.

So the application of conventional CT in detecting esophageal SMTs was limitad. Because SMTs could be showed more clearly in air insufflated esophageal lumen during gastroscopy, this study was conducted to determin the value and effective of air insufflation CT on diagnosis of esophageal SMTs.

AIMS&METHODS: To determine the value and sensitivity of air insufflation computed tomography (CT) on diagnosis of esophageal submucosal tumors (SMTs).

Conventional CT and air insufflation CT were performed on 40 patients who had been confirmed esophageal SMTs by gastroscopy and endoscopic ultrasonography (EUS).

Air insufflation CT procedure:

1) patient fasted for 4-6 h;

2) inserting a nasogatric tube into esophageal lumen 30 cm from the incisors;

3) connecting a air bag to nasogatric tube and insufflating air continually by pressuring the air bag;

4) performing chest CT scan after 5 seconds with patient's mouth closed.

RESULTS: he sensitivity for detecting esophageal SMTs of conventional CT was 57.5% (23/40) compared with that of air insufflation CT (90.0%, 36/40), the difference was of statistical significance (X^2=15.21, $P<0.05$). Furthermore, lesions were showed more clearly by air insufflation CT.

Compared lesion size on air insufflation CT with that after resection, 9 cases revealed measurement error more than 30%, but EUS finding matched excisional specimen in 4/9 cases; compared lesion size on EUS with that after resection, 8 cases revealed measurement error more than 30%, but air insufflation CT finding matched excisional specimen in 3/8 cases.

CONCLUSION: Air insufflation CT is more effective and significant than conventional CT on diagnosis of esophageal SMTs. Combined with EUS, air insufflation CT has added value in evaluating the origin of esophageal SMTs and the anatomic features of adjacent structures which benefit to predict the risk of endoscopic treatment and surgery.

P478 TYPE OF LUGOL-VOIDING LESIONS IS AN IMPORTANT CLINICAL PREDICTOR FOR RECURRENT SYNCHRONOUS/METACHRONOUS NEOPLASM AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR PRIMARY ESOPHAGEAL SQUAMOUS CELL CARCINOMA

C.-T. Lee[1,*], T.-H. Chiang[2], W.-L. Wang[1], J.-T. Lin[3]. [1]*Department of Internal Medicine, E-Da Hospital and I-Shou University, Kaohsiung,* [2]*Department of Internal Medicine, College of Medicine, National Taiwan University, Taipei,* [3]*School of Medicine, Fu Jen Catholic University, New Taipei City, Taiwan, Province of China*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is an advanced endoscopic procedure to resect early esophageal neoplasm; however, new synchronous/metachronous neoplasm may occur in the preserved esophageal mucosa.

AIMS&METHODS: This study assessed the risk of developing recurrent synchronous/metachronous esophageal neoplasm in patients receiving ESD for primary esophageal squamous cell carcinoma based on multiplicity of Lugol-voiding lesions (LVLs) observed by chromoendoscopy and patient characteristics. Fifty-three patients with early esophageal squamous cell carcinoma who underwent curative ESD were recruited. We collected individual factors, including the demographic characteristics, social habits, *co-morbidity*, and initial tumor characters to identify risk factors associated with the development of recurrent synchronous/metachronous esophageal neoplasm using the Cox proportional hazards regression models. According to previous study by M Muto, et al., Iodine staining pattern of background mucosa at initial ESD were divided into 4 groups as follows : Group A, no LVLs; B, several ($\leqq$10) small LVLs; C, many ($>$10) small LVLs; and D, many ($>$10) irregular-shaped multiform LVLs. We defined group A and B as low-risk group (type 1) while group C and D as high-risk group (type 2). Patients were followed by endoscopy with narrow-band imaging and iodine staining.

RESULTS: A total of 53 patients (mean age $\pm$ standard deviation: 51.7 $\pm$ 9.4 years) were followed up (mean follow-up interval: 88.9 $\pm$ 53.6 weeks). There were 15 (28.3%) patients having recurrent esophageal neoplasm during follow-up. Univariate analyses showed that the presence of type 2 background mucosa and multi-focal neoplastic lesions at initial ESD were potential risk factors, and regression analyses confirmed that only type 2 Iodine staining pattern (hazard ratio: 9.10, 95% CI: 1.17-70.49, p=0.035) was significantly associated with recurrent esophageal neoplasm.

CONCLUSION: The presence of numerous, irregular-shaped, multiform Lugol-voiding lesions is an important clinical predictor for recurrent synchronous/metachronous esophageal neoplasm after ESD for primary esophageal squamous cell carcinoma. Long-term, intensive endoscopic surveillance is required and further possible chemo-prevention seems to be warranted for these patients.

P479 MICROVASCULAR CALIBER CHANGES IN INTRAMUCOSAL AND SUBMUCOSALLY INVASIVE ESOPHAGEAL CANCER

E. G. Santi[1,2,*], H. Inoue[3], H. Ikeda[3], A. Yoshida[3], M. Onimaru[1], H. Sato[3], R. Maselli[1], S.-E. Kudo[3]. [1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama, Japan,* [2]*Department of Internal Medicine, De La Salle University Health Sciences Institute, Dasmarinas, Philippines,* [3]*Showa University Northern Yokohama Hospital, Yokohama, Japan*

INTRODUCTION: Intrapapillary capillary loops (IPCLs) show distinct pattern changes which correlate with tumor progression and depth of invasion important for the in-vivo characterization of superficial squamous cell carcinoma (SCCA).
AIMS&METHODS: We aim to correlate histopathologic diameter of IPCLs in resected SCCA and invasion depth. Methods: We conducted a prospective study to evaluate the diameter of abnormal IPCL using light microscopy and immunohistochemical staining in superficial SCCA resected by endoscopic submucosal dissection (ESD). Prior to resection, IPCL patterns were identified by magnification endoscopy (ME) with NBI. Twenty tissue samples (IPCL-V1,10; IPCL-VN,10) from patients who underwent ESD for superficial SCCA with IPCL-V1 and IPCL-VN (IPCL-I,103; IPCL-V1,113; IPCL-VN,100) were examined. Samples were stained with haematoxylin and eosin, CD34 and Desmin. Measurement of vessel diameter at light microscopy was averaged over 10 high-power fields at x200 magnification.
RESULTS: Histopathologic caliber of IPCL-V1, which corresponds to tumor limited to the mucosa (T1a-EP), was significantly dilated compared with caliber in the normal esophageal mucosa (IPCL-I (7.7+2.8um vs. 21.9+7.4um, $p<0.001$); whereas, caliber of IPCL-VN corresponding to tumors invading into the submucosa (T1b) were significantly larger than the caliber of T1a-EP lesions (21.9+7.4um vs. 65.2+22.9um, $p<0.001$).
CONCLUSION: Caliber of surface vessels in SCCA gradually increases according to depth of invasion. These changes in IPCL can be observed with ME, allowing in vivo discrimination between intramucosal from submucosally-invasive cancer allowing the endoscopist to make real-time assessment of tumor depth and aids in the decision whether a patient should undergo surgery or a less invasive treatment such as EMR/ESD.

P480 CLINICAL IMPACT OF SURVEILLANCE AND EARLY INTERVENTION FOR HEAD AND NECK SQUAMOUS CELL CARCINOMA IN PATIENTS WITH ESOPHAGEAL SQUAMOUS CELL CARCINOMA

H. Morimoto[1,*], T. Yano[1], Y. Yoda[1], A. Yagishita[1], T. Odagaki[1], Y. Oono[1], H. Ikematsu[1], K. Kaneko[1]. [1]*Endoscopy division, National Cancer Center Hospital East, Kashiwa, Japan, Chiba, Japan*

INTRODUCTION: Narrow-band Imaging (NBI) is effective in detecting synchronously and metachronously superficial head and neck squamous cell carcinoma (HNSCC) in patients with esophageal squamous cell carcinoma (ESCC), and most of these lesions can be treated endoscopically. However, it has not been clarified whether early detection and intervention for early HNSCC in ESCC patients decrease serious events related to presence of metachronous HNSCC or not.
AIMS&METHODS: Since the beginning of 2006, we have introduced the intensive surveillance for HN region using NBI for all ESCC patients before treatment, and during follow-up evaluation. The patients criteria was as follows: (1) newly diagnosed ESCC received definitive treatments (endoscopic resection (ER), surgery or chemoradiotherapy); (2) clinical stage I to III; (3) no history of any HNSCC; (4) absence of synchronously advanced cancer; (5) followed-up period over 6 months after treatment for ESCC. The patients were classified into two groups, such as Group A before the intervention of NBI surveillance between October 1992 and December 2000, and Group B after the intervention of that between January 2006 and December 2008. In these two groups, we examined the detection rate of superficial HNSCC, and the serious events related to metachronous HNSCC, which was frequency of loss of laryngopharyngeal function and death due to HNSCC during the follow-up periods.
RESULTS: A total of 698 patients (median age 65) consisting of 328 in Group A and 370 in Group B were recruited from our database. Synchronously superficial HNSCCs were found in only 1 patient (0.3%) in Group A, while those were found in 14 (3.8%) in Group B ($p=0.001$).
Of these 698 patients, 254 in group A and 307 in group B were followed up over 1 year. Metachronous HNSCCs were detected more frequently in group B (26 patients of 307; 8.5%) than in group A (9 of 254; 3.5%, $p=0.02$). Although all of the HNSCC lesions in group B were detected as early cancers with 38 lesions (81%) treated by ER, 60% of the lesions in group A were detected in advanced stage (III/IV) ($p<0.001$). Laryngopharyngeal dysfunction and death due to metachronous HNSCC were more frequent in Group A than in group B (1.6% v 0%, $p=0.048$; 2.0% v 0%, $p=0.018$). There was no serious problem related to ER for superficial HNSCC.
CONCLUSION: After the intervention of surveillance for HN region using NBI endoscopy, detection rate of early HNSCC was increased in ESCC patients. For early treatment, occurrence of metachronously advanced HNSCC and serious events related to metachronous HNSCC were decreased.

P481 HISTOLOGIC EVALUATION OF RESECTION SPECIMENS IN PATIENTS WITH ESOPHAGEAL NEOPLASIA: TYPE OF LESION DOES NOT PREDICT HISTOLOGY AND STAGING

M. Stefanova[1,*], J. Maluskova[2], J. Spicak[3], M. Kollar[2], J. Krajciova[3], J. Martinek[3]. [1] *Internal Medcine, Hospital Na Frantisku,* [2]*Dept. of Pathology,* [3]*Dept of Hepatogastroenterology, IKEM, Prague, Czech Republic*

INTRODUCTION: It remains controversial whether the macroscopic classification of the esophageal lesions (in contrast to early gastric cancer) according to the Japanese criteria has a prognostic value with regard to endoscopic therapy. The aim of this prospective, single-center study was to evaluate the clinical role of this macroscopic classification in patients with early esophageal neoplasia.
AIMS&METHODS: A total of 69 patients with 78 suspect esophageal lesions who were referred between January 2009 and April 2013 for endoscopic therapy were prospectively included in the study. A trimodal endoscopy with targeted biopsies prior to endoscopic resection/dissection included assessment of the macroscopic type according to the Japanese classification. Histology (both from biopsy specimen and resection specimen) was correlated with macroscopic assessment.
RESULTS: The overall distribution of the lesions by gross type was as follows: type Is, n = 6 (8%); type IIa, n = 34 (44%); type IIb, n = 29 (37%); type IIc, n = 4 (5%); type IIa+b, n = 3 (4%); type IIa+c, n = 2 (2%). Histology revealed no neoplasia in 8 lesions, low grade intraepithelial neoplasia (LGIN) in 18 lesions, high grade intraepithelial neoplasia (HGIN) in 13 lesions, early adenocarcinoma (EAC) in 35 lesions and early squamous carcinoma (ESC) in 4 lesions. The distribution of different macroscopic types was as follows: LGIN – Is 0%, IIa 22%, IIb 72%, IIc 0%, IIa + b 6%; HGIN- Is 15%, IIa 31%, IIb 38%, IIc 8%, IIa + c 8%; EAC + ESC – Is 8%, IIa 56%, IIb 23%, IIc 5%, IIa + b 5%, IIa + c 3%. Macroscopic type did not predict advanced cancers (G2 or 3, n=8) and penetration to the submucosa (n=9).

Histology of ER/ESD specimens (compared with prior forceps biopsy) led to a change in diagnosis in 43% of the focal lesions and a relevant change in the management in 26% of patients.
CONCLUSION: Most endoscopically resected early esophageal neoplasia are 0-IIa and 0-IIb types. Macroscopic type does not reliably predict histology, grading and penetration depth. Targeted biopsies of focal lesions are not accurate enough for precise diagnosis.

P482 USEFULNESS OF NEEDLE KNIFE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION IN SUPERFICIAL ESOPHAGEAL NEOPLASMS

M. Nishimura[1,*], H. Kita[2]. [1]*gastroenterology, SAITAMA MEDICAL UNIVERSITY, Hidaka-shi,* [2]*gastroenterology, Teikyo, University, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is commonly performed for large superficial GI tract lesions. Many kinds of device are used for ESD: the IT-knife, Hook knife, and Flush knife, however, the needle knife has been considered to cause a high rate of complications in ESD for esophageal lesions because of its shape. On the other hand, endoscopic mucosal resection with a cap (EMR-C) has been applied for superficial esophageal lesions since the 1980's. Only a few reports have compared EMR-C and ESD using a needle knife; therefore, in this study, we compared these two methods for esophageal lesions.
AIMS&METHODS: To compare the efficacy, usefulness, and complications between conventional EMR-C and ESD using a needle knife for superficial esophageal neoplasms. (Methods) Between 2001 and 2010, patients with superficial esophageal neoplasms were treated by EMR-C or ESD using a needle knife. For the EMR-C, using a cap to the top of the endoscope, the targeted lesion was resected with conventional EMR method. For the ESD method, attachment was used and, after the injection of sodium hyaluronate under the submucosal layer, using the needle knife, ESD was performed.
RESULTS: From the database, we collected a total of 87 patients who underwent esophageal treatment endoscopically. Complete resection was achieved in all 87 patients. Twenty-one patients were treated by EMR-C (19 males/ 2 females, mean age: 66.0), and 66 patients were treated by ESD using a needle knife (62 males/ 4 females, mean age: 67.5). The mean resected specimen size was 21.4 mm in the EMR-C group and 30.6 mm in the ESD group. The en-bloc resection rate was 61.9% in the EMR-C group and 98.5% in the ESD group. The negative horizontal margin rate was 85.7% in the EMR-C group and 90.9% in the ESD group. The negative vertical margin rate was 95.2% in the EMR-C group and 90.9% in the ESD group. There was no complication in the EMR-C group but 9 cases of complication in the ESD group (4 cases of stenosis, 3 cases of mediastinal emphysema, and 1 case of perforation). During the observation period, 2 patients, died of pneumonia and 1 died from acute myocardial infarction in the EMR-C group, and 1 patient died from pancreatic cancer and 1 died from liver cirrhosis in the ESD group.
CONCLUSION: ESD using the needle knife for esophageal neoplasms facilitated resection and achieved a larger resection than EMR-C. There are some problems regarding complications; however, ESD using the needle knife has a marked advantage for desirable en-bloc resection of esophageal neoplasms. Further investigations to evaluate the various other devices are needed.

P483 PLACEMENT OF BILIARY METAL STENTS FOR UPPER ESOPHAGEAL STRICTURES

M. Bechtler[1,*], E.-S. Fuchs[1], R. Jakobs[1]. [1]*Medizinische Klinik C, Klinikum Ludwigshafen, Ludwigshafen, Germany*

INTRODUCTION: The treatment of strictures of the cervical esophagus remains a challenge. Endoscopic dilation is the standard of care, but refractory or tumoral stenoses require some form of stenting. Placement of self-expanding metal stents (SEMS) has been considered impractical for cervical strictures. Metal stents placed near the upper esophageal sphincter cause problems like severe cervical pain, globus sensation, bleeding or compression of the trachea. Expansive force and diameter of regular esophageal stents are difficult to tolerate in the cricopharyngeal region. We report our results with the use of biliary SEMS in the upper esophagus, which have a smaller diameter and less expansive force.
AIMS&METHODS: We retrospectively reviewed all patients in our center between July 2011 and August 2012 who received a biliary metal stent because of a refractory stenosis in the cervical esophagus. All patients were informed about off-label-use and alternative treatments. We implanted covered biliary SEMS (Wallflex, Boston scientific) with a diameter of 1cm and length of 6-8cm. Technical and clinical success and duration of stenting were evaluated retrospectively using the clinical records. Results are presented as summary statistics.
RESULTS: Seven patients were treated with biliary SEMS in the upper esophagus. Strictures were located between 10 and 19cm from incisor teeth. We treated 2 patients with benign and 5 with malignant stenoses. Stent placement was successful in all (7/7) patients. One patient with the most proximal stricture was unable to tolerate the stent because of pain and globus sensation. This stent had to be extracted on the same day. All other patients (6/6) had good clinical success and were able to take up liquid and in some cases even solid food. We had no major complications and stent tolerability was good. . In one patient with a refractory postradiogenic stricture the stent was changed every three months on a regular basis. In patients with malignant strictures the stent was left in place as long as clinically successful. Median duration of stenting was 66 days.
CONCLUSION: In our series we report good clinical success with immediate improvement of dysphagia and no major complications. These results were received in complicated strictures refractory to other treatments. Stent tolerability, which has been a major concern in this situation, was good in 86% of patients. This compares favourably to other series using regular esophageal stents, where up to 45% of patients complain of chest and neck pain.

P485 CLINICOPATHOLOGICAL STUDIES OF ESOPHAGEAL CARCINOMA IN ACHALASIA: ANALYSIS OF ITS CANCERATION AND RISK FOLLOWING SURGICALLY TREATED ACHALASIA

O. Chino[1,*], A. Kazuno[2], E. Ito[2], T. Hayashi[2], K. Kamachi[2], A. Takechi[1], Y. Tanaka[1], T. Nakamura[1], H. Shimada[3], S. Ozawa[2], Y. Kondo[1], H. Makuuchi[1]. [1]*Surgery, Tokai University School of Medicine, Tokyo Hospital, Shibuya-ku,* [2]*Surgery, Tokai University School of medicine, Isehara,* [3]*Surgery, Tokai University School of Medicine, Oiso Hospital, Oiso, Japan*

INTRODUCTION: Achalasia of the esophagus is a benign disease, and an esophageal motor disorder characterized by insufficient relaxation of the lower esophageal sphincter. Esophageal carcinoma is the most serious late complication of achalasia clinically. Chronic inflammatory irritation by retained food may induce carcinogenesis of the esophageal squamous epithelium. However, the detailed mechanism of carcinogenesis in achalasia patients has not been clarified histopathologically.
AIMS&METHODS: We analyzed nineteen cases of achalasia-associated carcinoma of the esophagus clinicopathologically. We examined nine cases of achalasia-associated squamous cell carcinoma, surgically or endoscopically resected, using histological and immunohistochemical procedures. The invasive parts of each carcinoma, in situ carcinoma, dysplasia as well as hyperplasia were examined for histological mapping, and with immunohistochemical expression for p53 protein.
RESULTS: The patients ranged in age from 46 to 76 years, with a mean age of 61 years. The mean interval between the diagnosis of achalasia and carcinoma was 22.3 years. Nine of the nineteen cases were superficial cancers, and the other ten cases were advanced cancers. Radiographically, nine cases were sigmoid type, the other ten cases were flask type and none were spindle type. Six cases were grade III, the other thirteen cases were grade II and none were grade I. Endoscopically, eight carcinomas were protruding type, and the others were superficial depressed type and ulcerative type. Eighteen cases were composed of squamous cell carcinoma and the other one was basaloid-squamous carcinoma. Histological mapping of the resected specimens demonstrated marked hyperplastic changes of stratified squamous epithelium and multiple foci of dysplastic changes. The squamous cell carcinomas showed well to moderately differentiated type with low-grade atypia, closely associated with dysplastic foci. Immunohistochemical overexpression of p53 was detected in the invasive parts of the carcinoma, in situ carcinoma, and dysplasia.
CONCLUSION: Chronic inflammatory irritation by retained food may induce chronic hyperplastic esophagitis and eventually malignant transformation of esophageal epithelial cells, associated with dysplasia-carcinoma sequence. Achalasia seems to be a risk factor for developing squamous cell carcinoma of the esophagus, even if after surgically treated. Long-term follow-up for patients with achalasia by endoscopic screening with iodine staining is recommended.

P486 PALLIATIVE OESOPHAGEAL STENTING- THE EXPERIENCE OF A DISTRICT GENERAL HOPSITAL

S. Beg[1,*], M. Kasi[2], J. Deacon[1], I. Sargeant[1], D. L. Morris[1]. [1]*Gastroenetrology, North East Hertfordshire NHS trust, Hertfordshire,* [2]*Gastroenetrology, NHS, North East Hertfordshire, United Kingdom*

INTRODUCTION: Oesophageal cancer is often diagnosed late in it pathological process, resulting in limited options for curative treatment. As a consequence management is usually targeted at symptom control, with palliative oesophageal stenting an important procedure allowing for improved nutrition, hydration and comfort. This cohort of patients is usually elderly, with comorbidities and so striking the balance between symptom control and the risk of complications can be difficult. The aim of this study was to evaluate the use of oesophageal stenting in the setting of a large district general hospital.
AIMS&METHODS: We retrospectively reviewed all patients who underwent palliative oesophageal stenting between June 2010 and July 2012 across the North East Hertfordshire NHS trust. These cases were reviewed with respect to patient demographics, techniques employed, mortality at days seven, fourteen and thirty as well as complications with in the three months post procedure.
RESULTS: During this two year period 40 patients underwent palliative oesophageal stenting. There was a male preponderance, with the average age of 74 years old. The majority of tumours were adenocarcinomas, with squamous cell carcinomas accounting for approxiamately third of cases.
All procedures were carried out under fluoroscopic guidance, with successful deployment of covered metal stents (Boston Ultra-flex). A single endoscopist carried out 24 of the 40 procedures; however the remaining stents were performed by four different endoscopists, with the mean number of stents per consultant being four per year.

Short term mortality was 5% at day 7, 7.5% at day 14 and 15% at day 30, with the cause of deterioration due to background medical problems rather than as a direct consequence of this intervention.
The most common reason for failure of success of stent placement within 3 months was tumour infiltration, affecting 10% of patients in this time period. There were complications in a minority of patients, with food bolus obstruction in 5%, stent migration in 2.5%, and no cases of perforation and haemorrhage.
CONCLUSION: Our data has demonstrated that oesophageal stenting remains a safe option for symptom control in palliative oesophageal cancer. Mortality and morbidity rates are below that of the national average as described in the national oesophago-gastric cancer audit, this is likely to represent better patient selection and increased use of alternative palliative procedures such a laser therapy and dilatation. Complication rates are low despite the small numbers carried out per endoscopist, making the district general hospital a suitable environment to carry out such interventions.

P487 THE SALVAGE ENDOSCOPIC TREATMENT(SET) FOR THE THE SUPERFICIAL HEAD & NECK SQUAMOUS CELL CARCINOMA (SHESCC) FOUND IN THE RADIOTHERAPY FIELD

T. Omori[1,*], H. Kawakubo[2], R. Nakamura[1], H. Takeuchi[2], T. Takahashi[2], N. Wada[2], Y. Saikawa[2], Y. Kitagawa[2], A. Yokoyama[3], K. Koyanagi[4]. [1]*Center for Diagnostic and Therapeutic Endoscopy,* [2]*Surgery, Keio University, Tokyo,* [3]*Internal Medicine, NHO Kurihama Medical and Addiction Center, Yokosuka,* [4]*Surgery, Kawasaki Municipal Kawasaki Hospital, Kawasaki, Japan*

INTRODUCTION: The most of the squamous cell carcinoma in the head & neck region(HNSCC) is usually found at advanced stage. Surgical treatment is invasive and is greatly undermined the postoperative QOL. So the chemo-radiation therapy(CRT) has been globally accepted for the first treatment. The HNSCC has tendency for metachronous cancer, and some HNSCC had CRT resistance. So we often find the second cancer in the radiotherapy field. For such a patient, total laryngectomy is only the last treatment.If the second cancer is limited in local area, minimally invasive treatment should be a desirable. It has been known that some of the recurrent superficial esophageal cancer after CRT can be cured by endoscopic treatment (ET). So the second superficial-HNSCC(SHNSCC) without metastasis may be cured by endoscopic treatment, and it must be a very good for patients.
AIMS&METHODS: The purpose of this study is to assess the effectiveness of the SET for the second SHNSCC found in the radiotherapy field.The SHNSCC is defined as a carcinoma that the depth of invasion is within the sub-epithelial layer. From Jan 2000 to Feb 2013, we have 314patients (570lesions) of the SHNSCC. Of the 314patients, 253patients (475lesions) had been treated by ET. Of the 253cases, 22 patients were the SET cases. The indication of the SET is that the second HNSCC was superficial type and had no metastasis. For those SET cases, we investigated their clinical and pathological data.
RESULTS: Among 22patients,20 were men and 2 were women, mean age at first treatment was 68.9 years (range 57-84).10 have received CRT/RT for esophageal cancer, and 12 have received CRT/RT for HNSCC. Average dose of RT was 59.9Gy. 5Fu+CDDP had been given to 9patients and TAT had been given to 3patients as a chemotherapy.We could performed Endoscopic Laryngo-Pharyngeal Surgery(ELPS)safely and succeeded in complete en-bloc resection in all cases. We had 2 cases of postoperative bleeding, 2 of postoperative laryngeal edema and 1 of postoperative stenosis, but there were no fatal complications. After the ELPS, swallowing and vocal function was completely preserved in all cases, and QOL of patients was very good. Among the 22patients, 15(68.2%) are alive, 7(31.8%) died (2 for HNSCC, 5 for other disease).
CONCLUSION: The result of our trail indicated the usefulness and effectiveness of the SET for the second SHNSCC found in the radiotherapy field. For this purpose, gastrointestinal endoscopist should also focus on the SHNSCC detection

P488 DIAGNOSIS AND TREATMENT FOR EARLY PRIMARY MALIGNANT MELANOMA OF THE ESOPHAGUS (PMME)

T. Omori[1], H. Kawakubo[2], R. Nakamura[1], H. Takeuchi[2], T. Takahashi[2], N. Wada[2], Y. Saikawa[2], T. Matsuda[2,*], Y. Kitagawa[2]. [1]*Center for Diagnostic and Therapeutic Endoscopy,* [2]*Surgery, Keio University, Tokyo, Japan*

INTRODUCTION: Primary malignant melanoma of the esophagus (PMME) is a rare disease. Treatment for advanced PMME is basically esophagectomyor CRT, but treatment effect is very poor and it's prognosis is extremely poor. It is well-known fact endoscopic resection (ER; ESD/EMR) is the first treatment of the early GI tract cancer, and can cure the early cancer. Early PMME is more rare than advanced PMME and is very difficult to find because we do not know collect endoscopic findings. But there is a possibility early PMME has no metastasis just same as early cancer in theGI tract. With this fact and speculation, if we find the early PMME, ER
may also be effective for early PMME instead of operation.
AIMS&METHODS: The purpose of this study is to examine the effectiveness of the ER for the early PMME. From Jan 2000 to Feb 2013, we experienced 3 cases of early PMME. For those 3 cases, we investigated their clinical and pathological data.
RESULTS: 1 case was a 57y.o female, 2 cases were 65 and 57y.o male. There ware no symptoms in all cases, and all cases were found by screening endoscopy. Lesions were located in all part of esophagus. The size of lesion was 3-25mm, the shape was flat(0-IIb). The color of pigmented spots was a very clear black and the spots was composed of large and small size. The demarcation line was irregular, ill-defined and faded in color. Case1:A 65y.o men with 1 lesion. He was treated by total esophagectomy with LN dissection. Pathological diagnosis revealed the lesion was PMME and the depth of invasion was T1a-LPM and no lymphatic-vascular invasion, no LN metastasis. He died of pneumonia in five years after surgery, but there wasno recurrence of cancer.Case2:A 57y.o female with 4 lesions. After the CT examination showing no metastasis, ER was performed, as the patient chose ER rather than operation that was the standard therapy we suggested. Pathological diagnosis revealed the lesions ware PMME and the depth of invasion were T1a-LPM and no lymphatic and vascular invasion. We followed up every 6months by endoscopy, and went through 6 ERs in total for new early PMMEs during the follow-up period. 6.5 years has passed since the first treatment, the patient is still alive and free from disease.Case3:A 57-year old male with 2 lesions. After the informed consent that ER was an option to operation, 2 lesions were removed by ER. The pathological diagnosis revealed the lesions were PMME and the depth of invasion were T1a-LPM and no lymphatic and vascular invasion.
CONCLUSION: Our 3 cases indicate the possibility to cure early PMME by ER, and ER can be an adequate optional treatment for early PMME.

P489 A REQUIREMENT OF PROPHYLACTIC TREATMENT AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA (ESCC).

T. Tsuchida[1,*], A. Ishiyama[1], K. Morishige[1], N. Yoshizawa[1], Y. Horiuchi[1], H. Ishikawa[1], M. Omae[1], T. Hirasawa[1], Y. Yamamoto[1], J. Fujisaki[1]. [1]*Gastroenterology, CANCER INSTITUTE HOSPITAL, Tokyo, Japan*

INTRODUCTION: Since the ESD for superficial ESCC can now resect the lesions collectively, it has become possible to more detailed pathological evaluation. There is a lymph node metastasis of 10-20% in T1a-MM and T1b-SM1 ESCC, there is a approximately 40% in T1b-SM2 ESCC. When pathological examination of the ESD specimen confirms T1a-MM or T1b ESCC, it is necessary to provide the prophylactic treatment, chemoradiotherapy (CRT) or surgical resection. However, some patients are over-treated by the prophylactic treatment because it is not so high rate of metastasis for T1a-MM and T1b-SM1 ESCC.
AIMS&METHODS: The aim of this study is to inspect a requirement of the prophylactic treatment and a pathological risk factor of metastasis of T1a-MM and T1b ESCC. In the cases of pathological T1a-MM or T1b ESCC undergoing ESD in our hospital, I examined the relations with metastasis of vascular invasion and Droplet infiltration (DI), and more, I examined the presence or absence of the prophylactic treatment and the outcome of the cases. The DI, the infiltrative growth pattern that the nest of cancer infiltrates, is thought that it is one of the risk factor of metastasis.
RESULTS: In 40 cases of T1a-MM ESCC, there were 6 cases (15%) of vascular invasion-positive, 7 cases (18%) of DI-positive, and 3 cases (8%) were positive both. CRT was performed in 3 cases and surgical resection was performed in 2 cases and the other 5 cases are followed up without the prophylactic treatment. 30 cases without risk factor were followed up without the prophylactic treatment, but lymph node recurrence was observed in 1 case. In 4 cases of T1b-SM1 ESCC, there was 1 case (25%) of vascular invasion-positive, and CRT was performed. The other cases were negative of risk factor and followed up without the prophylactic treatment. In 11 cases of T1b-SM2 ESCC, there were 6 cases (55%) of vascular invasion-positive, 5 cases (46%) of DI-positive, and 5 cases (9%) were positive both. CRT was performed in 2 cases and surgical resection was performed in 6 cases. In 6 cases undergoing surgical resection, there were 2 cases (33%) of lymph node metastasis. 3 cases were not performed the prophylactic treatment for the elderly. In all cases of T1a-MM and T1b ESCC, death from original disease has not been seen.
CONCLUSION: For T1a-MM and T1b-SM1 ESCC without metastasis clinically, ESD is performed actively, it should be determined whether it is necessary to the prophylactic treatment by pathological evaluation. Although ESD indication may be expanded to T1b-SM2 ESCC, it is a theme which the prophylactic treatment is selected.

P490 THE REPRESENTATIVE CHARACTERISTICS OF SUPERFICIAL BARRETT'S ESOPHAGEAL CANCER ARE A REDDISH AREA LOCATED ON THE ANTERIOR TO RIGHT SIDE WALL IN JAPANESE PATIENTS.

T. Koike[1,*], K. Nakagawa[1], H. Shinkai[1], K. Iijima[1], T. Shimosegawa[1]. [1]*Division of Gastroenterology, TOHOKU UNIVERSITY GRADUTE SCHOOL OF MEDICINE, Sendai, Japan*

INTRODUCTION: Barrett's esophageal cancer (BC) is less common in Japan than in Western countries, so few clinical studies of this condition have been

conducted in this country. The aim of this study was to evaluate the clinicopathological characteristics of BC in Japanese patients.
AIMS&METHODS: Thirty four patients (36 lesions) with superficial BC (34 male (100%), mean age 66.5yr) and 43 patients with endoscopically detected Barrett's esophagus (BE) with a length of more than 2 cm (34 male (79.1%), mean age 64.0yr) were enrolled in this study. We evaluated clinicopathological factors, the body mass index (BMI), and the presence of reflux esophagitis (RE), specialized intestinal metaplasia (IM), hiatal hernia (HH), and *Helicobacter pylori* (HP) infection, and assessed gastric acid secretion using the endoscopic gastrin test (EGT) (mEq/10 min) (Am J Gastroenterol 1998).
RESULTS: Thirty one (86.1%) of 36 BC were visualized as a reddish lesion, 28 (77.8%) were located on the anterior to right side wall. Intestinal type adenocarcinoma was common in BC (94.4%). Most of BC was derived from short segment BE (85.2%). BMI in patients with BC (22.9) was not significant differences in those with BE (24.2). The prevalence of IM in patients with BC (73.5%) was not significant differences in those with BE (72.1%). The prevalence of RE in patients with BC (29.4%) was not significant differences in those with BE (37.2%). The prevalence of HH (52.9%) in patients with BC was not significant differences in those with BE (34.9%). The HP infection rate in patients with BC (38.3%) was not significant differences in those with BE (25.6%). EGT values in patients with BC (4.3mEq/min) was not significant differences in those with BE (5.7).
CONCLUSION: The representative characteristics of superficial BC are a reddish area located on the anterior to right side wall in Japanese patients. Additionally, most of the BC in Japan is derived from short segment BE.

P491 PREVENTING ESOPHAGEAL STRICTURE BY COVERING MUCOSAL DEFECTS WITH POLYGLYCOLIC ACID SHEETS FOLLOWING ENDOSCOPIC SUBMUCOSAL DISSECTION: A NOVEL APPROACH

T. Iizuka[1,*], D. Kikuchi[1], A. Yamada[1], S. Hoteya[1], M. Kaise[1].
[1]*Gastroenterology, TORANOMON HOSPITYAL, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) for superficial esophageal cancer is widespread. However, esophageal stricture following ESD can occur as a major complication in cases of larger mucosal defects and leads to a decrease in quality of life. The incidence of esophageal stricture at our hospital is 28% (n=231 cases) with mucosal defect size ranging from 2/3 to 11/12 the esophageal circumference. Although steroid injection into the submucoal layer and oral administration of prednisolone have recently been reported as preventive measures, ulcer formation due to steroid injection or severe pneumonia due to oral prednisolone has been experienced. Therefore, we examined the efficacy of polyglycolic acid sheets (Neovel®) for mucosal defects.
AIMS&METHODS: Of 104 patients with 116 lesions resected by ESD from May 2012 to March 2013, 10 patients were enrolled. All patients had a mucosal defect with an esophageal circumference of 2/3 to 11/12 and gave informed consent to participate. After confirming the size of the mucosal defect, Neovel sheets were cut into patches measuring 5 × 10 mm. As a first step, a small amount of fibrinogen, one part of fibrin sealant, was sprayed onto the artificial ulcer, and the Neovel patches were placed without overlapping. Remnant fibrinogen and thrombin were then sprayed onto the Neovel patches. The prevalence of esophageal stricture, remaining Neovel at one and two weeks after ESD, and adverse events were investigated.
RESULTS: Mean age was 66.7 years old, and 80% of the subjects were men. Invasion depth was confirmed by histological examination as follows: m1, n=1; m2, n=7; m3, n=1, and sm2, 1. Two patients who were diagnosed with m3 and sm2 were excluded because they underwent surgical resection after ESD. Mucosal defect circumference was as follows: 7/12, n=2; 8/12, n=4; 9/12, n=1, and 11/12, n=1. Residual Neovel was 87.5% at one week and 50% at two weeks after ESD. No esophageal stricture or adverse events were observed. As a minor complication, post-ESD bleeding occurred in 1 case, but was treated successfully by conservative treatment. No serious complications or treatment-related deaths were noted.
CONCLUSION: The present treatment resulted in no esophageal strictures and appeared to have a high level of safety. Therefore, polyglycolic acid sheets have the potential to prevent esophageal stricture. Nevertheless, the procedures are rather cumbersome, so further investigations are warranted.

P492 SUITABLE SETTING OF A TARGET-CONTROLLED INFUSION SYSTEM WITH A BISPECTRAL INDEX MONITOR FOR PROPOFOL SEDATION ADMINISTERED BY A NON-ANESTHESIOLOGIST DURING ESD

A. Imagawa[1,*], H. Terasawa[1], Y. Yoshida[1], K. Takeuchi[1], H. Sakae[1], H. Endo[1], H. Yasuhara[1], H. Jinno[1], E. Kaji[1], H. Hata[1], A. Moriya[1], M. Nakatsu[1], M. Ando[1]. [1]*Gastroenterology, MITOYO GENERAL HOSPITAL, Kan-onji, Japan*

INTRODUCTION: Propofol administration via a target-controlled infusion system with a bispectral index monitor (BIS/TCI system) is expected to prevent complications of sedation during complex and long endoscopic procedures such as gastric and oesophageal endoscopic submucosal dissection (ESD). There is a need for a suitable and safe method of propofol administration by non-anesthesiologists in order to maintain a moderate to deep sedation during procedures.
AIMS&METHODS: We evaluated the settings of the BIS/TCI system with propofol sedation during ESD. From May 2009 to Feb 2013, 250 patients with oesophagogastric neoplasms were treated with ESD using the BIS/TCI system of propofol sedation. In the TCI system, the initial target blood concentration of propofol was 1.2μg/ml. The titration speed of propofol was adjusted by increasing or decreasing the blood concentration of propofol by 0.2μg/ml according to the BIS score and the movement of the patients. The BIS target level ranged from moderate to deep sedation, at which a stable BIS score between 60 and 80 was obtained. In addition, the frequencies of oxygen desaturation (SpO2 < 90) and hypotension (BP < 90 mmHg) were evaluated during the procedures.
RESULTS: The mean procedure time was 89±59 min, and the mean dose of propofol was 4.19±1.32 mg/kg/h. In 80.4% of cases it was possible to maintain stable sedation with blood concentration of less than 1.6μg/ml using TCI. The default setting of ideal blood concentration for propofol was 1.2μg/ml because the medians of lower and upper bounds of the blood concentration were 1.2 (range 0.6-1.8)μg/ml and 1.4 (range 1.0-3.8)μg/ml, respectively. Although hypotension occurred in 27 cases (10.8%), oxygen desaturation occurred in only 9 cases (3.6%). All cases were resolved through conservative therapy or by increasing the concentration of supplied oxygen. There were no severe adverse events involving propofol sedation during the ESD procedures.
CONCLUSION: It was possible for a non-anesthesiologist using our settings to maintain stable sedation during a time-consuming endoscopic procedure through propofol sedation with a BIS/TCI system.

P493 CARCINOMATOSIS MATTERS: CLINICAL OUTCOMES AND PROGNOSTIC FACTORS FOR CLINICAL SUCCESS OF STENT PLACEMENT IN MALIGNANT GASTRIC OUTLET OBSTRUCTION

C. H. Park[1,*], H. H. Jeon[1], J. C. Park[1], C. N. Shim[1], S. Kim[1], H. J. Lee[1], H. Lee[1], S. K. Shin[1], S. K. Lee[1], Y. C. Lee[1]. [1]*Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Although one recent retrospective study has shown that carcinomatosis is not a contraindication to stenting in selected patients with malignant gastric outlet obstruction (GOO), associate factors for clinical success rate of self-expandable metallic stent (SEMS) placement in GOO patients with carcinomatosis have not been fully characterized.
AIMS&METHODS: We analyzed a total 228 patients who were scheduled for SEMS placement for malignant GOO in tertiary-care academic medical center. All patients were treated with an uncovered or covered SEMS by using the over-the wire placement procedure. We retrospectively evaluated clinical outcomes of SEMS placement.
RESULTS: Technical success was achieved in all patients. Patients were categorized into two groups according to the presence of carcinomatosis. Clinical success rates of patients without carcinomatosis group and with carcinomatosis group were 93.9% (92/98) and 80.8% (105/130), respectively ($P = 0.004$). Poor performance status (ECOG $\geq$ 3, $P < 0.001$) and carcinomatosis ($P = 0.016$) were independent poor predictive factors for clinical success of SEMS placement. In subgroup analysis in patients with carcinomatosis group, clinical success rates of patients without ascites group and with ascites group were 92.1% (70/76) and 64.8% (35/54), respectively ($P < 0.001$). Poor performance status (ECOG $\geq$ 3, $P = 0.025$) and ascites ($P = 0.002$) were independent poor predictive factors for clinical success of SEMS placement in carcinomatosis subgroup.
CONCLUSION: In palliation for malignant GOO, the status of carcinomatosis with ascites is a significant poor predictive factor for clinical success of SEMS placement.

P494 PROTECTION OF CHEMOTHERAPY-INDUCED MUCOSITIS BY EMU OIL: AN EXPERIMENTAL STUDY

S.-J. Nam[1], J. S. Lee[1], Y. T. Jeen[1], E. S. Kim[1], B. Keum[1], H. S. Lee[1], H. J. Chun[1], S. H. Um[1], C. D. Kim[1,*], H. S. Ryu[1], Division of Gastroenterology, Department of Internal Medicine, Korea University College of Medicine.
[1]*Internal Medicine, Korea University Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Emu oil, which is extracted from the subcutaneous or retroperitoneal fat of the emu, is mainly composed of fatty acids like oleic acid, linoleic acid, and linolenic acid. Recentrly, one study suggested that emu oil can decrease intestinal inflammation in mucositis rat model. Mucositis is one of the serious complications of cancer chemotherapy with no effective treatments.
AIMS&METHODS: The aim of this study is to validate the protective effect of emu oil on chemotherapy induced mucositis. Male Sprague dawley rats (n 36; 235-265g) were ramdomly allocated to one of the following groups (n 12), water and saline; water and 5-fluorouracil (5-FU); emu oil and 5-FU. The rats were orogastrically gavaged with emu oil (1ml) or water (1ml) for 5days before intraperitoneal injection of 5-FU (150mg/kg) or saline (control), and orogastric gavage with emu or water was continued up to the day of sacrifice (96h post 5-FU administration). Histologic parameters (inflammatory cell infiltration, villus height, crypt depth), myeloperoxidase (MPO) activity, which is a indicator of inflammation, by enzyme-linked immunosorbent assay were measured in intestinal tissues collected at sacrifice.

RESULTS: All 5-FU injected rats did not gain weight for the duration of the trial compared with saline injected controls. But MPO activity in the small bowel was decreased by emu oil compared with 5-FU treated controls 96 h post 5-FU administration. There were also increases in crypt depth in the small bowel of rats that receivied emu oil compared with 5-FU-treated controls.
CONCLUSION: This study suggest that emu oil has protective effect on chemotherapy induced mucositis. Further studies are required to define specific mechanisms of protective effect of emu oil on intestinal mucositis.

P495 IMPACT OF METABOLIC SYNDROME ON THE ONCOLOGIC OUTCOME AFTER RADICAL GASTRECTOMY FOR GASTRIC CANCER

E. H. Kim[1], H. S. Chung[1], J. C. Park[1], S. K. Shin[1], S. K. Lee[1], Y. C. Lee[1], H. Lee[1,*]. [1]*Department of internal medicine, Yonsei University college of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Several studies have shown that metabolic syndrome (MS) was a risk factor for colorectal cancer, breast cancer and prostate cancer. But few studies have reported the relationship between MS and the prognosis of gastric cancer.
AIMS&METHODS: Data were collected from 555 patients underwent radical gastrectomy for gastric cancer between January 2006 and December 2007 for pilot study. The patients with inadequate or missing data were excluded. Remaining 204 patients were divided into 2 groups based on the presence of MS. We tested the prognostic value of MS in the patients.
RESULTS: No significant differences were observed in tumor staging and grade of tumor differentiation between the 2 groups, MS (n = 60) and non-MS (n = 144) groups. Median follow-up periods were 53.2±23.5 and 54.7±22.1 months in MS and non-MS groups, respectively ($P = 0.677$). 17 (28.3%) and 21 (14.6%) patients showed recurrence of tumor in MS and non-MS group, respectively ($P = 0.022$). In addition, disease-free survival of the patients in MS group was inferior to those in non-MS group ($P = 0.036$). Cox regression hazard model demonstrated that advanced tumor stage (stage III or IV, HR = 13.9, 95% CI = 6.5 to 29.7) and presence of MS (HR = 2.4, 95% CI = 1.2 to 4.5) were independent risk factors for recurrence. Body mass index was the major factor with the influence on patients with gastric cancer accompanied by MS.
CONCLUSION: MS may be an important prognostic factor for gastric cancer. Control of metabolic syndrome would improve the therapeutic efficacy of gastric cancer.

P496 FEASIBILITY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR TYPE I GASTRIC CARCINOIDS COMPARED WITH ENDOSCOPIC SUBMUCOSAL RESECTION

H. H. Kim[1,2,*], G. H. Kim[3], J. H. Kim[4], M.-G. Choi[2]. [1]*Internal Medicine, Kosin University College of Medicine, Busan,* [2]*Internal Medicine, The Catholic University of Korea College of Medicine, Seoul,* [3]*Internal Medicine, Pusan National University School of Medicine,* [4]*Internal Medicine, Inje University College of Medicine, Busan, Korea, Republic Of*

INTRODUCTION: Conventional endoscopic submucosal resection (EMR) of carcinoid tumors is often associated with involvement of the resection margin, which necessitates further intervention. Endoscopic submucosal dissection (ESD) is a novel technique for the removal of carcinoid tumors.
AIMS&METHODS: The aim of the present study was to compare the clinical usefulness of ESD with that of EMR for the complete resection of gastric carcinoid tumors. Between January 2001 and October 2010, a total of 41 patients with 54 type I gastric carcinoid tumors that were estimated to be 10 mm or less in diameter and that were resected either using ESD or EMR were investigated for this study. The complete resection rate and complications associated with these two procedures were analyzed.
RESULTS: Among the 54 lesions, 36 were resected using EMR, and 18 lesions were resected using ESD. There were no significant differences between the EMR and ESD groups in terms of the location or the size of the tumors. The overall ESD complete resection rate was higher than that of EMR (88.9% vs. 75.0%, respectively, P=0.301). A lower vertical margin involvement rate was obtained when ESD was performed compared to that when EMR was performed (5.6% vs. 16.7%, respectively, P=0.403). However, there was no statistical difference. The complication rate was not significantly different between the two groups.
CONCLUSION: ESD showed higher complete resection rate, especially in vertical margin despite lack of statistical significance.

P497 MANAGEMENT OF URGENT UPPER GI REFERRALS: TIME FOR A RETHINK

J. Patel[1,*], A. McNair[1]. [1]*Gastroenterology, NHS, London, United Kingdom*

INTRODUCTION: Patients in the UK with upper gastrointestinal (UGI) symptoms suggestive of cancer are referred to hospital under the 'Two week wait (2WW)' pathway. Those patients with 'alarm' symptoms thought to indicate the presence of a gastric or oesophageal (GO) cancer are sent directly for an upper GI endoscopy (OGD), but the cost-effectiveness of this approach is uncertain. It is also uncertain whether dyspepsia should be included as an 'alarm symptom', although the NICE referral guidelines suggest patients aged >55 years with recent onset dyspepsia should be referred under the 2WW pathway. We reviewed our practice to establish the value of the 'direct to test' approach for upper GI 2WW patients.
AIMS&METHODS: Aim- To determine the frequency of GO carcinoma in 2WW patients with different combinations of symptoms.
Method - Patients referred with UGI symptoms on the 2WW pathway between April 2008 and January 2013 were identified. The frequency of a 'tumour' found in patients with a combinations of symptoms was determined; these include weight loss, dysphagia, vomiting, haematesis or malaena, anaemia and/or dyspepsia. To establish whether dyspepsia alone was of any value in identifying patients with gastric cancer, we expanded our search to determine the likelihood of finding a cancer in any patient (including non-2WW urgent and routine referrals)
RESULTS: In total, 154 GO cancers (92 in patients referred under 2WW) were identified in 14572 OGDs, performed during April 2008 and January 2013 (48% male, mean age 63 (18-99 years)).
No symptom (or symptom combination) yielded a cancer diagnosis rate of over 7%. GO cancer was most likely to be detected patients with dysphagia. To examine further the value of uncomplicated dyspepsia (dyspepsia alone) in detecting patients with cancer we looked at all patients referred over the same time period. Of 4168 patients referred with dyspepsia, 19 (0.46%) had cancers. After removing those patients who also had anaemia, weight loss or dysphagia and discounting those patients where biopsies of the 'tumour or mass' were negative on histology, only three patients with tumours were found: one leiomyoma, one GIST and a squamous cell carcinoma of the oesophagus. No gastric carcinomas were found in any patient with uncomplicated dyspepsia.
CONCLUSION: Summary
REFERENCES:
1. NICE suspected cancer guidelines, 2005
2. Predictive value of alarm features in a rapid access upper gastrointestinal cancer service. N Kapoor *et al*., Gut 2005;54:40–45.
3. Does endoscopy diagnose early gastrointestinal cancer in patients with uncomplicated dyspepsia? N Sundar et at., Postgrad Med J 2006;82:52–54.
1.Over 96% of patients referred on the upper GI 2WW pathway have no evidence of cancer at endoscopy 2.Only one cancer was identified in any patient with dyspepsia as the only clinical feature
Conclusion
Patients referred on the upper GI 2WW pathway should be reviewed in the clinic prior to endoscopy to ensure more efficient use of resources.
Dyspepsia is of no value in identifying patients with upper GI cancer and should be removed from 2WW referral proformas.

P498 ANALYSIS OF LYMPH NODE METASTASES AFTER ADDITIONAL SURGERY FOR EARLY GASTRIC CANCER TREATED BY ESD WITH PATHOLOGICAL LYMPHATIC INVASIONS

K. Fukase[1,*]. [1]*Gastroenterology, YAMAGATA PREFECTURAL CENTRAL HOSPITAL, Yamagata, Japan*

INTRODUCTION: If resected specimens have lymphatic invasions after ESD (Endoscopic Submucosal Dissection) for early gastric cancers, they are considered as non-curative and additional surgery is recommended. But the result of additional surgeries is not investigated enough.
AIMS&METHODS: The risk of lymph node metastases after additional surgery for early gastric cancers treated by ESD with pathological lymphatic invasions, is analysed. From January 2002 to December 2012, 611 cases (662 lesions) of early gastric cancers were treated by ESD at Yamagata Prefectural Central Hospital. Resected specimens were pathologically diagnosed with 2mm width step serial sections. If lymphatic invasions were diagnosed, such cases were recommended to be treated by additional surgery. Lymphatic invasions were confirmed by D2-40 immuno-staining.
RESULTS: 1) Out of 611 cases of early gastric cancers treated by ESD, lymphatic invasions were pathologically diagnosed in 20 cases (3.3%). All 20 cases were

given surgical treatments. 2) Out of 20 cases, lymph node metastases were pathologically diagnosed in 5 cases (25%).
CONCLUSION: After additional surgery, lymph node metastases were diagnosed in only 5 cases (25%). This result means that 75% of cases were overtreated by surgery. We need to research more diagnostic factors of lymphatic invasion patterns which indicate the risk factor for lymph node metastases.
Disclosure of Interest: None Declared

P499 PROGNOSTIC SIGNIFICANCE OF GLASGOW PROGNOSTIC SCORE IN PATIENTS WITH INCURABLE GASTRIC CANCER

X. Jiang[1,*], N. Hiki[2]. [1]*General Surgery, ZHONGDA HOSPITAL, SOUTHEAST UNIVERSITY, Nanjing, China,* [2]*Department of Gastroenterological Surgery, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*

INTRODUCTION: Systemic inflammation has been proved to be correlated with poor survival in many cancers. Recently, the inflammation based Glasgow prognostic score (GPS), based on serum levels of C-reactive protein (CRP) and albumin, has been used to predict survival in cancer, including gastric cancer. However, the significance of GPS in incurable gastric cancer has not been known. This study investigates the significance of the modified Glasgow prognostic score (mGPS) for the survival in patients with incurable gastric cancer.
AIMS&METHODS: The mGPS (albumin <35 g /L $=1$ and CRP >10 mg/L$=1$) was calculated on the basis of the data for 448 patients with metastastic gastric cancer. Patients were given an mGPS of 0, 1, or 2 according to the score. The prognostic significance was analyzed by univariate analyses.
RESULTS: Significant correlations were found between overall survival and CEA, CA19-9, CRP, Albumin,TNM stage and mGPS. Sex, white cell count, neutrophils, CEA, tumor stage were each significantly correlated with the mGPS. Univariate analysis showed that CEA, CA19-9,tumor stage and mGPS were significantly associated with overall survival, while multivariate analysis showed that only mGPS was significantly associated with overall survival (OR, 1.658; 95% CI, 1.203–2.286; $P=0.002$). Kaplan-Meier analysis demonstrated significant differences among patients with mGPS of 0, 1 and 2 ($P<0.001$), with the mortality rate higher for patients with a higher mGPS.
CONCLUSION: The inflammation based score, modified Glasgow prognostic score (mGPS), can predict survival in patients with incurable gastric cancer.

P500 PROGNOSTIC FACTORS OF THE PATIENTS WITH STAGE I / II GASTRIC CANCER

Y. Isobe[1,*], Y. Nishihara[1], A. Matsunaga[1], Y. Kawaguchi[1], J. Tokuyama[1], K. Osumi[1], H. Urakami[1], S. Seki[1], A. Shimada[1], A. Matsui[1], T. Oishi[1], S. Matsumoto[1]. [1]*Department of Surgery, National Hospital Organization Tokyo Medical Center, Tokyo, Japan*

INTRODUCTION: According to the recent report of Japanese nationwide registry[1, 2], 5-year survival rates of patients with stage I/II gastric cancer were satisfactory. The primary cause of death of the stage I patients were not cancer recurrence. Japanese Gastric Cancer Association (JGCA) guideline recommends that patients with stage I and T3N0 (stage II) cancer receive no adjuvant chemotherapy. However, it would be still important to select high risk patients for recurrence when applying modified surgery.
AIMS&METHODS: To investigate prognostic factors in stage I/II gastric cancer, clinical and pathological factors of consecutive 357 patients who received curative surgery for primary gastric cancer from 2001 to 2005 were analyzed retrospectively. Prognostic factors included age, sex, histological differentiation, size and depth of tumor, capillary invasion and number of node metastasis. Postoperative survival rates were calculated by Kaplan-Meier method. Cox regression model were used to search significant prognostic factors. JGCA (13th edition) and TNM (5th edition) classifications were used for definition of prognostic factors.
RESULTS: Among 357 patients, 298 were stage IA, IB and II. Overall 5-year survival rates were 91.8%, 85.4% and 62.1% respectively. Fourteen of 298 stage I/II patients died of recurrence. Median survival time of them was 32 months. Seven peritoneal, 5 liver, 3 local and 3 distant metastases were observed. Advanced age, male, JGCA-N (lymph node station) and undifferentiated tumor were selected as significant prognostic factors by Cox regression analysis.
CONCLUSION: Though the number of patients was too small, these data suggested that age, sex, lymph node metastasis and histological differentiation might be risk factors in stage I/II gastric cancer. Further study using a larger dataset seems to be needed.

P501 ENDOSCOPIC LIGATION AND RESECTION FOR GASTROINTESTINAL SUBMUCOSAL TUMORS SMALLER THAN 3 CM

Y.-J. Tsai[1,*], W.-H. Hsu[1], S.-T. Chen[2], C.-Y. Tsai[1], H.-W. Lo[1]. [1]*Division of Hepato-Gastroenterology, Internal Medicine,* [2]*Department of Pathology, Yuan's General Hospital, Kaohsiung, Taiwan, Province of China*

INTRODUCTION: For gastrointestinal (GI) submucosal tumors (SMTs) <3 cm, endoscopic ultrasound (EUS) guided fine needle aspiration (FNA) may obtain inadequate tissue for a conclusive diagnosis and their optimal treatment is controversial sometimes. We studied a relative safe endoscopic treatment with sufficient tissue retrieved for pathological diagnosis of these tumors.
AIMS&METHODS: Since Jan. 2010 till Mar. 2013, patients with GI SMTs <3 cm found by upper or lower GI endoscopy and confirmed by EUS without evidence of metastasis were enrolled to analyze the diagnostic yield and outcome of endoscopic ligation and resection (ELR). An endoscopic ligator with rubber band for tumor <1.2 cm or a detachable endoloop for tumor >1.2 cm was used to tighten around the tumor base, then, after EUS to confirm the lesion was located above the band or endoloop, endoscopic resection and retrieval of upper portion of the ligated tumor for pathological study was performed. The remnant portion was left for a spontaneous sloughing and follow-up EUS at 1 month and 6 months after ELR and every 12 months thereafter were scheduled. Further surgical intervention was carried out for those residual SMTs found during follow-up period and diagnosed as intermediate or high malignant potential.
RESULTS: A total of 23 patients (16 women, mean age 59.8 $\pm$ 11.1 years) with 27 GI SMTs <3 cm were treated by ELR and received follow-up period ranged from 1 to 39 (mean 15.6) months. The tumors number and location were 10 at gastric body, 8 at gastric fundus, 2 at gastric antrum, 3 at duodenum , 2 at esophagus and 2 at colon-rectum. The tumors size ranged from 0.3 to 2.9 (mean 1.3 $\pm$ 0.8) cm included 19 tumors were <1.2 cm, 4 tumors were 1.2 to 2 cm and 4 tumors were >2 cm. Pathological diagnosis of these tumors included 17 (62.9%) gastrointestinal stromal tumors (GISTs), 4 (14.8%) lipomas, 2 (7.4%) leiomyomas , 2 carcinoids, 1 (3.7%) Brunner's gland hyperplasia and 1 mesenchymal tumor. Two larger (2.6 and 2.9 cm) GISTs received further surgical resection due to >5 mitoses per 50 high power fields were found and residual tumors still existed during follow-up period. The other GI SMTs revealed complete sloughed without severe complications after ELR and all patients were still alive without recurrent tumors till last follow-up.
CONCLUSION: Our preliminary results support that ELR may provide a good diagnostic yield and may be considered as a safe alternative treatment for patients with localized low malignant potential GI SMTs <3 cm.

***H. PYLORI* I – Poster Area**

P502 EPIDEMIOLOGY OF HELICOBACTER PYLORI INFECTION: THE SORBO SAN BASILE STUDY

E. Suraci[1,*], T. Larussa[1], I. Leone[1], I. Nazionale[1], L. Abenavoli[1], M. Imeneo[1], F. Luzza[1]. [1]*Department of Health Science, Magna Graecia University of Catanzaro, Catanzaro, Italy*

INTRODUCTION: In 2001, a prospective study was planned in Sorbo San Basile, a small town in southern Italy (932 inhabitants).
AIMS&METHODS: The study started in 2002 (n.595, 64% representative participants) and continued in 2012 when subjects with no evidence of active *H. pylori* infection in 2002 were recruited (n.157, 76% representative participants). Blood was drawn from 518 (87%) and 117 (75%) participants in 2002 and 2012, respectively. A structured questionnaire dealing with sanitary and socioeconomic issues was administered (e.g.: breastfeeding, dyspepsia, smoking, antibiotics and alcohol consumption, parental occupation and education, social class, crowding). Active *H. pylori* infection was assessed by 13C-UBT. Serum VacA and CagA antibodies were determined by western blotting. IL-2, IL-10, IL-12, and IFN-g functional polymorphisms were genotyped. Data were analyzed by multivariable logistic regression analysis.
RESULTS: Active *H. pylori* infection was found in 351 (59%) of 595 participants (264M, 3-97 yr). Age (OR 1.06) and people per room (OR 2.18) were independent risk factors. Of 518 subjects, 479 (92%) and 369 (71%) were VacA and CagA positive, respectively, whereas 310 (60%) UBT positive. Age (OR 1.11), BMI (OR 0.91), and breastfeeding (OR 2.68) were independent risk factors for subjects serology positive and UBT positive or negative (n.479; 92%) compared to those serology and UBT negative (n.39; 8%) while age (OR 1.04) and female gender (OR 1.70) were for subjects serology and UBT positive (n.310; 60%) compared to those serology positive and UBT negative (n.169; 32%). Furthermore, age (OR 1.10) and IL-10 polymorphism (OR 2.72) were independent risk factors for subjects VacA, CagA, and UBT positive compared to those VacA positive and CagA and UBT negative. Ten years later, of 157 subjects only 4 (0.26%/yr) became UBT positive. BMI, social class, household people, and people per room significantly improved (p=0.00) in the 157 subjects. Of 117 subjects, 13 (5%/yr) and 50 (5.3%/yr), and 7 (0.8%/yr) and 2 (0.9%/yr) had VacA and CagA seroconversion and seroreversion, respectively.
CONCLUSION: In this general population, age and crowding at home are major determinants of active *H. pylori* infection while socioeconomic

improvement paralleled a very low incidence rate. Crosstabulation of serology and UBT indicates: 1. a very high exposure to *H. pylori* (up to 92%), particularly in older subjects, those with lower BMI and who had breastfeeding; 2. a dynamic infection with wide range of spontaneous clearance (14 to 84%), higher in the last 10 years, first decades of life, and males. 3. that polymorphism of IL-10 (high production) is associated with active CagA positive infection.

P503 EFFECTS OF SMOKING ON HELICOBACTER PYLORI-ASSOCIATED CHRONIC GASTRITIS AND THE DEVELOPMENT OF GASTRIC CANCER

I. Inoue[1,*], J. Kato[1], T. Maekita[1], M. Iguchi[1], H. Tamai[1], M. Ichinose[1]. [1]*Second Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan*

INTRODUCTION: Smoking, as a lifestyle factor, is considered to be deeply involved in gastric cancer (GC) development. Since the intra-gastric environment alters with progression of *Helicobacter pylori* (HP)-associated gastritis, it is reasonable to speculate that the effects of smoking on GC development differ at different stages of HP-associated gastritis.

AIMS&METHODS: Thus, the effects of smoking on GC development during the course of HP-associated gastritis were investigated.An occupational cohort of 4,585 healthy middle-aged men were followed for a mean (SD) period of 11.7 (4.4) years. The stage of HP-associated gastritis was evaluated with serum levels of HP antibodies and pepsinogen. The effects of smoking on gastritis activity level, extent of chronic atrophic gastritis (CAG), and GC development were investigated for each stage of the gastritis.

RESULTS: In an HP-uninfected group, smoking promoted exocrine gastric secretions, whereas in the infected group, smoking significantly reduced inflammation in mild CAG. In extensive CAG, smoking acted on the progression of atrophy in a positive dose-dependent manner with the number of cigarettes. In extensive CAG, smoking led to an increased cancer risk, and in the group excluding end-stage gastritis, a significant risk elevation correlating with the number of cigarettes was seen.

CONCLUSION: The effects of smoking on HP-associated gastritis and the cancer development differ depending on the stage of the HP-associated gastritis. Smoking reduced the gastritis activity level in mild CAG, strongly suggesting the possibility that smoking is involved in the progression of CAG, and enhanced the cancer development in extensive CAG, not including those in the terminal stage.

P504 HELICOBACTER PYLORI PREVALENCE REMAINS HIGH IN MIDDLE AGED HEALTHY, SOUTH-EAST HUNGARIAN, RURAL MALES. A POPULATION BASED STUDY.

L. Bálint[1,*], I. Dóczi[2], V. Szekeres[3], A. Tiszai[1], R. Róka[1], F. Izbéki[1], T. Wittmann[1], A. Rosztóczy[1]. [1]*First Department of Medicine,* [2]*Department of Clinical Microbiology, UNIVERSITY OF SZEGED,* [3]*Hungarian National Blood Transfusion Service, Szeged, Hungary*

INTRODUCTION: Epidemiologic studies indicate a decrease in prevalence of HP infection in Western Europe. In contrast, little is known about Central Europe, where substantial part of the population still lives outside of cities.

AIMS&METHODS: The **aim** of the study was to obtain data on the HP prevalence in Csongrád and Békés County in Hungary and to compare this value with the data collected 15 years ago in Vas County. The secondary aim was to study the differences between the prevalence of HP infection in people living in large cities and in the countryside.

Methods: Six-hundred and thirty-seven healthy blood donor volunteers (M/F: 319/318, mean age: 40 (19-65) years) were enrolled. Demographic data collection and clinical symptom analysis was carried out by means of a questionnaire. All subjects were tested for HP IgG antibody positivity by enzyme linked immuno assay. Subgroup analysis by age, gender, smoking habits, alcohol consumption, urban and non-urban population was also performed.

RESULTS: During the last 15 years the overall prevalence of HP infection is halved (65 vs. 32%) in the studied healthy subjects. It was higher in males (35 vs. 30%), as well as in rural people (37 vs. 27%). In contrast similar prevalence was found in younger (<40 years) urban and rural females. The highest prevalence was found in rural males over forty years (55%). Linear association was established according to age in both sexes ($p < 0.01$). Smoking and alcohol consumption were not related to HP infection.

CONCLUSION: The overall prevalence of HP infection is decreasing in South-East Hungary similarly to the Western countries, although it is still high in middle aged rural males. This increased HP prevalence in non-urban males and the age distribution of the HP positive subjects may be explained by hygienic circumstances.

P505 CONSISTENCY IN SOCIAL PATTERNING OF HELICOBACTER PYLORI INFECTION OVER A 10-YEAR PERIOD. A PROSPECTIVE MULTI-CENTRE EPIDEMIOLOGICAL STUDY IN THE CZECH REPUBLIC

M. Kopacova[1,*], I. Koupil[2], B. Seifert[3], M. Skodova Fendrichova[1], V. Vorisek[4], J. Spirkova[4], T. Douda[1], S. Rejchrt[1], I. Tacheci[1], J. Bures[1]. [1]*2nd Department of Internal Medicine - Gastroenterology, Charles University Faculty of Medicine and University Teaching Hospital, Hradec Kralove, Czech Republic,* [2]*Centre for Health Equity Studies, Stockholm University/Karolinska Institute, Stockholm, Sweden,* [3]*Institute of General Practice, First Faculty of Medicine, Charles University, Prague,* [4]*Institute of Clinical Biochemistry and Diagnostics, Charles University Faculty of Medicine and University Teaching Hospital, Hradec Kralove, Czech Republic*

INTRODUCTION: Prevalence of Helicobacter pylori (Hp) infection decreased significantly in the Czech Republic from 2001 (41.7%) to 2011 (23.5%) (1,2).

AIMS&METHODS: The aim of this project was to evaluate the effect of social and demographic characteristics on Hp infection. Two prospective multi-centre studies were accomplished in 2001 and 2011 using the same methods in a representative sample of general unselected population from the same geographical areas. A total of 2,509 persons (aged 5-100) were randomly selected out of 30,012 in 2001 and 1,837 subjects (aged 5-98 years) randomly selected out of 38,147 people, took part in the study in 2011. Hp status was investigated by means of 13C-urea breath test (INFAI, Köln, Germany). Breath samples were analysed by isotope ratio mass spectrometry (AP 2003, Analytical Precision Products, Cambridge, UK).

RESULTS: The prevalence of Hp increased with age, with grater relative differences in 2001 (OR 11.5 for age 65-74 compared to 5-14 years) than in 2011 (OR 2.3 respectively) (both $p < 0.001$). The absolute prevalence decreased significantly in all birth cohorts over the period of the study, e.g. 36.7% for age 25-34 in 2001 and 25.1% for age 35-44 in 2011 ($p < 0.001$). Hp infection was associated with low education of father (OR 2.6 in 2001 and OR 3.2 in 2011) and mother (OR 2.6 and 1.9), three or more siblings (OR 3.3 and 3.6), crowding in childhood with more siblings or parents (OR 3.1 and 3.4) and low own education (OR 2.4 in 2001 and OR 2.5 in 2011). Inaccessibility of running warm water in childhood was less important risk factor of Hp infection in 2011 (OR 1.1) compared to 2001 (OR 1.4, p=0.026). Never married adult subjects were at lower risk of Hp infection in 2011 (OR 0.66) compared to married, divorced or widowed persons. There was no significant difference between the prevalence of Hp in higher or middle social class compared to lower social class (OR 1.03 in 2001 and 1.07 in 2011). Place of residence in childhood in villages was associated with higher risk of Hp infection in 2001 (OR 1.6) but not in 2011 and current place of residence did not show statistically significant association with Hp prevalence in analyses adjusted for other social characteristics in either period.

CONCLUSION: We found a general consistency in how social and demographic characteristics affect Hp infection despite the significant decrease of its prevalence in the Czech Republic from 2001 to 2011.

P506 ETHNIC FEATURES OF ATROPHIC GASTRITIS PREVALENCE AND GASTRIC CANCER INCIDENCE IN THE POPULATION OF EASTERN SIBERIA.

V. V. Tsukanov[1], A. Vasyutin[1], O. Amelchugova[1,*], O. Tretyakova[1], A. Saaya[1], D. Rodina[1]. [1]*STATE SCIENTIFIC MEDICAL RESEARCH INSTITUTE FOR N, Krasnoyarsk, Russian Federation*

INTRODUCTION: It is known that atrophic gastritis is an independent risk factor for noncardial stomach cancer [1]. The determination of serum pepsinogens and *H. pylori* was recommended as screening method for stomach precancerous lesions [2].

AIMS&METHODS: Aim. To study prevalence of atrophic gastritis in Mongoloids and Europoids of Eastern Siberia using determination of serum pepsinogens and to compare data with gastric cancer incidence.

Methods. The screening of atrophic gastritis was performed in Evenkia, Tyva and Krasnoyarsk city. For the study we selected 801 persons (387 males, 414 females) in Krasnoyarsk, 527 Evenks (225 males, 302 females) in Evenkia, 466 Tyvins (203 males, 263 females) in Tyva aged over 45 years old by random sampling. In all patients we performed clinical examination and determination of pepsinogen-1, pepsinogen-2 and antibodies to Helicobacter pylori in blood serum by immunoassay method using test kits "GastroPanel" ("Biohit", Finland) and ''Vector Best'' (Russia). As a marker of severe atrophy of gastric body mucosa we considered the level of pepsinogen-1 less than 25 μg/L and the ratio pepsinogen-1/pepsinogen-2 less than 3. Data on gastric cancer incidence were collected from the file-data of the regional oncology registries of the three involved regions.

RESULTS: The prevalence of *H. pylori* infection among surveyed populations was equally high – about 90.0%. The prevalence of severe gastric body atrophic gastritis and gastric cancer incidence were lower in Evenks in comparison to Europoids and Tyvins (Table). Risk factor for severe atrophic gastritis in Europoids was age older 55 years (OR=1.7, CI 1.07-2.76; p=0,03), in Evenks and Tyvins - age older 50 years (OR = 0,18; CI 0,02-0,93; p=0,03).

Table. The prevalence of atrophic gastritis and gastric cancer incidence in Eastern Siberia.

Population	Atrophic gastritis		H. pylori		Gastric cancer incidence per 100 000
	Abs.	%	Abs.	%	
1.Evenks, n=527	27	5.3	496	94.1	20.2
2.Tyvins, n=466	44	9.4	436	93.5	50.7
3.Europoids, n=801	87	10.9	721	90.0	33.2
OR; CI; p_{1-2}	0.52; 0.32-0.85; 0.01		1.10; 0.66-1.84; 0.81		0.39; 0.23-0.66; <0.001
OR; CI; p_{1-3}	0.45; 0.29-0.70; 0.004		1.76; 1.15-2.70; 0.01		1.65; 0.95-2.88; 0,09

CONCLUSION: We found ethnic differences of atrophic gastritis prevalence and gastric cancer incidence in Mongoloids and Europoids of Eastern Siberia.

P507 HELICOBACTER PYLORI ERADICATION AND TYPE 2 DIABETES MELLITUS: IS THERE A LINK?

S. M. D. Giestas[1,*], D. Marado[1], C. Agostinho[1], M. Agundez[1], A. Figueiredo[1].
[1]*Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: The relationship between diabetes mellitus (DM) and infection by Helicobacter pylori (Hp) is controversial. However, a large number of studies have shown that eradication rates are lower in diabetic patients than in the general population.
AIMS&METHODS: To determine the rate of eradication of Helicobacter pylori infection in morbidly obese patients with type 2 DM compared with a control group not diabetic. PATIENTS AND METHODS: Retrospective analysis of patients followed in the outpatient medical morbid obesity. Included 80 patients: 40 with DM (95% female, mean age 49.5 ± 8.8, mean BMI 48 ± 3.5 kg / m^2, HgA1c average 7.3 ± 1.5%) and 40 non-diabetic patients (87 , 5% female, mean age 46.4 ± 7.9, mean BMI 46 ± 6.5 kg / m^2). All patients underwent gastric biopsy for research Hp. Patients with positive results in a histopathological study underwent triple therapy with amoxicillin (1g 2i.d.), clarithromycin (500mg 2i.d.) and omeprazole (20mg 2i.d) for 14 days. Eradication was determined by urease breath test 34 ± 5.7 days after completing treatment regimen.
RESULTS: The prevalence of Hp was 65% (n = 52). The difference in prevalence of Helicobacter pylori infection was not statistically significant between the two groups (62.5% (n = 25) in patients with DM, 70% (n = 27) in nondiabetics, p > .05). The eradication rate was 75% (n = 39). Hp was eradicated in 60% (n = 15) for patients with diabetes and in 88.8% (n = 24) of patients without diabetes. The eradication rate was significantly lower in patients with DM compared to the control group. The average duration of diabetes (5.3 ± 3.8 years vs 5.1 ± 3.6 years) and HgA1c average value (7.2 ± 1.2% vs 7.2 ± 1.4%) was not significantly different between diabetic patients with or without Hp eradication.
CONCLUSION: In this group of morbidly obese patients the rate of eradication of Hp was significantly lower in diabetic patients

P508 HELICOBACTER PYLORI INFECTION AND TYPE 2 DIABETES MELLITUS: THERE AN ASSOCIATION?

S. M. D. Giestas[1,*], D. Marado[1], M. Agundez[1], C. Agostinho[1], A. Figueiredo[1].
[1]*Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: The relationship between diabetes mellitus (DM) and infection by Helicobacter pylori (Hp) is controversial. In recent years, some studies indicate an increased incidence of infection, particularly in patients with long duration of disease, poor control diabetic, hypertensive, obese, female and cardiovascular autonomic neuropathy. However, other studies indicate that there is no difference in the prevalence of *H. pylori* infection among diabetics and non-diabetics
AIMS&METHODS: To determine the prevalence of Hp infection in morbidly obese patients with type 2 DM and to evaluate the relationship between Hp infection and glycemic control. Patients and methods: included retrospectively 80 patients with morbid obesity. Forty patients with DM (95% female, mean age 49.5 ± 8.8, mean BMI 48 ± 3.5 kg / m^2, HgA1c average 7.3 ± 1.5%) and 40 non-diabetics (87.5% female, mean age 46.4 ± 7.9, mean BMI 46 ± 6.5 kg / m^2). Endoscopy and gastric biopsies for research Hp were performed in all patients.
RESULTS: The prevalence of Hp was 65% (n = 52). The difference in prevalence of Helicobacter pylori infection was not statistically significant between the two groups (62.5% (n = 25) in patients with DM, 70% (n = 27) in nondiabetics, p > .05). The mean plasma glucose (219 ± 27.5 mg / dl vs 227 ± 22.3 mg / dl), the average level of HgA1c (7.2 ± 1.7% vs 7.3 ± 1.3%) and the average duration of DM (5.2 ± 2.8 years vs 4.9 ± 2.3 years) did not differ significantly (p > 0.05) between diabetic patients with and without Hp. There was no increased prevalence of Hp infection in DM patients with poor diabetic control (HgA1c > 7%) compared to patients with appropriate control (15 (60%) of 25 patients vs 10 (66.6%) of 15 patients, respectively).
CONCLUSION: The results of this study showed no significant difference in the prevalence of *H. pylori* infection among diabetic patients and the control group, not indicating association between *H. pylori* infection and DM.

P509 EXTRAGASTRIC PATHOGENICITY OF HELICOBACTER SUIS IN IDIOPATHIC PARKINSONISM: EXAMINATION OF ALL-CAUSE MORTALITY AND BLOOD INDICES.

S. M. Dobbs[1,2,*], R. J. Dobbs[1,2], A. Smet[3], A. Charlett[1,4], C. Weller[1], I. Bjarnason[2], A. Lawson[5], M. A. Ibrahim[6], D. Taylor[1,7], C. Blaecher[3], F. Pasmans[3], R. D. Ducatelle[3], F. Haesebrouck[3]. [1]*Pharmaceutical Science, King's College London,* [2]*Gastroenterology, King's College Hospital, London, United Kingdom,* [3]*Laboratory of Veterinary Bacteriology and Mycology, Faculty of Veterinary Medicine, Ghent University , Merelbeke, Belgium,* [4]*Centre for Infectious Disease Surveillance and Control,* [5]*Laboratory of Gastrointestinal Pathogens, Public Health England,* [6]*Diagnostic Immunology Laboratory, King's College Hospital,* [7]*Pharmacy, The Maudsley Hospital, London, United Kingdom*

INTRODUCTION: Relative frequency of *Helicobacter suis cf pylori* was 10 times greater in the first archived DNA-extract from gastric-biopsies in 60 patients with idiopathic parkinsonism (IP), than in 256 'controls' from UK gastroenterology-services.
AIMS&METHODS: We explore the pathological significance of *H. suis* in IP. DNA-extracts from gastric-biopsies had been examined for *H. suis* using a *ureA*-based species-specific qPCR, subsequent to routine culture for *H. pylori*, and, if negative, PCR targeting 16S rRNA and *vacA*.
RESULTS: *H. suis* was present in the first sample from 16/60 IP-patients. Of 20 follow-ups:- Co-existent *H. pylori* had been eradicated in 5/6 previously *H. suis*-positive: 4 remained *H. suis*-positive, as did the patient without *H. pylori*. *H. pylori* had been eradicated in 12/14 previously *H. suis*-negative: 3 became *H.* suis-positive afterwards, 2 remaining negative for both species. Risk of death during follow-up was 8.0 (95% CI 1.3, 47.4) times greater with *H. suis*-positivity at anytime (6/19), compared with those negative throughout (2/40 (one lost to follow-up)) (Cox proportional-hazards model, adjusted for age-at-diagnosis, gender: p=0.02). Independent effects of both species on blood indices were assessed in same regression model. With *H. suis*-positivity, platelet count tended to be lower (by 10 (-1, 20)%, p=0.06) whilst mean platelet volume was higher (0.83 (0.02, 1.6) fL, p=0.04), *H. pylori* having no effect. Total lymphocyte count was lower with *H. pylori* (0.19 (0.04, 0.34) $x10^9$/L, p=0.02), but not significantly so with *H. suis*. B-cell count was lower with each species (30 (3, 57)/μL, p=0.03; 42 (8, 77), p=0.02).
CONCLUSION: All-cause mortality associated with *H. suis* in IP requires further investigation. Usual anti-*H. pylori* therapy may be ineffective against *H. suis* and promote recrudescence. Fewer larger platelets implies destruction. Relative lymphopenia of IP could be related to *H. pylori*. Lower B-cell count, associated with both species, may signify acquired immune tolerance.

P510 CLINICOPATHOLOGICAL STUDY OF THREE GENERATIONS OF NODULAR GASTRITIS - WHEN SHOULD NODULAR GASTRITIS BE ERADICATED?

T. Okamura[1,*], Y. Iwaya[1], S. Okuhara[1], Y. Nakayama[2], H. Ota[3], T. Akamatsu[4], E. Tanaka[1]. [1]*Gastroenterology,* [2]*Pediatrics, Shinshu University School of Medicine,* [3]*Biomedical Sciences, School of Health Sciences, Shinshu University School of Medicine, Matsumoto,* [4]*Endoscopic Examination Center, Nagano Prefectural Suzaka Hospital, Suzaka, Japan*

INTRODUCTION: Nodular gastritis (NG) is typically and frequently found in children who are infected with *Helicobacter pylori* (HP). NG has been recognized in adults infected with HP as well, and although it is considered to be a pangastritis, NG has been strongly associated with diffuse-type gastric cancer of the corpus as well. The natural history of NG remains elusive. Thus, we aimed to evaluate the clinicopathological hallmarks of NG over three generations of patients.
AIMS&METHODS: We recruited 103 patients (average age: 29 years, range: 4-79 years) who were diagnosed as having NG by upper gastrointestinal endoscopy at our hospital. The subjects were divided into three groups: 13 patients aged younger than 15 years (9 female; average age: 10.5 years) were assigned to the pediatric group, 50 patients aged between 16 and 30 (25 female; average age: 19.1

years) were classified into the young group, and 40 patients older than 31 years of age (29 female; average age: 47.7 years) comprised the elder group. We evaluated the clinical, endoscopic, and pathological features of NG among these three generations. Pathological features were evaluated using the updated Sydney System (USS).
RESULTS: NG was more frequently found in women in the pediatric and elder groups. Although the endoscopic finding of atrophic gastritis tended to increase with age, it was generally mild in our cohort. There was no significant difference among the three groups regarding scores for mononuclear cell infiltration in the greater curvature of the antrum. However, scores for mononuclear cell infiltration in the greater curvature of the gastric body was significantly higher in the elder group than in the pediatric and young groups (1.31 vs. 1.36 and 1.98, both $P<0.001$). Scores for neutrophil infiltration in the greater curvature of the gastric body were also significantly higher in the elder group than in the other two groups (0.92 vs. 1.08 and 1.65, both $P<0.001$), but those for neutrophil infiltration in the greater curvature of the antrum were comparable among the groups. The scores for atrophy, intestinal metaplasia, and HP infection did not differ significantly in our study.
CONCLUSION: In pediatric and young patients, inflammatory cell infiltration in the gastric body is milder than in elder patients. As pangastritis is considered to be a risk factor for diffuse-type gastric cancer, HP eradication therapy in younger people, especially before 30 years of age, may prevent this type of cancer of the corpus.

P511 IMPROVEMENT OF GASTRIC ATROPHY AND INTESTINAL METAPLASIA 10 YEARS AFTER HELICOBACTER PYLORI ERADICATION

T. Yamasaki[1,*], H. Nebiki[1], M. Yamamura[1], N. Odagiri[1], Y. Wakahara[1], S. Hiramatsu[1], T. Suekane[1], E. Sasaki[1], K. Sano[1], H. Sato[1]. [1]*Gastroenterology, Osaka City General Hospital, Osaka, Japan*

INTRODUCTION: *Helicobacter pylori* (*Hp*) infection cause the gastric atrophy and intestinal metaplasia (IM) , both of which are considered precancerous change. Improvement of gastric atrophy and intestinal metaplasia after *Hp* eradication is controversial, because long term follow-up studies are few. We herein investigated the improvement of gastric atrophy and IM histologically and endoscopically for 10 years after *Hp* eradication.
AIMS&METHODS: We investigated the patients who were taken biopsy specimens from the greater curvatures of the gastric antrum and the corpus before and 10 years after *Hp* eradication. The histological findings of these specimens were analyzed according to updated Sydney's system. Gastric atrophy was also estimated endoscopically based on Kimura-Takemoto classification[1)]. In addition we divided into two groups according to age (<60 or over), then those scores were also compared. Statistical analysis was performed using R software.
RESULTS: This study included 46 patients (33 men, 13 women; mean age at *Hp* eradication: 55.7 ± 9.3, mean follow-up period: 4899 ± 816 days). Reasons of eradication were gastric ulcer: 22, duodenal ulcer: 14, gastroduodenal ulcer: 5, gastric adenocarcinoma: 2, others: 3. Scores of atrophy and IM at gastric antrum and corpus were improved significantly 10 years after *Hp* eradication (Table). Endoscopic atrophy was not improved significantly ($p = 0.413$). When we divided the patients into two groups, the atrophy and IM at the gastric antrum in the younger group were only improved significantly.

	Antrum		Corpus	
	Atrophy	IM	Atrophy	IM
Before *Hp* eradication	1, 1.1 ± 1.1	0, 0.8 ± 1.0	0, 0.4 ±0.8	0, 0.4± 0.9
10yr After *Hp* eradication	0, 0.5 ± 0.8	0, 0.4 ± 0.8	0, 0.1± 0.3	0, 0.1 ±0.3
p value	0.018	0.003	0.001	0.020

IM: intestinal metaplasia , (Median, Mean ± Standard deviation)
CONCLUSION: *Hp* eradication improved the gastric atrophy and IM after 10 years follow-up, especially in the gastric antrum in younger patients. This improvement needs long term follow-up, but could contribute the reduction of gastric adenocarcinoma.

P512 EFFICACY OF «TEST&TREAT» STRATEGY: IS THERE THE DIFFERENCE BETWEEN MALE AND FEMALE PATIENTS?

V. V. Chernyavskyi[1,*], L. S. Gvozdetska[2], A. K. Sizenko[1], V. P. Shypulin[3]. [1]*Internal medicine #1,* [2]*Gastroenterology, National Medical University,* [3]*Gastroenterology, National Medical Academy, Kyiv, Ukraine*

INTRODUCTION: A «test-and-treat» strategy is appropriate for uninvestigated dyspepsia (UD) in populations where the *H. pylori* (Hp) prevalence is high (1). This approach is subject to cost-benefit considerations, but clinical efficacy is variable in different subgroups of patients with uninvestigated dyspepsia (2). There are no adequate data of *H. pylori* prevalence among dyspeptic patients in Ukraine and the clinical efficacy of «test-and-treat» approach is not investigated..
AIMS&METHODS: Our aims were to analyze the strategy viability in male and female patients. 312 UD-patients (Caucasians - 156 male (m) and 156 female (f), without alarm signs, age <39 y.o., determined according to local cancer risk) were recruited in 4 centers. Hp status was established using 13C-urea breath test (UBT). 220 (70,5%±2,6%) was Hp-positive (119 (76,3%±3,4%)-m, 101 (64,7%±3,8%)-f). Hp-negative were 92 persons (m-37, f-55). Symptoms were assessed by scale 0 to 5 point before and after treatment. Hp-positive (group1) patients were treated with standard 10-days triple therapy, according to Maastricht-4 recommendations. Hp-negative patients (group 2) received standard dose of proton pump inhibitor (PPI) once daily for 4 weeks. Assessment of residual symptoms frequency and severity was performed after 1 month and 1 year after treatment finish. Eradication success was controlled by UBT after 1 month after end of the treatment.
RESULTS: Successful eradication was achieved in group 1: m -108 (90,8%±2,6%,), f- 88 (87,1%±3,3%), $p>0,05$. Complete or significant symptoms relief have noticed 92 (85,1%±3,4%) of successful treated male patients (OR 4.8 (95% CI 3,9-5,7)), this topic in female was 49 (55,7%±5,3%), OR =1,2 (95% CI=0,8–1,9). Clinically this approach is more effective in male patients (p=0,0076). After 1 year this results were not changed significantly ($p_i>0,05$). The effectiveness of PPI in group 2 was enough (significant symptomatic improvement) in 63,0%±5,0% of cases (m-64,9%±7,8%, f-61.8%±6,6%, $p>0,05$). After 1 year this results were not changed significantly ($p_i>0,05$), but relapses of dyspepsia appeared in 76.1%±4,4% of patients during the year.
CONCLUSION: The prevalence of Hp in UD-patients is high in Ukraine. A «test-and-treat» strategy is clinically effective and strongly appropriate for UD male patients of age <39 (in Ukraine) without alarm signs. The efficacy in female is significantly lower, possibly because of functional dyspepsia high prevalence in this subgroup.

P513 HELICOBACTER PYLORI COLONIZATION AND PREECLAMPSIA: THE GENERATION R STUDY

W. J. den Hollander[1,*], S. Schalekamp-Timmermans[2], I. L. Holster[1], V. W. Jaddoe[3], G. I. Perez-Perez[4], M. J. Blaser[4], E. A. P. Steegers[2], E. J. Kuipers[1]. [1]*Gastroenterology and Hepatology,* [2]*Obstetrics and Gynaecology,* [3]*Pediatrics, Erasmus MC University Medical Center, Rotterdam, Netherlands,* [4]*Medicine and Microbiology, New York Langone Medicine Center, New York, United States*

INTRODUCTION: Preeclampsia (PE) is characterized by endothelial dysfunction and related hypertension and coagulative disorders. It is a leading cause of perinatal and maternal morbidity and mortality. Although the exact pathogenesis is still unknown, certain infectious agents seem to play a role. *Helicobacter pylori (H. pylori)* has been reported to induce platelet aggregation, and we therefore hypothesized that this bacterium could be associated with PE.
AIMS&METHODS: The objective of this study was to assess the association between *H. pylori* colonization and PE. We measured IgG anti-*H. pylori* and CagA-antibodies in serum of pregnant women of the Generation R study, a population-based prospective cohort study in Rotterdam, the Netherlands. Delivery and medical records were retrieved for identification of subjects with PE, which were defined according to standard criteria. Information on demographics, education, and maternal risk factors was collected by questionnaires. Only women with a live born singleton pregnancy were included. Subjects with chronic hypertension, systemic lupus erythematosus, lupus anticoagulants or chronic heart disease were excluded from analyses. Odds ratios (OR) of PE for *H. pylori* colonization were calculated using logistic regression analyses after adjustment for potential confounders including maternal age, ethnicity, parity, smoking, body mass index and education level.
RESULTS: Serum of 6348 pregnant women was analyzed (mean age 29.7 ± SD 5.3). In total, 2923 women were *H. pylori* positive (46%) and 1028 of them were CagA-positive (35%). For 132 women pregnancy was complicated with PE (2.1%). *H. pylori* colonization rate in women with PE was 56% compared to 44% in subjects without PE (p=0.02). CagA-positivity rate was 20% in women with and 16% in women without PE (p=0.30). Adjusted for potential confounding effects, women colonized with *H. pylori* were more likely to develop PE (final OR 1.53; 95% confidence interval 1.04-2.26). CagA-positivity was not associated with PE.
CONCLUSION: Our data demonstrate that *H. pylori* colonization in pregnant women is associated with PE. *H. pylori* may be involved in different inflammatory mechanisms, which might potentially affect the pathogenesis of PE. Understanding and further validation of this association may contribute to effective intervention (e.g. *H. pylori* eradication treatment) for reducing morbidity and mortality from this disease.

P514 HELICOBACTER PYLORI INFECTION IS ASSOCIATED WITH THYROID NODULE PREVALENCE IN EUTHYROID POPULATION

Z. Shen[1,*], Y. Qin[2], C. Yu[1], Y. Li[1]. [1]*Department of Gastroenterology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou 310003, Zhejinag Province, China.,* [2]*International Health Care Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou 310003, Zhejinag Province, China., Hangzhou, China*

INTRODUCTION: Gastric epithelial cells are injuried by *Helicobacter pylori (H. pylori)* inducing autoantibodies, it is the same that it appears cross-reactivity through molecular modeling between *H. pylori* and thyroid tissue antigens, and it could result in pathological damage of thyroid tissue[1]. When *H. pylori* antigen is presented to T cells, the body produces cross-reactive immune response, it could cause immune injury to thyroid tissue. There were some reports which had shown a positive correlation between *H. pylori* infection and autoimmune thyroid diseases (ATDs)[2] , in clinical works, many patients who were diagnosed as thyroid nodules with normal thyroid function were found, but the risk factor for thyroid nodules among euthyroid population has not yet been fully clarified.
AIMS&METHODS: The aim of this study was to investigate the association of *H.pylori* infection with thyroid nodule in euthyroid population. A cross-sectional study was performed among 988 euthyroid chinese who underwent general health screening including thyroid ultrasonography, fasting ^{13}C urea breath test and laboratory data at International Health Care Center, the First Affiliated Hospital of Zhejiang University College of Medicine.
RESULTS: A total of 435 (44.0%) subjects were diagnosed as thyroid nodule and a total of 486 (49.2%) were . diagnosed as *H.pylori* infection. The thyroid nodule prevalence was significantly higher in *H.pylori* infection group than the control group (49.0% *vs.* 39.2%, $P = 0.002$). Age, gender, body mass index (BMI), systolic and diastolic blood pressure (SBP and DBP) status–adjusted correlation analysis showed that thyroid nodule was positively correlated with *H.pylori* infection [odds ratio (OR): 5.939, $P = 0.015$]. Stepwise logistic regression analysis was performed to evaluate the risk factors for thyroid nodule using the dichotomous variable logistic regression model. Nineteen variables including age, gender, SBP, DBP, BMI, serum thyroid- stimulating hormone (TSH), free thyroxine (FT4), free triiodothyronine (FT3) and *H.pylori* infection. It showed that thyroid nodule was significantly associated with age, female, serum thyroid-stimulating hormone (TSH), BMI, *H.pylori* infection (all $P < 0.05$).
Table1. Risk factors for thyroid node in euthyroid Chinese

Variables	Wald chi-squared	*P*	OR(95%CI)
female	35.953	0.000	2.578(1.892-3.514)
age	73.581	0.000	1.056(1.043-1.070)
TSH	8.630	0.003	0.784(0.667-0.922)
BMI	8.851	0.003	1.075(1.025-1.128)
H.pylori infection	5.633	0.018	1.390(1.059-1.824)

CONCLUSION: *H.pylori* infection is significantly associated with thyroid nodule prevalence in euthyroid population.

P515 LOCAL EXPERIENCE WITH NON-BISMUTH QUADRUPLE THERAPY AS FIRST LINE TREATMENT FOR HELICOBACTER PYLORI ERADICATION

A. Campillo[1,*], E. Amorena[1], M. Ostiz[1]. [1]*Hospital Reina Sofia, Tudela, Spain*

INTRODUCTION: In a previous study about effectiveness of eradication therapies for Helicobacter pylori (HP) prescribed in our area, we found that the first line combination most widely used (Amoxicillin + Clarithromycin + PPI) had a low efficacy (61.9% "per intention to treat" and 63.9% "per protocol"). In areas of high clarithromycin resistance recent guidelines recommend quadruple treatments, bismuth containing or not depending on the availability of this medicine. According to our previous data and the lack of availability of bismuth in Spain, in mid 2012 we started to prescribe a non-bismuth quadruple therapy (Amoxicillin + Clarithromycin + Metronidazole + PPI for 10 days).
AIMS&METHODS: Aim: To analyse the efficacy of the classical triple eradication therapy for HP and the non-bismuth quadruple combination, in the first year of its prescription in our area.
Methods: Retrospective observational study of all therapies prescribed in our hospital for HP eradication between 1st of January and 31st of December 2012 and their efficacy. Eradication was confirmed with ^{13}C-urea breath test at least 5 weeks after completion of treatment.
RESULTS: During 2012, 446 breath tests were made in our centre in 303 new patients, who constituted the study population. 56.9% were women, and the medium age was 47.9 years (SD 17.6 years). Among all those patients 198 (65.4%) got at least a first line therapy, that in 111 cases was the classical triple therapy (Amoxicillin + Clarithromycin + PPI) for 7-14 days. This combination was prescribed for 7 days in 62.2% of cases, while a 30.6% of patients (n=34) had a treatment duration of 10 days. Meanwhile, 75 patients (37.6%) received a first line therapy with non-Bismouth quadruple therapy. This quadruple combination showed a higher efficacy than the classical triple therapy, in both "per intention to treat" (86.1% vs. 69.2%, p=0.012) and "per protocol" analysis (89.9% vs. 69.8%, p=0.002). The sequence of Amoxicillin + Clarithromycin + PPI and Levofloxacin + Amoxicillin + PPI for 10 days as second-line therapy was used in 24 cases with an efficacy of 79.2%, while the combination of non-Bismouth quadruple therapy followed by Levofloxacin + Amoxicillin + PPI for 10 days was used only in 4 cases with a 75% of success.
CONCLUSION: In our area, non-Bismuth quadruple therapy has a high efficacy as first-line therapy for HP eradication, showing much better results than standard triple therapy with Amoxicillin + Clarithromycin + PPI.

P516 THE EFFECT OF EMPIRICAL RESCUE THERAPY FOR TWO OR MORE CONSECUTIVE H. PYLORI ERADICATION FAILURES

D. H. Oh[1,*], D. H. Lee[1], K. K. Kang[1], Y. S. Park[1], C. M. Shin[1], N. Kim[1], H. Yoon[1]. [1]*Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic Of*

INTRODUCTION: The eradication rate of first and second-line therapies have been decreasing progressively due to increasing antimicrobial resistance of Helicobacter pylori. After two or more consecutive *H. pylori* eradication failures, clinicians have faced the dilemma of determining which of the following therapy would be the most appropriate. The aim of this study was to elucidate clinical course and treatment strategies of refractory *H. pylori* infection.
AIMS&METHODS: From 2003 to 2012, total 123 (mean age 63.9: male 58, female 65) patients who had experienced at least two consecutive *H. pylori* eradication failures were enrolled at the Seoul National University Bundang Hospital. Efficacy of different rescue regimens was compared by confirming of eradication rate. *H. pylori* status was evaluated by histologic finding, campylobacter-like organism test and 13C urea breath test. Antibiotic susceptibility test for *H. pylori* was not done in all cases.
RESULTS: The clinical & endoscopic findings were as follows : 84 patients (67.7%) had erosive or atrophic gastritis and functional dyspepsia, 15 patients (12.1%) - gastric ulcer, 6 patients (4.8%) - duodenal ulcer, 10 patients (8.1%) - DU + GU, 18 patients - other findings (12 Tubular adenoma, 5 Gastric adenocarcinoma, 1 MALT lymphoma). There was no significant difference in the eradication rate between each rescue regimens. *H. pylori* eradication rates with the 3rd, 4th and 5th-line rescue regimens were 51.6% (62/120), 48.7% (20/41), and 20.0% (2/10), respectively. Finally, cumulative *H. pylori* eradication rate with the 3~7th rescue regimens (mean 3.51 times) was 73.0% (84/115). The cumulative incidence rate of gastric cancers did not differ between the eradicated group and failed group (mean observation period: 42.9 months).
CONCLUSION: Even with the consecutive treatments of refractory *H. pylori* infection using empirical regimens, *H. pylori* eradication rate was gradually declining. Finally, cumulative overall eradication rate could not achieve over 75%. Now that repeated empirical treatment without culture cause a significant limitation for effective eradication in the future, we should consider careful treatment strategies in refractory *H. pylori* infection.

P517 THE EFFICACY OF HYBRID AND SEQUENTIAL THERAPIES AS FIRST-LINE TREATMENT FOR H. PYLORI INFECTION IN KOREA

D. H. Oh[1,*], D. H. Lee[1], K. K. Kang[1], Y. S. Park[1], C. M. Shin[1], N. Kim[1], H. Yoon[1]. [1]*Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic Of*

INTRODUCTION: Recent prospective studies have shown sequential therapy has not achieved 85% *H. pylori* eradication rates in Korea. The aim of this study was to assess the efficacy of hybrid therapy as first-line treatment for *H. pylori* eradication.
AIMS&METHODS: From December 2012 to April 2013, A total 84 (mean age 57.6: male 29, female 55) patients who proven *H. pylori* infection were randomized to received either 14 day-Hybrid therapy (rabeprazole 20 mg b.i.d. and amoxicillin 1 g b.i.d. for 14 days plus clarithromycin 500 mg b.i.d. and metronidazole 500 mg b.i.d. for the remaining 7 days) or 14 day-sequential therapy (rabeprazole 20 mg b.i.d. and amoxicillin 1 g b.i.d. for the first 7 days, followed by rabeprazole 20 mg b.i.d., clarithromycin 500 mg b.i.d., metronidazole 500mg b.i.d. for the remaining 7days). Outcome of eradication was evaluated by the 13C-UBT at least 4 weeks later after cessation of treatment.
RESULTS: 84 patients (44 patients in the hybrid group and 40 patients in the sequential group) completed the study. The eradication rates of hybrid treatment group and sequential treatment group were 81.8% (36/44) (95% CI = 70.4 - 93.2%) and 80.0% (32/40) (95% CI = 67.6 – 92.4%) by intention-to-treat analysis (p=0.832). By the per-protocol, eradication rates were 83.7% (36/43) (95% CI = 72.6 - 94.7%) and 84.2% (32/38) (95% CI = 72.6 – 84.2%) (p = 0.952). There were no significant between-group differences in compliance and discontinuation due to severe side-effects.
CONCLUSION: 14 day-hybrid therapy failed to achieve significantly higher eradication rates than 14 day-sequential therapy. Both of them cannot achieve

over 85% of eradication rate. So, further studies are needed to find alternative first-line treatment for better eradication rate for Korean population.

P518 ERADICATION RATE OF HELICOBACTER PYLORI INFECTION ACCORDING TO THE STAGES OF PEPTIC ULCER DISEASE

H. Y. Kim[1,*], S. I. Seo[1], S. J. Kim[1], H. S. Kim[1], W. G. Shin[1], K. H. Kim[1], M. K. Jang[1], J. H. Lee[1]. [1]*Gastroenterology, KANGDONG SACRED HEART HOSPITAL, HALLYM UNIVERSITY, Seoul, Korea, Republic Of*

INTRODUCTION: The eradication rate of *Helicobacter pylori* infection might be affected by the inflammatory status of gastric mucosa and virulence factors such as CagA and VacA. The inflammatory status of gastric mucosa is different according to the stages of peptic ulcer disease. To our knowledge, there have been few studies about the eradication rate according to the peptic ulcer stages.
AIMS&METHODS: The aim of this study was to evaluate the eradication rate of *H. pylori* infection according to the stages of peptic ulcer disease. A total of 1,187 patients with peptic ulcer disease (382 gastric ulcer, 719 duodenal ulcer and 86 combined ulcer) who received proton pump inhibitor (PPI)-based triple therapy for 7 days were retrospectively included from January 2004 to December 2011. *H. pylori* eradication status was evaluated by ^{13}C urea breath test at 4~6 week after the completion of therapy. The patients were sorted into three groups by the ulcer stage and then the eradiation rates were compared.
RESULTS: The overall *H. pylori* eradication rate was 81.8%. There was no statistical difference in the eradication rate between gastric and duodenal ulcer (P=0.428; 80.1% *vs*. 82.1%). The eradication rates in active stage (n=330), healing stage (n=278) and scar stage (n=579) were 85.8%, 83.8% and 80.3%, respectively (P=0.016). In univariate analysis, active ulcer (P=0.028; 85.8% *vs*. 80.3%) and age < 50 (P=0.028; 84.5% *vs*. 79.5%) were associated with higher eradication rate. In multivariate analysis, active ulcer was a significantly independent predictor of successful eradication (Odd ratio; 3.04, 95% CI; 1.711-5.392, P=0.0001).
CONCLUSION: There was a significant difference in eradication rate according to the ulcer stages. Different eradication regimen or treatment duration in patients with scar stage ulcer might be necessary. Further prospective studies are warranted.

P519 INITIAL EMPIRICAL TREATMENT FOR HELICOBACTER PYLORI ERADICATION IN ROUTINE CLINICAL PRACTICE. NON BISMUTH SEQUENTIAL OR CONCOMITANT REGIMEN? A PRELIMINARY PROSPECTIVE COMPARATIVE STUDY IN SPARTA GREECE.

P. Kalapothakos[1,*], E. Georgakila[1], P. Georgantas[2], M. Bizanias[3], C. Spiliades[4]. [1]*Gastroenterology,* [2]*Internal Medicine,* [3]*General Surgery, Lakonia General Hospital, Sparta,* [4]*Pathologist, Iatriko Center, Athens, Greece*

INTRODUCTION: In areas of high clarithromycin resistance, the recent European guidelines recommend bismuth based regimens or if the bismuth is not available, non bismuth quadruple ''sequential'' or ''concomitant'' regimens
AIMS&METHODS: To assess the effectiveness, safety and acceptability of ten days sequential (ST) and concomitant (CT) therapies as first line empirical treatment for *H.pylori* eradication. In Greece the reported clarithromycin resistance approximates 20% or even higher.Prospective randomized 1:1, aaccording the number of endoscopy, single center study of two years duration. All patients included in the study were diagnosed with peptic ulcer disease, erosions or non ulcer dyspepsia by endoscopy. Helicobacter pylori infection was documented by at least two positive tests among rapid urease test, gastric histology, 13C Urea Breath test. Patients were randomly assigned to one of the following therapies: A. ST consisting of Omeprazole 20 mg and Amoxicillin 1000 mg for the first five days following by Omeprazole 20 mg, Clarithromycin 500 mg and Metronidazole 500 mg for the remaining five days, all twice daily. B. CT same four drugs taken concomitantly for ten days. Helicobacter pylori eradication was checked using a 13C Urea Breath test 8 weeks after treatment and histology for gastric lesions. Intention to treat (ITT) and per protocol (PP) eradication rates were determinate. Adverse events and treatment compliance (cut off 90%) were evaluated using specific questionnaire and residual medical count.
RESULTS: 102 patients per arm of therapy, 60% men, mean age 49,4 +/- 10,8 years in ST and 48,2 +/- 9,2 years in CT (p NS). In each arm, 49% had peptic ulcer, 25% erosions and the remaining non ulcer dyspepsia, while 31% were smokers. Eradication was achieved in 87/96 who returned for the follow up (2 lost 4 incomplete treatment) in the ST thus ITT was 85, 29% (95 %CI 83, 6- 92, 7%) and PP was 90, 62% (95 %CI 83, 3- 94%). In CT eradication was achieved in 88/95 (4 lost 3 incomplete treatment) who returned for the follow up thus ITT was 86,27% (95 %CI 82.1 – 91,9%) and PP was 92,63% (95 %CI 85,8 – 95,7%). Difference in ITT 0, 98% (95 %CI 0, 5 – 1, 2%) and in PP 2, 01% (95 %CI 1, 5-2, 9%). Adverse events were 28% in the ST, 30% in the CT (p NS). Drugs compliance was 95% and 96% in the two treatment groups.
CONCLUSION: In our area the two regimens appear to be equal effective, achieving 90% PP eradication rate, and well tolerated as first line empirical treatment for *H.pylori* eradication

P520 LACTOBACILLUS REUTERI IN MANAGEMENT OF HELICOBACTER PYLORI INFECTION IN DYSPEPTIC PATIENTS: A DOUBLE BLIND PLACEBO CONTROLLED RANDOMIZED CLINICAL TRIAL

M. H. Emara[1], S. Y. Mohamed[2,*], H. R. Abdel-Aziz[3]. [1]*Tropical Medicine,* [2]*Internal Medicine,* [3]*Pathology Department, ZAGAZIG UNIVERSITY, Zagazig, Egypt*

INTRODUCTION: The eradication rate of *Helicobacter pylori* after the standard triple therapy is declining and this may necessitates introduction of new antimicrobial agents.
AIMS&METHODS: This study was conducted to test the assumption that addition of *Lactobacillus reuteri* to the standard triple therapy improves eradication rate, clinical and pathological aspects in *H. pylori* infection. Seventy patients were enrolled and were randomly assigned into, group A the *L. reuteri* treated group and group B, the placebo control group. All patients were treated by the standard triple therapy for two weeks and either *L. reuteri* or placebo for four weeks. They were examined by symptom questionnaire, *H. pylori* antigen in stool, upper endoscopy with biopsies for rapid urease test and histopathological examination before and 4 weeks after treatment.
RESULTS: The eradication rate of *H. pylori* infection was 74.3% (26/35) and 65.7% (23/35) for both *L. reuteri* and placebo treated groups respectively (p =0.603). There was a significant difference regarding the reported side effects (p=0.002), patients treated with *L. reuteri* reported less diarrhea and taste disorders than placebo group. A significant difference within each group was noted after treatment for Gastrointestinal Rating Scale (GSRS) scores, patients treated with *L. reuteri* showed more improvement of gastrointestinal symptoms than placebo treated group (p < 0.000). The severity and activity of *H. pylori*-associated gastritis was reduced after 4-weeks of therapy in both groups. *L. reuteri* treated group showed significant improvement than placebo treated group (P < 0.000 and 0.034 respectively).
CONCLUSION: Eradication triple therapy of *H. pylori* supplemented by *L. reuteri* increased eradication rate by 8.6% (non significant), improved GSRS score (significant), reduced side effects (significant) and improved histological features (significant) in *H. pylori* infection when compared with triple therapy supplemented with placebo.

P521 EFFECTIVENESS OF HELICOBACTER ERADICATION IN THE TREATMENT OF GASTRIC MALTOMA

S. R. Jee[1,*], S. Y. Seol[1], S. H. Lee[1], J. S. Choi[1], K. S. Ok[1]. [1]*gastroenterology, INJE UNIVERSITY COLLEGE OF MEDICINE, Busan, Korea, Republic Of*

INTRODUCTION: *Helicobacter pylori* eradication induces remission in most patients with gastric mucosa-associated lymphoid tissue (MALT) lymphoma. However, there have been few reports about the effect of bacterial treatment on the gastric MALToma in Korea, a well-known *H. pylori* endemic area.
AIMS&METHODS: From January 2000 to December 2011, consecutive patients with stage-I gastric MALToma were enrolled in single centre retrospectively.
RESULTS: A total of 52 patients were enrolled and median age of the patients was 58 years (36-81 years). There were fewer male than female (M:F, 18:34) and male to female ratio was 1:1.9. The macroscopic tumour type was determined according to the classification of Watanabe, as follows : (1) ulceration (46.1%); (2) protruding (13.5%); (3) granular (9.6%); (4) infiltrative (25.0%); and (5) mixed (5.8%). Most of lesions were single (73.1%) and 68.4% of the neoplasm was located in body, 26.3% in antrum, and 5.3% in cardia or fundus. The median time of follow-up was 37.2 months (range 5–96 months). Among 51 of 52 patients who checked status of *H. pylori,* 33 (63.5%) was positive in *H. pylori* test. Eradication was done in 25 of 33 with *H. pylori*-positive. Among 23 of 25 assessable patients, 22 (96%) showed successful eradication. During the follow-up period, all of 22 showed CR (86.4%) or PR. Eight of 18 *H. pylori*-negative MALToma had eradication. Among them, seven patients showed CR and one showed no change.
CONCLUSION: In conclusion, irrespective of the existence of bacteria, *H. pylori* eradication is effective in the treatment of gastric MALToma.

P522 EFFICACY OF TWO LEVOFLOXACIN-CONTAINING SECOND-LINE THERAPIES FOR HELICOBACTER PYLORI: A PILOT STUDY

T. Calhan[1,*], R. Kahraman[1], A. Sahin[1], H. L. Doganay[1], K. Ozdil[1], H. M. Sokmen[1], E. Kanat[1]. [1]*Gastroenterology, Umraniye Training and Research Hospital, Istanbul, Turkey*

INTRODUCTION: An ideal second-line therapeutic regimen for the treatment of patients who do not respond to standard triple therapy is currently being investigated
AIMS&METHODS: We aimed to investigate the efficacy of two levofloxacin-containing second-line therapies for *Helicobacter pylori* (*H. pylori*).
148 consecutive *H. pylori*-positive patients who did not respond to the standard triple therapy (77 female, 71 male) were enrolled in the study. The patients were randomized consecutively to two second-line therapy groups; 73 to the

levofloxacin-containing sequential (LCS) and 75 to the levofloxacin-containing quadruple (LCQ) therapy group. The LCS therapy group received pantoprazole 40 mg and amoxicillin 1,000 mg twice daily for 5 days followed by pantoprazole 40 mg twice daily and metronidazole 500 mg three times daily and levofloxacin 500 mg one time daily for 7 days. The LCQ therapy group received pantoprazole 40 mg twice daily, tetracycline 500 mg four times daily, bismuth subcitrate 300 mg four times daily and levofloxacin 500 mg one time daily for 10 days. *H. pylori* eradication was confirmed by stool antigen testing at least 6 weeks after cessation of therapy. Side-effects and compliance were assessed by a questionnaire.
RESULTS: Per protocol cure rates were: 85.7% (95%CI; 75-92) and 93.1% (95%CI; 85-98) in the LCS and LCQ therapy, respectively. Intention-to-treat cure rates were: 82.2% (95%CI; 73-91) and 90.6% (95%CI; 79-95) in the LCS and LCQ therapy, respectively. No statistically significant difference was found between two groups (p=0.1). No differences in compliance or adverse effects were demonstrated between two groups.
CONCLUSION: This prospective trial demonstrates that both levofloxacin-containing sequential therapy and levofloxacin-containing quadruple therapy regimens have higher *H. pylori* eradication rates and are well tolerated. The levofloxacin-containing quadruple therapy is likely the best treatment option for a second-line therapy, at least in the Turkish population.

SMALL INTESTINAL I - Poster Area

P523 HUMAN ENTEROGLIAL CELLS-DERIVED SOLUBLE FACTORS MEDIATE PATHOGENIC AND PROBIOTIC BACTERIA EFFECTS ON INTESTINAL EPITHELIAL CELLS VIA A RAGE-DEPENDENT MECHANISM.

F. Turco[1], I. Palumbo[1,*], M. Della Coletta[1], P. Andreozzi[1], G. Sarnelli[1], R. Cuomo[1]. [1]*Clinical Medicine and Surgery, UNIVERSITY OF NAPLES "FEDERICO II", Naples, Italy*

INTRODUCTION: We have previously demonstrated that human enteroglial cells (EGCs) express TLRs and can release S100B, a neurotrophin which effects are mediated mainly by the receptor for advanced glycation endproducts (RAGE). The putative effects of mediators released by EGCs, after bacteria stimulation, on the surrounding cells have not been explored yet.
AIMS&METHODS: We aim to evaluate: 1) the effect of soluble factors released by EGCs, upon probiotic and pathogenic bacteria stimulation, on intestinal epithelial cells (IECs) viability and differentiation; 2) whether these effects are mediated by RAGE. Human EGCs were exposed to probiotic (Lactobacillus Paracasei F19, 10^8 bacteria/mL) and pathogenic (Enteroinvasive Escherichia Coli, 10^8 bacteria/mL) bacteria. After a 24 h incubation, conditioned media (CM) from these cultures were used to challange CaCo2 cells cultured to confluence, in presence or absence of a specific anti-RAGE antibody. CaCo2 viability and differentiation after 24 h were studied by MTT vitality test and lactase and sucrase enzyme activity test, respectively. CaCo2 cells with medium alone were used as control. Data are expressed as mean±SD of 3 independent experiments.
RESULTS: CM from EGCs alone and from EGCs stimulated with both probiotic and pathogenic bacteria did not affect CaCo2 cells viability (0.79±0.26, 0.85±0.36, 0.89±0.24 vs 0.89±0.31 $\lambda_{540\ -\ 630}$; p=NS). CM from EGCs alone and from probiotics stimulated EGCs significantly increased lactase (1.15±0.17 and 1.29±0.19 fold increase vs control; $p < 0.05$) as well as sucrase activity (2.09±0.30 and 1.95±0.23 vs control; $p < 0.05$), as compared to untreated CaCo2 cells. These effects are abolished when Caco2 cells are pre-treated with anti-RAGE. CM from pathogens stimulated EGCs has no effects on both lactase (0.85±0.23 fold increase vs control; p=NS)) and sucrase activity (0.55±0.15 fold increase vs control; p=NS).
CONCLUSION: We show that EGCs conditioned medium, with both pathogen and probiotic bacteria, may differently modulate IECs differentiation without exerting cytotoxic effects, with a mechanism involving RAGE stimulation on IECs. Our preliminary results provide further evidence on the role of EGCs in mediating the host-bacteria interaction and put forward the major contribution of EGCs in the control of epithelial barrier function.

P524 LINEAGE-SPECIFIC EXPRESSION OF BESTROPHIN-2 AND BESTROPHIN-4 IS REGULATED BY NOTCH SIGNALING IN HUMAN INTESTINAL EPITHELIAL CELLS.

G. Ito[1,*], R. Okamoto[1], T. Murano[1], H. Shimizu[1], S. Fujii[1], T. Nakata[1], K. Tsuchiya[1], T. Nakamura[1], M. Watanabe[1]. [1]*Tokyo Medical and Dental University, Tokyo, Japan*

INTRODUCTION: Bestrophins are newly identified family of ion channels, that can function either as Ca^{2+}-activated Cl^- channels or as HCO_3^- channels. Former study has indicated that, among four bestrophin genes, bestrophin-2 (BEST2) and bestrophin-4 (BEST4) might be expressed within the human intestinal tissue. However, their precise expression within the human intestine, or the mechanism regulating their expression remains largely unknown.
AIMS&METHODS: We aimed to clarify the cell population that expresses BEST2 or BEST4, and also the molecular mechanism regulating their expression, within the human intestine. Expression of BEST2 and BEST4 *in vivo* was identified by immunohistochemical analysis (IHC) using normal human intestinal tissues, or those from ulcerative colitis (UC) patients. Lineage-specific expression was further analyzed *in vitro*, by employing established human intestinal epithelial cell (IEC) line models of goblet cell differentiation or enterocyte differentiation. Involvement of Notch signaling was examined by using a cell-line in which Notch activation can be induced by a Doxycycline-dependent manner. Gene expression in those cell-lines was evaluated by both quantitative RT-PCR and immunocytochemistry.
RESULTS: In the normal human intestine, both BEST2 and BEST4 were expressed at the basolateral membrane of post-mitotic IECs. However, co-staining analysis revealed that BEST2 is expressed exclusively in MUC2-positive colonic goblet cells, whereas BEST4 is expressed exclusively in Villin-positive enterocytes of both small intestine and the colon. In UC patients, BEST2 expression was markedly downregulated in goblet cell-depleted crypts, which confirmed goblet cell-restricted expression of BEST2 under both normal and pathological conditions. Consistently, *in vitro* induction of enterocyte differentiation significantly upregulated expression of both Villin and BEST4, but not BEST2, in Caco-2 cells. Conversely, induction of goblet cell differentiation by a Notch inhibitor, LY411575, significantly upregulated expression of both MUC2 and BEST2, but not BEST4, in HT-29 cells. In sharp contrast, forced activation of Notch signaling, which is a key molecular event for enterocyte differentiation, significantly upregulated expression of both Villin and BEST4, but not BEST2, in LS174T cells.
CONCLUSION: Goblet cell-specific expression of BEST2, as well as enterocyte-specific expression of BEST4 is regulated by the activity of Notch signaling in human IECs. Results suggest the potential contribution of BEST2 and BEST4 to lineage specific functions of IECs, such as mucin secretion or nutrition absorption.

P525 COMPLETE CONVERSION OF CRYPT PROGENITOR CELLS INTO ATOH1-POSITIVE CELLS BY TARGETED DELETION OF DLL1 AND DLL4 IN LGR5-POSITIVE INTESTINAL STEM CELLS.

H. Shimizu[1,*], R. Okamoto[1], T. Nakata[1], S. Fujii[1], G. Ito[1], T. Murano[1], K. Tsuchiya[1], T. Nakamura[1], M. Watanabe[1]. [1]*Tokyo Medical and Dental University, Tokyo, Japan*

INTRODUCTION: Notch ligands Dll1 and Dll4 are functionally redundant, and both are required for the proper maintenance of the intestinal epithelium. These ligands have been shown to activate Notch signaling at both stem- and progenitor-cell level, and thereby contribute to maintain $LGR5^+$ intestinal stem cells (ISCs), as well as $Hes1^+$ or $Atoh1^+$ progenitor cells. However, whether an ISC that is deficient of both genes can maintain its stem cell function, and give rise to both $Hes1^+$ and $Atoh1^+$ progenitor cells, has never been identified.
AIMS&METHODS: In this study, we aimed to analyze the effect of Dll1 and Dll4 deficiency in $LGR5^+$ ISCs. Mice harboring the EGFP-Ires-creERT2 knock-in allele at the LGR5 locus ($LGR5^{EGFP\text{-}Ires\text{-}CreERT2}$) was crossed with both Dll1-floxed and Dll4-floxed mice to generate $LGR5^{EGFP\text{-}Ires\text{-}CreERT2}/Dll1^{flox/flox}Dll4^{flox/flox}$ mice. A control strain was also generated by crossing those CreERT2 mice with Rosa26-lacZ reporter mice ($LGR5^{EGFP\text{-}Ires\text{-}CreERT2}$/LacZ mice). These mice were subjected to Cre-mediated gene recombination by intraperitoneal injection of Tamoxifen (TMX) for 5 consecutive days. Mice were sacrificed at various days post induction, and their intestinal tissues were analyzed by immunohistochemistry (IHC).
RESULTS: Analysis of $LGR5^{EGFP\text{-}Ires\text{-}CreERT2}$/LacZ mice showed that in the small intestine, progeny of $LacZ^+$ $LGR5^+$ ISCs can completely replace the whole crypt, including Paneth cells, within 5 days post induction. In these mice, both $Hes1^+$ and $Atoh1^+$ cells were clearly observed in the crypts, which did not change upon TMX treatment. Small intestinal tissue of $LGR5^{EGFP\text{-}Ires\text{-}CreERT2}/Dll1^{flox/flox}Dll4^{flox/flox}$ mice collected at 5 days post induction revealed that the number of $EGFP^+$ ISCs remained unchanged, compared to control mice. IHC analysis showed that number of Paneth cells also remained unchanged, suggesting that the stem cell niche is insusceptible to Dll1 and Dll4 loss-of-function at this experimental period. However, in sharp contrast, IHC analysis also revealed that marked increase of $Muc2^+$ goblet cells can be observed exclusively in the villus extending from crypts containing $EGFP^+$ ISCs. Consistently in those $EGFP^+$ crypts, no $Hes1^+$ cell could be observed, but the progenitor region appeared to be completely dominated by $Atoh1^+$ cells, as confirmed by double immunostaining of Hes1 or Atoh1 with EGFP.
CONCLUSION: Targeted deletion of Dll1 and Dll4 in $LGR5^+$ ISCs can completely convert crypt progenitor cell population into $ATOH1^+$ cells. Compared to the stem cell compartment, progenitor cells may be more susceptible to loss-of-function of Dll1 and Dll4.

P526 HUMAN SMALL INTESTINAL BARRIER FUNCTION AND TIGHT JUNCTION INTEGRITY DURING ISCHEMIA REPERFUSION

I. Hundscheid[1,2,*], D. Schellekens[1,2], J. Grootjans[3], F. Verheyen[4,5], R. Van Dam[1], J. Derikx[1], K. Dejong[1], K. Lenaerts[1,2]. [1]*Dept. General Surgery, [2]School for Nutrition, Toxicology and Metabolism (NUTRIM), Maastricht University Medical Center +, Maastricht, [3]Dept. Internal Medicine, Slotervaart ziekenhuis, Amsterdam, [4]Center for Research Innovation, Support and Policy (CRISP), [5]Dept. of Molecular Cell Biology and Electron Microscopy, Maastricht University Medical Center +, Maastricht, Netherlands*

INTRODUCTION: The small intestine is lined with epithelial cells interconnected by tight junctions (TJ) to prevent exposure of the host interior to potentially harmful luminal content. Intestinal ischemia and reperfusion (IR) is associated with damage to this barrier which can lead to bacterial translocation, systemic inflammation, and eventually multiple organ failure. Previous studies showed that the human small intestine is able to morphologically restore IR-induced damage after 30 minutes of ischemia. However, it is unknown if the barrier is also functionally resealed within this time frame. This study aimed to assess intestinal barrier function during intestinal IR.
AIMS&METHODS: In a human experimental model 6 cm of jejunum, to be removed for surgical reasons, was selectively exposed to 30 minutes of ischemia (I) followed by 30 and 120 minutes of reperfusion (R). Before induction of ischemia, lactulose (L) and rhamnose (R) were injected into the lumen of the isolated bowel segment to assess intestinal permeability. A sham procedure without IR was performed in 3 patients. Blood and tissue were sampled at all time points. Arteriovenous (V-A) concentration differences of plasma sugars were measured using HPLC-MS and L/R ratios were calculated. Tissue was stained for ZO-1/occludin and analyzed by electron microscopy (EM) to visualize TJs.
RESULTS: Plasma L/R ratio significantly increased at 30I30R compared to control (0.75±0.10 vs 0.20±0.09, P < .05), indicating increased intestinal permeability after short reperfusion. At 30I120R, the ratio normalized to 0.17±0.06 and was not significantly different from control or sham. ZO-1/occludin staining showed continuous staining in control tissue, while at 30I, distortion of staining was observed, indicating TJ loss. An intact lining of ZO-1/occludin was observed at 120R. EM analysis revealed disrupted TJs after 30I, which are restored after 120R.
CONCLUSION: The human small intestinal barrier is damaged after ischemia followed by 30 minutes of reperfusion. Morphological and functional recovery of this barrier occurs within 120 minutes of reperfusion, highlighting the unique ability of the human gut to withstand short ischemic events.

P527 NEURAL MODULATION OF GLUCOSE ABSORPTION IN RAT JEJUNUM VIA SGLT1 AND GLUT2: DEPENDENCE ON INTRALUMINAL GLUCOSE CONCENTRATION

K. Barada[1,*], F. Mourad[1], R. Berkachy[2], C. Nassar[3], N. Saade[2]. [1]*Internal Medicine,* [2]*Anatomy, Cell Biology and Physiology, American University of Beirut Medical Center, Beirut,* [3]*Physiology, Balamand University, Balamand, Lebanon*

INTRODUCTION: Intestinal glucose absorption is a critical component of glucose homeostasis. This study aims to determine the role of capsaicin sensitive primary afferents (CSPA) in regulating rat jejunal glucose absorption and to determine if this regulation occurs via SGLT1 and/or GLUT2.
AIMS&METHODS: Glucose absorption was measured in-vivo by intrajejunal perfusion of various concentrations of glucose in control rats and rats desensitized to capsaicin. The effects of adding capsaicin, phlorizin or phloretin to the perfusate were determined. The effect of capsaicin, with and without phlorizin, phloretin or tetrodotoxin on glucose uptake by jejunal strips was also measured in-vitro.
RESULTS: Absorption of 0.1 to 50 mM glucose in vivo was saturable, and increased from 0.09+0.002 to 29.8±2.4 μmoles/hour/cm. Intaluminal perfusion of 1 mM phlorizin or phloritin reduced the absorption of 50 mM glucose by 34 and 21%, respectively ($P < 0.05$). Intrajejunal perfusion of 400μM capsaicin had no effect on the absorption of 0.1mM, 1mM, 5mM, or 20mM glucose, but absorption of 50 mM glucose was reduced by 50% ($p < 0.05$). Systemic desensitization to capsaicin decreased absorption of 20 and 50 mM glucose by 21% and 47%, respectively. The decrease of 50 mM glucose absorption was fully reversed by phloretin, but was accentuated by phlorizin. In vitro, SGLT-1 mediated steady state glucose uptake (1 and 20 mM) by jejunal strips was inhibited by capsaicin in a dose-dependent manner. This effect was more pronounced with lower concentration of glucose and was reduced by tetrodotoxin. In normal rats, one minute uptake of 1-50 mM glucose by strips was also saturable and increased from 2.97±0.02 to 40.1± 2.3μmoles/minute-gram dry weight. This uptake was reduced substantially in the presence of 10 or 25 μM phlorizin or phloretin, an effect that was more pronounced with the lower concentration of glucose. Systemic desensitization to capsaicin reduced basal 1-20 mM, but not 50 mM unidirectional glucose uptake. Low dose phloretin decreased unidirectional uptake of 50 mM glucose by 35% in normal rats, but had no effect in rats desensitized to capsaicin.
CONCLUSION: CSPA fibers are involved in regulating intestinal glucose transport. This regulation seems to depend on the intraluminal glucose concentration, and is at least partially mediated by both SGLT1 and GLUT2.

P528 THE EFFECTS OF ALCOHOL ON GUT WALL INTEGRITY AS MEASURED BY I-FABP, L-FABP AND LBP.

W.-J. J. de Jong[1,*], A. Cleveringa[1], B. Greijdanus[2], P. Meyer[3], J. B. Hulscher[1]. [1]*Surgery,* [2]*Pharmacology,* [3]*anesthesiology, UMCG, Groningen, Netherlands*

INTRODUCTION: The aim of this study is to determine the immediate effects of oral alcohol consumption on gut wall integrity. The gut wall integrity will be assessed using intestinal- and liver-fatty acid binding proteins (I-FABP and L-FABP) as a measure of the integrity of the enterocyt. Lipopolysaccharide Binding Protein (LBP), a protein that binds lipopolysaccharides (LPS), will serve as a measure of endotoxemia.
AIMS&METHODS: A clinical trial in randomized cross-over design, including fifteen healthy adult male volunteers was conducted. Seven blood samples were taken. One blood sample was collected pre-consumption, five hourly post-consumption and one 24 hours later. Each volunteer consumed alcohol (1g/kg) on the one day and water on another. Volunteers fasted during 6 hours pre-consumption to obtain a reproducible alcohol uptake. Concentrations I-FABP, L-FABP and LBP in blood plasma were analyzed using ELISA.
RESULTS: Fifteen males were included, median age 21 years (18-41). The mean IFABP (ng/ml) of all samples was significantly higher after drinking alcohol than after drinking water, 1.64 (0.81-5.63) vs. 1.15 (0.52-1.81) resp. p=0.001. The mean of the highest single IFABP samples per volunteer was also higher on the alcohol day compared to the water day 3.16 (1.31-13.29) vs. 1.80 (0.77-2.68) p=0.001 resp. The mean L-FABP (ng/ml) was significantly higher on the alcohol day 18.99 (9.25-37.19) vs. 16.16 (10.52-30.52) p=0.012. As was the mean of the highest single LFABP sample per volunteer on the alcohol day 31.70 (13.90-73.72) vs. 24.24 (16.98-36.80) p=0.009. The mean LBP (µg/ml) showed no significant difference between the alcohol and water group 15.13 [9.44 – 23.16] vs. 15.74 [9.20-41.39] resp. p=0.394 nor did the highest single LBP sample per volunteer: alcohol 20.50 [11.28-28.60] vs. water 20.32 [11.98-48.28] p=0.570.
The correlation between I-FABP and L-FABP was ρ=0.843, p=0.000. The correlation between LBP and I-FABP was 0.148, p=0.033 and LBP and L-FABP was 0.209, p=0.003. The highest concentrations of LBP per volunteer did not correlate significantly with highest I-FABP/L-FABP levels 0.479, p=0.071 and 0.211, p=0.451 resp.
I-FABP and L-FABP concentrations increase significantly during the first 3 hours after drinking alcohol. Levels then decrease significantly.
CONCLUSION: Acute alcohol consumption immediately effects the gut wall integrity, as measured with damage markers I-FABP and L-FABP and continues to do so up to three hours. LBP concentrations do not increase significantly so translocation of bacterial products does not seem likely after acute alcohol consumption.

P529 PHOSPHORYLATION OF SMAD2/3 IN STEM CELLS OF SMALL INTESTINE

Y. Takahashi[1,*], T. Fukui[1], R. Suzuki[1], M. Kishimoto[1], K. Uchida[1], K. Matsuzaki[1], A. Nishio[1], K. Okazaki[1]. [1]*Kansai Medical University, hirakata, Japan*

INTRODUCTION: The stem cells of intestine are ultimately responsible for the renewal of tissues undergoing continuous turnover and is possibly in the CBC cells and the +4 cell position from the bottom of crypts. We have previously identified the significant expression of Smad2/3, phosphorylated at specific linker threonine residues (pSmad2/3L-Thr), in specific epithelial cells of the murine stomach and have suggested these cells to be epithelial stem cells. In the present study, we explore whether pSmad2/3L-Thr can serve as a marker for stem cells of murine intestine.
AIMS&METHODS: The small intestines from C57BL/6 mice were examined. Double immunofluorescent staining of pSmad2/3L-Thr with Ki67, CDK4, and chromograninA was performed, to show the characteristics of pSmad2/3L-Thr positive cells. To study other supposed stem cell biomarkers expression, we perfomed double immunofluorescent staining of pSmad2/3L-Thr with DCAMKL1, MSI-1, Lgr5. After immunofluorescent staining, we stained the same sections with hematoxylin–eosin and observed these cells under a light microscope.
For BrdU label-retaining assay, mice were injected with BrdU 3 times a day for 2 days. At various times (5, 10, and 15 days) after labeling, each group of mice was sacrificed. We performed immunofluorescent staining of the pSmad2/3L-Thr with BrdU.
RESULTS: In the small intestine, pSmad2/3L-Thr positive cells were significantly confirmed in the CBCs or +4 cell position. Although pSmad2/3L-Thr positive cells were detected between the Ki67 cells, immunohistochemical co-localization of pSmad2/3L-Thr with Ki67 was never observed. pSmad2/3L-Thr positive cells showed co-localization with CDK4 positive cells, and didn't show co-localization with chromograninA positive cells Under a light microscope, pSmad2/3L-Thr positive cells indicated undifferentiated morphological features and were confirmed in the CBCs and +4 cell position. pSmad2/3L-Thr positive cells were co-localized with MSI-1, and adjacent localization with DCAMKL1 positive cells. In Lgr5-EGFP knock-in mice, some but not all pSmad2/3L-Thr cells showed co-localization with Lgr5.
For label-retention studies, on 5,10,15-day, a part of BrdU label-retaining cells were co-localized with pSmad2/3L-Thr.
CONCLUSION: We have identified the significant expression of pSmad2/3L-Thr in specific epithelial cells of the murine small intestine. We suggest these cells to be intestinal stem cells. These cells might be in the phase of cell cycle just before undergoing cell division.

P530 ACTIVITY OF RIFAXIMIN AGAINST BACTERIAL STRAINS ISOLATED FROM DUODENAL ASPIRATES OF PATIENTS WITH INTESTINAL BACTERIAL OVERGROWTH

A. Pistiki[1,*], I. Galani[1], E. Pyleris[1], M. Pimentel[2], E. Giamarellos-Bourboulis[1]. [1]*4th Department of Internal Medicine, Attikon Hospital, Haidari, Athens, Greece,* [2]*GI Motility Program, Cedars-Sinai Medical Center, Los Angeles, United States*

INTRODUCTION: In a recent publication on 320 patients, we confirmed a relationship between small intestinal bacterial overgrowth (SIBO) and irritable bowel syndrome (IBS) (Pyleris et *al*. DDS 2012). In this study, we extend this investigation to include 800 patients and analyze the in vitro activity of rifaximin on SIBO colonizers.
AIMS&METHODS: Duodenal aspirates were collected from 800 outpatients subjected to upper GI endoscopy and quantitatively cultured under aerobic conditions. SIBO was diagnosed in 159 based on the isolation of at least one coliform $>10^3$ cfu/ml. Identification of Gram-negative bacteria was made by API20E and API20NE systems. Minimum inhibitory concentrations (MICs) of rifaximin, ampicillin, cefuroxime, gentamycin and levofloxacin were performed by a microdilution technique at a final volume of 0.1ml using a log-phase inoculum of $5x10^5$ cfu/ml of the isolates. Strain ATCC 25922 (*E. coli*) was tested as a control. Time-kill studies were performed exposing a log-phase inoculum of $1x10^6$ cfu/ml of 29 isolates to various concentrations of rifaximin; 11 were *Escherichia coli* and 3 *Enterococcus faecalis*. Any >3log10 decrease of viable cells was considered significant killing effect.
RESULTS: MIC50/MIC90 (mg/l) of rifaximin (no of tested isolates in parethesss) were: on *E.coli* (n= 48) 16/64; on *Klebsiella pneumoniae* (n= 32) 64/128; on *Enterobacter* spp (n= 23) 64/128; on *Klebsiella oxytoca* (n= 7) 64/64; on *Enterococcus* spp (n= 14) 8/16; on *Staphylococcus aureus* (n= 12) 0.12 and 0.12; on other *Enterobacteriaceae** (n= 11) 32/64; and on non-*Enterobacteriaceae*** (n= 23) 16 and >256. According to the CLSI breakpoints, ampicillin, cefuroxime, gentamycin, levofloxacin and rifaximin inhibited 25.9, 46.5, 74.1, 85.3 and 89.6% of the total tested isolates respectively. The killing effect was 27.5% of isolates by the 500 mg/l concentration on *E.coli* after 4 hours; 36.4% after 6 hours; and 81.8% after 24 hours. This was 100% after 24 hours for *E.faecalis* and 33.3% for the non-*E.coli* isolates.
*species of *Citrobacter freundii*, *Proteus mirabilis*, *P. vulgaris* and *Serratia marcenscens;*
**species of *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, *Stenotrophomonas maltophilia* and *Moraxella spp*.
CONCLUSION: As rifaximin is poorly absorbed and reaches its maximum concentration in the small intestine, MIC values for most of the tested aerobes corroborate clinical data on the clinical efficacy of rifaximin in IBS (Pimentel et *al*. N Eng J Med 2011; 364). The time-kill effect of rifaximin indicates the most promising effect of rifaximin on *E.coli* and *E.faecalis in vitro*.

P531 MIRNA-MRNA PAIRING ANALYSIS IDENTIFIES THE INFLAMMATORY RESPONSE AND INTESTINAL PERMEABILITY AS POTENTIALLY DYSREGULATED FUNCTIONS IN THE JEJUNAL MUCOSA OF IBS-D PATIENTS

C. Martinez[1,*], B. K. Rodiño-Janeiro[2,3], M. Granzow[4], B. Lobo[3], M. Vicario[3], M. Pigrau[3], C. Frias[3], F. Azpiroz[3], B. Niesler[1], R. Pillai[2], J. Santos[3], on behalf of CIBERehd (Instituto de Salud Carlos III) and Genes in Irritable Bowel Syndrome (GENIEUR) European Network (European Coordination in Science and Technology (COST) Actions). [1]*Dept Human Molecular Genetics, Institut of Human Genetics, University of Heidelberg, Heidelberg, Germany,* [2]*EMBL, Grenoble, France,* [3]*Neuro-Immune-Gastroenterology Lab, Vall d'Hebron Institute of Research, Barcelona, Spain,* [4]*Molecular Cytogenetics Lab, Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany*

INTRODUCTION: There is growing evidence that miRNAs are aberrantly expressed in chronic inflammatory diseases, but their involvement in the development and symptom generation in irritable bowel syndrome (IBS) have not been fully explored to date.
AIMS&METHODS: Our aims were (1) to identify miRNAs differentially expressed in the small bowel mucosa of IBS-D patients and (2) to explore putative targets and identify genes controlled by specific dysregulated IBS-D miRNAs.
Healthy volunteers (n=9) and non-allergic, non-celiac, naïve participants fulfilling IBS-D Rome III (n=14) were studied. Total RNA isolated from jejunal biopsies was submitted to microarray analysis (Agilent's Unrestricted_Human_miRNA_V16.0 and Affymetrix Human Genome U133 Plus 2.0 GeneChips). Combined analysis of miRNA and mRNA profiles was subsequently carried out by investigating the co-expression profile of miRNA-mRNA pairs. Targets were then selected based on inversed expression (up-regulation of miRNA and down-regulation of the target mRNA, and vice versa) and further evaluated using the Ingenuity Pathway Analysis software to identify biological networks, functions and pathways most significant to those targets.
RESULTS: 30 miRNAs and 286 mRNAs were differentially expressed ($p<0.05$) between healthy and IBS-D samples. miRNA-mRNA pairing analysis identified 155 genes that were experimentally observed or predicted with a moderate/high score to be targets of the differentially expressed miRNAs. Pathway analysis of the target genes revealed their implication in biological functions related to gastrointestinal disease ($p<0,001$), inflammatory disease ($p<0,001$) and inflammatory response ($p<0,001$). Top molecular and cellular functions associated with the target genes related to cell growth and proliferation ($p<0,00001$) and cell assembly and organization ($p<0,00001$). Interestingly, three networks (score>37, $p<10^{-37}$) of potentially interacting target genes implicated in significant biological functions related to intestinal permeability, secretory diarrhea and caveolar-mediated endocytosis signaling were also identified.
CONCLUSION: Substantial differences in miRNA and mRNA expression exist between healthy and IBS-D jejunal mucosa. miRNA-mRNA pairing analysis will help us to select a battery of distinctive molecular targets for future studies aimed at promoting innovative treatment and prevention strategies for IBS management.

P532 EOSINOPHILIC ACTIVATION BY NEUROMEDIATORS REPRESENTS A MECHANISM LEADING TO IMMUNE ACTIVATION AND BARRIER DYSFUNCTION IN IBS

E. Salvo-Romero[1,*], C. Frias[1], B. Lobo[1], A. González-Castro[1], M. Pigrau[1], C. Alonso[1], C. Sevillano-Aguilera[1], M. D. Castillo[1], M. Morís[1], F. Azpiroz[1], J. Santos[1], M. Vicario[1]. [1]*Neuro-Immuno-Gastroenterology Group, Digestive Diseases Research Unit, Gastroenterology Department, Hospital General Vall d'Hebron, Vall d' Hebron Research Institute, CIBERehd, Barcelona, Spain*

INTRODUCTION: In irritable bowel syndrome (IBS), the mechanisms underlying altered bowel habit and visceral hypersensitivity remain unestablished, although barrier dysfunction mediated by neuro-immune interactions involving eosinophils and mast cells may contribute. The impact on immune function of neuropeptides, such as substance P (SP) and its receptor (NKR1), remains unexplored in these patients.
AIMS&METHODS: We study the immunomodulatory role of SP and acetylcholine on the eosinophil (Eo), a key regulator of barrier function. Healthy(H) subjects (n=12) and age-matched, naïve participants fulfilling diarrhea-prone IBS(IBS-D) Rome III (n=17) were included. Jejunal biopsies were obtained by Watson's capsule in all participants. Mucosal Eos counts, ultrastructure, activation and secretory activity (SNAP-23) were evaluated by immunohistochemistry (MBP), transmission electron microscopy or gene expression. The Eo cell line AML14.3D10 was stimulated with SP (10^{-6}M) or Carbachol (CCh, 10^{-4}M), gene and protein expression were assessed by qRT-PCR, immunofluorescence, or flow cytometry.
RESULTS: The number of MBP^+cells was similar in both groups (H:44±7; IBS-D:83±19 cells/mm^2). However, we observed Eos peacemeal degranulation, increased SNAP-23 expression, unchanged MBP, and decreased eotaxin, EDN and ECP gene expression ($P<0.05$) in IBS-D. The Eo cell line expressed NKR1 and responded to SP by upregulating IL-8, NFKB and MBP, downregulating CCL21 and without changing EDN and EPO gene expression ($P<0.05$). Moreover, Eos expressed M1, M2 and M3 muscarinic receptors and responded to CCh stimulation by upregulating IL-8, NFKB and CCL21 and downregulating EPO, MBP and EDN gene expression ($P<0.05$). Secretory activity was confirmed by localization of SNAP-23 on the membrane surface only in stimulated cells.
CONCLUSION: Similar to IBS-D intestinal mucosa, decreased Eo classical proinflammatory profile is identified by neuromediator stimulation of the Eo cell line. The relevance of neuroimmune activation of mucosal Eos in IBS warrants further investigation.

P533 REDUCED NUMBERS OF MAST CELLS IN THE JEJUNUM OF PATIENTS WITH IBS-D COMPARED TO HEALTHY VOLUNTEERS.

G. Mohammadian[1,*], A. Dlugosz[1], G. Lindberg[1]. [1]*Department of Medicine, KAROLINSKA INSTITUTE, Stockholm, Sweden*

INTRODUCTION: Mast cells are part of the innate immunity of the gut. The pathogenesis behind irritable bowel syndrome (IBS) is still unknown, but alterations in the mucosal immune system might have a role in development of the disease. Increase of mast cells has previously been described in duodenum, jejunum and colon of patients with IBS. However there are also studies that have been unable to detect differences and even decrease of mast cells has been reported[1]. The methods used in the different studies have not been unifying.
AIMS&METHODS: The aim of this study was to develop a standardized method for mast cell morphometry and to identify alterations in the prevalence of mast cells.
Jejunal biopsies were taken with a Watson capsule from 27 patients with IBS and 45 healthy volunteers (HV) and duodenal biopsies were taken with gastroscopy from 10 patients. Biopsies were paraffin embedded after fixation in formalin and stained by immunohistochemistry for tryptase and CD117. Stained cells were manually counted per mm^2 mucosa in lamina propria, intraepithelial and total. The area was calculated via image analysis program (Nikon NiS elements BR 3,22). Unpaired t-test with Bonferroni's correction was used for statistical analyses.
RESULTS: We found no difference in total numbers or mast cells using tryptase or CD117 between IBS patients and HV. When analysing subgroups of IBS, patients with IBS-D have significantly lower intraepithelial CD117-positive mast cells ($p<0.0125$) but not intraepithelial tryptase-positive cells compared to HV. Duodenal biopsies from patients exhibited significantly more mast cells than jejunum biopsies both for tryptase ($p<0.001$) and CD117 ($p<0.001$) stained biopsies.
CONCLUSION: In contrast to many other studies we found no increase of jejunal mast cells in IBS but possibly a decrease in jejunal intraepithelial mast cells in patients with IBS-D. The intraepithelial mast cells have previously not been described in IBS but since they are in direct contact with the gut lumen, they might have a role in IBS pathogenesis. We counted mast cells per mucosal area.

Others have mostly counted mast cells per high power field (hpf). Counting per hpf includes areas without mucosa and is therefore difficult to standardize for comparison. The number of mast cells in the duodenum was greater than in the jejunum. Further studies with a larger cohort are needed to confirm this finding.

P534 MESENCHYMAL STEM CELL-DERIVED MOLECULES PROTECT AGAINST RADIATION-INDUCED INTESTINAL INJURY THROUGH MODULATION OF ENDOGENOUS CELL HOMEOSTASIS AND INHIBITION OF SYSTEMIC AND LOCAL INFLAMMATION

H. Chen[1,*], W. Sha[1], Q. Chen[2]. [1]*Department of Gastroenterology, Guangdong General Hospital,* [2]*Department of Gastroenterology, Sun Yat-Sen Memorial Hospital, Guangzhou, China*

INTRODUCTION: Intestinal injury induced by radiotherapy can affect patient's quality of life and may be life threatening. Mesenchymal stem cells (MSC)-derived molecules have been shown to provide protection from intestinal injury. However, the mechanisms involved are barely understood. In this study, we evaluated the therapeutic capability of MSC-derived molecules after radiation-induced intestinal injury and identified the potential mechanisms invovled.

AIMS&METHODS: To study this, rats were exposed to a 10 Gy abdominal irradiation, MSC-conditioned medium (MSC-CM) was then delivered to rats by tail intravenous injection. Blood and tissue samples were collected for various measurements. The levels of various inflammatory cytokines were determined in small intestine and blood to assess the amelioration of inflammation. Parallel studies were performed in rat intestinal epithelial cells (IEC-6) co-coltured with MSCs after radiation. Proteomic analysis were performed to identify the key biomolecules correlated with the therapeutic effects in MSC-CM.

RESULTS: We report that systemic infusion of MSC-CM significantly ameliorated the clinical and histopathological severity of intestinal injury in rats, abrogating weight loss and inflammation, restituting intestinal structure and xylose absorption, increasing survival. We observed that the delivery of MSCs secretions leads to an intestinal cytoprotective effect by both stimulating regeneration and inhibiting death of irradiated intestinal epithelial cells *in vivo and vitro*. MSC-CM treatment also accelerates $Lgr5^+$ intestinal stem cells (ISCs) regeneration in the early stage of rehabilitation. In addition, we demonstrate that MSC-CM treatment has an inhibitory effect on inflammation response by down-regulation of pro-inflammatory cytokines and up-regulation of anti-inflammatory cytokines at both systemic and local levels. Conditioned medium from MSCs stimulated by radiation-induced inflammatory products ($MSC\text{-}CM^{IR}$) was more effective than conditioned medium from MSCs incubated under normal conditions ($MSC\text{-}CM^{NOR}$), an observation partly explained by its higher content of growth factors and chemokines, such as basic fibroblast growth factor (bFGF), vascular endothelial growth factor (VEGF).

CONCLUSION: Our results suggests that MSC-CM treatment provides therapeutic benefits to the injuried intestine by reducing apoptosis and increasing proliferation of intestinal epithelial cells, accelerating resident $Lgr5^+$ ISCs regeneration, limiting systemic and local inflammation and could be used as an attractive candidate for the treatments of radiation-induce intestinal injury.

P535 SELECTIVE ADENOSINE RECEPTOR MODULATORS: NEW APPROACHES FOR PREVENTION OF INFLAMMATION-INDUCED DISTURBED GASTROINTESTINAL MOTILITY

K. Nieber[1,*], S. Michael[2], C. E. Müller[3], O. Kelber[4], H. Abdel-Aziz[4], D. Weiser[4]. [1]*Institute of Pharmacy, University of Leipzig, Leipzig,* [2]*Löwen-Apotheke, Waldheim,* [3]*Institute of Pharmacy, PharmaCenter Bonn, Bonn,* [4]*Scientific Department, Steigerwald Arzneimittelwerk GmbH, Darmstadt, Germany*

INTRODUCTION: The purine nucleoside adenosine, which is involved in a variety of physiological functions, regulates immune and inflammatory responses and acts as a modulator of gut functions. By activation of different receptor subtypes adenosine is able to induce anti-inflammatory or pro-inflammatory impacts.

AIMS&METHODS: The current study examined the impact of the adenosine A_{2A} receptor ($A_{2A}R$) agonist CGS 21680 and the A_{2B} antagonist ($A_{2B}R$) PSB-1115 on acute inflammation in rat ileum/jejunum preparations. Further it focused on interactions of the multi-herbal drug STW 5 and its component *Iberis amara* (STW 6) with $A_{2A}R$ as a possible mechanism of the protective effect of STW 5 in gastrointestinal disorders.

Inflammation was induced by intraluminal instillation of 2,4,6-trinitrobenzene sulfonic acid (TNBS). Contractions were measured isometrically in an organ bath set up. Gene expression was determined using qRT-PCR. Radioligand binding assays (competition experiments) were carried out with rat brain homogenates. Morphological changes were estimated after van Gieson staining.

RESULTS: CGS 21680 (0.1-10 μM) restored concentration-dependently the TNBS-induced inhibition of the ACh-contractions. PSB-1115 (100 μM) diminished the contraction in TNBS-preincubated preparations. A significant amelioration of the TNBS-diminished contractions was found after combined application of CGS 21680 and PSB-1115 in subthresholds, which was in the same range as the effect of 1 μM methotrexate. STW 5 (64-512 μg/ml) and STW 6(3-24 μg/ml) reduced concentration-dependently the TNBS-induced morphological disturbances and in parallel the ACh-induced contractions. STW 5 but not STW 6 interacted with $A_{2A}R$ and inhibited the TNBS- increased TNFα gene expression which was blocked by the $A_{2A}R$ antagonist CSC (0.2 mM).

CONCLUSION: Our results demonstrate that the activation of A_{2A} or the blockade of A_{2B} receptors can decrease the inflammation-induced disturbance in small intestinal preparations. STW 5 but not STW 6 interacts with $A_{2A}R$ contributing to the inhibition of the TNFα gene expression which could be responsible for inhibition of TNBS-induced disturbed contractions.

P536 ROLE OF ENDOGENOUS GLP-2 IN THE RECOVERY PHASE OF DSS-INDUCED COLITIS IN MICE

M. Matsushita[1,*], T. Ando[1], K. Ishiguro[1], O. Maeda[1], O. Watanabe[1], M. Ujihara[1], Y. Hirayama[1], K. Morise[1], K. Maeda[1], K. Funasaka[1], M. Nakamura[1], R. Miyahara[1], H. Goto[1]. [1]*Gastroenterology and Hepatology, Nagoya University Graduate School Of Medicine, Nagoya, Japan*

INTRODUCTION: Glucagon-like peptide-2 (GLP-2) is a potent intestinotrophic growth factor that has been shown to stimulate intestinal growth and reduce disease severity. Dipeptidyl peptidase-4 (DPP-4) inhibition reduces GLP-2 degradation and enhances the intestinotrophic effect of exogenous GLP-2. GLP-2 and DPP-4 inhibitor may therefore have curative properties against colitis via the enhancement of endogenous GLP-2. In a previous study, we reported that anagliptin, a DPP-4 inhibitor, had little influence on the development of DSS (dextran sodium sulfate)-induced colitis in mice, but improved recovery from this colitis by enhancing the proliferation of colonic epithelial cells. We conjectured that this enhancement of the recovery phase was facilitated by an effect of GLP-2. In this study, to confirm the influence of the recovery phase in the absence of GLP-2, we evaluate DSS-induced colitis in mice deficient in GLP-2.

AIMS&METHODS: Mice deficient GLP-2 were established by disrupting Glucagon gene (Gcg) by the introduction of green fluorescent protein (GFP) cDNA in a knock-in mouse line. $Gcg^{gfp/gfp}$ mice were deprived of pro-Glucagon hormone, GLP-1 and GLP-2. Twelve-week-old $Gcg^{gfp/gfp}$ and $Gcg^{+/+}$ mice were individually housed with ad libitum access to drinking water containing 3.0% DSS for 6 days. DSS-containing water was replaced with filtered water without DSS on day 6. Severity of colitis was assessed daily by body weight (BW) loss and disease activity index (DAI).

RESULTS: On Day 9, after 3 days from restart of water without DSS, there was no significant difference in BW loss or DAI ($Gcg^{gfp/gfp}$ group, BW -15.9±4.4%, DAI 3.8±1.8; $Gcg^{+/+}$ group, BW -14.9±3.8%, DAI 4.1±3.3; NS, n=4 each). From day 10 to day 22, BW of the $Gcg^{gfp/gfp}$ group was lower than that of the $Gcg^{+/+}$ group within the range of 1.0 to 5.1%.

CONCLUSION: In our previous study, we reported a significant improvement in BW loss and DAI on day 10, after 3 days from restart of water without DSS, in the anagliptin-treated group compared to the untreated group (untreated group, BW -20.7±7.4%, DAI 7.0±1.8; anagliptin-treated group, BW-12.2±7.0%, DAI 3.9±3.0; $P<0.01$, n=15 each). In the present study, however, we saw only a minor difference between $Gcg^{gfp/gfp}$ mice and $Gcg^{+/+}$ in the degree of DSS colitis. On day 10, average BW in the $Gcg^{+/+}$ mice was only 2% higher than that of the $Gcg^{gfp/gfp}$ mice. We therefore conclude that GLP-2 and DPP-4 inhibitor may have curative properties against colitis, but that the absence of GLP-2 does not exacerbate the recovery phase of DSS-induced colitis in mice.

P537 PHENOTYPIC AND FUNCTIONAL CHARACTERIZATION OF INTRAEPITHELIAL AND LAMINA PROPRIA INFLAMMATORY CELL INFILTRATE IN AUTOIMMUNE ENTEROPATHY.

M. Paroni[1], G. Nizzoli[1], A. Magarotto[2], U. Gianelli[2], C. Ciafardini[2], D. Conte[2,3], S. Abrignani[4], J. Geginat[1], **F. Caprioli**[2,3,*]. [1]*Autoimmunity, National Institute of Molecular Genetics,* [2]*Department of Pathophysiology and Transplantation, University of Milan,* [3]*Unit of Gastroenterology 2, Fondazione IRCCS Cà Granda, Ospedale Policlinico di Milano,* [4]*National Institute of Molecular Genetics, Milan, Italy*

INTRODUCTION: Autoimmune enteropathy (AE) is a rare disease characterized by diarrhea, malabsorption, and association with other autoimmune conditions. Histological hallmarks of AE include villous atrophy, lamina propria infiltration by T lymphocytes and increased intraepithelial lymphocytes (IELs). Few data exist regarding functional and phenotypic characterization of mucosal inflammatory cells in the small intestine during AE.

AIMS&METHODS: Duodenal biopsies were obtained from a 26-year old female diagnosed with AE, at baseline and following steroid therapy. Biopsies were treated with DTT, EDTA and collagenase to extract IELs and lamina propria mononuclear cells (LPMCs). Cells were analyzed for surface marker expression and intracellular cytokine profile by flow cytometry and immunohistochemistry.

RESULTS: The majority of IELs were CD8+CD103+ and produced interferon(IFN)-γ; noteworthy, a relevant amount of them co-produced interleukin(IL)-17. Steroid treatment reduced IL-17 production by IELs. Analysis of LP T cells revealed a similar proportion of CD4+ and CD8+ lymphocytes. Most of LP $CD4^+$ T cells exhibited a memory phenotype ($IL7R^{high}CD25^{low}$),while a low percentage of Tregs ($CD4^+CD25^{high}FoxP3^+$) was observed. Within CD4+ memory compartment, Th1 ($CXCR3^+$) and Th17 ($CCR6^+$) cells were equally represented; interestingly, a significant proportion of $CXCR3^+CCR6^+$ cells was observed. Prednisone treatment reduced CCR6+ and $CXCR3^+CCR6^+$ cells, while increasing the expression of $FoxP3^+$ in$CD4^+CD25^{high}$ cells. Upon stimulation, LP CD4+ T cells expressed IFN-γ, IL-17 and IL-22, while CD8+ cells mostly expressed IFN-γ. Prednisone treatment markedly reduced the production of IFN-γ by LP CD4+ cells. Phenotypic analysis of LP dendritic cells revealed that a small fraction of them expressed the myeloid cell marker CD11c and CD103. A significant number of CD11c- DCs expressing fractalkine receptor (CX3CR1) was found within the LP. Immunohistochemistry data confirmed the results.
CONCLUSION: These data demonstrate a massive infiltration by Th1 and Th17 cells, and activated CD8+ lymphocytes, in the small intestinal LP during AE. Noteworthy, LP Treg infiltration at baseline was remarkably low. The majority of IEL were CD103+IFN-γ+ CD8+ cells; among these, a relevant proportion co-produced IL-17. Most of these phenotypic and functional alterations were corrected by steroid therapy. These results could be relevant for the identification of novel therapeutic targets in patients with AE.

P538 DOES HIGH DOSE IRRADIATION AFFECT FUNCTIONS OF THE INTERSTITIAL CELLS OF CAJAL IN THE MURINE SMALL INTESTINE?

S.-B. Ryoo[1,*], J.-S. Kim[2], M.-S. Kim[3], S. A. Yu[4], M.-J. Bae[2], H.-K. Oh[1], S. H. Moon[1], E. K. Choe[1], I. S. So[4], K. J. Park[1]. [1]*Surgery, Seoul National University College of Medicine, Seoul,* [2]*Research Center,* [3]*Pathology, Dongnam Institute of Radiological & Medical Sciences, Pusan,* [4]*Physiology, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Motility of murine small intestine is composed of migrating motor complex (MMC) from enteric nervous system and phasic contraction from slow waves originating in interstitial cells of Cajal (ICC). ICC have plasticity, meaning that they can be reduced and recovered in various stages of diverse gastrointestinal disorders. High dose irradiation has been known to alter the intestinal motility by neurotransmitter related to inflammation. However, detailed analysis of changes in ICC functions after high dose irradiation is lacking.
AIMS&METHODS: We sought to determine whether high dose irradiation affects the plasticity of ICC. High dose of irradiation (13Gy) was given to 8-12 week old female C3H/HeN mice. Tension recordings for MMCs and phasic contractions from small intestinal segment and conventional microelectrode recordings for slow waves were performed at 0, 1, 3 and 5 day after irradiation with compared to sham mice.
RESULTS: Amplitude, area under the curve (AUC), and frequency of MMCs were 4.31 ± 1.59 mN, 61.94 ± 17.42 sec×mN/wave and 0.52 ± 0.09 /min in sham mice (N=6). Frequency of MMCs were faster at day 0 (0.88 ± 0.24 /min, p=0.009, N=4) and day 1 (0.73 ± 0.14 /min, p=0.013, N=5). MMCs almost disappeared at day 3 (N=3) with lower amplitude (0.86 ± 0.01 mN, p=0.009) and AUC (5.88 ± 0.20 sec×mN/wave, p=0.001). MMCs were recovered at day 5 (N=4) with no difference in amplitude (3.08 ± 0.75 mN), AUC (45.43 ± 17.42 sec×mN/wave) and frequency (0.52 ± 0.05 /min) compared to sham mice.
Amplitude, area under the curve (AUC), and frequency of phasic contractions were 0.47 ± 0.11 mN, 0.25 ± 0.06 sec×mN/wave, 36.25 ± 5.76 /min in sham mice (N=6). The phasic contractions were sustained at day 0, 1, 3 and 5 and were not significantly different from the sham mice. Resting membrane potential (RMP), amplitude, spike amplitude and frequency of slow waves were -54.32 ± 10.41 mV, 7.87 ± 3.46 mV, 15.48 ± 12.60 mV, 46.49 ± 6.92 /min in sham mice (N=5). The slow waves were also preserved at day 0, 1, 3 and 5 and were not significantly different compared to the sham mice. Mucosal inflammation was confirmed by H&E staining and c-kit immunohistochemistry confirmed the presence of ICC at day 0, 1, 3 and 5. Expressions of c-kit were not different at each day compared to sham mice.
CONCLUSION: There were changes in MMCs related to enteric nervous system after high dose irradiation. But, in contrast to our expectations, there were no changes in phasic contraction and slow waves, suggesting radiation resistance of the ICC

P539 REDUCTION OF NSAID-INDUCED ENTEROPATHY IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING ANTI-TUMOR NECROSIS FACTOR THERAPY: A PROPENSITY-MATCHED ANALYSIS

T. Watanabe[1,*], T. Tanigawa[1], M. Shiba[1], Y. Nadatani[1], Y. Nagami[1], S. Sugimori[1], K. Tominaga[1], Y. Fujiwara[1], T. Arakawa[1]. [1]*Department of Gastroenterology, Osaka City University Graduate School of Medicine, Osaka, Japan*

INTRODUCTION: The role of tumor necrosis factor-α (TNF-α) in the pathogenesis of nonsteroidal anti-inflammatory drug (NSAID)-induced small intestinal damage remains unclear. Biologics that antagonize the biological activity of TNF-α are being increasingly used in patients with rheumatoid arthritis (RA), and these drugs have the potential to induce mucosal healing in patients with intestinal diseases.
AIMS&METHODS: The aim of this study was to evaluate the preventive effect of anti-TNF therapy against small intestinal damage due to chronic NSAID use in RA patients. Capsule endoscopy was performed in 95 consecutive RA patients who received NSAIDs for more than 3 months, with or without anti-TNF therapy over a period of 3 months. The findings were scored from 0 to 4: 0, normal; 1, red spots; 2, 1 to 4 erosions; 3, >4 erosions; and 4, large erosions/ulcers. The relationship between the use of anti-TNF therapy and the risk of severe damage (score 3 or 4) or the most severe damage (score 4) was assessed using multiple logistic regression analysis. Furthermore, a propensity-score matching analysis was performed to reduce the effects of TNF-selection bias.
RESULTS: By stratifying the patients on the basis of anti-TNF therapy, we obtained crude odds ratios of 0.23 for severe damage (95% confidence interval [CI], 0.09 to 0.65) and 0.37 for the most severe damage (95% CI, 0.16 to 0.86). This protective effect of anti-TNF therapy remained robust to adjustments for baseline characteristics, with the adjusted odds ratios for severe damage and most severe damage ranging from 0.23 to 0.26 and 0.06 to 0.41, respectively. Propensity score matching yielded similar results and showed the protective effects of anti-TNF therapy against severe and most severe damage.
CONCLUSION: Anti-TNF therapy may protect against NSAID-induced small intestinal damage in RA patients. Drugs targeting TNF-α may be effective in the treatment of NSAID-induced enteropathy.

P540 RIFAXIMIN FOR TREATMENT OF SMALL INTESTINE BACTERIAL OVERGROWTH (SIBO): A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Gatta[1,2,*], C. Scarpignato[2]. [1]*Gastroenterology and Digerstive Endoscopy Unit, Versilia Hospital, Lido di Camaiore,* [2]*Department of Clinical & Experimental Medicine, University of Parma, Parma, Italy*

INTRODUCTION: SIBO is a condition caused by an increased number and/or abnormal type of bacteria (i.e. oropharyngeal or colonic type bacteria) in the small bowel. Eradication of SIBO relies on antibiotic therapy that must cover both aerobic and anaerobic enteric bacteria. Rifaximin is a poorly absorbable antibiotic, with a broad spectrum of antibacterial activity, covering Gram-positive and Gram-negative micro-organisms, both aerobes and anaerobes.
AIMS&METHODS: To investigate the efficacy of rifaximin to eradicate SIBO performing a systematic review and meta-analysis. MEDLINE, EMBASE, the CCRCT as well as abstract from the DDW, ACG, AGA, UEGW, BSG as well as Asian Pacific Digestive Week were searched up to November 2012. Case series, open label studies, cross-over and RCTs in adult patients with proven SIBO, treated with rifaximin, were eligible. The proportion of individuals eradicated was combined from all studies to give a pooled eradication rate using a random effects model in order to provide a more conservative estimate.
RESULTS: 28 studies were identified containing 921 subjects. 7 studies were RCTs: 2 compared rifaximin to placebo, 2 to systemic antibiotics, and 2 compared different doses of rifaximin. Finally the last RCT compared rifaximin 1200 mg/daily for 10 days vs. rifaximin 1200 mg/daily plus partially hydrolysed guar gum 5 g/ day for 10 days. To diagnose and follow-up the patients 16 studies used the hydrogen-glucose breath test and 12 the hydrogen-lactulose breath test. Pooled eradication rate was 67.0% (95% CI: 59.1 to 69.8) with evidence of heterogeneity ($I^2 = 78.17\%$). In the 2 RCTs comparing rifaximin to placebo, the pooled eradication rates for rifaximin was of 89.7% vs. 7.4% for placebo, with a difference of 82.3% (95% CI: 63.1 to 91.8). In the 2 RCTs comparing rifaximin to other antibiotics, the pooled eradication rates for rifaximin was of 64.1% vs. 41% for placebo, with a difference of 22.7% (95% CI: 7.4 to 37). It was possible to perform sensitivity analysis only in trials using rifaximin at the dosage of 1200 mg/daily according to the duration of treatment. Treatments lasting 10 days eradicated 10.9% (95% CI: 3 to 18.6) more than treatments lasting 7 days. Similarly, therapies lasting 14 days eradicated 26.3% (95% CI: 18.5 to 33.6) and 15.4% (95% CI: 7.7 to 22.7) more than treatment lasting 7 and 10 days respectively. Pooled prevalence of adverse events was 10.3%.
CONCLUSION: Rfaximin is effective and safe for treating SIBO, with an efficacy that appears to be time-dependent. However, large and well-performed RCTs are needed to substantiate these findings and establish the optimal regimen (daily dose and, especially, duration) of therapy.

P541 DO ENDOSCOPISTS ALWAYS RECOGNIZE SEVERE CASES OF CELIAC DISEASE?

E. Waszczuk[1], A. Mulak[1,*]. [1]*Department of Gastroenterology and Hepatology, WROCLAW MEDICAL UNIVERSITY, Wroclaw, Poland*

INTRODUCTION: Human IgA class antibodies against tissue transglutaminase (TTGA) and endomysium (EMA) are sensitive and specific markers for celiac disease (CD). Strongly positive titers of these antibodies (>10 times above the upper limit of normal) have been shown to significantly correlate with Marsh type 3 lesions in histopathological evaluation of duodenal biopsies and are currently considered to be sufficient for the diagnosis of CD in pediatric patients. In adult patients a duodenal biopsy during upper gastrointestinal (GI) endoscopy remains the gold standard in diagnosing CD. The presence of endoscopic markers of CD is a reliable indicator of histological villous atrophy that helps select patients for duodenal biopsies. However, it is not clear if advanced histopathological findings typical for CD are always associated with macroscopic changes of the duodenal mucosa.
AIMS&METHODS: To assess the relationship between duodenal histology and high levels of TTGA and EMA with endoscopic markers in adult patients with CD. Thirty two suspected CD patients with the titers of TTGA or EMA at least 10 times above the upper limit of normal were included in the study. All the patients underwent routine upper GI endoscopy with duodenal biopsies. The endoscopists were not informed about the high levels of antibodies, but the suspicion of CD was mentioned as a cause for referring the patients for endoscopy.
RESULTS: Based on the histopathological evaluation, in 30 patients (94%) Marsh type 3 lesions were described, while 2 patients (6%) had Marsh type 2 lesions. The endoscopists reported a normal endoscopic appearance of the duodenum in 20 out of 32 patients (62.5%). In 12 patients (37.5%) at least one endoscopic marker of CD was present: reduction or loss of Kerckring's folds (n=6), scalloping of the folds (n=6), coexisting reduction and scalloping of the folds (n=3), a micronodular appearance of the duodenal bulb mucosa (n=1), and duodenal erosions (n=2).
CONCLUSION: High titers of TTGA and EMA strongly correlate with histopathological but not endoscopic findings in CD. A normal endoscopic duodenal mucosal appearance does not exclude villous atrophy. Despite careful inspection of the duodenum during upper GI endoscopy, lack of endoscopic findings in patients with the suspicion of CD may be misleading, therefore duodenal biopsies with histopathological evaluation in adult CD patients are always required.

P542 INTESTINAL INTRAEPITHELIAL LYMPHOGRAM AND SUBEPITHELIAL DEPOSITS OF ANTI-TISSUE TRANSGLUTAMINASE IGA FOR COELIAC DISEASE DIAGNOSIS IN LYMPHOCYTIC DUODENOSIS

A. Carrasco[1,*], M. Rosinach[1], R. García-Puig[2], M. Esteve[1], C. González[3], M. Aceituno[1], C. Loras[1], V. Gonzalo[1], R. Temiño[1], X. Andujar[1], M. Forné[1], J. M. Viver[1], A. Salas[3], F. Fernández-Bañares[1]. [1]*Gastroenterology,* [2]*Pediatrics,* [3]*Pathology, HOSPITAL UNIVERSITARI MUTUA TERRASSA, Terrassa, Spain*

INTRODUCTION: Lymphocytic Duodenosis (LD) may have multiple aetiologies and the differential diagnosis is complex. It has been suggested that $\gamma\delta$+ intraepithelial lymphocytes (IEL) studies by immunohistochemistry or flow cytometry (FCM) or the presence of subepithelial deposits of transglutaminase IgA (TGd) by immunofluorescence could be useful for the diagnosis of coeliac disease (CD) in these patients. Data on these issues are scarce.
AIMS&METHODS: To evaluate the diagnostic utility of the celiac FCM IEL pattern (increase in $\gamma\delta$+IEL) in comparison with TGd and serum anti-TG IgA (TGs) in patients with LD.
We prospectively included 200 patients with clinical suspicion of CD and positive genetics (DQ2 and/or DQ8). 73% women; 28.5±1.4 years. Duodenal biopsies were taken for histopathological studies (LD was defined as >25% IEL), FCM and TGd. TGs cut-offs (Celikey, Varelissa) were: TGs<2u negative; between 2-7 u doubtful; and >7u positive. In doubtful TGs titres, EmA were evaluated. Gold standard was considered the presence of one of the following: 1) atrophy or LD with TGs+ (Doubtful TGs with EmA+); 2) atrophy or LD with TGs-, TGd+ and/either FCM+. TGd were blindly analyzed 2 different times by the same experienced observer and the intra-observer concordance degree was analyzed. Only moderate to high intensity TGd were considered as positive (since low intensity TGd are frequently seen in non-celiac controls). Sensitivity (95% CI) to detect CD was computed. Concordance degree was studied using Kappa statistics.
RESULTS: Concordance degree between both readings of TGd was moderate (K=0.56). There were 13 doubtful cases (moderate intensity in only one of both readings) which were considered as positive. Fifty patients had atrophy and all them fulfilled the gold standard criteria: Sensitivity of $\gamma\delta$+IEL, TGd and TGs were 96% (CI, 85-99) in each case. Sixty-five patients had LD and 27 (41.5%) fulfilled the gold standard criteria: Sensitivity of $\gamma\delta$+IEL, TGd and TGs were 85% (CI, 65-95), 54% (CI, 34-73), and 30% (CI, 14.5-50), respectively. Concordance between TGd and TGs was excellent (K=0.82).
CONCLUSION: Celiac FCM IEL pattern is a reliable parameter to diagnose CD among patients with LD with higher sensitivity than both TGd and TGs. FCM seem also better than TGd assay since the latter is cumbersome and user-dependent and repeated analyses show only moderate reproducibility.

P543 A RAPID AND SENSITIVE METHOD TO DETECT HLA CLASS II ALLELES IN THE SALIVA ASSOCIATED WITH CELIAC DISEASE

A. Carroccio[1,*], G. Maggiore[2], G. Iacono[3], G. Giuliana[4], D. Compilato[4], F. Carroccio[4], G. Stampone[5], P. Mansueto[1], R. Nenna[6], F. Lucantoni[6], A. Polimeni[7], M. Bonamico[6]. [1]*Internal Medicine, University of Palermo,* [2]*Biodiagene,* [3]*Pediatric Gastroenterology, Di Cristina Hospital,* [4]*Oral Medicine, University of Palermo,* [5]*BioNat Italia S.r.l., Palermo,* [6]*Pediatric Department,* [7]*Odontostomatologic Department , University of Rome, Rome, Italy*

INTRODUCTION: The major predisposing genes in celiac disease (CD) are the HLA- DQ2 and DQ8 genotypes, found in at least 95% of patients. HLA typing is increasingly performed in CD-at-risk categories and in cases of uncertain CD diagnoses.
AIMS&METHODS: To evaluate a new rapid method for HLA typing using saliva samples and oral swabs. Patients and Methods: Sixty-five newly diagnosed CD patients (28M, 37F), mean age (+SD) 15.4 + 8.1 years were included. All patients showed serum positive IgA anti-transglutaminase antibodies and intestinal villi atrophy. The determination of CD-related HLA genotypes was performed using: a) a drop of whole blood taken by a lancet device and absorbed on filter paper, b) in 0.5ml of saliva and c) on an oral swab. Samples were stored at -20°C, and then sent to the Biodiagene laboratory within one month. A DQ-CD Typing Plus kit (Biodiagene, Palermo, Italy) was used for the identification of HLA class II alleles DQA1*0201, *03, *05, DQB1*02, *0301/04, *0302, DRB1*03, *04, *07, *11, *12 and DQB1*02 homozygosis. This kit allows rapid DNA extraction from dried blood absorbed onto filter paper and we developed a modified method using oral swab or saliva.
RESULTS: In whole blood absorbed on filter paper we found that 50 patients carried the alleles codifying for the DQ2 genotype, 9 patients carried both the DQ2 and the DQ8 genotypes and 6 patients carried the DQ8 genotype. In the saliva samples we found a concordance with the results obtained on blood in all 65 samples (100%), while no results were obtained in two samples. Using the oral swabs we observed concordant results with the assays performed on whole blood in 39 of 65 samples (60%), while no results were obtained in 26 samples.
CONCLUSION: These preliminary data showed that HLA typing for DQ2 and DQ8 genotypes can be performed with excellent efficiency using saliva samples but not with oral swabs. The rapid method used in this study allowed HLA typing, while saving time and avoiding the more invasive taking of blood samples.

P544 IMPACT OF HLA TYPE II ON CLINICAL EXPRESSION OF CELIAC DISEASE

G. Malamut[1,*], S. Caillat-zucman[2], V. Verkarre[3], F. Sanaa[1], L. Chatenoud[4], N. Brousse[4], N. Cerf-Bensussan[5], C. Cellier[1]. [1]*HOPITAL EUROPEEN GEORGES POMPIDOU - APHP,* [2]*Hôpital Robert Debré,* [3]*Hôpital Necker Enfants Malades,* [4]*Hôpital Necker-Enfants Malades,* [5]*Inserm U989, Université Paris Descartes, Paris, France*

INTRODUCTION: Celiac disease occurs in genetically predisposed people having HLA-DQ2 and /or HLA-DQ8 genotyping in 90-95% and 5-10% of cases, respectively. It has been suggested that patients with two copies of HLA-DQ2 are more at risk of developing celiac disease than patients having only one copy. It remains unknown whether the type and number of copy of HLA- DQ2/DQ8 modify expression of celiac disease.
AIMS&METHODS: Aim: to assess impact of HLA of type II on clinical, biological and histological features of celiac disease (CD).
Patients and Methods: Analysis of computer database of European Georges Pompidou Hospital in Paris listed 655 patients with possible diagnosis of CD registered between 2000 and 2012. Up to date we analyzed retrospectively 376 medical files (57% of the series) ascertaining diagnosis of CD in 297 patients. HLA of type II genotyping had been performed 222 (75%) of these patients who were considered for statistical analysis.
RESULTS: Among the 222 patients (158 F, 64M, mean age at diagnosis of CD: 28 years), 211 (95%) and 28 (13%) patients had HLA-DQ2 and HLA-DQ8 genotyping, respectively. Eighteen patients (8%) were homozygous for HLA-DQ2 (DQ2/DQ2) and 16 (7%) were DQ2/DQ8. Frequency of patients with anaemia and low serum albumin levels at diagnosis did not significantly differ between HLA-DQ2 and HLA-DQ8 patients. In contrast HLA-DQ2 patients had more frequently severe villous atrophy (subtotal or total) (72%) than HLA-DQ8 patients (42%) who had more frequently partial villous atrophy ($p = 0.001$). Frequency of associated autoimmune diseases at diagnosis (autoimmune thyroiditis, type I diabetes, autoimmune hepatitis...) was similar in patients HLA-DQ2 (23%) and HLA-DQ8 (18%) (N.S). In contrast, patients developing intestinal T cell lymphoproliferative disorder (refractory celiac diseases, high grade T cell lymphoma, large granular lymphocytic leukemia) were all HLA-DQ2 with higher rate of homozygosity DQ2 (22%) than uncomplicated celiac patients (8%) ($p = 0.05$).

CONCLUSION: This preliminary study performed on half of our series suggests that HLA type II genotyping impacts the degree of villous atrophy of celiac disease with less severe villous atrophy in patients with HLA-DQ8. In contrast with frequency of autoimmune diseases not impacted by the number of copy DQ2, lymphomatous complications appear more frequently in celiac patients homozygous for HLA-DQ2.

P545 COMBINED CLINICAL, SEROLOGICAL AND DIET ADHERENCE ASSESSMENT WITH HISTOLOGICAL EVALUATION AFTER 1 YEAR OF GLUTEN-FREE DIET: AN INNOVATIVE FOLLOW-UP APPROACH IN CELIAC PATIENTS.

G. Esposito[1,*], G. Galli[1], E. Lahner[1], V. D. Corleto[1], E. Pilozzi[2], E. Di Giulio[1], B. Annibale[1]. [1]*Digestive and Liver disease, Sant'Andrea Hospital,* [2]*Pathology, Sant'Andrea Hospital, Sapienza University, Rome, Italy*

INTRODUCTION: Adherence to a gluten-free diet (GFD) is the only effective treatment for celiac disease (CD). It has been recommended that patients be followed up by regular visits and serological markers of CD, although a follow-up procedure has not been standardized.
AIMS&METHODS: This study aimed to evaluate the usefulness of a combined clinical, serological and diet adherence assessment together with histological evaluation of duodenal mucosa after one year of GFD. Between 2009 and 2012 we enrolled 61 consecutive adult patients (70% F; median age 37 yrs, range 17-70) with biopsy-proven atrophic CD. Patients were reevaluated after 12-15 months of GFD with duodenal histology, serology (Ab IgA to anti-tissue transglutaminase and to anti-endomysium) and a dietary interview based on a validated structured questionnaire considering as strict or no adherence to GFD a score of 3-4 or 0-2, respectively (Biagi et al., Br J Nutr 2009). Clinical status was assessed considering well-being a complete resolution of the sign/symptom that brought to diagnosis and improvement a partial resolution of their signs/symptoms. Histology was scored following Marsh classification.
RESULTS: At 1 yr-follow-up, strict adherence to GFD was found in 49 (80%) patients (F 71,5%) (Group 1), while no adherence to GFD in 12 (20%) patients (F 67%) (Group 2). The two groups were similar with regard to age, gender, sign/symptom of diagnosis, comorbidity, positivity to antibodies and Marsh score at diagnosis time. At 1-yr follow-up, 35 Group 1 patients had normal duodenal histology compared to none in Group 2 ($p < 0.0001$), and 42 Group 1 pts yielded clinical well-being compared to 2 Group 2 pts ($p < 0.0005$), but the proportion of pts with positive serology was similar in the two groups (10 in Group 1 (20,5%) pts vs 3 in Group 2 (25%) pts; p=0.682). Positive serology was found in 7 (20%) of the 35 pts with normal duodenal histology after 1 year of strict adherence to GFD.
CONCLUSION: After 1 year of strict adherence to GFD, evaluated by a validated dietary questionnaire, the majority of celiac patients (72%) shows a total histological recovery from duodenal damage. The clinical status keeps in step with histological recovery, but serology seems to be a poor predictor for strict adherence to GFD. In patients with strict adherence to GFD the histological evaluation of duodenal biopsies seems to be a valid approach to assess the efficacy of GFD.

P546 MORPHOLOGICAL FEATURES OF ENDOTHELIAL CELLS OF ENDOMETRIUM BEFORE AND AFTER INCUBATION WITH ANTI-TRANSGLUTAMINASE ANTIBODIES IN BOTH HEALTHY AND CELIAC WOMEN

G. Gasbarrini[1], G. Ianiro[2,*], M. Amici[3], R. Castellani[4], V. Palmieri[3], F. Scaldaferri[2], F. Beghella Bartoli[2], G. Gigante[2], C. Tersigni[4], M. De Spirito[3], N. Di Simone[4], A. Gasbarrini[2]. [1]*Ricerca in Medicina ONLUS Foundation, Bologna,* [2]*Dept of Internal Medicine, Division of Gastroenterology,* [3]*Institute of Physics,* [4]*Dept of Obstetrics and Gynecology, CATHOLIC UNIVERSITY SCHOOL OF MEDICINE, ROME, Italy*

INTRODUCTION: Celiac disease is a well-known cause of recurrent miscarriage. Previous studies have evaluated the effect of the tissue transglutaminase antibody (tTGA) on the differentiation of endometrial endothelium (that plays a main role in the development of the fetus), in terms of angiogenesis, cytoskeleton structure, fluidity and strength of membranes.
AIMS&METHODS: Aim of the study is to investigate if the tTGA may induce damage of endothelial cells in both healthy and celiac women.
The endometrial tissue obtained from 5 healthy fertile women and 2 celiac ones was incubated in a M199 culture medium. The cell suspension was centrifuged and the cells placed in a endothelium-specific medium, then detached and subjected to magnetic immunoselection and plated on glass slides with Matrigel; finally, it was incubated with tTGA and held in fixative solution. After post-fixation and a further fixation in a mixture of acetone and EPON, it was cut into section of about 0.5 uM, for the study on the optical microscope (confocal microscope, also with fluorescence and phase contrast) and, respectively, of 70 ηm for the study to the transmission electron microscope (TEM). Five parameters have been evaluated: connection among cells, plasmatic membrane, nuclei, cytoplasm, pseudopods.
RESULTS: Results are summarized in the table below.

	HEALTHY WOMEN		CELIAC WOMEN	
	BASELINE	*tTGA INCUBATION*	*BASELINE*	*tTGA INCUBATION*
CONNECTION AMONG CELLS	Present	Reduced	Present	Almost disappeared
PLASMATIC MEMBRANE	Well defined	Reduction of protofilaments. Presence of collagenous structures	Not well defined	Only collagenous structures
NUCLEI	Compact	Widely fragmented	Less defined, with multiple breaks	Not defined, higher number of breaks
CYTOPLASM	Abundance of rybosomes	Leakage of rybosomes	Decreased No of rybosomes	Rybosomes almost absent
PSEUDOPODS	Present. Branching structures	Shortened	Reduced in No, lenght, elasticity	Not displayed (isolated cells)

CONCLUSION: In healthy women endothelial cells of endometrium show, at incubation with tTGA, morphological damages that may play a role in modifying motility and cell adhesion. In celiac women, even at baseline, there are alterations of both nuclear and cytoplasmatic structures. At incubation with tTGA, these differences become deeper, with disappearance of pseudopodes, that lead to cell isolation. These modifications may lead to angiogenesis abnormalities that could bring to recurrent episodes of miscarriage.

P547 THE DIAGNOSTIC UTILITY OF COELIAC SEROLOGY IN LYMPHOCYTIC DUODENOSIS

I. Aziz[1,*], D. M. Smillie[1], D. S. Sanders[1]. [1]*Department of Gastroenterology, Sheffield Teaching Hospitals, Sheffield, United Kingdom*

INTRODUCTION: Lymphocytic duodenosis (LD) is defined by normal villous architecture and intraepithelial lymphocytes (IELs) >25 per 100 enterocytes. Such patients should not be diagnosed with coeliac disease (CD), solely by histology, as recent studies have suggested other associations with LD. Coeliac serology (tissue transglutaminase [TTG] and/or endomysial antibodies [EMA]) may play a useful role although their diagnostic value in such settings is unknown.
AIMS&METHODS: We aimed to provide diagnostic outcomes in our cohort of LD patients whilst also assessing the clinical utility of coeliac serology.
Two hundred patients with LD were rigorously investigated for CD and other known associations of LD, by means of revisiting the patient's history and recent investigations including the initial coeliac serology, followed by a combination of gluten challenge, HLA typing, repeat duodenal biopsies, and exclusion of infection/inflammatory bowel disease.
In the absence of an alternative cause, a diagnosis of CD was based on the persistence or progression of LD on a gluten-containing diet, the presence of HLA DQ2 or DQ8, and a clinical response to a gluten free diet.
RESULTS: 150 female, 50 male, mean age 49, SD 16, age range 17-83
An identifiable association was found in 70% of patients: CD (20%), NSAIDs (17%) and *H.pylori* (16%) accounting for the majority. In 30% no cause was found, although reassuringly 2/3rd normalised their histology. The role of coeliac serology in LD for diagnosing CD is shown in table 1.
Table 1: Evaluation of coeliac serology for diagnosing CD

LD coeliac serology test result (n 200)	PPV	NPV	Sensitivity	Specificity
If only TTG performed	54%	92%	70%	85%
If only EMA performed	95%	89%	50%	99%
Both TTG and EMA normal	6%	44%	20%	16%
TTG raised but EMA normal	33%	83%	30%	85%
TTG normal but EMA positive	80%	82%	10%	99%
Both TTG and EMA raised	100%	87%	40%	100%

CONCLUSION: As a single test, EMA has a greater diagnostic accuracy than TTG when assessing patients with LD.
As a combination test, only the presence of both a positive EMA and a raised TTG has a 100% predictive value for CD.

Therefore, although coeliac serology is useful in LD, most cases still require further work-up for diagnostic confirmation.

P548 WHITE MULBERRY SUPPLEMENTATION AS ADJUVANT TREATMENT OF OBESITY.

G. Ianiro[1,*], E. Dal Toma[2], A. Vitale[2], F. Beghella Bartoli[1], S. De Martino[1], G. Dinoi[1], G. Gigante[1], G. Cammarota[1], G. Gasbarrini[3], A. Gasbarrini[1], G. Da Villa[2]. [1]*Dept of Internal Medicine, Division of Gastroenterology, CATHOLIC UNIVERSITY SCHOOL OF MEDICINE, ROME,* [2]*"F. De Ritis" Institute, Naples,* [3]*"Ricerca in Medicina" ONLUS Foundation, Bologna, Italy*

INTRODUCTION: Body weight is partially controlled by our genes, and managed by a neuro-hormonal system, in particular by insulin and glucagon. The extract of Japanese white mulberry is known to inhibit the alpha-glucosidase and then the intestinal hydrolysis of polysaccharides, thereby reducing the glycemic index of carbohydrates.
AIMS&METHODS: Our aim was to evaluate the slimming effect of the extract of white Japanese mulberry as an adjuvant of the dietary treatment of obese or overweight subjects.
In this randomised, placebo-controlled trial, 46 overweight patients (F:M/40:6 – range 35-55 yo) were enrolled and divided into two subgroups (A and B). Both subgroups were given an identical balanced diet of 1300 kcal. Group A received 2400 mg of white Japanese mulberry extract (800 mg three times at day) for 3 months; group B received instead an identical dose of placebo. Each subgroup had a follow-up visit every 30 days until day 90 of treatment. During every follow-up visit, body weight and waist circumference in all the subjects and, only in women, thigh circumference, were measured. The following blood tests were performed during each follow-up visit: blood glucose curve and insulin glucose load, complete blood count, blood urea nitrogen, creatinine and electrolytes.
RESULTS: In group A, weight loss was about 9 kg in three months, equal to approximately 10% of the initial weight. Plasma insulin and glucose curves in group A at the end of the trial were significantly lower than baseline. In the 20 women of group B, treated with only low-calorie diet and placebo, weight reduction was globally of 3.2 kg, approximately equal to 3% of the initial weight; moreover, the blood glucose curves and the insulin curves showed a slight decline compared to baseline, but not so significantly as group A. Waist circumference and thigh circumference (in women) decreased in all participants, obviously more evidently in subjects who had a deeper weight loss.
CONCLUSION: The extract of white Japanese mulberry may represent a reliable adjuvant therapy of the dietary treatment for obesity and overweight. Further studies, with an adequate sample size, are needed to confirm this results.

P549 ONE YEAR WEIGHT LOSS OUTCOMES USING INCISIONLESS ENDOSCOPIC SURGERY FOR PRIMARY OBESITY: THE POSE PROCEDURE

G. Lopez-Nava[1,*]. [1]*Bariatric endoscopy Deparment, Hospital Universitario Madrid Sanchinarro, Madrid, Spain*

INTRODUCTION: Background: Obesity is a multifaceted, metabolic condition in which excess body fat has accumulated to the extent that it has an adverse effect on health. Bariatric surgical procedures provide the most consistent and long-lasting weight lossoutcomes. However, risks associated with bariatric surgerygive rise to the need for less invasive and safer alternatives. The POSE procedure (Primary, Obesity, Surgery,Endolumenal) utilizes the Incisionless Operating Platform (IOP) to durably plicate gastric tissue endoscopically.
AIMS&METHODS: Objective: The purpose of this analysis was to quantify weight loss, body mass index (BMI) and the incidence of complications up to one year after the POSE procedure forthe treatment of primary obesity.
Methods: A descriptive analysis was conducted based on all patients having received a POSE procedure during the time period of July 11, 2011 to January 23, 2013 at a single center,private hospital in Madrid, Spain. Weight loss results were summarized and presented as mean averages for weight loss, % excess weight loss, and % total body weight loss.
RESULTS: Results: A total of 147 patients were included in this analysis: 69% female and 31% male with a mean age of 45. At baseline: mean weight (kg) 106.8, SD 18.2; body mass index (BMI, kg/m2kg) 38.2 (28.1-50.2). Three-month mean weight was 95.6, SD 15.9, Twelve-month mean weight was 92, SD 16.38; BMI decreased to 33.3 (22.4-44.4); EWL was 42.7%; TBWL, 14.6%. Adherence to follow patients was 100% at 3 months, 91% at 6 months and 79% at 12 months. All operations were performed by the same endoscopist. Each patient and procedure is unique unto itself, but on average, the POSE procedure took about 35 minutes from the time the transport is inserted until the time removed. On average, 7 - 8 suture anchors were placed in the fundus of the stomach and 3-4 suture anchors were placed in the distal body. Oropharyngeal pain and dyspepsia was observed in 80% of patients only on the first day postoperatively. Mortality rate was 0%. Patients reported less hunger and earlier satiety post procedure.
CONCLUSION: Conclusions: At 12-month follow-up, the POSE procedure has demonstrated that it is a safe and effective weight loss treatment option without the recovery issues associated with open and laparoscopic bariatric surgery.Overall, weight loss at one year post POSE procedure is promising and combined with a multi-disciplinary team approach may support long term improvement in patient health outcomes. Further research is needed to determine optimal patient profiles and ongoing support needed to assist patients in sustaining lifelong health.

P550 RISKS OF COLORECTAL ADENOMA AND LIFE TIME ANTHROPOMETRY. A PROSPECTIVE STUDY IN GREECE.

P. Kalapothakos[1,*], E. Georgakila[1], S. Sotirianakos[2], M. Bizanias[2], G. Solomou[2]. [1]*Gastroenterology,* [2]*General Surgery, Lakonia General Hospital, Sparta, Greece*

INTRODUCTION: Obesity has been recognized as a risk factor for colorectal adenoma, but the influence of weight changes, adipose tissue distribution, and possible differences between genders remains unanswered, as the results of previous studies show considerable heterogeneity due possibly to ethnic/ racial differences and probably aren't reproducible in Greece.
AIMS&METHODS: To assess the association between adiposity and weight changes from early adulthood and colorectal adenoma risk, in a well predefine population in Sparta area in Greece. Prospective, single centre study, three years duration. Colonoscopies were conducted on 700 patients regardless of symptoms, whose mean age at colonoscopy was 62 +/- 7, 8 years, 45% men. During colonoscopy the number, size and location of each polyp were recorded. A detailed history was obtained from each subject, using clothing size to assess early adulthood body weight at age 20, at age 30, and weight change over the 5 and/or 10-year period before colonoscopy. Multivariate logistic regression analyses were used to assess the association between change in body weight at various age intervals and adenomas of any size, including advanced neoplasm (adenomas >10mm or any adenoma with villous histology, high-grade dysplasia).
RESULTS: Obesity, measured at the time of colonoscopy, was positively associated with risk of colorectal adenomas (OR 2.06; 95% CI, 1.13-3.14), was stronger in women (OR 1, 95; 95% CI, 1.23- 3, 17) than in men (OR 1. 56; 95% CI, 0.52-3.07). The prevalence of adenomas was 11% in individuals whose BMI was normal at age 20 and remained normal at present, 19% and 30% in those who became overweight/obese at present, 25% in those who they were stable overweight and 31% in those who have been consistently obese. The risk of adenomas increased among participants who gained weight compared with those who maintained weight over the previous 5 years (OR 1, 75; 95% CI, 1.25-3.22) and 10 years (OR 2.12; 95% CI, 1.25-3.62). These associations were similar for both advanced and nonadvanced adenomas.
CONCLUSION: In our area these results suggest a positive association between colorectal adenoma risk and actual obesity, recent and from early adulthood weight gaining. Given the endemic of childhood obesity in our country further evaluation of adiposity as a modifiable risk factor against colon cancer are warranted.

P551 ANALYSIS OF 1050 PATIENTS SUBMITTED TO ENDOSCOPIC TREATMENT OF EXCESS WEIGHT WITH AN INTRAGASTRIC BALLOON

R. J. Fittipaldi-Fernandez[1,*], C. F. Diestel[2]. [1]*Digestive Endoscopy,* [2]*Nutrition Division, Endogastro Med Service, Rio de Janeiro, Brazil*

INTRODUCTION: Endoscopic methods, especially the intragastric balloon (IGB), have been shown to be effective for the treatment of excess weight.
AIMS&METHODS: AIMS: To assess the efficacy and complications of excess weight treatment with an IGB in patients seen at the Endogastro Med Service clinic. METHODS: A total of 1050 patients were analyzed. An Allergan IGB (BIB®) with a volume of 600 to 700 ml was used. The patients had a minimum initial body mass index (BMI) of 27 kg/m2 and were followed up by a multidisciplinary team consisting of a nutritionist, a doctor and a psychologist.

For statistical analysis, the patients were divided into groups according to sex and degree of excess weight (overweight and grade I, II and III obesity). Data were analyzed using descriptive statistical methods, the Student t-test, Spearman correlation, and analysis of variance followed by the Tukey post-test. The level of significance was set at $p<0.05$.
RESULTS: 75 patients were excluded from the analysis: 45 (4,28%) due to early IGB removal, 9 (0.85%) due to absence of weight loss, 10 (0.95%) due to weight gain, 10 (0,95%) due to incomplete data and 01 due to pregnancy (0,09%). The incidence of fungus was 0.38% (n=4) and the incidence of leakage was 0.47% (n=5). Of the 975 remaining patients, 764 were women and 211 were men. Mean age was 38.09 years. The patients showed a significant weight loss, with a significantly lower final BMI (mean: 29.78±4.86 kg/m2; range: 19.14-57.39) than the initial BMI (mean: 36.72±5.36 kg/m2; range: 26.77-69.29) ($p<0.0001$). Mean BMI reduction was 6.95±2.99 kg/m2 (range: 0.36-20.52). Mean percent weight loss was 18.83±7.20% and mean percent excess weight loss was 67.55±36.81% (range: 3,86-336,14). Regarding percent initial weight loss there was a higher reduction in patients with grade III obesity than patients with overweight and grade I obesity ($p<0,05$) and there was a higher BMI reduction in men then in women (p=0.0147). There was a positive correlation between the numbers of visits to a nutritionist and a greater loss of initial weight (p=0.0001).
CONCLUSION: Endoscopic treatment of excess weight with an IGB has been established as an excellent therapeutic option for patients of both genders with overweight or different degrees of obesity.

P552 PRIMARY OBESITY SURGERY ENDOLUMENAL (POSE): WEIGHT, SATIATION, AND METABOLIC CHANGES IN A PROSPECTIVE COHORT OF OBESE PATIENTS.

R. Turro[1,*], J. P. Espinos[1], A. Mata[1], J. Turro[1], S. A. Delgado[2], F. Mearin[1]. [1]*Unidad Endoscopia Digestiva, Centro Medico Teknon,* [2]*Neuroenteric Translational Science Group , Hospital del Mar Medical Research Institute, Barcelona, Spain*

INTRODUCTION: The Incisionless Operating Platform™ (USGI Medical, San Clemente, CA, USA) utilizes the g-Cath EZ ™ suture anchor, which has demonstrated the ability to durably plicate gastric tissue endoscopically at 2+ years. Prior work at our institution for primary obesity revealed mean total % excess weight loss (%EWL) of 60.6% at 1 year (N=21).This study evaluates possible mechanisms of weight loss and predictors for success.
AIMS&METHODS: A prospective, single site study was initiated with Ethics approval. Enrolled patients were aged 21-60 with a BMI of ≥ 30 and ≤ 40 and no history of bariatric procedure. Diet was advanced post procedure to full solids over 4-6 weeks to allow time for suture plication healing. Serial nuclear gastric images over 3 hours (solid meal) were done pre-procedure and at 2/6 months. Serial peptide levels were recorded over 2 hours both pre-procedure and at 2/6 months in response to a standard solid meal. 6 month peptides pending. A validated intake capacity test (kcals) was done before and at 2/6 months. Weights were recorded regularly through 12 months. Regression modeling assessed variables that influenced % EWL (BMI25 method). Models were selected based on higher R^2 with lowest degrees of freedom. Data reported in means (95% CI).
RESULTS: 18 patients were enrolled (78%F/22%M). Mean age =39.1. Baseline mean body mass index (BMI) = 36.3±2.3. A total mean 13.6 plications were placed in the fundus and gastric body. Mean operative time, 51±9.0 minutes. No significant operative or post-op adverse events. Mean 6, 9 & 12 month %EWL to date was 56.6±27 (N=18), 60.5±29 (n=17) and 69.9±22 (n=11) respectively. Mean time to satiation decreased significantly from baseline at both 2&6M post-POSE ($p<0,001$), as did mean kcal intake at 2&6 months [from 901Kcal to 473 and 574 respectively ($p<0,001$)]. Gastric retention rate at 30 minutes increased significantly post-POSE at 2 months ($p<0,03$) but was not significant at 6 months. Glucose/Insulin ratio improved 2&6M post-POSE (all $p<0,05$). Postprandial ↓ in Ghrelin was enhanced post-POSE compared to pre-POSE (-21 [-2; -40] vs. -59 [-22; -95]; p=0.03) as well as postprandial ← in PYY (6 [0; 13] vs. 14 [7; 20]; p=0.001). Regression-modeling showed that gender ($p<0,01$), weight (p=0,03) and pre-POSE GE ($p<0,01$) were independent predictors of %EWL at 6M (R^2 :54%).
CONCLUSION: POSE is followed by significant weight loss, improved glucose-homeostasis and satiation-peptide responses. Weight loss post-POSE might be enhanced selecting subjects with slower pre-POSE gastric emptying. Further study is required.

P553 GIP- AGONIST IMPROVES OBESITY-INDUCED FAT INFLAMMATION

S. Fishman[1,*], C. Varol[1], I. zvibel[1], E. Santo[1], Z. Halpern[1]. [1]*Gastroenterology, Tel Aviv Sourasky Medical Center affiliated to Tel Aviv University, Tel Aviv, Israel*

INTRODUCTION: Obesity gives rise to low-grade chronic inflammation, manifested by pro-inflammatory polarization of adipose tissue innate and adaptive resident and recruited immune cells that contribute to development of insulin resistance (IR). The glucose-dependent insulinotropic polypeptide (GIP) incretin hormone is responsible for mediating 50-70% of the postprandial insulin secretion. The recent past has seen differences of opinion concerning GIP having a deleterious or beneficial role in IR
AIMS&METHODS: Here, we aimed to decipher the metabolic and immunoregulatory role of GIP in diet- induced obesity (DIO) using the long-acting GIP analogue [d-Ala^2]GIP.
RESULTS: Treatment with [d-Ala^2]GIP improved insulin sensitivity. Treated mice had increased levels of adipose tissue lipid droplet proteins, indicating better lipid storage capacity. Moreover, [d-Ala^2]GIP- treated mice exhibited reduced numbers of circulating neutrophils and pro-inflammatory $Ly6C^{hi}$ monocytes and their $Ly6C^{hi}$ macrophage descendents within the adipose tissue. Importantly, [d-Ala2]GIP treatment significantly reduced adipose tissue $Ly6C^{lo}CD11c^{+}$ $F4/80^{hi}$ macrophage population, reported to be associated with IR. Furthermore, infiltration of IFNγ - producing $CD8^{+}$ and $CD4^{+}$ T cells was strongly attenuated. Lastly, [d-Ala2]GIP treatment induced a favorable adipokine profile, with prominent reduction in TNFα and inflammatory chemokines and enhanced adiponectin expression.
CONCLUSION: Our results show that augmentation of GIP improves DIO insulin sensitivity and ameliorates adipose tissue inflammation

P554 MULTIPROBIOTIC THERAPY PREVENTS THE DEVELOPMENT OF EXPERIMENTAL OBESITY

T. Falalyeyeva[1,*], O. Savcheniuk[1], G. Mykhalchyshyn[2], N. Kobyliak[2], I. Leschenko[2], P. Bodnar[2], T. Beregova[1], D. Yankovskyy[3]. [1]*TARAS SHEVCHENKO NATIONAL UNIVERSITY OF KYIV,* [2]*National Bohomolets Medical University,* [3]*O.D. Prolisok, Kyiv, Ukraine*

INTRODUCTION: World Health Organization (WHO) declared obesity a global epidemic and took him under its control. WHO experts predict that the number of those suffering from this disease will reach 300 millionby 2025. Therefore, the search of new non-toxic drugs for preventing the development of obesity is the most important challenge of modern science. The question about impact of probiotics on fat metabolism and obesity is being actively debated in the scientific literature. One of the indicators of metabolic syndrome is the adiponectin concentration decrease in the blood. In connection with mentioned above the aim of the study was to investigate the effect of multiprobiotic "Symbiter acidophilic concentrated" on adiponectin level in the rats serum under experimental obesity.
AIMS&METHODS: The study was carried out on 36white rats, that were divided into 6 groups (I-III – males, IV-VI – females). I and IV groups were intact control (4-month old rats). Newborn rats of groups II and III subcutaneously in volume 8 µl/g were administered a placebo (saline) or monosodium glutamate (MSG) (4 mg/g) at 2, 4, 6, 8, 10 days of life. Since the age of 1 month, rats of III and V group had been injected with water in a volume of 0.25 ml/100 g (placebo), rats III and VI groups-multiprobiotic "Symbiter acidophilic concentrated" in a dose of 140 mg/kg dissolved in water of a volume 0.25 ml/100 g. Introduction had been performed with two-week course for 3 months. After 4 months in the blood serum of all groups adiponectin level was measured with ELISA.
RESULTS: In male rats, there were more pronounced changes - body weight and visceral fat exceeded benchmarks in 3 ($p\leq0.001$) and 5 ($p\leq0.001$) times, respectively. Body weight and visceral fat of female rats in group III was higher by 125% ($p\leq0.001$) and 338% ($p\leq0.001$), respectively. It was established that under condition of obesity caused by the introduction of MSG, the level of adiponectin in serum decreased in male rats by 59% ($p\leq0,05$) and 23% ($p\leq0,05$) in females compared with intact rats. The use of probiotic therapy led to recovery of adiponectin level: its concentration in serum grew in 1.9 times ($p\leq0,05$) in males and in 1.4 times ($p \leq 0,05$) in females which were treated with multiprobiotic compared with rats injected with placebo.
CONCLUSION: Thus, the introduction of multiprobiotic increased adiponectin levels in animals injected with MSG, that shows the effectiveness of probiotic therapy for the prevention of obesity.

P555 UK HPN DATA SUGGEST A CONTINUED RISE IN PAEDIATRIC HPN USE: A REPORT ON BEHALF OF THE BSPGHAN/BAPS BRITISH INTESTINAL FAILURE SURVEY WORKING GROUP

A. Barclay[1,*], H. Gowen[2], P. Henderson[3], B. BIFS Contributing Centres[4]. [1]*Paediatric Gastroenterology, RHSC, Glasgow,* [2]*British Intestinal Failure Survey, Birmingham Childrens Hospital, Birmingham,* [3]*Child Life and Health , University of Edinburgh , Edinburgh ,* [4]*BSPGHAN , 32 Centres, United Kingdom*

INTRODUCTION: Paediatric HPN (PHPN) usage has risen within the UK in the last 2 decades (1). Studies reporting improved outcomes for patients with intestinal failure due to advancing surgical technique and novel medical therapies would suggest short term increases in the requirements for PHPN. Due to the large requirement for health resources for such patients, accurate PHPN epidemiology is vital for service planning. The British Society for Paediatric Gastroenterology Hepatology and Nutrition (BSPGHAN) and British Association of Paediatric Surgeons (BAPS) collate UK PHPN data through the British Intestinal Failure survey (BIFS).
AIMS&METHODS: We aimed to perform a PHPN point prevalence survey and compare this with previously published data (1). The BIFS administrator

contacted the 32 recognised PHPN UK centres for data relating to 26.11.2012. Anonymysed data were collected on patients ≤16yr receiving HPN (or being trained for imminent discharge) including demographics, diagnosis and duration of PN. Publicly available population statistics were used to account for missing data and to provide point prevalence figures.

RESULTS:

Year	Centres	Patients	Calculated point prev/million	SBS (%)	Enterocyte (%)	Neuro (%)	Other (%)
1993	21	46	4.4	18 (27)	12 (18)	12 (18)	24 (37)
2010	25	145	13.7	-	-	-	-
2012	25	172	15.9	84 (46)	40 (23)	36 (20)	12 (6)

25/32 PHPN responded corresponding to approximately 92% of the UK population under 16yrs (10.9 million). There was a 19.3% rise in PHPN patients from 145 in 2010 to 172 in 2012. This represents an increase in point prevalence of 13.9/million in 2010 to 15.9/million in 2012 and a signicant rise from the 1993 figure previously reported (1). The relative proportion of patients with short bowel syndrome (SBS) rose from 27% in 1993 to 46% in 2012.

CONCLUSION: BIFS data suggest that UK PHPN point prevalence has risen significantly in the short term, in-line with inidividual centres reporting improved early survivial in intestinal failure. Increased survival from neonatal surgical procedures also appear to be reflected by increased numbers and proportions of SBS patients. The limitations of point prevalence surveys in terms of service planning have been previously highlighted (2). Improvements in the ascertainment of the prospective arm of BIFS are warranted to gather accurate incidence, period prevalence and outcomes for UK PHPN.

P556 LAPAROSCOPIC GASTROSTOMY IS SAFER THAN PERCUTANEOUS ENDOSCOPIC GASTROSTOMY IN CHILDREN: RESULTS OF A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Suksamanapun[1], F. A. Mauritz[1,2,*], D. C. van der Zee[1], M. Y. van Herwaarden-Lindeboom[1]. *[1]Pediatric Surgery, Wilhelmina Children's Hospital, University Medical Center Utrecht, [2]Gastroenterology and Hepatology, University Medical Center Utrecht, Utrecht, Netherlands*

INTRODUCTION: A gastrostomy is frequently performed in children who require long-term enteral feeding. Nowadays gastrostomy placement is a minimally invasive procedure via either percutaneous endoscopic gastrostomy (PEG) or laparoscopic assisted gastrostomy (LAG). Both procedures are widely used in pediatric patients. However, no consensus exists on which type of approach is best practice in these patients.

AIMS&METHODS: The aim of this study was to determine if PEG or LAG is the most effective and safe procedure in pediatric patients requiring a gastrostomy. A systematic review and meta-analysis was performed according to the guidelines in the PRISMA-statement. PubMed, EMBASE, and the Cochrane Library were searched to identify eligible articles. Results were pooled in meta-analyses and expressed as risk ratios (RR).

RESULTS: Our extensive literature search provided 2,342 articles. After title, abstract and full-text screening five original studies comparing PEG to LAG placement in children were identified. All studies had retrospective study designs. The completion rate (PEG 98% *vs*. LAG 100%) and time to full-enteral feeds (PEG 0.7 *vs*. LAG 0.8 days) of both procedures were similar. No studies reported data comparing the efficacy of feeding via the gastrostomy or its effect on developing gastroesophageal reflux (GER). Intraperitoneal leakage (RR 0.28; p=0.36; and after tube exchange RR 3.14; p=0.28) was as frequently encountered after both PEG and LAG. However, PEG was associated with significantly more adjacent bowel injuries (RR=5.55; p=0.05) and early tube dislodgements (RR=7.44; p=0.02). Moreover, overall rate of all reinterventions that require general anesthesia (RR=2.79; p=0.0008) was significantly higher after PEG. The risk of developing minor complications was similar after both procedures.

CONCLUSION: This systematic review and meta-analysis demonstrates that PEG and LAG are equally effective; however, LAG was associated with significantly less complications such as adjacent bowel injury, early tube dislodgements and a lower rate of all reinterventions that require general anesthesia. Therefore, we conclude that LAG is the safest approach and should be the first choice in children requiring gastrostomy placement.

P557 STOOL SECRETORY IGA LEVELS IN PRETERM INFANTS WITH AND WITHOUT NECROTISING ENTEROCOLITIS

L. Beattie[1,*], M. Wenwen[2], D. J. Morrison[2], C. A. Edwards[2], E. Combet-Aspray[2]. *[1]Neonatal Unit, Royal Hospital for Sick Children, Glasgow, [2]Department of Human Nutrition, University of Glasgow, Glasgow, United Kingdom*

INTRODUCTION: Secretory Immunoglobulin A (SIgA) is the most prolific immunoglobulin of the GI tract, and high levels in preterm infants may prevent necrotising enterocolitis, the most devastating disease of the gut of early life. Our aim was to determine and compare the levels of SIgA in stool samples of preterm neonates and breast milk in their mothers.

AIMS&METHODS: We sequentially recruited infants <32 weeks gestation and <1.5Kg birth weight within week 1. NEC was staged according to Bell's Criteria. SIgA titres of 34 preterm neonates and 9 mothers were determined from 100 mg of stool and 100 µl of milk collected weekly for the first month using an enzyme linked immunosorbant assay.

RESULTS: Among all preterm infants (n=34), stool sIgA concentration were significantly higher in week 3 (p=0.020) and week 4 (p=0.027) than week 1. There were no significant differences in stool sIgA concentration between infants with NEC and those who did not ($p > 0.05$) within all the four weeks. A significant increase in mean stool sIgA concentration appeared from week 2 to week 3 (p=0.0485) in NEC infants and from week 1 to week 2 (p=0.005) for those without NEC. For all breastfed preterm neonates (n=6) in the first four weeks, the level of milk sIgA was significant higher on week 1 (colostrum) than week 2 (p=0.021) and week 3 (p=0.034).

CONCLUSION: Our study illustrates immunological adaptation of maternal milk sIgA level for the preterm newborn and that exclusive breast milk feeding may increase stool sIgA more than mixed breast milk and formula. Levels found in stool and milk are significantly higher than for infants and mothers at term.

P558 TRANSIENT TEMPERATURE GEL ELECTROPHORESIS OF STOOL SAMPLES OF PRETERM INFANTS WITH AND WITHOUT NECROTISING ENTEROCOLITIS IN A MULTICENTRE OBSERVATIONAL STUDY

L. Beattie[1,1,*], D. J. Morrison[2], C. A. Edwards[2], A. R. Barclay[2], J. H. Simpson[1], K. Gerasimidis[2], K. Brunner[2]. *[1]Neonatal Unit, Royal Hospital for Sick Children, Glasgow, [2]Department of Human Nutrition, University of Glasgow, Glasgow, United Kingdom*

INTRODUCTION: Despite the effect of enteral feeding on the development of intestinal microbiota in preterm infants remaining poorly understood, trials aiming to prevent necrotising enterocolitis (NEC) using probiotics are well-established. Exclusively breast milk fed preterm infants have a reduced risk of developing NEC and this may be linked with a more 'beneficial' gut microbiota.

AIMS&METHODS: We sequentially recruited infants <32 weeks and <1.5Kg birth weight. Non-meconium faecal samples from the first and fourth weeks of life in 22 VLBW preterm neonates, 12 with NEC, were analysed by PCR-TTGE using universal bacterial primers. Species richness and similarities were compared between infants according to feed type.

RESULTS: There was large variability between number (1-17) and species diversity (25-36 different species). Number of predominant bacterial species did not increase between the 1st and 4th week of life. Bacterial composition varied largely between the 2 sample points, No difference in species richness or similarity within the 2 feeding groups was observed. 4 bands were identified in >50% of infants. Intra-individual similarity varied greatly and ranged from a similarity index (Cs) of 0% to 66.8%. There was no statistical difference between the similarity indices of the feeding groups (p=0.8852) or between those with and without NEC (p=0.1719).

CONCLUSION: Microbial community of preterm neonates undergoes several changes during their first month of life. The feeding mode did not seem to have a major impact on the development of bacterial diversity, but data was insufficient to comment on significant differences with regard to NEC.

P559 NEW TRENDS IN NUTRITIONAL STATUS ASSESSMENT IN A GROUP OF CHILDREN WITH CANCER FROM ROMANIA

M. I. Chincesan[1], O. Marginean[1,*], A. Grama[1]. *[1]PAEDIATRICS I, UNIVERSITY OF MEDICINE AND PHARMACY TG MURES, TG MURES, Romania*

INTRODUCTION: Nutritional status is an important considerant in the treatment of pediatric cancer patients because it is linked to poor outcomes. There are still controversies regarding the criteria used to assess nutritional status in children with cancer.

AIMS&METHODS: We proposed to define the best modalities to assess nutritional status in children with cancer using anthropometric and biochemical parameters.A prospective study was performed on 64 children hospitalized and diagnosed with cancer in the Pediatric Clinic Targu-Mures, Romania, between 2009- 2012. We evaluated anthropometric and biochemical parameters: weight, height, body mass index (BMI), middle-upper arm circumference (MUAC), triceps skin fold thickness (TSF), total protein, albumin and Insulin-like growth factor-1 (IGF-1). The values of anthropometric parameters were converted in Standard Deviation (SD) for age and sex using Switzerland Growth Chart 1989.

RESULTS: Of the 64 children with cancer, 40,6% were diagnosed with leukemias, 28,1% with lymphomas and 31,2% with solid tumors. Medium valus of weight, height and BMI were -0.26 SD, -0.19 SD, and -0.36 SD. Assesssing arms anthropometry, we found lower values of MUAC (-0.56 SD) and TSF (-0.77 SD) than weight and height indicators. At the onset of malignant disease, 28.1% of patients had low serum protein values and 25% had low levels of serum albumin. IGF-1 was decreased in 65,6% of patients. We found a good correlation, statistically significant between MUAC and serum proteins (r=0.30; p=0.01), MUAC and albumins (r=0.27; p=0.02) and MUAC and IGF-1 (r=0.40; p=0.001) and

between TSF and albumins (r=0.28; p=0.02), TSF and IGF-1 (r=0.38 ; p=0.002).
CONCLUSION: The arms anthropometry better identify malnutrition in children with cancer than simply assessing weight or height measurements. MUAC and TSF in conjunction with serum protein, albumin and IGF-1 most accurately characterizing the nutritional status.

P560 IL-6-572 G/C GENE POLYMORPHISM IN A ROMANIAN POPULATION OF OBESE AND MALNOURISHED CHILDREN

O. I. Marginean[1,*], C. Banescu[2], C. Duicu[1], A. M. Pitea[1], L. Man[1], M. Marginean[1], M. Chincesan[1], C. Marginean[3]. [1]*Pediatrics I,* [2]*Genetics,* [3]*Medicine, MEDICINE UNIVERSITY TARGU MURES, Targu Mures, Romania*

INTRODUCTION: Genetic variation in the human IL-6-572 gene (G allele or C allele) has been associated with many heritable traits, including nutritional disorders, expecialy malnutrition and obesity. In malnutrition and obesity multiple anomalies occur including cytokine production, which increse the severity and frequency of infections
AIMS&METHODS: ***To*** study the clinical and genetic factors in children with obesity and malnutrition. IL-6-572 genotype is correlated with cashexia. We examined whether obese and malnourished subjects differ from IL-6-572 genotype distribution, and whether this genotypes polimorfism is correlated with the anthropometric parameters (upper arm anthropometry - skinfold thicknesses) or the degrees of body mass index (BMI) and biochemical characteristics.The study included three comparable age and sex groups of children: 120 malnourished children (39,5%), 83 children with obesity (27,3%) and 101 (33,2%) with normal body weight/ random controls. We assessed anthropometric indices, lipid profile. All children were genotyped for IL-6-572 G/C gene polymorphism which was determined by the polymerase chain reaction using specific primers.
RESULTS: The median age was 74,72 ± 59.68 months in malnutrition group and 117.2 ± 57.93 months in obese group. The distribution of IL-6-572 CC, CG and GG genotypes in malnourished patients were 4.16; 27.50 and 68.33%, respectively; the corresponding numbers for the obese group were 49.39; 50.60 and 0.00%, while for the control group were 7.92; 25.74 and 66.33% respectively. Comparing the obese group with control group we obtained a 11.25 higher risk for the allele C to develop obesity ($p = 0.001$) and 13.53 higher risk comparing the obese group with the malnourished group ($p = 0.001$). Although the age, the protein, cholesterol concentrations and anthropometric parameters differ between random control and obese and malnutrished children, IL-6-572 G/C genotype did not differ. Also we observed an association of alleles CC with obese children, comparing with malnourished children ($p = 0.0001$, 22.45 times higher risk), while the presence of allele G (CG/GG) is more frequent associated with malnutrition.
CONCLUSION: IL-6-572 G/C gene polymorphism is a significant factor for nutritional disorders and alleles CC is associated with obesity, while the presence of allele G is associated with malnutrition in children from central part of Romania. Further studies are warranted to investigate the genetics of fatness and failure to thrive phenotypes in romanian children.

P561 DIFFERENCES IN GLUTEN CONSUMPTION AT EARLY AGE AMONG INFANTS FROM DIFFERENT EUROPEAN COUNTRIES. THE PREVENT-CD COHORTS.

P. Crespo[1,*], J. Calvo[1], G. Castillejo[2], E. Martinez[3], E. Stoopman[4], S. Vriezinga[4], B. Funke[4], K. Werkstetter[5], R. Auricchio[6], I. Polanco[3], S. Koletzko[5], R. Troncone[6], M. L. Mearin[4], C. Ribes Koninckx[1], Prevent CD group. [1]*Gastroenterology, Hospital Universitario La Fe, Valencia,* [2]*Gastroenterology, Hospital Universitari Sant Joan, Reus, Reus,* [3]*Gastroenterology, Hospital Universitario La Paz, Madrid, Spain,* [4]*Gastroenterology, University Medical Center, Leiden, Leiden, Netherlands,* [5]*Gastroenterology, University of Munich Medical Center, Munich, Germany,* [6]*Gastroenterology, University Federico II, Naples, Naples, Italy*

INTRODUCTION: OBJECTIVES: To evaluate mean daily gluten intake (MDGI) in children DQ2/DQ8 positive with a 1st degree relative with CD recruited from 2007-2010 shortly after birth (EU-PreventCD project,www.preventcd.com)
AIMS&METHODS: Methods: A prospective evaluation of MDGI in 11-36 months old infants in the PreventCD cohorts from Spain (Valencia, Madrid, Reus), Italy, Germany and the Netherlands, was accomplished by specific previously developed food records (FR), adapted to local dietary habits. All of FR corresponds to a period of 7 days and these were completed at 11, 12, 14, 16, 18, 22, 24, 28, 30, 34 and 36 months of age. The MDGI was calculated by the accepted method of multiplying the grams of vegetable protein, derived from gluten-containing cereals according to the food product composition, by 0.80.
RESULTS: Results: 3423 FRs (2-3 per child) were evaluated. MDGI increased progressively from 12 months onwards in all centers, the highest MDGI being registered in the older age group (25-36months). MDGI (in grams) for Valencia, Madrid, Reus, The Netherlands,Germany and Italy are respectively: 2.95, 3.26, 2.09, 5.82, 4.09, 5.44 (11-12months); 4.35, 4.11, 4.75, 7.81, 6.54, 8.14(14-18 months); 4.80, 4.28, 4.77, 8.33, 7.21, 10.46 (20-24months) and 5.18, 4.14, 4.63, 8.91, 7.94, 12.15 (25-36months).
Differences in MDGI are statistically significant between Spanish children and those from Italy, The Netherlands and Germany ($p < 0.001$), for all age groups
Differences in MDGI between Italy and Germany is SS for all age groups; between Italy and The Netherlands, differences however is SS only in the group of 25-36 months of age
The highest MDGI is obtained for Italy at any age and at 25-36 m of age double MDGI from Spain
CONCLUSION: CONCLUSION: In 4 different European countries MDGI increases sharply in-between 12 and 18 months of age, but it remains quite constant thereafter, except for Italy. However, The Netherlands and Italy have overall the highest gluten consumption at any age. Further analysis including genetics and breast feeding as well as longer follow up of this cohort is mandatory to ascertain the true relevance of gluten intake at early ages in the natural history of CD in European children.

P562 CHARACTERIZATION OF MUCOSA-ASSOCIATED AND FECAL MICROBIOTA OF CHILDREN WITH AUSTISM SPECTRUM DISORDER

V. Iebba[1,*], S. Schippa[1], F. Valitutti[2], F. Santangelo[1], S. Gatti[2], I. Celletti[2], S. Leoni[2], C. M. Trovato[2], D. Iorfida[2], P. Di Matteo[2], M. Marazzato[1], M. P. Conte[1], M. Barbato[2]. [1]*Public Science, Sapienza University of Rome,* [2]*Pediatrics, Pediatric Gastroenterology and Liver Unit, Sapienza University of Rome, Rome, Italy*

INTRODUCTION: It has often been suggested that there might be an intriguing relation between the gut microbiota and ASD (Autism Spectrum Disorder), and some authors have previously addressed the existence of a possible disbiosis in gut microbiota of autistic children. Our aim was to evaluate duodenal mucosa-associated and fecal microbiota of autistic children compared to age-matched controls.
AIMS&METHODS: 11 autistic patients and 8 controls underwent upper GI endoscopy and stool collection. All upper GI endoscopies were performed because of alarm symptoms (unexplained iron-deficiency anaemia; food impaction; weight loss; vomiting; chronic diarrhoea). Samples of total DNA were extracted both from duodenal biopsies' and stools. PCR with species-specific primers and ''Temperal Temperature Gel Elettrophoresis'' (TTGE) were employed to analyze the composition of dominant intestinal microbiota. In particular, the primers GCclamp-U968 (5'GCclamp-GAA CGC GAAGAACCT TAC) and L1401 (5'GCG TGT GTA CAA GAC CC) were used to amplify the V6 to V8 regions of bacterial 16S rRNA. TTGE profiles were then analyzed through PLS-DA (Partial Least Square Discriminant Analysis).
RESULTS: Preliminary results showed a significant (p=0.001) partition of fecal TTGE profiles from autistic patients and fecal TTGE profiles of control group. In addition, species specific PCR analysis disclosed the absence of Parabacteroides Distasonis among autistic children, while it was present in 75% of controls. No significant difference was disclosed as regard to mucosa-associated TTGE profiles.
CONCLUSION: The difference of TTGE profiles might be interpreted as a possible dysbiotic event in the intestinal microbiota in ASD; moreover, the lack among autistic patients of Parabacteroides Distasonis, previously described as a beneficial strain in the gut microbiota for its anti-inflammatory effects, warrants further investigations.

P563 NEW TECHNOLOGY THERAPY USING HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) FOR PANCREATIC CANCER

A. Sofuni[1,*], F. Moriyasu[1], T. Sano[1], F. Itokawa[1], S. Tsuji[2], T. Kurihara[1], T. Tsuchiya[1], K. Ishii[1], N. Ikeuchi[1], R. Tanaka[1], J. Umeda[1], R. Tonozuka[1], M. Honjyo[1], S. Mukai[1], T. Itoi[1]. [1]*Gastroenterology and hepatology,* [2]*TOKYO MEDICAL UNIVERSITY, Tokyo, Japan*

INTRODUCTION: Recently, High-intensity focused ultrasound (HIFU) is most expected as new advanced therapy for pancreatic cancer (PC). HIFU therapy with chemotherapy is being promoted as new method to control local advance by cauterizing tumor and achieve relief of pain caused by PC.
AIMS&METHODS: We have evaluated the therapeutic effect and applicability of HIFU therapy in locally advanced and metastatic PC. We treated PC patients using HIFU therapy as optional local therapy as well as systemic chemo / chemo-radiotherapy, with whom an agreement was obtained in adequate IC, from the end of 2008 in our hospital. This study took approval of member of ethic society of our hospital. HIFU device used is FEP-BY02 (China Medical Technologies Co.LTD., China). The subjects were 54 PC patients, i.e. 35 cases in stage III, 19 cases in stage IV.

RESULTS: All tumors were visualized by HIFU monitor system. Treatment data in Stage III and IV were followed; mean tumor size was 34.4 vs 30.8 mm, mean treatment sessions: 3.0 vs 2.5 times, mean total treatment time: 2.6 vs 2.1 hours, mean total number of irradiation: 3024 vs 1838 shots, respectively. There was no significant difference in treatment data between two groups. The effects of HIFU therapy in Stage III and IV were the following; the rate of complete tumor ablation was 85.7 vs 63.2%, the rate of symptom relief effect was 65 vs 58%, the effectiveness of primary lesion was CR:0, PR:4, SD:29, PD:2 vs CR:0, PR:3, SD:14, PD:2, primary disease control rate (DCR) more than SD was 94.3% vs 89.5%. Comparison of mean survival time (MST) after diagnosis in Stage III and IV was 35.0 vs 15.2 months, respectively ($p<0.05$, $p=0.021$). MST after diagnosis in HIFU with chemotherapy and chemotherapy alone (38 patients in our hospital) was 29.3 vs 12.2 months, respectively ($p<0.001$). Combination therapy of HIFU with chemotherapy was better result than common chemotherapy alone.
CONCLUSION: This study suggested that HIFU therapy has the potential of new method of combination therapy for PC.

P564 ENDOSCOPIC SUBMUCOSAL DISSECTION BY USING A NOVEL VERSATILE KNIFE: AN ANIMAL FEASIBILITY STUDY

C.-I. Kwon[1,*], G.-I. Kim[2], I.-K. Chung[3], W. H. Kim[1], S. P. Hong[1], S. Jeong[4], D. H. Lee[4]. [1]*Digestive Disease Center,* [2]*Department of Pathology, CHA Bundang Medical Center, CHA University, Seongnam,* [3]*Division of Gastroenterology & Hepatology, Department of Internal Medicine, Soon Chun Hyang University College of Medicine, Cheonan Hospital, Cheonan,* [4]*Division of Gastroenterology, Department of Internal Medicine, Inha University School of Medicine, Incheon, Korea, Republic Of*

INTRODUCTION: Endoscopic submucosal dissection (ESD) with a knife is technically difficult and requires special skills and a long time for the quality controlled procedure. To overcome these problems, ESD may require several different knives and frequent change of knives, depending on the location and shape of the tumor. For the purpose of reducing the procedure time and the number of accessory changing, we developed a novel versatile knife (Optimos® knife), which has combined advantages of several conventional knives (Performing several steps of ESD; marking, circumferential incision and cutting, dissection, vessel coagulation and water injection function).
AIMS&METHODS: The aim of this study was to introduce the Optimos knife and evaluate its efficacy and safety in ESD, compared to when using several conventional knives.
This was a prospective, animal case control trial comparing 2 different modalities (Optimos knife and combination of conventional knives) for the removal of target mucosal lesions. Two micro-pigs were to undergo 18 removals of the stomach mucosa, with target resected specimen size around 3 x 3cm squares. The ESD procedure was repeated by using the assigned ESD knife. Completion time of each resection was documented, and the resected specimen was retrieved and evaluated for completeness. To assess quality control of ESD procedures and procedure-related complications, detailed histopathological examinations were performed.
RESULTS: We resected a total of 18 ESD specimens safely and easily (9 specimens by using the Optimos knife; 9 specimens by mixing conventional knifes). There was no significant difference in the procedure time and cutting speed between the two groups. Significant bleeding occurred with equal frequency (1 vs. 1). There was no perforation in the two groups (endoscopic and histological). Histologic quality analysis of both resected specimen and remaining gastric bed tissue revealed no statistical difference.
CONCLUSION: New Optimos knife, the multifunctional knife developed by combining advantages of various conventional knives, can carry out multiple steps of ESD procedure, and is deemed quite helpful when performing quality controlled ESD safely and rapidly. Further large-scaled, prospective clinical studies are required for more accurate determination of its safety and efficacy.

P565 A NEW PROTOTYPE USING INDOCYANIN GREEN (ICG) AS A CONTRAST AGENT FOR PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY (PCLE)

E. Coron[1,*]. [1]*CHU Nantes, Nantes, France*

INTRODUCTION: Probe-based Confocal Laser Endomicroscopy (pCLE) is a new imaging technology, enabling in vivo microscopic evaluation in real-time. However the system currently available (blue laser after injection of fluorescein) has some limitations: (1) fluorescein exposes a few patients at risk to allergic reactions, and (2) the depth of exploration is limited.
AIMS&METHODS: Our aim was to develop a new system encompassing two lasers and indo cyanine green (ICG) as a fluorescent agent.
We used a porcine model, with first injection of ICG (5ml at 5mg/ml at 785nm, and an additional 15ml at 3.3 mg/ml at 640nm). Images of the esophageal, duodenal, biliary and hepatic tissues were collected using standard pCLE probes working with the 785nm system. Then, the same procedure was repeated after fluorescein injection with the 488nm system. Images were compared qualitatively for each tissue site.
RESULTS: Good quality images could be obtained using intravenous ICG in all organs. Appropriate fluorescence signal levels could be visualized based on the dosages used. The fluorescence signal was very low at 640nm and close to the lower detection threshold of the system, even after a repeat injection of ICG. The fluorescence signal was acceptable at 785nm. Dynamics of ICG appeared radically different than that of fluorescein, with a rapid extravasation, enabling the observation of microarchitectural structures as a negative signal. Repeat injection enabled further visualization of microarchitectural and cellular details. Image quality was similar after repeated injections.
CONCLUSION: This study provided promising perspectives on future combinations between optical biopsy devices and contrast agent, especially with new near-infrared molecules being developed. Since a 785nm wavelength can penetrate deeper into the tissue, provided chromatic probes are developed in the future, it might be possible to obtain pCLE images at increased depths with the 785 nm system.

P566 IS OVER-THE-SCOPE CLIP A PERMANENTLY IMPLANTED DEVICE? OUTCOME AND FOLLOW UP OF CLIP DELIVERY FOR FISTULAS, PERFORATIONS AND BLEEDING

G. Donatelli[1,*], S. Leblanc[2], M. Gaudric[2], L. Mangialavori[2], J. C. Duchmann[2], R. Coriat[2], S. Chaussade[2], F. Prat[2]. [1]*Gastroenterology and Endoscopy Unit, Hôpital Cochin - APHP, Paris - Descartes University,* [2]*Gastroenterology and Endoscopy Unit, Hôpital Cochin - APHP, Paris - Descartes University, Paris, France*

INTRODUCTION: Over-the-Scope Clip (OTSC) is a new clipping device providing strong grasping and compression of tissue without provoking ischemia and laceration, proposed for the closure of gastrointestinal defects iatrogenic visceral perforation or bleeding. Once applied, OTSC® remains attached to the mucosa, and cannot be removed, but like standard clips it may be bound to fall over time.
AIMS&METHODS: The aim of this study was to report our experience of the outcome of OTSC® placement in GI fistulas, perforations and bleeding and to evaluate spontaneous detachment rate.Between 10/2010 - 4/2013, 31 OTSC® were placed in 29 patients (15F), median age 62.62 years (20-88), 10 (32%) for iatrogenic visceral perforation, 4(13%) for bleeding and 17 (55%) for leaks following surgery. Anatomic position was: esophagus, n=11, stomach, n=3, duodenum, n=9 and colon, n=8. The median (range) timespan from the primum movens to OTSC® implantation was 71 days (0-570), with 112 days (7-570) for leaks, 30 days (0-90) for bleeding, and 2 days (0-15) for perforation. The size of OTSC® used was 9mm in 27 cases and 14mm in 4. Outcome was evaluated by clinical follow-up and detachment rate by radiological imaging or endoscopy at distant time.
RESULTS: All 31 OTSC® were delivered with no procedure-related complication. The treatment was successful in 21 patients (72,4%) at 15 months (1-32) follow up and the clip was still in place after a median of 195,80 days (30-570). 8pts (27,6%) clipped for surgical leak required repeat endoscopic interventions for persistence of fistula a median of 120 days (33-240) after the clip application. In 2 out of 6 patients OTSC® was not found at repeat endoscopy (122 and 160 days after OTCS® placement). One leak was treated by stenting and the other one by a second OTSC®, which was again not in place at the time of endoscopic control for persistence of the leak. In 1 out 8 patients, the misplaced clip was removed with a foreign body forceps 200 days later, this patient was definitively treated with stenting. In the last 5 patients OTSC® was found to be present but misplaced at the time of second endoscopy after a median of 82,6days (10-240). 3 of these patients underwent surgery and the other 2 are still under stent treatment.
CONCLUSION: OTSC® looks successful for the treatment of iatrogenic acute visceral perforation, gastrointestinal bleeding and leaks follows surgery. Clips seem to remain in place for a long time if rightly placed with clinical efficiency; by contrast OTSC® may slough off spontaneously in case of inefficient application and/or misplacement.

P567 USEFULNESS OF THE INFRARED ENDOSCOPY (IRE) IN ASSESSMENT OF BARRETT'S EARLY NEOPLASIA: PRELIMINARY RESULTS FROM A PILOT STUDY.

J. Ortiz-Fernández-Sordo[1,*], S. Sami[1], V. Subramanian[2], J. Mannath[3], E. Telakis[4], K. Ragunath[1]. [1]*Gastroenterology Department, Nottingham University Hospitals, Nottingham,* [2]*Gastroenterology Department, Leeds Teaching Hospitals NHS Trust, Leeds,* [3]*Gastroenterology Department, University Hospitals Coventry and Warwickshire NHS Trust, Coventry, United Kingdom,* [4]*Gastrointestinal Endoscopy Department, Bioclinic of Piraeus, Piraeus, Greece*

INTRODUCTION: An accurate staging of early Barrett's cancer is mandatory to identify patients with neoplasia limited to the mucosa, who can be candidates for endoscopic treatment. Infrared endoscopy (IRE) using indocyanine green (ICG) as a fluorescence marker has been shown to be useful in detecting submucosal (SM) invasion in early gastric cancer. Its role in the endoscopic assessment of Barrett's neoplasia has not been reported.
AIMS&METHODS: To evaluate the utility of IRE in the endoscopic assessment of Barrett's early neoplasia.
Patients with dysplastic Barrett's oesophagus (BO) referred for endoscopic therapy were prospectively enrolled in the study. White light High Resolution Endoscopy, Narrow Band Imaging and IRE were sequentially performed using

an Infrared endoscope prototype (GIF-RQ260Z; Olympus Optical Co.). 2 mg/kg of ICG was intravenously administered before the IRE. Characteristics of BO and any visible lesion (VL) were recorded. IRE findings were classified as no stain, faint stain and dense stain. Biopsies were obtained from flat Barrett's segment. Endoscopic mucosal resection (EMR) was performed for all VL if appropriate. Final histology by biopsies/EMR/surgery was included for analysis.
RESULTS: 21 patients were included (median age 69 years, 86% men); median length of BO 5 cm (range 1-16 cm). Biopsy results from 7 patients with flat BO and 16 VL (Is=1, 0-IIa=9, 0-IIa+c=2, 0-IIb=4) from 14 patients were analyzed. IRE findings after ICG injection (median dose 160 mg) and its correlation with final histology are summarized in Table 1.

Table 1. IRE Staining and final histology

NO STAIN=7				STAIN=16			
≤LGD	HGD	IMC	SMC	≤LGD	HGD	IMC	SMC
5	1	1	0	1	6	5	4

STAIN=16							
FAINT=11				DENSE=5			
≤LGD	HGD	IMC	SMC	≤LGD	HGD	IMC	SMC
1	6	2	2	0	1	2	2

No stain was noted in 7 cases; histology was <HGD in 5 (71%) and ≥HGD in 2 (29%). Staining was noted in 16 cases; 15 (94%) had at least HGD. There was statistically significant difference between cases with no stain and any staining on IRE with regard to the presence of at least HGD [2/7 (29%) vs. 15/16 (94%) p=0.005].
Stain was reported as faint in 11 cases and dense in 5. There was no statistically significant difference between cases with faint and dense staining on IRE with regard to the presence of SM invasion [2/11 (18%) vs. 2/5 (40%) p=0.755].
CONCLUSION: IRE can provide additional information to the currently available imaging techniques for detecting HGD in BO. The presence of inflammation and hypervascularization within the BO makes the accurate visualization of SM vessels challenging. IRE may not have role to predict SM invasion in early Barrett's neoplasia.

P568 USEFULNESS OF RADIAL EUS SCANNING TO ASSESS ADEQUACY OF ENDOSCOPIC RESECTION OF GASTRODUODENAL CARCINOID TUMORS (GDCT)

J. C. Ardengh[1,*], T. Baron[2], E. Taglieri[1], O. Micelli-Neto[1], E. T. Orsini[1], G. Motta[1], R. Kemp[1], J. S. dos Santos[1]. *[1]Surgery and Anatomy of HCFMRP-USP, Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil, [2]Gastroenterology, Mayo Clinic, Rochester, United States*

INTRODUCTION: Gastroduodenal carcinoid tumors are rare neuroendocrine tumors, usually present as foregut submucosal tumor or polypoid lesions. Accurate diagnosis and endoscopic resection remain a challenge.
AIMS&METHODS: To evaluate the accuracy, diagnostic features, and role of EUS radial scanning in the therapeutic decision making in patients with gastroduodenal carcinoid tumors. From September 2006 to January 2012, 52 patients were identified as having suspected gastric or duodenal carcinoids by our endoscopic services. After excluding obvious subepithelial tumors, ampullary location, and inconclusive pathology a total of 27 patients remained and were analyzed based upon EUS images/video by endoscopists blinded to final clinical and pathological outcomes.
RESULTS: 27 patients with 44 GDCT (30 GCT and 14 DCT) were analyzed. EUS showed GDCT in the second layer in 100% and were homogeneous and hypoechoic in 93%. The median size of GCT was 11 mm (5-18 mm) and DCT was 7mm (6-16 mm). Based on EUS staging; 23 uT1 (85%) underwent ER and 4 uT2 (15%) underwent surgery. We performed 29 ER (16 GCT and 13 DCT) using polypectomy snare in 19 after submucosal injection in 7 and the by band ligation / snare resection (3). ER was complete in 23/29 (79.3%). Accuracy of EUS to determine the correct indication surgery (uT2) or ER (uT1) was 79.3%. Early adverse events (AEs) occurred in 2 patients (6.8%): pain [1] and perforation [1], the latter treated surgically. The mortality rate was 3.4%. Recurrence occurred in 3/23 (13%).
CONCLUSION: Most GDCT are less than 10mm in size, with well-defined margins and hypoechoic nature present in deep mucosal and submucosal layers. Tumor locations (eg. proximal stomach and duodenal bulb) and EUS features are factors predictive of GDCT. EUS provides information to assist ER. GCT located in the middle and distal portion and DCT in the second portion are difficult to be precisely evaluated by EUS.

P569 DIAGNOSTIC PERFORMANCE AND LIMITATIONS OF MAGNIFYING NARROW-BAND IMAGING IN SCREENING ENDOSCOPY OF EARLY GASTRIC CANCER: A PROSPECTIVE MULTICENTER FEASIBILITY STUDY

K. Yao[1,*], H. Doyama[2], T. Gotoda[3], H. Ishikawa[4], T. Nagahama[5], C. Yokoi[6], I. Oda[7], H. Machida[8], K. Uchita[9], M. Tabuchi[10]. *[1]Department of Endoscopy, FUKUOKA UNIVERSITY CHIKUSHI HOSPITAL, Chikushino-city, [2]Department of Gastroenterology, Ishikawa prefectural central hospital, Kanazawa-city, [3]Department of Gastroenterology and Hepatology, Tokyo Medical University, Tokyo, [4]Department of Molecular-Targeting Cancer Prevention, Kyoto Prefectural University of Medicine, Osaka-city, [5]Department of Gastroenterology, FUKUOKA UNIVERSITY CHIKUSHI HOSPITAL, Chikushino-city, [6]Department of Gastroenterology, National Center for Global Health and Medicine, [7]Endoscopy Division, National Cancer Center Hospital, Tokyo, [8]Department of Gastroenterology, Osaka City University Graduate School of Medicine, Osaka-city, [9]Department of Gastroenterology, Kochi Red Cross Hospital, Kochi-city, [10]Department of Gastroenterology, Izumiotsu Municipal Hospital, Izumiotsu-city, Japan*

INTRODUCTION: Curative treatment of the patient with gastric cancer requires reliable detection of early gastric cancer. Magnifying endoscopy with narrow-band imaging (M-NBI) is useful for the accurate diagnosis of early gastric cancer [1, 2]. However, the role of M-NBI in screening endoscopy has not yet been established.
AIMS&METHODS: The aims of this study were to investigate the feasibility and the limitations of M-NBI in screening endoscopy. We conducted a multicenter prospective uncontrolled trial of patients undergoing routine screening endoscopy. We determined the diagnostic accuracy, sensitivity and specificity of M-NBI according to the degree of certainty and need for biopsy as assessed using the VS (vessel plus surface) classification system [1]. We analyzed the endoscopic and histopathological characteristics of both false negative and false positive cases which were diagnosed using M-NBI with a high degree of confidence. We then developed a provisional diagnostic strategy based on the diagnostic performance and limitations identified in this study.
RESULTS: A total of 1094 patients were enrolled in the study. We analyzed 371 detected lesions (20 cancers and 351 non-cancers). The accuracy, sensitivity and specificity of M-NBI diagnoses with a high degree of confidence were 98.1%, 85.7% and 99.4%, respectively. The false negative lesion was a pale mucosal lesion with a tissue diagnosis of signet-ring cell carcinoma. When we excluded pale mucosal lesions, the accuracy, sensitivity and specificity of M-NBI diagnoses with a high degree of confidence increased to 98.1%, 100% and 99.4%, respectively. We therefore propose a practical strategy for targeting non-pale mucosal lesions.
CONCLUSION: With a refined strategy considering its limitations, M-NBI can act as an "optical biopsy" in screening endoscopies.

P570 ESOPHAGEAL REGENERATION WITH CELL SHEETS FOLLOWING ESD: DEVELOPMENT OF ENDOSCOPIC DELIVERY DEVICES FOR CELL SHEETS

N. Kanai[1,2,*], S. Kobayashi[3], T. Ohki[2], N. Tanaka[1], M. Yamato[1], T. Okano[1]. *[1]Institute of Advanced Biomedical Engineering and Science, [2]Department of Surgery, Institute of Gastroenterology, Tokyo Women's Medical University, Tokyo, [3]Department of Surgery, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

INTRODUCTION: We have developed a novel strategy for regenerative medicine to recover tissue functions using temperature-responsive cell culture surfaces. To overcome of conventional methods such as the usage of single-cell suspension injection, we have applied transplantable cell sheets fabricated with temperature-responsive culture surfaces for cell delivery. In the field of gastroenterology, these regenerative medicine and tissue engineering approaches have attempted to prevent postoperative stricture by structurally and functionally reconstructing normal tissues through the promotion of early re-epithelialization after endoscopic large size mucosal resection. Our group previously reported a method of regenerative therapy involving the transplantation of fabricated autologous oral mucosal epithelial cell sheets in a canine model and demonstrated its human clinical application. So far, the endoscopic technique of cell sheet transplantation was not easily procedure. Presently, we are developing two types of novel endoscopic device for cell sheets transplantation, and we also show recent our research for esophageal regeneration using cell sheet engineering after circumferential endoscopic large size mucosal resection. We examined allogeneic epidermal cell sheet transplantation using a novel endoscopic delivery device in porcine.
AIMS&METHODS: The novel devices were designed with a computer-aided design system, and the three-dimensional data were transferred to a 3D printer. And then, primary epidermal cells were isolated from the lower abdominal skin of miniature pigs, cultured for 18 days at 37°C on temperature-responsive culture inserts. Transplantable cell sheets were harvested from the inserts by reducing temperature to 20°C. Immediately after creating full circumferential esophageal endoscopic submucosal dissection (ESD), an allogeneic epidermal cell sheet was endoscopically transplanted to the ulcer site. The pigs were endoscopically monitored, and sacrificed 2 weeks after transplantation.

RESULTS: 2-3 pieces of the epidermal cell sheets (20mm in diameter) were successfully transplanted onto the ulcer site after circumferential ESD. In addition, early epithelialization and moderate stricture were observed by a number of transplanted cell sheets.
CONCLUSION: These endoscopic delivery devices for cell sheet would enable easily transplantation of cell sheets onto the lumen of the esophagus. Additionally, fabricated allogeneic epidermal cell sheets might be useful for prevention of stricture after esophageal ESD as well as autologous oral mucosa epithelial cell sheets in swine model.

P571 DOUBLE TYPE METALLIC STENTS FOR MANAGEMENT OF POST-OPERATIVE FISTULA AND LEAKAGE OF THE UPPER GASTROINTESTINAL TRACT

R. Garces[1,*], G. Vanbiervliet[2], J.-M. Gonzalez[3], J.-C. Grimaud[3], M. Barthet[3]. [1]*gastroenterology, HOPITAL NORD, Marseille cedex 20,* [2]*gastroenterology, CHU L'Archet 2, Nice,* [3]*gastroenterology, Hopital Nord, marseille, France*

INTRODUCTION: Post-operative anastomotic leakage and fistula of the upper GI tract are still challenging to manage. Because of the need of removability, fully covered stents are used with a high risk of migration in patients with usually severe conditions and sepsis. The aim of our study was to evaluate the effectiveness of a new type of endoscopic stenting in post-operative GI leakage or fistula. The secondary endpoint was to determine the ability to withdraw the stent.
AIMS&METHODS: Thirty patients treated for upper GI fistula with a double type stent (Taewong, Seoul, Korea) were included in this retrospective study. Eighteen were indicated for post-operative fistula or leakage. Double type stents were used because they added to an inner fully covered stent, an outer uncovered spherical metallic stent. Thus, the inner part ensured the tightness of the stent whereas the outer part decreased the risk of migration. Double type metallic stent (DTMS) were planned to be retrieved after 4 postoperative weeks.
RESULTS: Twelve patients had a post-operative fistula (Sleeve gastrectomy in 8 cases), six had an anastomotic leakage. Eight patients out of the eighteen have undergone a previous failed stenting and eight an associated treatment with OTSC clips. A complete healing was obtained in fifteen among eighteen patients (83%). Those patients were healed with primary success (one session) in 12 cases and required a second treatment session in 3 cases. Among patients with fistulas (12), the success rate was 75% (9/12) and it was 100% (6/6) in patients with anastomotic leakages. All the stents were withdrawn without any complications after a median stenting time of 33 days. The spontaneous migration rate of the stent was 16%.
CONCLUSION: This new double type stent is a new and efficient method to treat post-operative fistulas and leakages of the upper GI tract. The stents were always removable despite the external uncovered part with a low migration rate

P572 EXPERIMENTAL EVALUATION OF PHOTOCROSSLINKABLE CHITOSAN HYDROGEL AS INJECTION SOLUTION FOR ENDOSCOPIC RESECTION

T. Ishizuka[1,*], T. Shibata[1], T. Tahara[1], M. Ohkubo[1], M. Miyata[1], K. Sumi[1], Y. Ichikawa[1], I. Hirata[1]. [1]*Fujita Health University, Toyoake, Japan*

INTRODUCTION: Saline and sodium hyaluronate as injection solution for endoscopic resection techniques have several disadvantages such as short lasting effect leading to a potentially higher risk of bleeding and perforation. The new substance of photocrosslinkable chitosan hydrogel in a DMEM/F12 medium (PCH) can be converted into an insoluble hydrogel by ultraviolet (UV) irradiation for 30 seconds. So, we think PCH can maintain submucosal thickness and reduce bleeding and perforation after mucosal resection.
AIMS&METHODS: First, The gastric submucosal layer of rats was injected with PCH (which was then irradiated with ultraviolet light to form a hydrogel), or with sodium hyaluronate, or hypertonic saline, and two investigations about the thickness of the layer and the amount of bleeding were done, using three different sets of rats, respectively. Second, twelve pigs were divided in the two groups: endoscopic submucosal dissections (ESD) were performed with either PCH or hypertonic saline. Thirdly, the effects of both agents on wound healing were examined endoscopically and histologically using six pig stomachs.
RESULTS: Gastric submucosal layers of chitosan hydrogel-treated animals remained significantly thicker than those of other groups for at least 6 h after injection. The total amount of bleeding 20 min after mechanical mucosal resection was 170.0±20.0mg, 678.3±226.3mg, and 1020.0±104.1mg in the PCH, sodium hyaluronate, and hypertonic saline groups, respectively. PCH injection led to a longer lasting elevation with clearer margins as compared with hypertonic saline, thus enabling precise ESD along the margins of the elevated mucosa. The endoscopic aspect after ESD was similar in both groups. PCH biodegradation was completed within 8 weeks on endoscopic and histologic analyses.
CONCLUSION: PCH is a promising agent for submucosal injection prior to various techniques of endoresection. It should be evaluated in clinical trials.

P573 SERRATED POLYPOSIS: ENDOSCOPIC, PATHOLOGICAL AND CLINICAL DATA FROM A COHORT OF ITALIAN PATIENTS.

D. Moneghini[1,1,*], G. Missale[1], R. Nascimbeni[2], V. Villanacci[3], L. Minelli[1], G. Cengia[1], R. Cestari[1]. [1]*Digestive Endoscopy Unit,* [2]*Surgery,* [3]*Pathology, SPEDALI CIVILI - UNIVERSITY OF BRESCIA, Brescia, Italy*

INTRODUCTION: Serrated polyposis syndrome (SPS) is a recently identified colonic polyposis associated to an increased risk of colorectal cancer (CRC). According to World Health Organization (WHO) diagnostic criteria for SPS are: 1) at least 5 serrated polyps (SP) proximal to sigmoid colon, of which 2 are greater than 10 mm in diameter, or 2) any number of SP occurring proximal to sigmoid colon in an individual who has a first-degree relative (FDR) with SPS, or 3) greater than 20 SP distributed throughout the colon. Polyps occurring in SPS are part of a spectrum of SP including hyperplastic polyps (HP), traditional serrated adenomas (TSA), sessile serrated adenomas (SSA). Little is known about SPS genetics, inheritance and clinical manifestations. Few dozens of SPS cases have been described all over the world, especially from Australia, U.S.A and northern Europe. No data on SPS patients from Italy are known.
AIMS&METHODS: We report the first Italian cohort of 15 SPS patients (from 13 different families) identified at our Endoscopy Unit between 2009 and 2012.
RESULTS: Six patients (40%) met the WHO criterion n.1; 2 patients (13,3%) the n.2 and 7 (46,7%) the n.3. 12 (80%) were males; the mean age was 64,2 years (range 52-77). A total number of 592 polyps were removed during 55 colonoscopies performed with high-definition scopes and indigo carmine or electronic chromoendoscopy in case of known SPS. 501 polyps (84,6%) were SP, 91 were tubular or tubular-villous adenomas; 66 polyps (11,1%) were greater than 1 cm in diameter. Regarding SP, 442 (88,2%) were HP, 39 (7,9%) were SSA and 20 (3,9%) were TSA. Regarding the anatomical distribution of all the polyps, 183 (30,9%) were found in the right colon, 304 (51,4%) in the left colon and 105 (17,7%) in the rectum; taking into account the SP only, 118 (23,5%) were located in the right colon, 282 (56,3%) in the left colon and 101 (20,2%) in the rectum. Interestingly, no polyps with high grade dysplasia were found. We observed only one patient with CRC (6,7%), located in the rectum. A familial history of CRC was recorded in 7,7% of cases. 33,3% of SPS patients had an extraintestinal previous cancer. We also observed an high incidence of any cancer (23,8%) in 42 FDR investigated.
CONCLUSION: Our study shows some differences with previous series: high percentage of male patients; low rate of CRC; low incidence of CRC familial history but high incidence of cancer in FDR; SPS distal presentation predominance. Larger studies are needed to confirm these findings.

P574 EFFICACY AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION IN AN EUROPEAN CENTER

F. Baldaque-Silva[1,*], M. Marques[1], F. Vilas Boas[1], E. Duarte[2], J. Lopes[3], F. Carneiro[4], G. Macedo[1]. [1]*Gastroenterology,* [2]*Anesthesiology,* [3]*Pathology, Centro Hospitalar de São João,* [4]*IPATIMUP, Porto University, Porto, Portugal*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is gaining acceptance in the West as a therapeutic technique for removal of epithelial and subepitelial gastrointestinal lesions. It allows en bloc resection but demands skilful endoscopic teams. Comparing to endoscopic mucosal resection, it is associated with prolonged procedure time and increased risks of perforation and bleeding. European reports on ESD are scarce and limited in size.
AIMS&METHODS: In this prospective study, we aim to evaluate the efficacy and safety of this technique in our center. Consecutive patients with gastrointestinal lesions referred for ESD were invited to participate in this study, between November 2010 and February 2013. The study was approved by the Ethical Committee of our Institution and each patient gave written informed consent. All ESDs were performed in the endoscopy unit under propofol sedation using IT-knife 2, IT-knife nano and Dual-knife according to lesions localization. Follow-up endoscopies were performed 2 months after ESD and subsequently each 6-12 months, according to pathology result.
RESULTS: 104 patients (45 female, mean age 63,7 ± 13 years-old) were invited to participate in the study. The corresponding 109 lesions were located in the esophagus (n=5), stomach (n=77), duodenum (n=3), colon (n=6) and rectum (n=18). En bloc resection and R0 resection were obtained in 94% and 81% of cases, respectively. The specimens size ranged between 17-140mm (mean 36± 18 mm), corresponding to lesions with 9-105mm (mean 28± 18mm). The median procedure length was 94 ± 80 minutes. Six lesions were subepithelial, being the remaining epithelial. The most frequent pathological results were low-grade dysplasia (n=35), high-grade dysplasia (n=26), intramucosal adenocarcinoma (n=14), invasive carcinoma (n=7). Two patients had acute surgery due to perforation (n=1) and bleeding (n=1). One patient had emphysema and 6 patients had delayed bleeding, all treated conservatively. In 69% of cases ESD was performed in an outpatient basis, being all patients discharged in up to 7 days. Three patients were operated electively due to non curative ESD and one patient had a second ESD because of residual neoplastic tissue in the scar on follow-up. The remaining patients had no recurrence on a strict follow-up protocol.
CONCLUSION: In this prospective study, ESD enabled accurate resection, with low rate of complications and no mortality.

P575 ENDOSCOPIC MANAGEMENT FOR PATIENTS WITH SERRATED POLYPOSIS SYNDROME IS FEASIBLE AND EFFECTIVE : A PROSPECTIVE OBSERVATIONAL STUDY AT A TERTIARY CENTER.

M. Knabe[1,*], I. Messer[1], A. Behrens[1], A. Tannapfel[2], G. Mayer[1], C. Ell[1], J. Pohl[1]. [1]*Gastroenterology, DR. HORST-SCHMIDT- KLINIKEN, Wiesbaden,* [2]*Pathology, Ruhr-University, Bochum, Germany*

INTRODUCTION: Serrated polyposis syndrome is a rare condition with multiple serrated lesions all over the colon and is believed to have an increased risk for developing cancer. The recognition of these polyps as well as the clinical and pathological classification is important to determine treatment and surveillance strategy. However, clinical strategy remains unclear as prospective data based on large numbers of patients are scarce

AIMS&METHODS: The aim of this study was to investigate the feasibility of endoscopic treatment and standardized surveillance in patients with this increasingly recognized syndrome. From september 2010 to april 2013 we included consecutive patients in this prospective study. All patients underwent chromoendoscopy at first presentation and during surveillance. The strategy included initial complete resection of all colonic lesions > 5mm. Follow-up was performed in 3-6 months until complete remission was achieved. Afterwards , patients entered a standardized surveillance protocol with chromoendoscopic colonoscopy in annual period.

RESULTS: In 24 patients, 79 colonoscopies, with endoscopic resection of 369 lesions were undertaken. In 22 patients (91.6%) total remission could be accomplished after 2.51 (1-8) colonoscopies. Histology revealed predominantly diminutive hyperplastic polyps (81.7%),31 (8.4%) sessile serrated adenomas and 33 (8.9%) low-grade adenomas and one patient with advanced colorectal cancer. Only 9 (38%) patients had serrated polyps > 10 mm in size. During surveillance period 63 additional lesions were detected and resected. The mean follow-up time was 17.99 months (2-31). No interval carcinoma was detected during surveillance.

CONCLUSION: The present study indicates that endoscopic management in patients fulfilling the diagniostic criteria of serrated polyposis syndrome is feasible and safe. We cannot confirm the previously described association between serrated polyposis syndrom and colonic cancer in general. As the predominant phenotype was small hyperplastic polyps (WHO III◦), it appears likely that cancer risk is associated with larger serrated lesions rather than small hyperplastic polyps itself.

P576 COLORECTAL SESSILE SERRATED ADENOMA/POLYP WITH DYSPLASIA MAY LOSE TYPICAL MUCOUS-CAP APPEARANCE

W.-H. Hsu[1,*], M.-S. Sun[1], H.-W. Lo[1], C.-Y. Tsai[1], Y.-J. Tsai[1]. [1]*Gastroenterology, Yuan's General Hospital, Kaohsiung, Taiwan, Province of China*

INTRODUCTION: The colorectal serrated polyp is morphologically conspicuous and the diagnosis by endoscopy is difficult, although mucous-cap is most often mentioned for sessile serrated adenoma/polyps (SSA/P). In pathology, the diagnosis and terminology among each subtypes remains a debate. The ambiguity of diagnosis in endoscopy and pathology may impede the well recognition of serrated polyp and may account for inferior protection of colonoscopy for right-sided colon cancer. Latest differentiation about serrated polyps was released in 2010. Our pathology unit also adjusted and followed the classifications since then.

AIMS&METHODS: To improve our understanding about endoscopic diagnostic capability and clinical features according to the latest pathological proposal for colorectal serrated polyps.

From 2011/01 to 2012/12, diagnosis with sessile serrated adenoma/polyps (SSA/P) and traditional serrated adenoma (TSA) in colorectum were selected from the pathology database. Basic demographic data were reviewed and compared between SSA/P and TSA. SSA/P with cell dysplasia was also selected. The endoscopic pictures of each polyps were reviewed again by one endoscopist to judge whether mucous-cap appearance was shown in SSA/P. In TSA, polyps with villiform pit appearance in white-light endoscopy were regarded as endoscopy-diagnosis capable cases.

RESULTS: A total of 34 SSA/P and 17 TSA were enrolled for study. There were no difference in age (59.0/59.18), gender ratio (men, 52.9%/76.5%, p= 0.187), and polyp size (8.9/9.2, mm) between SSA/P and TSA. Same to current report, SSA/P appeared more frequently in right-sided colon (67.6%) whereas TSA was more common in left-sided colon (76.5%). Common characteristics of serrated polyps in endoscopy were seen in 50% (17/34) and 41.2% (7/17) of SSA/P and TSA, respectively. Ten of SSA/P (29.4%) presented with cell dysplasia. In SSA/P with cell dysplasia, the polyp size tended to be larger than SSA/P without dysplasia, though not statistically significant (1.160/0.783, cm, p=0.31). Besides, SSA/P with dysplasia seldom reveal mucous-cap appearance when comparing to SSA/P without dysplasia (without mucous-cap, 90%/33.3%, p= 0.008).

CONCLUSION: Our result showed that SSA/P with dysplasia seldom presented with mucus-cap appearance. We assumed the process of dysplasia would be associated with mucous secretion. The endoscopic diagnostic capability was not good for SSA/P and TSA. All sessile polyps at right-sided colon should be removed even without mucous-cap appearance if technically available.

P577 SAFE EN BLOC RESECTION PROCEDURE WITH ESD AND LAPAROSCOPY ENDOSCOPY COOPERATIVE SURGERY (LECS) FOR COLORECTAL TUMORS ACCOMPANIED WITH FIBROSIS IN SUBMUCOSAL LAYER

Y. Tamegai[1,*], T. Kishihara[1], A. Chino[1], S. Suzuki[1], T. Suganuma[1], M. Igarashi[1]. [1]*Endoscopy Division, Cancer Institute Hospital, Tokyo, Japan*

INTRODUCTION: The possibility of en bloc resection of colorectal tumor using endoscopic submucosal dissection (ESD) sometime depends on the existence of fibrosis in the submucosal layer (SM). In these cases, submucosal dissection by using endoscopic devices will becomes more difficult due to the risk of muscular injury and perforation. We developed safe technique of ESD and its applied laparoscopy endoscopy cooperative surgery (LECS) to complete en bloc resection for tumors accompanied with firm fibrosis in SM.

AIMS&METHODS: ESD was performed for 565cases of tumor in 551 patients (male: female = 329:222; mean age, 66.2years). Among these, 135 cases were accompanied with fibrosis in SM. We analyzed these lesions in order to establish a safe en bloc resection procedure.

RESULTS: ESD cases were divided into three groups, absent with fibrosis: type A, fibrosis due to benign causes: type B, and fibrosis due to SM cancer invasion: type C. We classified endoscopic findings of mild degree as B-1and C-1. moderate degree as B-2 and C-2, and screen-like firm fibrosis as B-3 and C-3. We performed en bloc resection for 529 (93.6%) cases of 565 ESD cases, and experienced only one case (0.18%) with perforation, which was accompanied with fibrosis. En bloc resection rate of the tumor without fibrosis (type A) was 96.7% (416/430), and the tumor accompanied with fibrosis was 83.7% (113/135). En bloc resection rate of type B (n=96) and type C (n=39) were as follows, type B; B-1: 48/51(94.1%), B-2:20/23(87.0%), B-3:14/22 (63.6%), type C; C-1:19/19(100%, average SM depth:884 micron), C-2:4/5(80%, average SM depth:2,474 micron), C-3:8/15(53.3%, average SM depth:3,377micron). These results of B-3 and C-3 were significantly lower than type A statistically. From these results, we designed a safe ESD technique by using endo-clips to prevent perforation in 2 cases with type B-3. In cases accompanied with more wide and firm fibrosis in SM, en bloc resection will become more difficult due to the risk of perforation. From these reasons, we established LECS procedure applied ESD technique. And we have completed safe en bloc resection with adequate surgical margin, and performed LECS for 4 cases of colorectal tumors.

CONCLUSION: We have developed safe ESD technique with very low rate of perforation (0.18%) and its applied LECS procedure in order to complete curative en bloc resection for tumors accompanied with firm fibrosis in submucosal layer.And we will present safe ESD technique and LECS procedure for above mentioned colorectal tumors.

P578 EUS IMPROVES QUALITY OF ERCP IN PATIENTS WITH SUSPECTED CHOLODOCHOLITHIASIS

Y. Hashimoto[1,*], T. Tsuji[1]. [1]*Endoscopy center, Gastroenterology , Saimtama Municipal Hospital , Saitama, Japan*

INTRODUCTION: EUS is a sensitive diagnostic modality to detect choledocholithiasis. Beyond standard therapeutic ERCP, improving quality of ERCP is important by minimizing radiation exposure, reducing therapeutic procedures and preventing ERCP-related pancreatitis. For suspected choledocholithiasis, performing EUS before ERCP potentially makes it possible for endoscopists to determine necessity of ERCP in patients without any biliary disorder on EUS, minimize biliary procedures and therapeutic devices on EUS findings when choledocholithiasis seen on EUS.

AIMS&METHODS: Aim: To analyze the efficacy of EUS on minimizing radiation exposure, avoiding ERCP-related pancreatitis and reducing therapeutic procedures/devices in patients with suspected choledocholithiasis. Method: From 2011 March to 2012 March, 82 Japanese patients with suspected choledcolithiasis(elevated liver enzyme upper than three times of normal limits and acute onset of right upper abdominal pain) were prospectively enrolled in our study.

RESULTS: Results: 41 patients (EUS group: 25 female, mean 55 year old) underwent EUS before ERCP and 41 (ERCP group: 28 female, mean 62 year old) underwent ERCP. All procedures were performed by experienced endoscopists at our single tertiary medical center. In EUS group, 8 patients were found to have no choledocholithiasis on EUS. 6 patients were considered as passing stone and did not proceed to ERCP. 2 patients were complicated by biliary pancreatitis and proceeded to required only biliary sphincterectomy. 33 patients were found to have choledocholithiasis(single stone to three stones) on EUS and underwent ERCP. Of 33 patients undergoing ERCP, 30 patients underwent basket stone removal followed by biliary sphincterectomy and 3 patients required biliary stenting due to cholangitis. ERCP-related pancreatitis occurred in 2 patinents (4.8%). Mean radiation time is 1minutes 31 seconds in EUS group. In ERCP group, 41 patients underwent biliary sphincterectomy, basket stone removal and balloon occlusion cholangiography in a standard way. 5 patients were found to have no biliary stones and considered as passing stone. 36 patients were found to have single to three stones on cholangiography. 2 patients required biliary stenting in addition because of cholangitis. ERCP-related pancreatitis occurred in 4 patients (9.8%). Mean radiation time is 6 minutes 49 seconds in ERCP group. No recurrence was seen in both groups within observation period (55-302 days). EUS group avoided 8 ERCPs and 41 balloon catheters in comparing with ERCP group.

CONCLUSION: Performing EUS before ERCP in patients with suspected choledocholithiasis is significantly beneficial to minimizing radiation exposure, lowering incidence of ERCP-related pancreatitis and reducing therapeutic procedures.

P579 EVALUATION OF 4 PUBLICLY AVAILABLE 3D RECONSTRUCTION ALGORITHMS FOR CAPSULE ENDOSCOPY

E. Rondonotti[1], A. Karargyris[2], G. Mandelli[3], A. Koulaouzidis[4,*].
[1]Gastroenterology Unit, Ospidale Valduce, Como, Italy, [2]National Library of Medicine, National Institutes of Health, Bethesda, United States, [3]Gastroenterology Unit, Ospedale Valduce, Como, Italy, [4]CLDD, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom

INTRODUCTION: Three-dimensional (3D) imaging is gaining popularity; it has been already adopted in laparoscopic/robotic surgery but has yet to be applied widely in gastrointestinal endoscopy. Furthermore, due to current technological limitations, 3D imaging in capsule endoscopy (CE) is yet to be available. To overcome this, a software approach [called Shape-from-Shading (S/S)] has been proposed [1,2]. Essentially, S/S is a large family of software algorithms which attempt to extract the 3D shape of structures or lesions by minimising image constraints (e.g. lighting, surface reflectance, texture) present in every CE frame. At present, there are 4 freely available S/S algorithms for CE [3-6]. If there are to be applied in CE, the prime question is which S/S algorithm is more appealing to CE reviewers.
AIMS&METHODS: We aim to assess 4 publicly available (Tsai,Imperial,Fourier,Barron) 3D reconstruction algortihms in CE. Carefully selected CE frames of bowel structures and/or lesions were evaluated by 3 reviewers -blind to others- with extensive experience in CE review in a Matlab environment (**fig. 1**). Each image was 3D reconstructed with all 4 S/S algorithms.The reviewers were advised to select for each image the best performing (in regard to structure/texture enhancement) S/S algorithm. Scores were tallied (**max** 162) and inter-observer agreement was calculated witht the free-marginal ***Kappa*** (K) coefficient [7].
RESULTS: Overall, a total of 54 CE images (26 PillCam®/28 MiroCam®: 23 luminal protrusion, 16 inflammatory lesion, 15 vascular lesion) were evaluated. Of the 4 S/S algorithms, Tsai's 3D algorithm outperformed the rest in 45/54 images (125 selections) , followed by Imperial's (7/54 images; 31 selections) and Fourier's (1/54 image; 6 selections); there was a single image for which each reviewer selected (as best performing) a different 3D algorithm. Of note, Barron's 3D algorithm was evaluated as not offering imporvement. In 26/54 images, Tsai's algorithm was unanimously selected as the best performing 3D reconstruction software. Tsai's 3D algorithm superiority was independent of lesion category (protrusion/inflammatory/vascular; ***P***: 0.678) and/or CE system used to obtain the 2D images (MiroCam®/PillCam®; ***P***: 0.558). Lastly, the inter-observer agreement was good (K: 0.55).
CONCLUSION: Of the 4 evaluated (S/S) algorithms, Tsai's 3D reconstruction algorithm is the best performing 3D representation software in CE.

P580 TREATMENT OF ANASTOMOTIC COMPLICATIONS AFTER COLORECTAL RESECTION WITH SELF EXPANDING METAL STENTS.

A. Lamazza[1,*], E. Fiori[1], S. Pontone[1], D. Scoglio[1], A. Antoniozzi[1], A. V. Sterpetti[1], M. Brighi[1], E. Lezoche[1]. *[1]"SAPIENZA" UNIVERSITY OF ROME, Rome, Italy*

INTRODUCTION: The role of self expandable metallic stents (SEMS) in patients with colorectal obstruction due to benign disease is controversial and high complication rates have been reported in this clinical setting, especially a significant incidence of stent migration. SEMS can also be adopted to treat patients with symptomatic anastomotic complications after colorectal resection.
AIMS&METHODS: All patients who had SEMS placement for anastomotic stricture and/or fistula were included in this study. No patient was excluded. During a 8 year period 16 consecutive patients had SEMS placement for anastomotic stricture after anterior rectal resection and they represent the basis of our study. Patients were prospectively analysed. Seven patients (mean age = 71.7 y; F=2).had "simple" anastomotic stricture. In the remaining 9 patients a fistula was associated to the stricture.
RESULTS: SEMS was placed successfully in all patients with resolution of the symptoms of obstruction (technical success 100%). There was no case of mortality or major morbidity. Two patients complained of anorectal pain, easily under control with light pain medications. Overall symptoms of obstruction were completely relieved in 10 out of 16 patients (62.5%). Four patients (25%) required balloon dilatation for recurrent symptoms of obstruction. In 2 patients the fistula did not heal and the ileostomy was not closed. Overall the fistula healed in 7 out 9 patients (77.7%) The two patients with persistent fistula had a permanent ileostomy.
CONCLUSION: In patients with fistula and stricture, endoscopic stenting with covered stents has many potential leading to healing of the fistula in the majority of the cases. In this scenario, a covered stent should be used, with the creation of a proximal diverting stoma. Thus, SEMS represent a valid adjunctive to treat patients with symptomatic anastomotic complications after colorectal resection for cancer.

P581 DIGITAL HOLOGRAPHIC MICROSCOPY TO ASSESS INFLAMMATION IN CROHN'S DISEASE AND TO MONITOR INTESTINAL WOUND HEALING IN VITRO

D. Bettenworth[1,*], L. Philipp[2,3], P. Krausewitz[1], M. Brückner[1], D. Domagk[1], B. Kemper[4]. *[1]Department of Medicine B, University Hospital Münster, [2]Department of Medicine B, University of Muenster, [3]European Institute for Molecular Imaging, University Hospital Münster, [4]Center for Biomedical Optics and Photonics, University of Muenster, Muenster, Germany*

INTRODUCTION: The current therapeutic armamentarium for treating Crohn's disease (CD) is limited due to severe side effects and loss of efficacy over the course of disease. Preclinical evaluation of new anti-inflammatory drugs is usually performed in wound healing assays *in vitro*. In CD patients, quantitative read out parameters to assess intestinal inflammation are limited and objective measurement of wound healing is rather complex. Digital holographic microscopy (DHM) enables stain-free quantitative phase contrast imaging and provides tissue density by measuring optical path length delay (OPD) and accordingly refractive index (RI).
The aim of this study was to evaluate DHM for assessment of severity of CD in humans as well as intestinal epithelial wound healing *in vitro*.
AIMS&METHODS: Cryostat biopsies of patients with CD (n=6) and healthy controls (n=6 per group) were examined via DHM. To quantify tissue density, segmental OPD/RI was performed according to anatomic structure (epithelium (e), submucosa (sm) and stroma (st)). Moreover, proliferation and migration of Caco-2 cells were studied in wound healing assays in the presence of stimulating epithelial growth factor (EGF) and inhibiting mitomycin c and were assessed in time-lapse series for 48 hrs (digital holograms were recorded every 3 min).
RESULTS: In human IBD patients, average RI differed significantly in all parts of the colonic wall between active disease and healthy control (e: 1.352 ± 0.002 vs. 1.355 ± 0.003; $P < 0.001$, sm: 1.360 ± 0.007 vs. 1.364 ± 0.005; $P < 0.001$, st: 1.350 ± 0.004 vs. 1.360 ± 0.008 vs.; $P < 0.001$). Assessment of wound assays via DHM as reflected by the area covered by living *Caco-2 cells* detected significantly stimulated growth in plane axis (EGF-stimulated : T1(12h)=0.043 mm^2, T2(24h)=0.074 mm^2 und T3(36h)=0.112 mm^2, vs. mitomycin c-inhibited : T1(12h)=0.070 mm^2, T2(24h)=0.202 mm^2 und T3(36h)=0.382 mm^2; $P < 0.001$, n=3). The cellular dry mass showed significant differences between stimulated and inhibited cells ($P < 0.05$) and realtime thickness profiles of cell cultures were obtained.
CONCLUSION: DHM reliably assesses density changes of the colonic wall in CD patients and therefore can quantify the inflammatory damage. This technique enables automated histological examinations in terms of "digital pathology" in the future. In addition, DHM facilitates preclinical evaluation of drug candidates and assessment of their impact on intestinal cell migration and proliferation *in vitro*.

P582 STUDY OF THE SIGNIFICANCE BETWEEN PURINE INDUCED LYMPHOPENIA AND INFLAMMATORY BOWEL DISEASE RELAPSES

H. H. Shim[1], E. Salazar[1,*], S. W. Chuah[1], K. L. Ling[1], S. C. Kong[1]. *[1]Department of Gastroenterology and Hepatology, Singapore General Hospital, Singapore, Singapore*

INTRODUCTION: Purines are used as second-line immunosuppressive agents in maintaining remission of inflammatory bowel disease(IBD). Studies looking at leukopenia/neutropenia to predict the treatment efficacy of purines have shown mixed results. As lymphocytes play important roles in the pathogenesis of IBD relapses, we aim to evaluate the significance between purine induced lymphopenia and IBD relapses

AIMS&METHODS: Retrospective study of IBD patients under the follow up of a tertiary IBD centre. Patients on purines for a minimum 6 months were included. Information collected included lowest lymphocyte level within first 4 months of therapy, purine doses, types of complications and number of relapses per year. Relapse was defined as flare of symptoms , or surgical intervention was required (eg for fistula or stricture). Surgical interventions for complications (eg abscess or adhesions) were excluded. Lymphocytes level of $<1.0x10*9/L$ was used to define lymphopenia and to divide patients into 2 groups for subsequent analysis using Mann-Whitney U test.
Patients on infliximab/ methotrexate , non-compliant or lymphopenia from other secondary causes were excluded.
RESULTS: 300 patients were screened with total 46 patients eligible. This included 24 Crohn's Disease, 21 Ulcerative Colitis and 1 Indeterminate Colitis. Duration of treatment ranged from 6 months to 12 years (median 4.5 years). Median Azathioprine dose was 2.0mg/kg. There was no statistical significance effect between achieving lymphopenia and the rate of IBD relapses (p=0.98). Further subgroup analysis based on type of IBD revealed similar result for Crohn's Disease (p=0.93). Subgroup analysis for Ulcerative Colitis suggested positive association between lymphopenia with higher rate of flares (p=0.019) but this may possibly be confounded by the small sample size.
CONCLUSION: Lymphopenia during purine treatment does not predict the rate of IBD relapses. This may be limited by our small sample size or possibly the main pathway of IBD inflammation is not mediated through lymphocytes.

P583 GENOME-WIDE COPY NUMBER VARIATION SCAN IDENTIFIES COMPLEMENT COMPONENT C4 AS NOVEL SUSCEPTIBILITY GENE FOR CROHN'S DISEASE

I. Cleynen[1,*], P. Konings[1], E. Théatre[2], L. Amininejad[3], D. Laukens[4], N. Ardeshir Davani[1], H. Cuppens[1], K. Machiels[1], T. Coopmans[1], C. Robberecht[1], W.-J. Wollants[1], K. Claes[1], S. Organe[1], P. Rutgeerts[1], D. Franchimont[3], M. De Vos[4], E. Louis[5], K. Van Steen[5], M. Georges[5], Y. Moreau[1], J. Vermeesch[1], S. Vermeire[1]. [1]*KU Leuven, Leuven,* [2]*Université de Liège, Liège,* [3]*Université libre de Bruxelles, Brussels,* [4]*UGent, Gent,* [5]*Université de Liège, Liège, Belgium*

INTRODUCTION: Genome-wide association studies and meta-analyses have identified 140 loci associated with Crohn's disease (CD). Even this large number of loci explains only a minority of the variance in disease risk, suggesting other factors such as copy number variation (CNV) make substantial contributions to disease pathogenesis.
AIMS&METHODS: The aim was to identify CNV regions associated with CD using array comparative genomic hybridization (aCGH). 848 CD patients and 486 healthy controls were included for aCGH. They were assembled in pools of 5 cases - each of identical gender and disease location - and a gender and age matched 5-sample control pool. Eligible regions were finemapped using MAQ (Multiplex Amplicon Quantification). Validation of CNVs was done with qRT-PCR on 2 independent Belgian validation cohorts for a total of 1549 CD and 784 controls. C4 serum levels were determined in 60 CD patients and 116 controls using nephelometry. Statistical analysis was done in R.
RESULTS: The average $\log_2$ ratio per clone was ranked from high (duplicated) to low (deleted). Three of the 10 lowest ranked clones ($\log_2 \leq -15$) were located on 6p21, in the central MHC. MAQ confirmed copy number differences for this region and suggested that the CNV was centered on the RCCX module, containing the *RP*, *C4*, *CYP21* and *TNX* genes. The *C4* gene (either *C4A* or *C4B*) can be present in 1-8 copies, and can occur in two sizes: short (*C4-S*) or long (*C4-L*). qRT-PCR validation showed a shift towards a lower *C4*-L copy number for CD patients compared to controls ($p_{Mann\text{-}Whitney}$=4.38e-03). *C4A* and *C4B* copy number distribution was not different. C4 serum levels were correlated with the C4 copy number, both in cases and controls (p_{ANOVA}=2.81e-4 and p_{ANOVA}=3.39e-10). There were no differences in C4 serum levels between cases and controls ($median_{CD}$=0.33g/L, $median_{CON}$=0.32g/L).
CONCLUSION: A delicate balance exists between a well-regulated immune response against infections, and an over-exuberant response that can lead to (auto)immune disease. C4 is part of the classical pathway that can activate the complement system cascade. We showed that low copy number of *C4-L* is one of the genetic risk factors that can tip the balance towards CD. A low copy number for *C4-L* has also been shown to be a risk for systemic lupus erythematosus.

P584 CYTOKINE PROFILES IN PERIPHERAL BLOOD OF IBD PATIENTS; THE KEY TO CONNECTING GENOTYPE TO PHENOTYPE.

N. W. Duijvis[1,*], F.H. van Dooren, D. Oudejans, D. Harmankaya, F.W. Vergouwe, S.C. Wolfkamp, E.W. Vogels, F.W. Vergouwe, P. Henneman, P.C. Stokkers, G.R.A.M D'Haens, A.A. te Velde. [1]*Tytgat institute, AMC, Amsterdam, Netherlands*

INTRODUCTION: Inflammatory bowel diseases (IBD), comprised of ulcerative colitis (UC) and Crohn's disease (CD), are increasingly recognized as a rather heterogeneous group of conditions with distinct pathogenetic pathways. A variable range of cytokines are involved, perhaps influenced by different therapeutic approaches. As key messengers in the immune system, cytokines are known to participate in the disregulation of otherwise controlled inflammation in the gut. In previous studies we observed differently regulated cytokines in IBD, involved in diverse pathways. Currently, we aim to assess these functional differences in the immune response of IBD patients and correlate them to genetic susceptibility loci for IBD, as established by genome-wide association studies (GWAS), as well as to phenotypic patient profiles. More in-depth analysis will then be performed, possibly leading to novel insights in pathways linking these together.
AIMS&METHODS: Whole blood of 40 CD patients was stimulated with aCD3/ aCD28 antibodies and LPS/MDP to mimic the adaptive and innate responses. Twenty-eight cytokines were measured with a multiplex cytokine assay. Genotyping by use of a customized Illumina GWAS chip (Immunochip) includes the single nucleotide polymorphisms (SNPs) from recent GWAS meta-analyses. The phenotype of patients was assessed using the Montreal classification.
RESULTS: Counter to regarding the CD patient population as a whole, we did find cytokine levels to be significantly up- or downregulated when stratifying for the presence of IBD-associated risk alleles. For instance, IL-10 expression drops significantly (p=0.0024), while TNFa expression doubles (p=0.02) when both risk alleles for SNPX resp. SNPY are present. Independent of this cytokine association, this genetic variance also correlates to a worse clinical phenotype, underlining the idea that a causal relationship between genetic variance and clinical phenotype can be identified.
CONCLUSION: Our aim is to unravel the heterogeneous background of IBD, by linking genetic variation to the immunological and clinical phenotype, subsequently elucidating causally involved pathways, contributing to developing patient-specific therapies based on genetic profiling. By firstly correlating altered cytokine expression to IBD risk alleles, we can then study the effects of this SNP in the gene it is physically linked to, and assess its functionality or find epigenetic changes that alter gene expression. When the SNP is correlated to a specific disease phenotype, hypotheses can be built upon linking altered gene expression to the phenotype via altered immunological responses. This route can be applied to our multiple interesting SNP-cytokine associations.

P585 GENE EXPRESSION PROFILES OF ILEAL INFLAMMATORY BOWEL DISEASE CORRELATE WITH DISEASE PHENOTYPE AND ADVANCE UNDERSTANDING OF ITS IMMUNOPATHOGENESIS

S. Ben-Shachar[1,2], H. Yanai[2,3,*], L. Baram[2,3], H. Elad[3], A. Ofer[2,3], E. Brazowski[2,4], H. Tulchinsky[2,5], M. Pasmanik-Chor[6], I. Dotan[2,3]. [1]*Genetic Institute, Tel Aviv Medical Center,* [2]*Sackler Faculty of Medicine, Tel Aviv University,* [3]*IBD center, Department of Gastroenterology and Liver Diseases,* [4]*Department of Pathology,* [5]*Department of Surgery, Tel Aviv Medical Center,* [6]*Bioinformatics unit, G.S.W. Faculty of Life Sciences, Tel Aviv University, Tel Aviv , Israel*

INTRODUCTION: The etiology of inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC) is yet unknown. Inflammation in UC is limited to the large bowel, thus large bowel resection may be curative. In most UC patients undergoing proctocolectomy due to intractable disease an ileal pouch is created. Inflammation of the pouch (pouchitis) develops in most of these patients.
AIMS&METHODS: We aimed to evaluate the *de-novo* inflammation developing in the ileal pouch, hypothesizing it may be similar to ileitis in Crohn's disease (CD).
UC pouch patients were prospectively recruited, stratified according to disease behavior into normal pouch (NP), chronic pouchitis (CP), and Crohn's-like disease of the pouch (CLDP) groups, and compared to controls. Gene expression analysis was performed using microarrays, validated by real-time PCR. Gene ontology and clustering were evaluated using bioinformatic tools.
RESULTS: Sixty six subjects were recruited. While in UC ileum there were no significant gene expression alterations, NP patients had 168 significant alterations (fold change $\geq$2, corrected p value $\leq$ 0.05). In CP and CLDP 490 and 1152 alterations were detected, respectively. High degree of overlap in gene expression alterations between the pouch subgroups was demonstrated. The magnitude of change correlated with pouch disease behavior. Gene expression profiles were more reflective of disease behavior compared to inflammatory indices. CD ileitis had 358 alterations, with a 90% overlap with pouchitis.
Gene ontology analyses revealed multiple biological processes associated with pouch inflammation, including response to chemical stimulus, small molecule metabolic and immune system processes and specific infectious-related pathways such as *staphylococcus aureus*, leishmaniasis and tuberculosis.
CONCLUSION: Gene alterations in pouch inflammation and CD overlap, suggesting that IBD is a spectrum, rather than distinct diseases. Pouchitis may serve as a model of CD. The novel pathways associated with IBD may decipher pathophysiology and suggest targets for intervention.

P586 ASSOCIATION BETWEEN FUNCTIONEL POLYMORPHISMS IN THE NFKB SIGNALLING PATHWAYS AND RESPONSE TO ANTI-TNF TREATMENT IN DANISH PATIENTS WITH INFLAMMATORY BOWEL DISEASE

S. Bank[1,*], on behalf of The anti-TNF group and The anti-TNF group.
[1]*Department of medicine, Viborg Hospital, Viborg, Denmark*

INTRODUCTION: Anti-tumor necrosis factor-α (TNF-α) is used for treatment of severe cases of inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC). However, one-third of the patients do not respond to the treatment. Genetic markers may predict individual response to anti-TNF therapy.
AIMS&METHODS: Thirtynine functional single nucleotide polymorphisms (SNPs) in 26 genes involved in the inflammatory NFκB pathway were assessed in 738 prior TNF-α naive Danish patients with IBD. The results were analysed using logistic regression (crude and adjusted for age, gender and smoking status).
RESULTS: Nineteen functional polymorphisms which modify the activity of NFκB (*TLR2* (rs3804099, rs11938228, rs1816702, rs4696480), *TLR4* (rs5030728, rs1554973), *TLR9* (rs187084), *LY96*(MD-2) (rs11465996), *CD14* (rs2569190), *MAP3K14*(NIK) (rs7222094)), TNF-α (*TNFA*(TNF-α) (rs1800630, rs361525), *TNFRSF1A*(TNFR1) (rs4149570), *TNFAIP3*(A20) (rs6927172)) and other cytokines regulated by NFκB (*IL1B* (rs4848306), *IL1RN* (rs4251961), *IL6* (rs10499563), *IL17A* (rs2275913), *IFNG* (rs2430561)) were associated with response to TNF-α inhibitors among patients with CD, UC or IBD ($p < 0.05$).
CONCLUSION: Patients with genetically determined strong TNF-α mediated inflammation had higher response rates to anti-TNF therapy. Furtheremore, the results suggest that genes regulating inflammation through NFκB are important predictors for the response to anti-TNF therapy among patients with IBD. In addition, the cytokines IL-1β, IL-6 and IFN-γ may be potential targets for treating patients with IBD who do not respond to anti-TNF therapy. Confirmation of these findings in an independent cohort are required before clinical decisions based on this study can be drawn.

P587 GENETIC POLYMORPHISM OF MYD88 GENE (RS7744) IS CLOSELY ASSOCIATED WITH THE SUSCEPTIBILITY TO ULCERATIVE COLITIS

T. Arisawa[1], T. Tahara[2,*], M. Nakamura[1], H. Yamada[1], T. Nomura[1], R. Hayashi[1], K. Matsunaga[1], N. Kawada[1], T. Otsuka[1], T. Shimasaki[1], N. Toshikuni[1], H. Shiroeda[1], T. Shibata[2]. [1]*Gastroenterology, Kanazawa Medical University, Uchinada-machi,* [2]*Gastroenterology, Fujita Health University, Toyoake, Japan*

INTRODUCTION: Toll-like receptors activation firstly recruits myeloid differentiation primary response gene (88) (MyD88) protein, a common adaptor protein that is fundamental in the innate immune response activation. There is not the other polymorphism except rs7744, with above 0.01 of HWE p value and above 0.05 of minor allele frequency, within 10kbp around MyD88. In addition, there are binding sites of several microRNAs (miRs) nearby rs7744, including miR-29b-2-5p, miR-150-3p and miR-1236. Therefore, we attempted to clarify the association of MYD88 gene polymorphism (rs7744, *1244 A>G) with susceptibility to UC.
AIMS&METHODS: The studied population comprised 922 subjects, including patients with UC (UC cases, n=200), who were enrolled Fujita Health University Hospital, and the healthy subjects without UC (controls, n=722). We employed the PCR-SSCP method to detect a gene polymorphism.
RESULTS: In controls, mean age was 54.5 years old and male/female ratio was 424/298. In UC cases, mean age was 40.0 years old, mean age of onset was 32.7 years old and male/female ratio was 113/87. The distribution of rs7744 genotype in controls was 320AA, 331AG and 71GG (HWE p=0.31), whereas the distribution in UC cases was 63AA, 100AG and 37GG. The genotype frequency of rs7744 AA homozygote was significantly lower and those of GG homozygote was significantly higher in UC cases than in controls (p=0.0012 and 0.0012, respectively). The minor allele frequency of rs7744 were 32.8% and 43.5% in controls and UC cases, respectively ($p < 0.0001$). By logistic regression analysis after adjustment for gender and age, the rs7744 minor allele was significantly associated with the increased risk for UC using both dominant (AG+GG vs. AA) and recessive (GG vs. AA+AG) genetic models (OR, 1.64; 95%CI, 1.15-2.34; p=0.0063 and OR, 1.87; 95%CI, 1.17-3.00; p=0.0094, respectively). These associations were found in male subjects, not in female subjects. In addition, rs7744 minor allele was closely associated with the risk of not chronic continuous phenotype, cases developed after 30 years old, not total colitis type and steroid needless cases using both dominant and recessive genetic models.
CONCLUSION: Our results provided the first evidence that MYD88 gene polymorphism was significantly associated with the development of UC. The genetic polymorphism of MYD88 gene (rs7744) influences the susceptibility to and pathophysiological features of UC.

P588 NFKB1 POLYMORPHISM (RS28362941, -94 ATTG INS/DEL) IS ASSOCIATED WITH THE SUSCEPTIBILITY TO ULCERATIVE COLITIS

T. Arisawa[1], T. Tahara[2,*], M. Nakamura[1], K. Matsunaga[1], N. Kawada[1], T. Shibata[2]. [1]*Gastroenterology, Kanazawa Medical University, Uchinada-machi,* [2]*Gastroenterology, Fujita Health University, Toyoake, Japan*

INTRODUCTION: Nuclear factor-kappa-B (NF-kB) plays a role in inflammation and carcinogenesis in various organ tissues by inducing translation of many key molecules. A polymorphism -94 ATTG ins/del (rs28362941) is identified. Many studies have reported the association between rs28362491 and various inflammatory diseases. However, these results do not always lead to the same conclusions. We attempted to clarify the associations between ulcerative colitis (UC) and this polymorphism in Japanese population.
AIMS&METHODS: The studied population comprised 949 subjects, including patients with UC (UC cases, n=198), who were enrolled Fujita Health University Hospital, and the healthy subjects without UC (controls, n=751). We employed the PCR-SSCP method to detect a gene polymorphism.
RESULTS: In controls, mean age was 57.0 years old and male/female ratio was 439/312. In UC cases, mean age was 41.7 years old, mean age of onset was 33.1 years old and male/female ratio was 115/83. The distribution of rs28362941 genotype in controls was 283ins/ins, 383ins/del and 85del/del, whereas the distribution in UC cases was 77ins/ins, 84ins/del and 37del/del. The rs28362941 minor allele frequencies in controls and UC cases were 36.8% and 39.9%, respectively (p=0.27). The ratio of del/del homozygote in UC cases was significantly higher than that in controls (p=0.008), and del/del homozygote has a significant risk for the development of UC (OR, 1.83; 95%CI, 1.15-2.92; p=0.011). The male del/del homozygote had an increased risk for the development of UC (OR, 2.03; 95%CI, 1.11-3.73; p=0.022). In female subjects, however, there was no significant difference of genotype distribution between controls and UC cases. In addition, del/del homozygote was closely associated with the risk of not total colitis phenotype. (OR, 1.88; 95%CI, 1.07-3.30, p=0.028), cases developed before 20 years old (OR, 3.62; 95%CI, 1.42-9.26, p=0.0072), not chronic continuous type (OR, 2.01; 95%CI, 1.16-3.47; p=0.012), having no hospitalization (OR, 2.08; 95%CI, 1.23-3.52; p=0.0062) and steroid independent or needless cases (OR, 1.77; 95%CI, 1.05-2.97; p=0.031).
CONCLUSION: Our results provided the evidence that NFKB1 gene polymorphism rs28362941 was significantly associated with the development of UC in Japanese. NFKB1 -94 ATTG del/del homozygote influences the susceptibility to and pathophysiological features of UC.

P589 X-LINKED INHIBITOR OF APOPTOSIS PROTEIN IN THE PATHOGENESIS OF EARLY-ONSET INFLAMMATORY BOWEL DISEASE

Y. Zeissig[1,*], B. S. Petersen[2], S. Milutinovic[3], S. Billmann[2], M. Kohl[1], M. Schrappe[1], P. Rosenstiel[2], J. C. Reed[3], S. Schreiber[4], A. Franke[2], S. Zeissig[4]. [1]*Department of General Pediatrics, UKSH Kiel,* [2]*Institute of Clinical Molecular Biology, Christian-Albrechts-University , Kiel, Germany,* [3]*Sanford-Burnham Medical Research Institute, La Jolla, United States,* [4]*Department of Internal Medicine I, UKSH Kiel, Kiel, Germany*

INTRODUCTION: The genetic contribution to inflammatory bowel disease (IBD) is only partially understood and it has been suggested that rare variants that escape detection by genome-wide association studies contribute to the genetic risk in IBD.
AIMS&METHODS: Exome-sequencing and functional studies were performed in cases of familial and sporadic early-onset IBD with the aim to discover rare high penetrance variants and novel candidate genes involved in disease etiology.
RESULTS: Exome sequencing revealed a novel hemizygous nonsense mutation (E99X) in the gene encoding for the X-linked inhibitor of apoptosis protein (*XIAP*) in a three-year old patient with a one-year history of colonic, stricturing and fistulizing CD refractory to treatment with corticosteroids, immunosuppressants, and anti-TNFα antibodies. XIAP was not detectable by flow cytometry in various peripheral blood mononuclear cell (PBMC) populations. Lack of XIAP protein expression in the patient was confirmed by western blot analysis. Relative and absolute frequencies of PBMC subsets, T cell proliferation, apoptosis, and immunoglobulin levels were unaltered in the patient. However, while responses to toll-like receptor 2, 3, 4, 7, and 9 stimulation and NLRP3-dependent IL-1β secretion were unimpaired in XIAP-deficient PBMCs and monocytes, NOD2-dependent IL-8 and IL-1β release were not detectable across a range of muramyl dipeptide (MDP) concentrations. Furthermore, wildtype but not E99X XIAP associated with NOD2 in a RIP2-dependent manner as revealed by co-immunoprecipitation. Lentiviral *XIAP* reconstitution in primary monocyte-derived dendritic cells restored MDP-induced NOD2 signaling thus confirming a critical role of XIAP deficiency in the observed NOD2 defects.
CONCLUSION: Our studies reveal a novel *XIAP* mutation associated with early-onset IBD and suggest that *XIAP* deficiency may contribute to disease pathogenesis via impaired NOD2 signaling. In addition, given the central role of *XIAP* deficiency in XLP, these results support the concept that at least a subset of IBD cases may result from congenital or acquired immunodeficiency, potentially in a NOD2-dependent manner.

P590 MITOCHONDRIAL NEUROGASTROINTESTINAL ENCEPHALOMYOPATHY (MNGIE): THE LIVER AS A NEW SOURCE OF THYMIDINE PHOSPHORYLASE

E. Boschetti[1,2,*], R. D'Alessandro[3], F. Giancola[1], F. Bianco[1], E. Bonora[1], S. Bonora[2], V. Stanghellini[1], V. Tugnoli[2], C. Casali[4], R. De Giorgio[1]. [1]*Surgical and Medical Science,* [2]*Biomedical and neuro-motor science,* [3]*Neurological Unit, University of Bologna Italy, Bologna,* [4]*Medico-Surgical Sciences and Biotechnologies, University 'La Sapienza', Rome, Italy*

INTRODUCTION: MNGIE is a rare autosomal recessive disease associated with the nuclear *TYMP* gene mutation. As a result, the thymidine phosphorylase (TP) enzyme activity is markedly reduced (or completely deficient) and this leads to mitochondrial DNA mutation and multiple deletions. On a clinical standpoint, MNGIE is characterized by severe gastrointestinal (GI) dysmotility (gastroparesis and intestinal pseudo-obstruction) and neurological impairment. The onset is usually between the second and fifth decades and life expectancy and quality of life are rather poor. So far, there are no established therapeutic options for MNGIE. In the attempt to restore a normal TP activity, allogenic hematopoietic stem cell transplantation (AHSC) has been used as a cellular source of TP. Current data obtained on about 20 MNGIE patients undergone AHSC showed GI and neurological improvement, although 5-year survival rate is roughly 50%.
AIMS&METHODS: In this work, we tested whether the liver may serve as an alternative source of TP. A number of n= 11 patients (7 males; age range: 35-55 years) undergone hepatic resection for focal disorders (i.e., uncomplicated tumors in non-cirrhotic liver) were included. Margins of normal liver tissue were processed for a variety of methodological approaches aimed to identify, quantify and localize TP protein, i.e. WB, ELISA, and immunohistochemistry (IHC). *TYMP* mRNA specific expression has been evaluated via qPCR. Bone marrow and intestinal mucosa were used as positive controls while skeletal muscle as negative control.
RESULTS: WB showed the presence of TP protein in liver tissue with a densitometric ratio TP/GAPDH of 0.9 ± 0.5 A.U. ELISA estimates TP content as 0.5 ± 0.07 ng/μg total proteins. The liver localization of TP with IHC was identified in the nuclei and cytoplasm of hepatocytes and reticular cells. *TYMP* mRNA specific liver expression has been detected in the liver tissue providing evidence of in situ synthesis.
CONCLUSION: The results of this study demonstrate that the liver is an important source of TP. Likewise AHSC, also orthotopic liver transplantation might be a therapeutic alternative for MNGIE patients, hopefully with a better outcome in terms of survival rate.

P591 ANTI-PROLIFERATIVE EFFECTS OF BUTYRATE DURING THE POSTNATAL MATURATION OF THE ENTERIC GLIAL NETWORK.

F. Cossais[1,*], M. Boudaud[1], J. Mazzocco[1], J. Chevalier[1], T. H. Nguyen[2], M. Neunlist[1]. [1]*Inserm U913,* [2]*Inserm UMR1064, nantes, France*

INTRODUCTION: The postnatal period is crucial for the development of gastrointestinal (GI) functions. The enteric nervous system is a key regulator of GI functions. Increasing evidences demonstrate that 1) postnatal maturation of enteric neurons participate in the control of the development of GI functions (De Vries, *et al*., 2010), and 2) microbiota derived short chain fatty acid can be involved in this maturation (Suply, *et al*., 2012). Although enteric glial cells (EGC) are central regulators of GI functions (Neunlist, *et al*., 2013), the postnatal evolution of their phenotype remains unknown.
AIMS&METHODS: We aimed to characterize 1) the postnatal evolution of EGC phenotype in the colon of rat pups 2) the impact of SCFAs upon their maturation and 3) the postnatal evolution of transcriptional networks involved in neuro-glial embryogenesis.
Enteric glial markers evolution, EGC proliferation and specific transcription factors evolution in colonic myenteric plexus of rat pups were assessed by immunohistochemistry and RT-qPCR betweeen 1 and 36 days after birth. Impact of butyrate on EGC phenotype and proliferation was analysed in EGC culture *in vitro* and by performing acute and chronic butyrate enemas *in vivo*.
RESULTS: In rat pups, we showed that mRNA and protein expressions of the glial markers GFAP and S100β strongly increased within five weeks after birth and the glial network appears fully organized by 36 days after birth. We showed that butyrate enemas significantly inhibited the proliferation of EGC both *in vivo* and *in vitro* but had no impact upon glial markers expression. Furthermore, we showed that transcription factors involved in the control of embryonic development of the ENS continued to be expressed after birth. Furthermore, PCA analysis showed that their global expression within the distal colon was characteristic of the stage of maturation.
CONCLUSION: These results demonstrate that the EGC network continues to set up after birth. The factors, in particular of nutritional origins, and the mechanisms responsible for EGC maturation *in vivo* remain to be identified.

P592 MICROBIOTA ANALYSIS IN IBS AND IBD/NON-IBD PATIENTS AND NORMAL SUBJECTS

H. Vebø[1], C. Casén[1,*], M. Sekelja[1], R. Nestestog[1], E. Ciemniejewska[1], G. Perminov[2], P. Ricanec[3], M. H. Vatn[4]. [1]*Genetic Analysis AS,* [2]*Department of pediatrics,* [3]*Department of gastroenterology,* [4]*Department of Medicine, Oslo University Hospital, Oslo, Norway*

INTRODUCTION: The increasing awareness of the gut microbiota's effect on our health has triggered the need for tools to monitor these microbes. The GA-map™ technology platform has been developed to demonstrate profiles of the composition of gut microbiota. The platform provides analysis of a large number of fecal samples in a rapid and cost-effective way. In a multi-center trial among patients diagnosed for IBS in Norwegian hospitals, fecal samples have been collected and compared to a population of normal subjects using GA microbiota test. In addition, a sub-cohort of IBD and non-IBD patients has been analyzed.
AIMS&METHODS: Based on peer-reviewed literature and our own research, special sets of DNA probes were designed to facilitate separation between patient groups and normal subjects based on their bacterial profile. The assay was tested in a population of 31 fecal samples from diagnosed IBS patients (confirmed by Rome III criteria and exclusion of inflammation by colonoscopy and/or calprotectin analysis) and a population of 78 normal subjects with no clinical signs of gut disorder (not confirmed by colonoscopy), in addition to 187 samples from the IBSEN II cohort, comprising treatment naïve IBD patients and symptomatic non-IBD patients, confirmed by colonoscopy (1, 2). The GA microbiota test was performed essentially as described in (3), using the BioCode-1000A system for detection and quantification of labeled DNA probes (indicative of presence of different bacteria). Classification was performed using Partial Least Squares Discriminant Analysis (PLS-DA) and the model was validated using leave-one-out validation. Further studies will be performed including independent patient populations.
RESULTS: The results from the studies are outlined in table 1. The results are preliminary and will be confirmed in further studies. Age-group of subjects ranged from 18 to 55 years.
Table 1. Results from GA microbiota PLS-DA analysis of diagnosed IBS patients vs normal subjects, and IBD vs non-IBD patients diagnosed by colonoscopy.

Cohort	N	Sensitivity*	Specificity*
IBS vs normal	31/78	87%	77%
IBD vs non-IBD	105/82	78%	70%

* Leave-one-out validation, not independent patient population
CONCLUSION: The GA microbiota test gives a unique opportunity to study specific profiles of the gut microbiota that may be associated with GI related disorders. The results suggest that the GA test may be a useful tool in differentiating between IBS and normal subjects, and IBD/non-IBD patients, and thus an aid in the diagnosis and follow up of patients with inflammatory and functional GI disorders.

P593 APPLICATION OF HUMAN ADULT STEM CELL BASED TISSUE ENGINEERING STRATEGY ON RECONSTRUCTION OF ORAL TISSUE

M.-L. Liu[1,*], J.-H. Cherng[2], S.-J. Chang[3], M.-L. Hsu[4]. [1]*General Surgery, Cheng Hsin General Hospital,* [2]*Dentistry, National Yang-Ming University, ,* [3]*Dentistry, National Yang-Ming University,, Taipei,* [4]*Dentistry, National Yang-Ming University,, Taipei (R.O.C.), Taiwan, Province of China*

INTRODUCTION: A defect in oral tissues is commonly affected by a number of clinical disorders in oral cavity. Studies had demonstrated that the bioengineered oral mucosa samples, such as collagen and gelatin, can develop a multilayer epithelium *in vitro* and *in vivo*. Resveratrol (RSV, trans-3, 4H, 5-trihydroxystilbene), a phytoalexin belongs to the group of compounds known as stilbenes

which has been studied for anti-oxidative, anti-proliferative activities and inhibition of nitric oxide pathway in mammalian macrophages, represents a feasible and productive approach to support dermal wound healing.

AIMS&METHODS: This study is going to combine the human adipose stem cells and resveratrol contained gelatin-collagen I (GCI) membrane for oral reconstruction and clinical application.

We evaluated the synergistic effect of human adipose tissue-derived stem cells and resveratrol contained collagen membrane as a novel substrate in oral tissue reconstruction. The physical characterization of GCI membrane and stem cells *in vitro* was done and rat *tongue defect model in vivo* was applied.

RESULTS: The scanning electron microscopic photos, RSV releasing test, immunofluorescence results, chemical staining indicated the excellent bio-characteristics of stem cells and resveratrol contained collagen biomaterials *in vitro*. The histological results *in vivo* also demonstrate some typical structures of native oral mucosa such as rete ridges and corial papillae re-growing under this model of tongue defected animals.

CONCLUSION: This study not only proved that stem cells and resveratrol contained collagen membrane can be a good bioengineering substrate for oral reconstruction but also produced a robust protocol for clinical application in the future.

P594 EXTRACOLONIC SCREENING STRATEGIES IN HEREDITARY COLORECTAL CANCER SYNDROMES: PRELIMINARY DATA

V. Stigliano[1,*], L. Sanchez Mete[1], M. Caterino[1], R. Baldelli[1], R. Lapenta[1], D. Assisi[1], M. Anti[1]. [1]*Regina Elena National Cancer Institute, Rome, Italy*

INTRODUCTION: The major hereditary colorectal cancer syndromes (HCCS), Lynch syndrome (LS), Familial Adenomatous polyposis (FAP) and its attenuated variant (Mutyh Polyposis, MAP) predispose apart from CRC, to early onset extracolonic malignancies (EC). A major concern for clinicians is the definition of surveillance programs for target organs. Few prospective studies are available and the optimal strategies, timing for surveillance, spectrum of EC associated remains to be defined.

AIMS&METHODS: Aims of the present study are: to define HCCS-associated EC; to evaluate the efficacy of prevention strategies in the affected.

From January 2010, patients (pts) who refer to the Cancer Family Clinic of Regina Elena National Cancer Institute, with a diagnosis of LS, FAP or MAP, are prospectively included in the study. FAP/MAP pts undergo: side viewing gastroscopy and videocapsule endoscopy (VCE) every 3 years by the age of 20; thyroid ultrasound (US) every year by the age of 15; abdominal TC or RMN every 3 years by 1 year after colectomy.

LS affected undergo by the age of 30: endoscopic upper US or abdominal TC for pancreato-biliary surveillance, urine cytology, dermatological screening, transvaginal US with endometrial sampling, breast US and mammography every year; gastroscopy and VCE every 3 years. We report an ''ad interim'' analysis of the data after 3 years of follow-up.

RESULTS: We recruited in the study 86 FAP (44M/42F), 17 MAP (11M/6F) and 71 LS (33M/38F). We did not detect any EC in MAP. In the 86 FAP pts we observed: 10 duodenal adenomas (11,6%); 3 jejunal adenomas (3,5%); 2 thyroid papillary cancer (PTC)(2,3%); 6 intrabdominal desmoid (ID) (6,9%), one of which was aggressive and required chemotherapy. In the 71 LS we detected: a cholangiocarcinoma, a ureteral carcinoma and a sebaceous skin carcinoma, These four cases carried a MSH2 gene mutation.

CONCLUSION: In our MAP series, so far we did not observe EC. In 2,3% of FAP we found PTC, vs 1-2% reported in other studies. Considering PTC detected in our series before 2010, the prevalence goes up to 4,6%. These data seem to justify US screening. Once a year appeared an adequate timing. 6,9% of FAP had ID, less than reported in FAP cancer registries studies (20%). In our LS series, we did not find any endometrial cancer, the second most common cancer of the syndrome. We observed EC only in MSH2 carriers. If these data will be confirmed on a larger series and longer surveillance, could justify a tailored and more intensive surveillance in MSH2 rather than MLH1 carriers.

P595 LIVER TRANSPLANTATION IN ALCOHOLIC PATIENTS: IMPACT OF AN ALCOHOL ADDICTION UNITWITHIN A LIVER TRANSPLANT CENTER

A. Mirijello[1], G. Vassallo[1,*], A. Ferrulli[1], L. Leggio[1], C. d'Angelo[1], M. Antonelli[1], A. Cossari[2], S. Agnes[3], R. Landolfi[1], A. Gasbarrini[1], G. Addolorato[1], G. Gasbarrini[1]. [1]*Department of Internal Medicine, Catholic University of Rome, Rome,* [2]*Department of Economics and Statistics, University of Calabria, Rende,* [3]*Department of Surgery, Catholic University of Rome, Rome, Italy*

INTRODUCTION: Many concerns about liver transplantation in alcoholic patients are related to the riskof alcohol recidivism. Starting from 2002, an Alcohol Addiction Unit (AAU) was formed within theliver transplant center for the management of alcoholic patients affected by end-stage liver disease andincluded in the waiting list for transplantation. We evaluated retrospectively the impact of the AAU onalcohol recidivism after transplantation. The relationship between alcohol recidivism and the durationof alcohol abstinence before transplant was evaluated as well.

AIMS&METHODS: AIM: To evaluate the impact of the AAU inside the Liver Transplantation Centre on alcohol recidivism and mortality after OLT, using a retrospective design. **Methods:** Between 1995 and 2010, 92 cirrhotic alcoholic patients underwent liver transplantation. Clinical evaluation and management of alcohol use in these patients was provided by psychiatrists with expertise in addiction medicine not affiliated to the liver transplant center before 2002 (n = 37; group A), or by the clinical staff of the AAU within the liver transplant center starting from 2002 (n = 55; group B).

RESULTS: Comparing the two groups of patients, those followed by the AAU showed a significantly lower prevalence of alcohol recidivism (16.4% vs. 35.1%; p=0.038) after OLT. Patients followed by the AAU showed a significantly lower prevalence of death with respect of those patients who were not followed-up by the AAU (14.5% vs. 37.8%; p=0.01). There were no differences between the two groups regarding the mean age, mean MELD score, mean time of abstinence before OLT and mean alcohol intake. Analyzing the group of patients followed by AAU, there were no differences in term of alcohol recidivism after OLT (21.1% vs. 15.4%; p=0.623) between patients with an alcohol abstinence time pre-OLT >6 moths vs. <6 months.

CONCLUSION: The present study shows that the presence of an AAU inside a Liver Transplantation Center reduces the risk of alcohol recidivism and of mortality after OLT. Moreover, when clinical conditions do not allow a 6 months waiting time, the abstinence time before OLT could be shortened at least in selected patients managed by AAU.

P596 A SYMPTOM TRIGGERED CHLORDIAZEPOXIDE REGIMEN EMPOWERS STAFF AND SIGNIFICANTLY REDUCES ADMISSION DURATION FOR ALCOHOL WITHDRAWAL SYNDROME

D. Tate[1,*], R. Topan[1], K. Morgan[1], C. Levick[1], T. Johnston[1], E. Moore[1], M. Hegde[1]. [1]*Department of Gastroenterology, Great Western Hospitals NHS Foundation Trust, Swindon, United Kingdom*

INTRODUCTION: The management of the Alcohol Withdrawal Syndrome (AWS) is often complex. At the Great Western Hospital Swindon we anecdotally noted a long length of stay for AWS and a significant number of adverse events (e.g. oversedation and aggression) relating to incorrect dosing. We hypothesised that this was due to the fixed dose regimen of withdrawal medication used within the trust, often written up by the most junior medical staff. We proposed a variable dose prescribing regimen based on the CIWA-Ad score[1] and the positive experiences of other centres in the region.

AIMS&METHODS: We undertook a retrospective casenote audit of patients with AWS presenting to the acute medical assessment unit over a 6 month period in 2011. We collected data on length of stay, length of detoxification regime, evidence of adverse events and correct prescribing of vitamin supplementation. We then undertook a programme of nursing and junior doctor education to promote the introduction of a symptom triggered chlordiazepoxide (CDP) dosing regimen in January 2012. This regimen was based on nursing staff assessing the CIWA-Ad score and administering a variable dose of CDP. A doctor was called only if the patient was not responding to treatment or excessively high doses of CDP were being administered. We reaudited the same outcomes over 3 months at the end of 2012. The patient populations in each study were broadly comparable.

RESULTS: In the initial analysis 36% of patients (n=103) had CDP prescribed at an efficacious starting dose. Mean length of stay was 15.1 days. Adverse events were reported in many cases. Prescribing of supplements was incorrect in half of patients. On reaudit (n=41) all patients had an efficacious starting dose of CDP prescribed. Mean length of stay had reduced to 10.9 days. Prescribing of supplements was correct in 80% of cases. On interviewing nursing and medical staff a significantly reduced number of patient adverse events were noted and staff felt empowered to provide individualised care to this vulnerable group of patients.

CONCLUSION: We conclude that a variable dose regimen for CDP prescribing is safe and leads to a significant reduction in admission duration at a cost saving to the NHS. We have also shown that this approach empowers staff, especially nursing colleagues, to take ownership of the management of AWS and ultimately reduces adverse events. This outcome was achieved by opportunistic education of fellow professionals and a drive to improve outcomes for this notoriously complex patient group. We propose that such a regimen be adopted as standard for the management of AWS across Europe[2].

P597 POISONING MUSHROOMS INTOXICATION: EVALUATION OF LIVER TRANSPLANT SCORES

J. M. Carvalheiro[1,*], J. M. Romaozinho[1,2], P. Amaro[1], M. Ferreira[1], R. Ferreira[3], C. Sofia[1,2]. *[1]Gastroenterology, Centro Hospitalar e Universitário de Coimbra, [2]Center of Gastroenterology, Faculty of Medicine, University of Coimbra, Coimbra, [3]Gastroenterology, Hospital Beatriz Ângelo, Loures, Portugal*

INTRODUCTION: Intoxication by poisonous mushrooms (PM) is a potentially fatal entity and there is no consensus in the application of liver transplant (LT) scores.
AIMS&METHODS: Aims: The aim of this study was to evaluate the accuracy and precocity of the different LT scores in PM intoxication. **Methods:** Retrospective study of patients with PM intoxication diagnosis between January 1997 and December 2012. Accuracy and precocity have been assessed for the following LT criteria: King's College (KC), Clichy, Ganzert and Escudié.
RESULTS: The study focused on 22 patients (average ages: 50,8 ± 15,8 years old, extreme ages: 16 e 75 years old; 11 men), coming from 6 national districts, all of them during Autumn and 45% related among each other. The beginning of the symptoms (vomiting: 100%, diarrhea: 90% and abdominal pain: 68%) occurred, in average, 11 hours after CV ingestion, being the interval between ingestion and internment > 48h in 32% of cases. When admitted, 36% of patients already exhibited encephalopathy and 75% a V factor < 30%. There was ventilatory support need in 36% of patients and renal in 23%. 7 (58%) out of the 12 patients (55%) who fulfilled the KC criteria were transplanted. 7 patients died [mortality global rate: 32% (57% non transplanted, 43% transplanted)]. The evaluation of the different criteria on the 3rd day of evolution showed that Escudié's criteria had superior accuracy (100%) in the assessment of LT need comparing to the remaining ones (KC: 95%, Clichy: 91%, Ganzert: 86%).
CONCLUSION: 1. PM intoxication reveals a high parental and seasonal incidence (Autumn); **2.** The high mortality rate of this serie might be related with the delay in hospital admission; **3.** The combination of precocity and accuracy parameters recommends the usage of Escudié LT criteria within the PM intoxication context.

P598 EVALUATION OF OXIDATIVE STRESS LEVELS IN CHRONIC LIVER DISEASE

K. Endo[1,*], K. Oikawa[1], H. Mizugai[1], A. Watanabe[1], J. Oikawa[1], K. Kasai[1], Y. Takikawa[1], K. Suzuki[1]. *[1]Gastroenterology and Hepatology School of Medicine, IWATE MEDICAL UNIVERSITY, Morioka, Japan*

INTRODUCTION: Evaluating oxidative stress levels is important in the diagnosis and treatment of chronic liver disease. Recently, a convenient measurement device for active oxygen and free radicals has become available, and this device is reportedly useful in various fields. In this study, we measured oxidative stress levels in chronic liver disease and compared the findings with biochemical test results.
AIMS&METHODS: Thirty-nine NAFLD patients (15 men, 24 women; mean age 51.3±14.8 years, range 24-76 years), 20 healthy subjects (10 men, 10 women; mean age 34.7±10.5 years, range 21-63 years), and 35 patients with chronic hepatitis (HCV) (15 men, 20 women; mean age 63.9±9.9 years, range 36-80 years) were included in the study. The NAFLD patients were further placed in separate SS and NASH groups based on histologic differential diagnosis. For measurement of oxidative stress levels, oxidative stress (d-ROM test; reactive oxygen metabolites, U.Carr), and antioxidant potential (biological antioxidant potential [BAP], μmol/L) were measured using an FRAS4 autoanalyzer (Wismerll, Italy).
RESULTS: d-ROM in the NAFLD (358.7±67.1), SS (354.7±55.8), NASH (360.1±58.9), and CHC (364.1±82.5) groups was significantly increased compared to that in healthy subjects (281.5±48.56) ($P<0.05$). BAP in the NAFLD (2107.7±201.4), SS (2109.5±125.3), NASH (2082.2±188.4), and CHC (2172.4±194.1) groups was not significantly different from that in healthy subjects (2109.5±125.3). The adjusted BAP/d-ROM ratio in the NAFLD (0.807±0.184), SS (0.809±0.184), NASH (0.784±0.132), and CHC (0.819±0.144) groups was significantly lower than that in healthy subjects (1.022±0.194) ($P<0.05$). d-ROM exhibited a significant correlation with γ-GTP ($r=0.499$, $P=0.0003$).
CONCLUSION: In patients with liver disease, oxidative stress levels were higher and antioxidant potential and potential antioxidant ability were lower than those in normal subjects. Oxidative stress levels did not significantly differ between SS and NASH. This finding suggests the presence of oxidative stress, similar to NASH, even at the stage of SS. Oxidative stress levels were correlated with γ-GTP. As a mechanism, γ-GTP is thought to be an enzyme involved in the conversion of oxidized glutathione (generated by oxidative stress) to reduced glutathione.

P599 BACLOFEN AS AN ADJUNCT PHARMACOTHERAPY FOR THE MAINTENANCE OF ABSTINENCE IN ALCOHOL DEPENDENT PATIENTS WITH ESTABLISHED LIVER DISEASE

L. Owens[1,2,*], A. Rose[3], M. Pirmohamed[1], S. Williams[4], W. Gao[2], R. Shaw[2], P. Richardson[2]. *[1]Institute of Translational Medicine, University of Liverpool, [2]Hepatology, Royal Liverpool University Hospital Trust, [3]Department of Psychological Sciences, [4]medical school, University of Liverpool, Liverpool, United Kingdom*

INTRODUCTION: It is axiomatic that effective treatment of patients with established ALD necessitates that patients achieve abstinence [1, 2] Pharmacotherapy for this indication is limited for this patients group, however Baclofen is one of a number of contemporary pharmacotherapies that have been shown to be safe, and effective in reducing craving[3] [4] and withdrawal symptoms[5]. To date, experimental research shows some promising results. However, there is a paucity of evidence for its effectiveness and tolerability in acute hospital and ambulatory settings.
AIMS&METHODS: AIM: The primary aim of this study was to measure the effectiveness of Baclofen in maintaining abstinence in patients with evidence of ALD.
An observational prospective clinical audit was performed to review the effectiveness of Baclofen. Patients with liver disease and concomitant alcohol use were commenced on Baclofen at 10mg TDS, and titrated according to tolerability and response up to 30mg TDS. The primary outcome measures were severity of physical dependence, as determined by Severity of Alcohol Dependence Questionnaire (SADQ score), days abstinent, and biochemical markers of liver function (GGT and ALT). These were compared at baseline, and 3 months.
RESULTS: Of the 75 patients commenced on Baclofen 57 (76%) remained on the treatment and returned for all follow-up sessions at 1 week, 2 weeks, 6 weeks and 3 months.
There was a significant reduction in alcohol consumption. ($P < 0.0001$ 95% CI for difference 20 to 26) with 49 of the 57 patients (93%) maintained total abstinence. There was a significant reduction in the presence of physical dependence ($Chi^2 = 0.5$ (1 DF) $P = 0.4795$) as measured by SADQ.
Data were available for 3 month post treatment GGT for 36 (63%) of the 57 patients. Paired t-tests on log transformed data identified a significant difference between GGT levels at baseline and at 3 month follow-up [$t(34)=3.625$, p.001].
CONCLUSION: Baclofen has a positive impact on alcohol consumption in this very difficult to treat, high risk patient group. Those patients who attended follow-up; adhered to the treatment regime and significantly decreased their alcohol consumption. There was also a significant improvement in liver biochemistry. These results are promising however a well-designed randomised control trial is needed to investigate the utility and efficacy of Baclofen in this patient group, and intitiate in acute hospital settings.

P600 AMINOPYRINE BREATH TEST AS A DIAGNOSTIC TOOL TO EVALUATE HEPATIC FUNCTIONAL RESERVE IN NEOPLASTIC PATIENTS RECEIVING HIGH DOSE CHEMOTHERAPY.

M. Tabuso[1], S. Maiero[1,*], M. Michieli[2], M. Rupolo[2], E. Orzes[1], M. Fornasarig[1], R. Cannizzaro[1]. *[1]SOC Gastroenterology, [2]Medical Oncology, CENTRO RIFERIMENTO ONCOLOGICO, Aviano, Italy*

INTRODUCTION: Liver toxicity is a frequent and serious complication of hematopoietic stem cell transplantation following high dose chemotherapeutic preparative regimens. Altered hepatic clearance may cause increased hepatic and non hepatic chemotherapy-induced toxicity. Common liver function tests do not reflect hepatic reserve function, therefore an additional diagnostic tool is needed. Aminopyrine breath test is a non invasive quantitative liver function test based on the hepatic clearance of a test substance. Its utility to assess liver function in patients with liver disease has been well documented.
AIMS&METHODS: We sought to determine hepatic functional reserve in patients with relapsed or refractory lymphomas and multiple myeloma undergoing high dose chemotherapeutic preparative regimens and hematopoietic stem cell transplantation.
From 2001 to 2013 we evaluated 227 consecutive patients with relapsed or refractory Hodgkin lymphoma, non-Hodgkin lymphoma and multiple myeloma who underwent aminopyrine breath test before initiation of high dose chemotherapy.

13-C aminopyrine (2 mg/kg) was administered at baseline and breath samples were collected every 15 minutes up to two hours after 13-C aminopyrine administration. Results were expressed as the cumulative percentage of administered dose of 13 C recovered at 120 min. Cut-off value of 3.5% was used for severe reduction of metabolism rate.
RESULTS: In 6 out of 227 (2.6%) patients the cumulative percentage of administered dose of 13-C recovered at 120 min was below 3.5 % showing severe reduction of metabolism rate.
CONCLUSION: We propose the aminopyrine breath test as a diagnostic tool to evaluate hepatic functional reserve in neoplastic patients undergoing high dose chemotherapy for appropriate chemotherapy regimens and dosing in order to prevent severe hepatic chemotherapy-related toxicity.

P601 LOW FRUCTOSE DIET IMPROVES OUTCOME IN PATIENTS WITH SEVERE ALCOHOLIC LIVER DISEASE DURING FOLLOW UP IN AN OUTPATIENT CLINIC

S. Vadstrup[1,*], I. A. Lisbjerg[1], J. Jensen[1]. [1]*gastroenterology, Holbaek Hospital, Holbaek, Denmark*

INTRODUCTION: Fructose is metabolized only in the liver. Fructose is firstly metabolized to fructose-1-P. This reaction is not regulated leading to uncontrollable degradation of fructose and severe depletion of ATP in the liver, when excess fructose is presented to the liver. Severe depletion of ATP is a characteristic finding in different types of acute liver failure.
AIMS&METHODS: We have since 2008 followed patients with severe alcoholic liver failure in an outpatient slinic after they have survived one episode of hepatic encephalopathy. They had open access to our stationary department and could be transported directly in the department day and night, if they experienced a new episode of encephalopathy. The patients were followed in the outpatient clinic with 2-8 week intervals. Different liver parameters and serum alcohol was measured at each visit and at acute admissions. The patients should abstain from alcohol. A diet low in fructose was introduced to all the patients in january 2011 both in the department and at home.
RESULTS: A total of 63 patients were included until may 2013 of which 19 died (age 35-75). Two patients were transplanted, 5 patients left the clinic, all still alive, Two patients died from cerebrovascular events and not from liver related disease. Intermittently positive serum alcohol was recorded at controls in 9patients but not in any of the patients at acute admissions.

Year	new patients	non surviving	surviving (cummulative)
2008	13	1	12
2009	10	8	14
2010	10	7	17
2011	9	0	26
2012	14	3	35
2013	7	0	42

Mortality First 3 years against 3 last years significant different p=0,001 (Fisheŕs test)
CONCLUSION: A diet low in fructose improves outcome in a group of patients with severe alcoholic liver disease during a 2,5 year period compared with a similar group of patients not treated with fructose restriction durign the preceeding 3 years.

P603 PREDICTORS OF QUALITY OF LIFE IN PATIENTS WITH CHRONIC LIVER DISEASE

D. D. Popovic[1], D. Kisic-Tepavcevic[2], N. Kovacevic[1], D. Culafic[1,*], T. Alempijevic[1], M. Spuran[1], M. Krstic[1], M. Perisic[1]. [1]*Clinic for Gastroenterology and Hepatology, Clinical centre of Serbia,* [2]*Institute of Epidemiology, Faculty of Medicine, Belgrade, Serbia*

INTRODUCTION: Undoubtedly proven that patients with Chronic liver disease (CLD) have impaired Health related quality of life (HRQoL). However, the relative contribution of sociodemographic, clinical and behavioral factors in the reduction of HRQoL, has not been fully elucidated.
AIMS&METHODS: The aim of our study was to evaluate the effect sociodemographic, clinical and behavioral characteristics in patients with CLD, as predictors of physical (PCS) and mental component of HRQoL (MCS).We performed a cross sectional study. As a HRQoL questionnaire was used Short Form Health Survay-36 (SF-36). For psychometric assessment we used: Hamilton depression rating scale, Hamilton anxiety rating scale and Fatigue severity scale. An individual effect of variables on the quality of life was assessed by univariate and multivariate regression analysis, adjusted for potential confounding factors. Hierarchical multiple regression analysis was conducted to identify predictors of HRQoL, separately for PCS and MCS as outcome variables.
RESULTS: The study included 103 patients with CLD, average age 53.8±12.9 years.The average values of the total SF-36 scores were 52.6±20.4. The mean score of the composite scores were 49.8±21.3 for the PCS, and 53.5±19.6 for the MCS. Sociodemographic variables (gender, age, employment) explained 16.7% of the variance ($p<.01$) of the PCS as outcome measure. Addition of the variables Depression and anxiety in the second model caused an increase of 26.7% in the variance explained ($p<.01$). After adding the Fatigue in the third block an additional 16.7% of the variance in PCS was explained ($p<.01$). The final model explained 60.1% of the variance in PCS ($p<.01$). The results in the final block have shown that employment (B=8.64±4.09, $\beta=.18$, $p<.05$), depression (B=-1.02±.27, $\beta=-.45$, $p<.01$) and fatigue (B=-4.82±.77, $\beta=.47$, $p<.01$) significantly influenced PCS. With MCS as dependent variable, sociodemographic variables explained 6.0% of the variance in the outcome variable ($p<.01$). Depression and anxiety explained additional 39.1%, while Fatigue accounted an additional 10.7% of the variance in MCS ($p<.05$). The final model explained 55.8% of the variance in MCS ($p<.01$). Among all investigated variables statistically significant impact on mental component of quality of life was observed only for depression (B=-1.04±.26, $\beta=-.49$, $p<.05$) and fatigue (B=-3.56±.75, $\beta=-.38$, $p<.01$).
CONCLUSION: Depression and fatigue are negative predictors of physical and mental components of quality of life, while employment has a positive predictive significance only for the physical components of quality of life, in patients with CLD.

P604 ASSOCIATION BETWEEN SINGLE NUCLEOTIDE POLYMORPHISM OF INTERLEUKIN-21 GENE AND CHRONIC HEPATITIS B VIRUS INFECTION IN A CHINESE POPULATION

J. Yao[1,*], K. Chao[1], M. Li[1], X. Gong[1], M. Chen[1], B. Zhong[1]. [1]*the First Affiliated Hospital of Sun Yat-sen University, Guanghzou, China*

INTRODUCTION: Previous studies have revealed that three SNPs (rs13143866, rs2221903 and rs907715) in IL-21 gene were associated with autoimmune disease among both Asian and non-Asian populations; however, these associations have not been evaluated in chronic HBV infection diseases yet.
AIMS&METHODS: The aim of this study was to examine the association of SNPs in IL-21 gene with susceptibility to chronic HBV infection in a Chinese population. Chronic HBV infected patients and healthy controls were from the First Affiliated Hospital of Sun Yat-sen University from Jun 2011 to October 2012. Three SNPs (rs13143866, rs2221903 and rs907715) within the IL-21 gene intronic region were genotyped by SNaPshot SNP technique.
RESULTS: (1) A total of 303 independent chronic HBV infected patients and 208 unrelated healthy controls were recruited for the case–control association study. (2) There were no significant differences in the frequencies of all alleles and genotypes (rs13143866, rs2221903 and rs907715) between chronic HBV infection group and control group (P=0.417, 0.126, 0.870 for alleles, P=0.399, 0.285, 0.120 for genotypes). (3) According to the existence of hepatocellular carcinoma (HCC), the chronic HBV infection group was divided into HCC group (n=94) and non-HCC group (n=209), unfortunately, no significant differences were found in the frequencies of all alleles and genotypes between HCC group and non-HCC group (P=0.199, 0.307, 0.979 for alleles, P=0.307, 0.571, 0.208 for genotypes). (4) In subgroup analysis, non-HCC group was classified into three clinical subsets, chronic hepatitis B (CHB) (n=76), HBV carrier (n=101), and HBV related cirrhosis (n=32). no significant differences were found in the frequencies of all alleles and genotypes among all groups (P=0.506, 0.313, 0.965 for alleles,, P=0.319, 0.097, 0.510 for genotypes). (5) When compared to the healthy controls, the effect of recessive model (AA versus GG+GA, OR (95%CI)=0.154 (0.030~0.776) was observed in HBV carrier group. (6) Distributions of allele and genotype frequencies of the SNPs rs907715 and rs2221903 showed no significant differences among all groups. (7) In haplotype analysis, although no haplotype was found to be associated with chronic HBV infection, our study found the ATA and GTA haplotypes (rs13143866, rs2221903 and rs907715) tended to be associated with HBV-related HCC (P=0.070, 0.104, respectively).
CONCLUSION: Our study demonstrate that the allele G of rs13143866 may be a protective factor for chronic HBV infection. However, further studies are needed to determine the associations and functional consequences of these polymorphisms with chronic HBV infection susceptibility.

P605 THE RATIOS OF PRO TO ANTICOAGULANT FACTORS: INDEX OF HEMOSTATIC IMBALANCE IN CIRRHOTIC PATIENTS

A. Laabidi[1], M. Fekih[1,*], H. Baccouche[2], M. Serghini[1], N. Ben Mustapha[1], J. Boubaker[1], N. Ben Romdhane[2], A. Filali[1]. [1]*Gastroenterology "A",* [2]*Hoematology, La Rabta hospital , El Manar Faculty, Tunis, Tunisia*

INTRODUCTION: Patients with cirrhosis are characterized by decreased levels of most of pro- and anti-coagulant factors. This state results in an unstable balance. Therefore, patients are prone to hemorrhagic or thromboembolic events particularly in advanced stages. The aim of this study was to evaluate the ratios of pro coagulant to inhibitor coagulation factors in cirrhotic patients according to disease severity
AIMS&METHODS: A case control study including cirrhotic patients and healthy subjects matched by age and sex was conducted. Patients were stratified according to Child Pugh classification. Pro coagulant factor activity (factor VII, II, V, VIII, XII) and inhibitor factor activity were determined (Protein C, protein S and ant thrombin). Mean value of pro coagulant to inhibitor coagulation factor ratios in patients were compared to those in controls and investigated in patients according to Child Pugh classification.

RESULTS: 51 cirrhotic patients and 51 controls were included. Their mean age was 56.8 years. Sex ratio (men to female) was 0.9. Patients were classified in Child Pugh A in 13 patients (25.5%), B in 23 patients (45.1%), C in 15 patients (29.4%). Among ratios, II/PC, V/PC, VII/PC, XII/PC were significantly higher in cirrhotic patients than in controls (respectively, p=0.001, p=0.002, p=0.001, p=0.001) but there wasn't any difference between Child Pugh classes. Likewise, VIII/PC, VIII/PS and VIII/AT were significantly higher in cirrhotic patients than in controls ($p<0.001$) and increased significantly from class A to C ($p<0.001$), reaching a value of 5. On the other hand, II/PS was lower in cirrhotic patients than in controls showing marginal significance (p=0.04). However, II/PS, V/PS, VII/PS decreased significantly from class A to C (p=0.006, p=0.013, p=0.002, p=0.024).
CONCLUSION: The ratios of pro- to anti-coagulant factors showed a coagulation imbalance in our patients with trend to hypercoagulabilty state. This hemostatic change was significantly correlated with severity of cirrhosis.

P606 ROSUVASTATIN HAD THE INHIBITED EFFECT OF LIVER FIBROSIS AND PRENEOPLASTIC LESION IN RAT LIVER CIRRHOSIS MODEL

N. Yamamoto[1,2,*], K. Uchida[1], T. Takami[1], K. Fujisawa[1], S. Terai[1], I. Sakaida[1]. [1]*Gastroenterology & Hepatology ,* [2]*Health Administration Center, Yamaguchi University Graduate School of Medicine, UBE, Japan*

INTRODUCTION: Non-alcoholic steatohepatitis(NASH) may progress to advanced liver fibrosis and ultimately to hepatocellular carcinoma. Hyperlipidemia is known to enhance the risk of fatty liver and carcinogenesis, which is associated with hydroxyl radical formation. The HMG-CoA reductase inhibitor(Rosuvastatin) has greater lipid-lowering efficacy than any of the other statins.
AIMS&METHODS: The aim of this study was to investigate whether Rosuvastatin has the effect of inhibiting liver fibrosis as well as the development of preneoplastic lesions.We were examined using the choline-deficient L-amino acid-defined(CDAA) diet-induced liver fibrosis model.The total study periods were 12 and 16 weeks. Rosuvastatin in powder was mixed into the CDAA diet at concentrations of 5.0% (w/w). One group was CDAA diet containing Rosuvastatin, the other group was CDAA diet without Rosuvastatin. Liver fibrosis was analyzed with Azan, Sirus–red, aSMA, TGFb expression, hydroxyproline level. The enzyme-altered lesion was analyzed with Glutathione S-transferase placental form (GST-P) expression. The change of laboratory data was analyzed. Type I procollagen, TIMP-1, 2 TGFb mRNA expression was analyzed by real time-PCR system and many gene expression in liver by DNA array. We analyzed the expression of IL-1b,2,4,6,10,MCP1,TNFa,CRP,TGFb,ACRP30,PDGFb in liver.
RESULTS: After 16 weeks, Rosuvastatin prevented fibrosis in a dose-dependent manner by Azan, Sirius Red, aSMA, TGFb expression ($p<0.05$). Hydrocyproline level in liver was decreased (mean value:CDAA+Rosuvastatin 4.4 vs CDAA only 12.1 umol/Wg $P<0.05$). Rosuvastatin reduced the area of preneoplastic lesions in the liver by GST-P stain ($p<0.01$). Administration of Rosuvastatin significantly reduced serum alanine aminotransferase (AST) (mean value: CDAA+Rosuvastatin 460.4 vs CDAA only 548.0 IU/l $P<0.05$), Albumin(mean value:CDAA+Rosuvastatin 3.80 vs CDAA only 2.52 g/dl $P<0.01$), Hyaluronic acid (mean value:CDAA+ Rosuvastatin 86.8 vs CDAA only 181.4 ng/ml $P<0.01$). Rosuvastatin significantly inhibited Type 1 procollagen, TIMP-1, 2,and TGFb mRNA expression (all of $P<0.01$). The Rosuvastatin treated groups decreased the level of IL-4,IL-6,TNFa, TGFb and increased the level of IL-10,IFNγ.
CONCLUSION: Our results show that Rosuvastatin inhibited liver fibrosis as well as preneoplastic lesions. These results suggested that Rosuvastatin will be the new drug for liver fibrosis in NASH
Disclosure of Interest: None Declared

P608 ARTIFICIAL NEURONAL NETWORKS IN DIAGNOSIS AND PROGNOSIS OF LIVER CIRRHOSIS

B. D. Procopet[1,2,*], V. M. Cristea[3], M. A. Robic[4], M. Grigorescu[1], P. S. Agachi[5], S. Metivier[4], J. M. Peron[6], M. Tantau[1,2], J. P. Vinel[6], C. Bureau[4]. [1]*gastroenterology, Regional Institute of Gastroenterology and Hepatology,* [2]*3rd Medical Clinic, University of Medicine and Pharmacy ''Iuliu Hatieganu'',* [3]*Chemical Engineering, Babeş-Bolyai University, Faculty of Chemistry and Chemical Engineering, Cluj-Napoca, Romania,* [4]*Hepato-Gastroenterology, Purpan Hospital, CHU Toulouse, Toulouse, France,* [5]*Babeş-Bolyai University, Faculty of Chemistry and Chemical Engineering, Cluj-Napoca, Romania,* [6]*Purpan Hospital, CHU Toulouse, Toulouse, France*

INTRODUCTION: The prognosis cirrhosis is determined by the presence portal hypertension (PHT) that is best evaluated by hepatic venous pressure gradient (HVPG). Recently, non-invasive methods were proposed to evaluate PHT. The aim of this study was to create a new model using artificial neural networks (ANNs) and to compare-it with other non-invasive tests and HVPG for diagnosis of clinical significant portal hypertension (CSPHT) (HVPG > 10 mmHg) and esophageal varices (EV).
AIMS&METHODS: One hundred seven cirrhotic patients were included to create and validate the ANNs: 82 patients in the ANNs training group and 25 patients for validation of this model. The ANNs training have been performed using MATALB (The MathWorks Inc., USA) software. Only the variables correlated with HVPG were included in the ANN (age, albumin, platelets count, bilirubin, prothrombin index and liver stiffness (LS)). Two ANNs were created: one for predicting CSPH and one for presence of EV. All patients underwent HVPG measurement, serological test (AST/ALT index, APRI, Lok, FIB-4, GUCI, Risk score) and LS measurement. All patients from validation group were follow-up for 2 year or until decompensation.
RESULTS: The ANN was able to predict CSPH with Se=100%, Sp=83.3%, PPV=94.7%, NPV=100% and AUROC=0.97 (p=0.001). These performances were superior to all serum scores but slightly inferior to LS. For EV presence, ANN had Se=100%, Sp=75%, PPV=95.4%, NPV=100% and AUROC=0.87 (p=0.02), inferior only to HVPG, LS and Lok score. During the follow-up, 13 patients (52%) experienced at least one clinical complication within a mean period of 403 days. The ANNs performance to predict clinical decompensation was modest, AUROC=0.605 (p=0.38). None of the non-invasive tests reached statistical significance in decompensation prediction.
CONCLUSION: ANNs may be useful in diagnosis of CSPH or EV but the prognostic relevance is modest.

P609 COMPARISON OF RIFAXIMIN AND CONVENTIONAL ORAL THERAPY FOR THE TREATMENT OF HEPATIC ENCEPHALOPATHY: A META-ANALYSIS

C. M. Malijan[1,*], I. H. Y. cua[1]. [1]*gastroenterology, st. luke's medical center, quezon city, Philippines*

INTRODUCTION: Hepatic encephalopathy is a serious neuropsychiatric condition occurring in patients with liver disease. The efficacy of rifaximin is well documented in the treatment of acute hepatic encephalopathy, but its efficacy for prevention of the disease has not been established. This meta-analysis aims to review data concerning the efficacy and safety of Rifaximin in comparison to conventional oral therapy in the treatment of cirrhotic patients with hepatic encephalopathy.
AIMS&METHODS: We performed a systematic review and random effects meta-analysis of all eligible trials identified through electronic and manual searches. Two authors independently assessed trial quality and extracted data. Four randomized controlled trials met the inclusion criteria with a total of 236 patients. Statistical analyses were performed using the random effects model and the results expressed as weighted mean difference for continuous data with 95% confidence intervals. Heterogeneity was measured using the Chi-square and I statistic.
RESULTS: The effectiveness of Rifaximin in terms of changes in hepatic encephalopathy index was equivalent to oral disscharides and oral antibiotics [odds ratio 1.02; 95% CI: 0.48-2.18] as well as to change in mental status [odds ratio 0.91; 95% CI 0.18-4.68]. Rifaximin also showed lower serum ammonia levels [weighted mean difference= -34.93; 95%CI -39.41- -30.95; P = <.00001] and less asterixis [WMD = -0.06; 95% CI -0.22 - 0.10; P = 0.38]. Rifaximin was well tolerated with few side effects.
CONCLUSION: Rifaximin is somewhat equivalent to non-absorbable disaccharides or antibiotics for treatment of hepatic encephalopathy. Adverse effects of rifaximin were mostly minor gastrointestinal complaints. Moreover, no significant difference was found between rifaximin and oral conventional therapy in terms of their efficacies.

P610 NONINVASIVE PREDICTORS OF HIGH-RISK VARICES IN CHRONIC LIVER DISEASE PATIENTS

D. V. Balaban[1,2,*], B. G. Florea[2], A. R. Cazan[2], A. Stanca[2], A. L. Popescu[1,2], V. Jinga[2], I. P. Nuţă[1], R. S. Costache[1,2], F. Ioniţă Radu[1], M. Jinga[1,2]. [1]*Gastroenterology Clinic, "Dr Carol Davila" Central Military Emergency University Hospital,* [2]*"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania*

INTRODUCTION: Esophageal varices (EV) are a major complication of portal hypertension in chronic liver disease patients. Follow-up of cirrhotics by

periodical upper GI endoscopy can be quite costly and poorly accepted by patients. In this setting we need to identify noninvasive models to predict the presence of high-risk varices (large varices and varices with red marks).
AIMS&METHODS: We retrospectively studied 104 patients with chronic liver disease (hepatitis or cirrhosis) of various etiologies (viral, ethanolic, autoimmune, drug-induced) admitted to out unit in 2012. Clinical, biological, ultrasonographic and endoscopic data were collected from their charts and used to calculate the APRI (AST to platelets ratio index), ASPRI (age-spleen-platelets ratio index) and SPRI (spleen to platelets ratio index) scores. The diagnostic performance of these scores was evaluated by the area under the receiver operating characteristic curve (AUROC).
RESULTS: Of the 104 patients (62.5% males, mean age 62 years), 83 (79.80%) were cirrhotic. On EGD, 25% were without EV, 55.77% had small varices (Paquet I-II) and 19.23% had large varices (Paquet III-IV). Portal vein, splenic vein and spleen diameter were significantly higher in patients with large varices than those with small or no varices, while platelet count was significantly lower. APRI, ASPRI and SPRI scores were good predictors for the presence of large varices on endoscopy (AUROC 0.652, 0.703 and 0.702 respectively). The three scores performed even better when predicting both large varices or small varices with red marks (AUROC 0.758, 0.806 and 0.803). They also had good accuracy for predicting gastric varices (AUROC 0.676, 0.711 and 0.719).
CONCLUSION: These simple non-invasive scores can accurately predict high-risk esophageal varices in liver disease patients, targeting those who need to undergo EGD and prophylactic treatment.

Gasbarrini[1]. *[1]Internal Medicine and Gastroenterology, A Gemelli Hospital, [2]Pediatrics Department, Sapienza University, [3]Nuclear Medicine, A Gemelli Hospital, [4]IBPM, CNR, Rome, Italy*

INTRODUCTION: The impairment of gut barrier and microbial translocation are frequent in liver cirrhotic patients, predisposing to infectious complications such as spontaneous bacterial peritonitis (SBP). Little is known about the role of SIBO in SBP development.
AIMS&METHODS: To investigate the relationship between SIBO, IP and the development of SBP in liver cirrhotic patients.
31 patients were enrolled in this study (10 Child A, 10 Child B and 11 Child C; mean age 60 years, all viral etiology or previous alcohol abuse). SIBO was diagnosed by glucose-hydrogen breath test. IP was evaluated by the (51)Cr-EDTA test (Cr excreted in urine, UCr); UCr higher than 3% indicated increased IP. Statistical analysis was performed using chi-squared test, t-test, ANOVA and cluster analysis.
RESULTS: IP was increased in all patients: mean UCr was 4+3% for Child A , 4+2% for Child B and 5+3% for Child C patients (p=0.607). SIBO was diagnosed in 4/10 (40%) patients with Child A, 7/10 (70%) Child B, 9/11 (82%) Child C (p=0.123); 4/10 (40%) Child B and 8/11 (73%) Child C patients had at least one episode of SBP (p=0.130). Therefore among patients who presented with ascites, 16/21 (76%) also presented with SIBO, which was significantly associated with at least one episode of SBP (p=0.05). According to UCr, two subgroups could be identified: G1 (no SIBO, mean UCr 3+2%) and G2 (SIBO, mean UCr 5+2%). 92% of patients with at least one episode of SBP belonged to the group 2 (p=0.05). Notably no difference in IP was found between patients with and without SBP if the presence of SIBO was not considered (mean Ucr 4.5+3% and 4.5+2%, respectively).
CONCLUSION: Increased IP "per se" is not the only determinant of SBP development, which is rather more frequent in cirrhotic patients with SIBO.

P612 LIVER STIFFNESS MEASUREMENT PREDICTS THE PRESENCE OF LARGE OESOPHAGEAL VARICES IN PATIENTS WITH CHRONIC LIVER DISEASES

G. Par[1,*], A. Trosits[1], F. Pakodi[1], P. Kenyeres[1], A. Vincze[1], A. Par[1]. *[1]FIRST DEPARTMENT OF MEDICINE, UNIVERSITY OF PECS, Pecs, Hungary*

INTRODUCTION: One of the most serious complications of liver cirrhosis is the variceal bleeding. The early recognition of the oesophageal varices is of primary importance in the prevention of their bleeding. Liver stiffness (LS) measured by transient elastometry (FibroScan) may associate with portal pressure and could predict the presence of oesophageal varices.
AIMS&METHODS: We studied the diagnostic accuracy of LS by FibroScan for selecting patients at risk of bearing large oesophageal varices and high risk (Paquet =>II grade) of bleeding. We performed oesohago-gastro-bulboscopy and FibroScan examination in 74 patients with chronic liver disease simultaneously. We examined the relation between the presence of oesophageal varices (Paquet grade 0-IV) and the LS (kPa) as well as the blood hematological and biochemical laboratory parameters (INR, platelet count, ALT, AST, albumin). We analysed the predictive role of LS by FibroScan for selecting patients at high risk of variceal bleeding (Paquet =>II).
RESULTS: LS values correlated to the grade of oesophageal varices (Paquet–grade) r= 0,67, p<0,0001. The LS value was highly predicitve of the presence of oesophageal varices (AUROC:0,885, 95% CI: 0,81-0,96) and allowed to predict the high grade varices (Pq=>II) (AUROC: 0,85, 95% CI: 0,754-0,94). We found high measurement sensitivity: (sens) 85 %, specificity (spec): 87%, positive predictive value (PPV): 85%, negative predictive value (NPV):87% and validity: 86% at the cutoff 19,2 kPa LS value. LS measurement value <19,2 kPa was highly predicitive of the absence of oesophageal varices grade =>II (sens.: 95%, spec.: 70%, PPV:54%, NPV: 97%), thus we verified that below LS 19,2 kPa the high grade of oesophageal varices (Pq=>II) is not probable. The laboratory parameters did not predict oesophageal varices.
CONCLUSION: The non-invasive LS measurement by FibroScan may select patients who are at high risk of bearing large oesophageal varices (Paquet =>II) and variceal bleeding and need endoscopic screening. LS above 19,2 kPa indicates an oesophageal-gastro-buboscopy for the judgement of varices.

P613 NON-INVASIVE ASSESSMENT OF LIVER FIBROSIS BY REAL-TIME SUPERSONIC SHEAR WAVE ELASTOGRAPHY (SWE™) IN PATIENTS WITH CHRONIC VIRAL HEPATITIS

I. Grgurevic[1,*], T. Bokun[1], D. Radic[2], R. Heinzl[3], I. K. Lukic[4], Z. Puljiz[5], B. Luksic[6], D. Kardum[1], M. Kujundzic[1]. *[1]Gastroenterology, University Hospital Dubrava, [2]Gastroenterology, University Hospital Center Zagreb, [3]Pathology, University Hospital Dubrava, Zagreb, [4]Research in Biomedicine and Health, University of Split School of Medicine, [5]Gastroenterology, [6]Infectious diseases, University Hospital Center Split, Split, Croatia*

INTRODUCTION: Supersonic Shear wave elastography (SWE™) is new quantitative real-time ultrasound based elastography method for non-invasive assessment of liver fibrosis (LF) with only preliminary results on its clinical performance published so far.
AIMS&METHODS: To investigate if it was possible to distinguish between the LF stages by using SWE in pts with CVH. Naive fasting CVH pts underwent SWE of the liver (SWEL) on Aixplorer® Ultrasound system (SuperSonic Imagine), by right intercoastal approach following expiration, with 5 measurement performed per patient. Patients with ALT values >3x ULN, cholestasis and liver congestion were not included in the study. The result were expressed in kPa as the average of 5 measurements and compared to LF stage as assessed by liver biopsy (LB). The LF was classified as mild (Ishak stages F0-2), moderate (F3-4) or severe (F5-6, i.e. compensated cirrhosis). In a subgroup of patients with decompesated cirrhosis the diagnosis relied upon clinical, biochemical, ultrasound and endoscopic criteria and these pts were analysed separatelly.
RESULTS: Out of 105 pts with CVH B (N=24) and C (N=81) SWEL was succesfully performed in 82 pts (failure rate 22%). Liver stiffness (LS) as assessed by SWE was signifficantlly different between the pts with mild, moderate and severe LF: 6,3 *vs* 10,0 *vs* 16,2 kPa respectivelly (p<0,001). Cut-off values for Ishak F≥3 and F≥5 were 8,1 (sens. 95,5%, specif. 100%, AUC 0,993) and 11 kPa (sens. 87%, specif. 92,7%, AUC 0,955). LS was significantlly different between the pts with compensated (Ishak F5-6) and decompensated cirrhosis (16,2 *vs* 33,7 kPa, p<0,001; cut-off 25,2, sens. 88,9%, specif. 95,7%, AUC 0,953). In 46 pts spleen stiffness (SS) was also assessed by SWE and signifficant difference was observed between the non-cirrhotic LF stages (F0-4) and compensated cirrhosis (F5-6) (21,2 *vs* 26,7 kPa, p=0,001; cut-off 24 kPa, sens.66,7% specif. 85%, AUC 0,795) as well as compensated *vs* decompensated cirrhosis (26,7 *vs* 37,0 kPa, p=0,001; cut-off 38kPa, sens. 54,6%, specif. 100%, AUC 0,845).
CONCLUSION: The performance of Supersonic SWE™ for non-invasive assesment of LF in CVH pts was excellent especially for differentiation between the mild and more advanced stages of LF. Both LS and SS were significantly different between compensated cirrosis and non-cirrhotic stages of LF, as well as between compensated and decompensated cirrhosis with better performance of liver SWE.

P614 DO ENDOSONOGRAPHY FINDINGS PREDICT VARICEAL RECURRENCE AFTER ENDOSCOPIC BAND LIGATION?

L. Masalaite[1,2,*], J. Valantinas[1,2], J. Stanaitis[1]. *[1]Vilnius University Hospital Santariskiu Clinics, [2]Clinic of gastroenterology, nephrourology and surgery, Medical Faculty, Vilnius University, Vilnius, Lithuania*

INTRODUCTION: Endoscopic band ligation (EBL) has a considerable tendency of variceal recurrence.
AIMS&METHODS: The aim was to analyse the value of esophageal collateral veins (ECV) evaluated on endosonography (ES) as predictors for variceal recurrence after EBL.
31 patient with large esophageal varices and EBL indicated was enrolled in prospective study. ES was performed before EBL and ECV were classified into 3 types (peri-ECV, para-ECV and perforator) and 2 grades - mild (peri-ECV <2mm; para-ECV <5mm) and severe (peri-ECV ≥2mm and para-ECV ≥5mm). EBL was repeated every 2 weeks until varices were obliterated and

endoscopy was repeated every 3 month for 1 year period to detect recurrence - reappearance of any form of varices or red-color signs. Relationship between ES findings and variceal recurrence was analysed. Quantitative results are presented as mean±SD. Student's t-test for unpaired data was used. Qualitative data were analysed by the chi-square test. A p value <0,05 was considered significant.
RESULTS: From September 2011 to January 2013 31 patient (21 men (67,7%); average age 53,6 ±8,9 years) was enrolled in the study. To this day 31 patient was being followed for 3 months, 22 – for 6 months, 21 – for 9 months and 16 - for 1 year. Recurrence of varices was detected in 16,1% of patients within 3 months, in 36,6 % of patients within 6 months and in 75% of patients within 1 year. Patients, followed for a year, were divided into recurrent (n=12) and non-recurrent (n=4) groups. Mean diameter of peri-ECV in the recurrent group was 2,42±0,37 mm (75% severe and 25% mild) and in the non-recurrent group - 2,34±1,16 mm (50% severe and 50% mild) (p=0,8). Mean diameter of para-ECV in recurrent group was 3,76±1,75 mm (33% severe and 67% mild) and in non-recurrent group - 4,2±1,09 mm (100% mild) (p=0,5). Perforators were detected in 58% of patients in the recurrent group and in 50% of patients in the non-recurrent group (p=0,5). Further, the recurrent group was divided into early recurrent (≤ 6 months (n=8)) and late recurrent (> 6 months (n=4)) groups. No significant difference (p>0,05) regarding ECV type and grade was found between the early and the late recurrent groups. Regarding clinical characteristics only spleen diameter had a statistically significant difference between these groups (p= 0,012). Mathematical cox proportional hazards model of data found that severe peri-ECV are associated with higher and earlier recurrence risk after EBL (hazard ratio 1,57), but in our small sample size did not reach statistically significant difference.
CONCLUSION: Our study showed that ES findings do not predict variceal recurrence after EBL.

P615 DIAGNOSTIC VALUE OF SECONDARY HYPERALDOSTERONISM IN DEVELOPMENT OF RESISTANCE TO NONSELECTIVE BETA-BLOCKERS(BB) PORTAL HYPERTENSION(PH) WITH CIRRHOSIS

L. Fedulenkova[1,*], V. Drozdov[1]. [1]*Central Scientific Research Institute of Gastroenterology, Moscow, Russian Federation*

INTRODUCTION: Diagnostic value of secondary hyperaldosteronism in development of RESISTANCE TO NONSELECTIVE BETA-BLOCKERS(BB) PORTAL HYPERTENSION(PH) WITH CIRRHOSIS
AIMS&METHODS: Aim: To study the influence of activity RAAS on the hemodynamic response to BB of PH in patients with cirrhosis.
Methods: 32 patients with cirrhosis (mean age 56 ±3,0) were studied. All patients were divided into two groups: the 1st group (n = 18) were administered with propronolol 40 mg titrated up, the 2nd group (n = 14) were administered with propronolol +spironolactone 100 mg. There were no significant differences on a degree of Child-Pugh in both groups (mean score 6,9). Hepatic venous pressure gradient (HVPG), renin and aldosteron plasma levels were measured before and after 4 weeks of treatment.
RESULTS: Propronolol significant reduced HVPG at 10 patients 1st group (15,1±14,6 %,p=0,04). 8 patients 1st group were resistance to propronolol(mean change of HVPG−1.7 ± 2.4 mm Hg).Aldosteron and renin plasma levels a prior to the beginning of therapy was significant above (p=0,047) in the resistance BB group. There was a significant reduction in the HVPG in the propronolol + spironolactone group (−5.7 ± 3.9 mm Hg; p=0,02) as compared to the 1st group. 11 of 14 patients 2nd group significant reduced HVPG (p=0,003). 3 patients were resistance to BB and had aldosteron plasma levels exceeded norm in 2 times. At an estimation of interrelation between aldosteron plasma levels and a negative effect of therapy propronolol with method ROC- analysis, taps relative risk of a negative effect of therapy at patients with aldosteron plasma levels from 300 ng/ml and more = 1,75 (1,03-2,95; 95%DI), p=0,03 (sensitivity of 85,7 % and specificity of 55,6 % (AUCROC=0,651; p=0,1).
CONCLUSION: In the study of resistance BB of portal hypertension should be screened for the main parameters of the renin-angiotensin-aldosterone system. Patients with initially high levels of aldosterone, regardless of the presence of ascites to the treatment of portal hypertension should be added aldosterone antagonists.

P616 BODY MASS INDEX (BMI) AND NUTRITIONAL RISK INDEX (INR): HOW USEFUL ARE FOR ASSESSING THE NUTRITIONAL STATUS IN PATIENTS WITH CHRONIC LIVER DISEASE?

M. Sendroiu[1,*], M. Danila[1], I. Sporea[1], A. Popescu[1], R. Sirli[1], S. Bota[1]. [1]*Department of Gastroenterology and Hepatology, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania*

INTRODUCTION: There is no consensus regarding the parameters that we should consider for assessing the nutritional status in patients with chronic hepatitis or cirrhosis.
AIMS&METHODS: AIM: to evaluate the parameters used in general population for assessing nutritional status in patients with chronic hepatitis or cirrhosis of different ethiologies.
METHODS:
We used the data of a prospectiv study performed in our department on 98 consecutive patients with chronic liver disease, in which we evaluated the nutritional status using 2 questionnaires: Subjective Global Assessment (SGA) and Mini-Nutritional Assessment (MNA). For every patient we calculated the body mass index (BMI) and we evaluated the nutritional status using nutritional risk index (INR).
RESULTS: RESULTS:
Using the combined value of the 2 tests (SGA and MNA) we obtained the following results: 10/64 (15.6%) were malnourished, 24/64 (37.5%) had malnutrition risk and 30/64 (46.9%) had normal nutritional status. We considered these 2 tests as the standard in diagnosing malnutrition and we evaluated the other 2 parameters: BMI and INR. For BMI we obtained 88.4% sensibility, 33.3% specificity, 85.1% positive predictive value, 40% negative predictive value, with 0.781 accuracy in diagnosing malnutrition. Using INR we obtained 61.5% sensibility, 33.3% specificity, 80% positive predictive value, 16.6% negative predictive value, with 0.562 accuracy in determining the correct nutritional status.
CONCLUSION: CONCLUSIONS: Using BMI and INR we can identify the cases of malnutrition with a good sensibility (60-90%), but they have a poor negative predictive value (16-40%), especially because of the presence of ascites, edemas and hypoalbuminemia which are modifing these 2 parameters.

P617 PROCALCITONIN AND MACROPHAGE INFLAMMATORY PROTEIN-1 BETA (MIP-1BETA) IN SERUM AND PERITONEAL FLUID OF PATIENTS WITH DECOMPENSATED CIRRHOSIS AND SPONTANEOUS BACTERIAL PERITONITIS

M. Lesińska[1,*], M. Hartleb[1], K. Gutkowski[1], E. Nowakowska-Duława[1]. [1]*Department of Gastroenterology & Hepatology, Medical University of Silesia, Katowice, Poland*

INTRODUCTION: Spontaneous bacterial peritonitis (SBP) is the most frequent infection in patients with cirrhosis causing significant mortality which requires rapid recognition for effective antibiotic therapy, whereas ascitic fluid cultures are frequently negative.
AIMS&METHODS: The aim of this study was to evaluate the SBP diagnostic efficacy of procalcitonin (PCT) and macrophage inflammatory protein-1 beta (MIP-1b) measured in serum and peritoneal fluid.
Thirty-two participants with liver cirrhosis and ascites were included into the study (11 females and 21 males, mean age 49,5 ±11,9 years). The peritoneal fluid and venous blood were collected for routine laboratory examinations and measurements of PCT and MIP-1b. Patients were divided into two groups according to the ascitic absolute polymorphonuclear leukocytes count (>250/mm^3 and <250/mm^3).
RESULTS: Ascites was sterile in 22 participants and SBP was diagnosed in 10 patients. Serum and ascitic levels of PCT and MIP-1b did not correlate with clinical and routine laboratory parameters. MIP-1b in the ascitic fluid was significantly higher in patients with SBP (213 +279 pg/ml vs 66,3 +49,8 pg/ml; p=0,01). The sensitivity and specificity for diagnosis of SBP with ascitic MIP-1b was 80% and 72,7%, respectively (cut-off value 69,4 pg/ml) with AUROC 0.77 (95%CI 0.58-0.96). Serum levels of MIP-1b showed lower diagnostic yield. Serum and ascitic PCT levels were not different in patients with and without SBP.
CONCLUSION: MIP-1b concentration in ascitic fluid may distinguish patients with and without SBP with satisfactory sensitivity and specificity. Chemokines should be further explored for diagnostic use.

P618 CO-EXISTENCE OF PANCREATIC AND LIVER DISEASE IN ALCOHOLICS: A PROSPECTIVE AND RETROSPECTIVE ANALYSIS

K. Romeo Singh[1], A. Das[2], K. K. Prasad[1], S. Appasani[1], J. Basha[1], M. Manrai[1,*], V. Singh[3], K. Singh[1], R. Kochhar[1]. [1]*Gastroenterology,* [2]*Pathology,* [3]*Hepatology, PGIMER, Chandigarh, India*

INTRODUCTION: On genetic basis co-existence of alcoholic pancreatitis (ALP) and alcoholic liver disease(ALD) was considered rare. Fibroscan and endoscopic ultrasound (EUS) have revolutionized fibrosis detection in liver and pancreas respectively.
AIMS&METHODS: ***AIM:*** To prospectively evaluate pattern of liver and pancreatic involvement prospectively using fibroscan and EUS and retrospectively on autopsy data in alcoholics.
MATERIALS & METHODS: Daily alcohol consumption was evaluated. Patients with BMI>40, HBV, HCV, HIV, gallstones and diabetes mellitus were excluded. In group A, 68 ALD patients (mean age 42yrs, all males) were classified as alcoholic hepatitis/cirrhosis based on signs of portal hypertension, biochemistry and imaging. Pancreatic parenchymal and ductal changes were characterized using Rosemont's classification on EUS. In group B, 70 symptomatic ALP patients with imaging features on USG/CT/EUS/ERCP were fibroscanned for liver stiffness and graded per protocol. In group |C autopsy specimens of liver and pancreas of 51 alcoholics(mean age=46yrs, all males) who died of alcohol related liver and pancreatic diseases from Jan 2008-Dec 2010 were analyzed.
RESULTS: Of 68 ALD patients (group A), 40%(27) had pancreatic involvement on EUS (chronic pancreatitis(CP)-7%, suggestive CP–12%, indeterminate CP-21%). Of 70 ALP patients (group B), 26(37%) had liver involvement on fibroscan (cirrhosis-6%, severe fibrosis-13%, significant fibrosis-19%). Altered liver function with raised bilirubin, AST, ALT, ALP and low albumin were observed in 23(30%), 39(51%), 24(32%), 27(35%) and 27(35%) patients

respectively. Of 51 autopsy patients (group C), 82%(42) had ALD and 18%(9) had ALP. Of these 42 ALD patients, 25(60%) had some form of pancreatitis (CP-31%, acute on CP-17% and acute pancreatitis-12%). Of these 9 ALP patients, 44%(4) had liver injury (fatty liver-33%, steatohepatitis-11%). There was no difference in age, type, frequency and pattern of alcohol consumption in both groups. Amount and duration of alcohol intake in ALD(211gm, 21yrs) was more than in patients with ALP(183gm, 13yrs)(p=0.038, p=0.003).

CONCLUSION: Our study shows that 37% ALP had evidence of liver disease on fibroscan and 40% ALD had evidence of pancreatic disease on EUS. High degree of co-existence of ALD and ALP (60%) was noted in our autopsy data. ALD patients consumed more alcohol and for longer periods than ALP. This is the first study of its kind.

P619 RISK FACTORS OF ARTERIAL OR VENOUS THROMBOEMBOLISM IN CIRRHOTIC PATIENTS

A. Laabidi[2], H. Baccouche[1], M. Fekih[2,*], N. Ben Mustapha[2], M. Serghini[2], J. Boubaker[2], N. Ben Romdhane[1], A. Filali[2]. [1]*Hoematology,* [2]*Gastroenterology "A", La Rabta hospital , El Manar Faculty, Tunis, Tunisia*

INTRODUCTION: Cirrhosis results in a complex pattern of defects in haemostatic functions with reduced synthesis of pro and anticoagulant factors. As possible complication of coagulation disorders in cirrhosis, could be the development of arterial or venous thromboembolism (AVTE). The purpose of our study was to determine thrombotic risk factors in cirrhotic patients.

AIMS&METHODS: Cirrhotic patients were enrolled. The presence of personal and familial history of AVTE was investigated. Patients were divided into 2 groups. Group1 included patients who developed arterial or venous thromboembolism after cirrhosis diagnosis and group 2 cirrhotic patients without thrombotic event. White blood cells, platelet count, prothrombine time, INR, albumin, urea, pro coagulant factors (VIII, XII, VII, II, V) were determined. Level of antithrombin, protein C and protein S were measured. Search for factor V Leiden and prothrombin gene mutation (G20210A) were performed with PCR-RFLP. Anticardiolipin and antiB2glycoprotein antibodies were also investigated. Both groups of patients were compared with regard of clinical and biological findings.

RESULTS: Fifty one cirrhotic patients were included. Their mean age was 56.8 years. They were men and women. Among the 51 cirrhotic patients, 7 (13.7%) had experienced AVTE after cirrhosis diagnosis: deep venous thrombosis (n=2), pulmonary embolism (n=1), Budd Chiari syndrome (n=1), portal thrombosis (n=3). They were compared to 46 cirrhotic patients without thrombosis. No patient with AVTE had neither personal nor familial history of thrombosis. In an univariate analysis, white blood cell count and platelet count were significantly higher in patients with AVTE than other cirrhotic patients (respectively 8795 vs 5032/mm^3,p $<$ 0.018 and 91133 vs 154375/mm^3, p=0.03) However,In a multivariate analysis only the platelet count was independently predictive of VTE in cirrhotic patients (P=0.05). Moreover, prothrombin time, INR, albumin, urea, level of pro and anticoagulant factors were not statistically different in both groups. There was no link between the presence of Factor VLeiden, prothrombin gene mutation (G20210A), anticardiolipin and antiB2glycoprotein antibodies to thrombosis.

CONCLUSION: Approximately 13.7% of cirrhotic patients resulted in a thromboembolic event. Platelet count was predictive of increased risk of AVTE as it was supported by other studies. Understanding the factors predisposing to thrombosis in cirrhotic patients could play a role in identifying a subgroup of patients at high risk of thrombosis and making decisions regarding the utility of anticoagulation therapy.

P620 CAN TERLIPRESSIN REDUCE ACUTE KIDNEY INJURY INCIDENCE IN PATIENTS WITH PORTAL HYPERTENSION AND ACUTE UPPER GASTROINTESTINAL BLEEDING?

R. Cardoso[1,*], A. R. Alves[1], T. Correia[1], P. Amaro[1], M. Ferreira[1], J. M. Romãozinho[1], C. Sofia[1]. [1]*Department of Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: Terlipressin is currently only approved for the treatment of variceal upper gastrointestinal bleeding (VB) and Hepatorenal Syndrome type I. There are no data regarding its use in the prevention of acute kidney injury (AKI) in patients with portal hypertension, namely in the context of non-variceal upper gastrointestinal bleeding (NVB).

AIMS&METHODS: AIM: To determine if the use of terlipressin in patients with VB reduces the incidence of AKI as compared with patients with portal hypertension and NVB.

METHODS: All patients with portal hypertension and NVB admitted to a Gastrointestinal Intensive Care Unit during a 5-year period were included (NVB group). Patients with VB treated in the same unit with terlipressin in the same time frame were randomly selected for the VB group. The criteria used for AKI were a rise of serum creatinine of $>$50% compared with the value at admission or a rise of $\geq$0.3 mg/dl in less than 48 hours.

RESULTS: Seventy-five patients were recruited (NVB group: 25; VB group: 50). There were no significant differences between groups regarding sex (males: 72% vs. 68%), age (mean age: 60.8 vs. 59.0 years), severity of hepatic disease (Child-Pugh Class C: 52% vs. 32%, p = 0.094) or magnitude of bleeding (initial hemoglobin value 7.6 vs. 8.7 g/dL, p = 0.067). Patients with NVB had a significantly higher initial creatinine value than those with VB (1.42 vs 0.88 mg/dL; p $<$ 0.001).Even though AKI incidence was very low (5 patients in both groups combined), it was significantly greater in those with NVB (16% vs. 2%, p = 0.04).

CONCLUSION: The low incidence of AKI in our sample is probably related to the admission to a dedicated intensive care unit and stresses the importance of treating patients with portal hypertension and upper gastrointestinal bleeding in this setting, irrespective of its cause. The use of terlipressin in the VB group was associated with a lower incidence of AKI. However, the reduced sample size and heterogeneity between groups may have played a significant role in the results and thus a prospective validation of these findings is justified.

P621 A NEW SCORE FOR PREDICTING THE MORTALITY IN CIRRHOTIC PATIENTS WITH INFECTIONS

S. Bota[1,*], I. Sporea[1], R. Sirli[1], A. Popescu[1], F. Bende[1], C. Popescu[1], T. Moga[1], C. Ivascu-Siegfried[1], M. Danila[1], D. Suseanu[1], A. Martie[1], M. Sendroiu[1]. [1]*Gastroenterology and Hepatology, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania*

INTRODUCTION: Liver cirrhosis is a disease with lots of complications, infections being common in these patients.

AIMS&METHODS: Aim: to assess the factors correlated with mortality in cirrhotic patients with infections and to obtain a new score for predicting the mortality in these patients.

Methods: Our retrospective study included 170 episodes of infection in 141 cirrhotic patients admitted in our Department between January 2011-December 2012. We performed univariant analysis to evaluate the correlation of the following parameters (obtained at admission) with mortality: age, gender, Child-Pugh score, MELD score, AST, ALT, total bilirubin, direct bilirubin, INR, blood nitrogen urea (BUN), serum creatinine, serum Na, serum K, albumin, prothrombin time, serum cholinesterase, hemoglobin, white blood count and platelet count. The factors correlated with mortality in univariant analysis were included in multiple regression analysis in order to create a new score for predicting mortality in cirrhotic patient with cirrhosis.

RESULTS: In our cohort of cirrhotic patients with infections, 20/141 (14.1%) died during hospitalization. In univariant analysis, the following factors were correlated with mortality: BUN (r=0.342, p$<$0.0001), serum creatinine (r=0.285, p=0.002), MELD score (r=0.260, p=0.001), white blood count (r=0.248, p=0.001) and INR (r=0.216, p=0.007), while the following factors were not correlated with the mortality: age (r=-0.059, p=0.43), gender (r=-0.025, p=0.76), Child-Pugh score (r=0.116, p=0.14), AST (r=0.053, p=0.45), ALT (r=0.022, p=0.77), total bilirubin (r=0.072, p=0.35), direct bilirubin (r=0.188, p=0.06), serum Na (r=0.029, p=0.70), serum K (r=0.083, p=0.28), serum albumin (r=-0.121, p=0.16), prothrombin time (r=-0.134, p=0.09), serum cholinesterase (r=0.013, p=0.87), hemoglobin (r=-0.150, p=0.06) and platelet count (r=-0.031, p=0.68).

Using multiple regression analysis the following score was obtained: **Prediction mortality in infected cirrhotic patients (PMIC)**: -0.125+0.005xcreatinine (mg/dl) + 0.02xINR+ 0.0015xwhite blood count/1000 (cells/mm^3) + 0.0005xMELD + 0.002xBUN (mg/dl).

For a cut-off value $>$0.120, PMIC score had 86.7%Se, 77.9% Sp, 30.2% PPV, 98.1% NPV and 78.8% accuracy (AUROC=0.854, p=0.0001) for predicting mortality in cirrhotic patients with infections.

CONCLUSION: PMIC score had a good accuracy and an excellent NPV for predicting mortality in cirrhotic patients with infections.

P622 EVALUATION OF PORTAL HYPERTENSIVE DOPPLER PARAMETERS IN PATIENTS WITH PERIPORTAL BILHARZIAL HEPATIC FIBROSIS

H. Ali[1,*], S. F. Ahmed[2], M. A.-E. Al-Senbesy[2], M. S. Badawy[3]. [1]*Tropical medicine and Gastroenterology,* [2]*internal medicine ,* [3]*Chest department, Qena faculty of medicine, Qena, Egypt*

INTRODUCTION: Schistosomiasis is the third most devastating tropical disease in the world and is a major source of morbidity and mortality in developing countries.

AIMS&METHODS: Aim: To assess portal hypertensive Doppler parameters; using color Doppler ultrasonography, in patients with bilharzial hepatic periportal fibrosis. **Patients and Methods**: This case/ control study included 50 patients; 44 males and 6 females with their mean age 34± 9 years and 40 subjects as a control group. Diagnosis of bilharziasis was established by history, examination and investigations. Patients were classified into patients with fine and thick periportal fibrosis (PPF) by abdominal US. All included subjects underwent hepatosplenic Color Doppler Ultrasonographic examination.

RESULTS: No statistically significant differences in portal vein diameter (PVD), portal vein velocity (PVV) and portal vein flow volume (PVFV) between patients and control. Patients with thick PPF showed statistically significant higher values in PVD (P value= 0.001) and PVFV (P value= 0.05) than those with fine PPF. Congesion index of the portal vein (CI) was significantly higher in patients than

control (P value= 0.001), also in patients with thick than those with fine PPF (P value= 0.000). Statistically significant higher values of splenic vein diameter (SVD) (P value=0.026), splenic Index (SI), splenoportal index (SPI) (P value=0.000) were detected in patients than control, also in patients with thick than those with fine PPF (P value= 0.000).
CONCLUSION: Color Doppler portal hypertensive parameters are greater in patients with more advanced bilharzial hepatic periportal fibrosis.

P623 IL-28B POLYMORPHISM IS A PREDICTIVE FACTOR FOR SUSTAINED VIRUOLOGICAL RESPONSE, INSULIN RESISTANCE AND HEPATIC STEATOSIS IN CHRONIC HEPATITIS C INFECTION

C. Radu[1,2,*], M. D. Grigorescu[1,2], D. Crisan[2], D. Damian[2], P. Szanto[1,2], A. Habic[2], M. Grigorescu[1,2], First two authors equaly contributed to this study. [1]*"Iuliu Hatieganu"University of Medicine and Pharmacy,* [2]*Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca, Romania*

INTRODUCTION: Sustained virologic response (SVR) in patients with chronic hepatitis C (CHC) depends on several factors. One of the most investigated was single nucleotide polymorphism (SNP) of IL-28B gene (rs12979860) important even in the new era of the triple therapy.
AIMS&METHODS: The aim of the study was to evaluate the role of IL-28B polymorphism on SVR, and the association of these polymorphisms with insulin resistance (IR) and hepatic steatosis in naive patients with CHC treated with peginterferon plus ribavirin(Peg IFN si RBV).
One hundred and three non-diabetic CHC patients with liver biopsy proven CHC genotype 1 were studied. The SNPs rs12979860(IL-28B) were investigated by RT-PCR. Insulin resistance (HOMA-IR) stages of fibrosis and degrees of steatosis were also evaluated. SVR and rate of relapse were assessed for each polymorphism of IL-28B.
RESULTS: According to IL-28B polymorphysms SVR was obtained as follows: 89.6% for genotype CC, 55.7% for genotype CT and 23,0% for genotype TT. The rates of relapse were 10.3%, 44.3%, 76.9% for before mentioned genotypes. IR was lower in CC genotype (1.81±0.88) compare to CT (3.7±2.75) and TT genotypes (4.2±2.78), $p < 0.0001$. T allele carriers had a higher frequency of IR irrespective of stages of fibrosis. Cholesterol levels in IL-28B CC genotype were higher (265.2±57.6 mg%) than in genotypes CT (187.1±43.5mg%) or TT (210±57.4 mg%), $p < 0.005$, and degree of steatosis was lower in patients with CC genotype (p=0.015). In multivariate analysis IL-28B CC genotypes and stages of fibrosis were independent predictors of SVR.
CONCLUSION: Apart from the predictive role of SVR in patients with CHC treated with PegIFN plus RBV double therapy, IL-28B CC genotype was associated with the degree of IR and hepatic steatosis. In our study, IR do not undermine the advantage of IL-28B polymorphism.

P624 INCREASED CYTOTOXIC POTENTIAL OF CD160 RECEPTOR POSITIVE NATURAL IMMUNE CELLS IN CHRONIC HCV INFECTION

G. Par[1,*], C. Odpadlik[2], B. Koszegi[3], A. Czeh[3], A. Par[1], A. Barakonyi[2,4]. [1]*First Department of Medicine,* [2]*Department of Medical Microbiology and Immunology, Clinical Centre, University of Pecs,* [3]*Soft Flow Hungary Ltd,* [4]*János Szentágothai Research Centre, Pécs, Pecs, Hungary*

INTRODUCTION: Since innate immune cells are uniquely enriched in the inflammatory cell infiltrate of HCV infected liver, the importance of these innate cells in the pathogenesis of liver inflammation emerges. Altered natural killer (NK) cell activity in chronic HCV infection is still controversial, since both impaired and intact NK cell function have been described. Activation of CD160 receptor causes strong cytotoxic activity and Th1 type pro-inflammatory cytokine production in NK cells. Very little information is currently available about the expression pattern and function of CD160 receptor in innate immune cells during chronic HCV infection.
AIMS&METHODS: In our study we analyzed cytotoxic characters of different CD160 receptor positive (CD160+) natural immune cells during chronic HCV infection.We investigated the expression of Fas molecule (a marker of susceptibility to apoptosis), TIM3 (a marker of Th1 phenotype) and intracellular cytotoxic granule content (perforin, granzyme) of peripheral blood CD160+ gamma/delta T cells, NK cells and invariant NKT (iNKT) cells by Flow Cytometry in 10 patients with chronic HCV hepatitis and in 12 healthy controls.
RESULTS: TIM3 expression and cytolytic granule content of CD160+ gamma/delta T cells were significantly enhanced in chronic HCV infection compared to controls. The CD160+ iNKT cells had also increased TIM3 expression but did not show elevated cytotoxic potential. The perforin expression of the CD160+ NK cells was also significantly higher in chronic HCV hepatitis compared to healthy controls. HCV infection was associated with elevated expression of Fas molecule on CD160+ iNKT lymphocytes, but the susceptibility to apoptosis of CD160+ gamma/delta T cells and CD160+ NK cells did not differ from control.
CONCLUSION: Our results suggest that chronic HCV hepatitis is associated with increased cytotoxic granule content of CD160+ NK, CD160+ gamma/delta T cells and Th1 phenotype of CD160+iNKT cells. These innate immune cells infiltrating the liver might induce inflammatory cytotoxic response and contribute to the pathogenesis of chronic HCV hepatitis. Therapeutic strategies modifying innate immune cell function may be of benefit for limiting intrahepatic inflammatory process and liver injury.

P625 NUCLEOTIDE SUBSTITUTIONS IN THE HEPATITIS E VIRUS GENOME: A PRIME AGENT IN ACUTE LIVER FAILURE

J. Borkakoti[1,*], G. Ahmed[2], P. Kar[1]. [1]*Medicine, Maulana Azad Medical College, Delhi,* [2]*Biotechnology, Gauhati University, Guwahati,Assam, India*

INTRODUCTION: Previous studies suggest that the genotype of Hepatitis E virus influences the severity of hepatitis E. Viral capsid proteins play extensive role in interacting cellular proteins during capsid assembly and virus entry. Studies at the molecular level of the capsid protein of the HEV genome are hence warranted.
AIMS&METHODS: We aimed to scrutinize the molecular alterations in the HEV genome in patients with acute liver failure and acute viral hepatitis.A total of 28 patients with acute liver failure and 155 patients with acute viral hepatitis were screened for the study during the years 2010-2012. HEV IgM was detected by anti HEV IgM ELISA. HEV RNA was detected using Viral RNA extraction kit. The Open Reading Frame 2(ORF 2) region of the HEV genome was amplified using Reverse Transcriptase PCR. Representative samples were directly sequenced. Full length nucleotide sequences of HEV isolates were retrieved from the Gen Bank /EMBL/DDBJ databases and compared with the strains. Sequences were aligned by CLUSTAL W software.
RESULTS: The mean age of the AVH and ALF patients were 23.9 ± 3.71 years and 24.6±3.33 years respectively. HEV RNA was detected in 84 (54.19%) AVH and 22 (78.57%) ALF patients respectively. A total of 15 nucleotide substitutions at various positions of the ORF 2 were observed after aligning the obtained sequence of 5 ALF patient with the other reference sequences. The nucleotide substitutions obtained were mainly silent substitutions with some conserved substitutions with only one amino acid change from Lysine to Cysteine
CONCLUSION: The single amino acid substitution and the silent substitutions may be associated with the poor outcome in ALF patients. Substitutions covering these regions may play crucial role in enhancing HEV replication through interactions with other proteins thus leading to disease severity.

P626 EXPRESSION OF IL-21 IN CHRONIC HEPATITIS B VIRUS INFECTION

J. Yao[1,*], K. Chao[1], M. Chen[1], B. Zhong[1]. [1]*the First Affiliated Hospital of Sun Yat-sen University, Guanghzou, China*

INTRODUCTION: Interleukin-21, as a multifunctional immunoregulator playing a role in control of chronic viral infections, is prospective in the antiviral therapy and vaccine preparation. The role of IL-21 in hepatitis B virus (HBV) infection is not understood.
AIMS&METHODS: The main purport of this study is to confirm the relationship between IL-21 and chronic HBV infection. Serum IL-21 levels collected from chronic HBV-infected patients and healthy controls were measured by Cytometric Bead Array (CBA). IL-21 mRNA and IL-21 receptor mRNA was measured by real-time PCR. Meanwhile, HBV-DNA and liver function were tested.
RESULTS: (1) A total of 79 chronic HBV-infected patients, including 34 patients with chronic hepatitis B (CHB), 19 HBV carriers and 24 patients with HBV related cirrhosis, and 25 healthy controls were involved, with no obvious difference of age or gender. (2) Serum IL-21 level in chronic HBV-infected patients was higher than in healthy controls (57.80±31.23 pg/ml *vs*. 31.90±12.48 pg/ml, $P < 0.001$). (3) Serum IL-21 level in the group of CHB (70.67±28.41 pg/ml) was also higher than in the groups of HBV carriers (26.52±10.13 pg/ml) and healthy controls (31.90±12.48 pg/ml) (both $P < 0.001$), but not higher than group of HBV related cirrhosis (63.83±29.93 pg/ml) (P=0.425). Serum IL-21 level in the group of HBV related cirrhosis was higher than in the groups of HBV carriers and healthy controls (both $P < 0.001$). Meanwhile, there were no significant differences between group of HBV carriers and healthy controls (P=0.138). (4) Considering the different statements of CHB, the group of CHB was divided into three subgroups, mild-CHB, moderate-CHB and severe-CHB, including 16, 12, 6 patients respectively, yet there was no difference of serum IL-21 levels among the three subgroups (P=0.204). (5) A total of 79 chronic HBV-infected patients were divided into to two groups according to HBeAg, HBeAg-positive group and HBeAg-negative group, 25 and 53 patients for each, yet there was no difference of serum IL-21 levels among the two subgroups (P=0.756). (6) mRNA of IL-21 in the group of HBV related cirrhosis was higher than in the groups of HBV carriers and healthy controls (both $P < 0.001$), and mRNA of IL-21 in the group of CHB was higher than the groups of HBV carriers (P=0.041). (7) mRNA of IL-21 receptor in the group of CHB was higher than in the groups of HBV related cirrhosis, HBV carriers and healthy controls (P=0.032, P=0.001, $P < 0.001$, respectively). (8) Serum IL-21 levels had no association with gender, age, HBV-DNA level and other clinical characteristics.
CONCLUSION: The up-regulation of serum IL-21 levels may related to chronic HBV infection, and the mechanisms have to be studied further.

P627 RS2230201 POLYMORPHISM MAY DICTATE COMPLEMENT C3 LEVELS AND RESPONSE TO TREATMENT IN CHRONIC HEPATITIS C PATIENTS

S. J. Chowdhury[1,*], V. K. Karra[1], P. K. Gumma[1], R. Bharali[2], P. Kar[1].
[1]*Medicine, Maulana Azad Medical College, New Delhi,* [2]*Biotechnology, Gauhati University, Gauhati, India*

INTRODUCTION: Complement is a group of serum proteins which participate in antigen antibody reactions leading to irreversible cell damage and eventually lysis. The serum concentration of C3 closely reflects the total complement activity. Individuals affected by C3 deficiency, often manifestation of SNP, suffer from recurrent pyogenic infections.
AIMS&METHODS: This study aims to find out if there is any relation between chronic hepatitis C infection and levels of C3 in serum.The study included 132 chronic hepatitis C (CHC) patients out of which 48 obtained conventional IFN+Ribavirin. Control groups comprised of 81 healthy blood donors who did not have any history of liver disorders. C3 levels in serum were determined utilizing commercially available kit. Genotyping of SNP was done by Allele-specific PCR.
RESULTS: Out of 132 chronic hepatitis C patients included 81 were males (61.36%) and 51 were females (38.63%) with mean age±S.D. of 35.11±11.40 years. Out of 81 healthy controls included in the study 48 were males (59.26%) and 33 were females (40.74%) with mean age±S.D. of (37.34±15.2). C3 Level of the healthy group was 88.5±19 mg/dl whereas that of the CHC group was 56±18 mg/dl ($p<0.01$) indicating lowering of C3 during CHC. 9 out of 12 non-responders were CT-genotypes and 33 out of 36 responders were CC genotype. It was observed that patients carrying rs2230201 heterozygous CT allele had an increased risk of not attaining sustained virological response after being administered conventional interferon + Ribavirin (p=0.00041). It was observed that before initiation of treatment there was no significant difference between the mean viral loads of CT and non CT allele carrying patients (p=0.25) but significant variation was observed after treatment (p=0.0011). The CT genotype of rs2230201 was found to be associated with decreased C3 levels when compared to other allele in CHC group (CT=**48±14** mg/dl, CC=59±15 mg/dl, TT=61±10.4 g/dl; P=**0.00046**, F=8.14).
CONCLUSION: This is the first study that attempts to co-relate the C3 levels and the single nucleotide polymorphism that influences its expression in chronic hepatits C infection and also its relation to treatment.The significant difference between the chronic hepatitis C patient and healthy control C3 level indicates that there is reduction in C3 levels during CHC and the rs2230201 CT allele is associated with lowered C3 expression during infection and subsequently resulting in significantly increased fraction of SVR failures in therapy group. Hence C3 levels should be included as one of the factor monitored during hepatitis C infection and its SNP rs2230201 included as predictor of treatment response.

P628 ALCOHOLIC LIVER DISEASE: THE PRESENTATION FEATURES AND CLINICAL SIGNIFICANCE OF VIRUS B INFECTION IN HOSPITALIZED PATIENTS WITH ALCOHOLIC CIRRHOSIS

A. Babameto[1,*], E. Elezaj[2], V. Demiraj[3]. [1]*Gastroenterology & Hepatology, University Hospital center "Mother Theresa",* [2]*Gastroenterology & Hepatology, Specialities Polyclinic ,* [3]*Emergency Department, University Hospital Center "Mother Theresa", Tirana, Albania*

INTRODUCTION: Alcoholic liver disease(ALD)remains one of the major causes of morbidity and mortality in the world. In Western countries alcohol is responsible for approximately 40-80% of the alcoholic cirrhosis. In fact 25% of the alcoholics people develop ALD. Patients with liver cirrhosis, are often infected with B or C virus, which can change the clinical course of the disease.
AIMS&METHODS: To evaluate the epidemiological, clinical and laboratoric patterns of ALD, also seroprevalence of B and C virus and their impact over the clinical profile of the hospitalized patients with alcoholic liver cirrhosis. A descriptive study was performed in 170 patients with confirmed diagnosis of alcoholic liver disease, age 51.56 ± 8.15 (range 28 – 72),The data collected for each patients were: Use frequency of alcoholic drinks, kind of the drink, daily amount and the time of use. For all the patients were done: serological markers of hepatitis B and C, Child-Pugh classification. All the patients were devided in two groups according to the etiology, (with or without the viral infection) and according to the clinical forms (liver cirrhosis, alcoholic hepatitis and steatosis of the liver).
RESULTS: Virus B infection was found in 17.14% of the cases and all these cases were liver cirrhosis. It was found significant change between liver cirrhosis and alcoholic hepatitis related to the diagnostic time (p=0.05) and the age (p=0.008). In clinical examination we found jaundice more in alcoholic and viral forms (p=0.037), haemorrhagic diatesis (p=0.04) and ascites (p=0.02). We don't found significant change related to the Child-Pugh classification. For the etiological forms, with and without virus B infection there were significant changes related to the total bilirubin ($p< 0.05$), AST(p=0.013), ALT (p=0.045), total protein (p=0.001), albumin (p= 0.01), globulin (p=0.04), kreatinine (p=0.01). In total was found significant correlation through use of alcoholic drinks and ALD forms : for daily use r= -0.09, time of use r= - 0.06, frequency r= -0.09 and Child-Pugh. (daily use r= 0.06, time of use r= 0.18 and frequency r= -0.33). At the group with liver cirrhosis, 96.6 % had used alcoholic drinks over a 5 years period, in steatosis 66.7% and alcoholic hepatitis 80% (p=0.01).
CONCLUSION: The virus B infection is frequently found in patients with ALD. This infection may agravate the clinical course of the patients with ALD and jaundice, increase of ALT/AST, also significant changes of the total protein, albumin and creatinine are most common in the patients with Virus B superinfection.

P629 A MATHEMATICAL MODEL FOR CLASSIFYING CHRONIC HEPATITIS C EGYPTIAN PATIENTS AS EASY AND DIFFICULT TO TREAT

A. Khairy[1,*], A. Awad[2], M. Mabrouk[1], N. Zayed[1], W. El-Akel[1], M. Seif[1].
[1]*Endemic Medicine Department, Faculty of Medicine, Cairo University,* [2]*Comuter Science Department, Faculty of computers and information, Cairo University, Cairo, Egypt*

INTRODUCTION:
Egypt has the largest burden of HCV infection in the world. Current therapy is associated with adverse events in addition to the high cost and sub-optimal response. Data mining can explore tremendous volumes of data to discover hidden patterns and relationships in highly complex dataset and thus can enable the development of predictive models.
AIMS&METHODS: To develop a mathematical model for prediction of therapeutic outcome in chronic HCV genotype-4 patients using routine pretreatment data.
This cross sectional nationwide study included retrospective data of 3719 chronic HCV patients who had received PEG-IFN/RBV therapy at Cairo-Fatemia Hospital, Egypt. Factors predictive of SVR were explored using data mining analysis. Weka implementation C4.5, classification and regression tree (CART), Fast decision tree learner (FDTL) were constructed using the pretreatment patients' data (19 attributes).
RESULTS: The estimated SVR was 52.5%. Out of 19 attributes, the applied decision-tree models showed that serum AFP ≥4.7 ng/ml (most decisive), alanine transferase (ALT) >1.74 folds upper limit of normal (ULN), serum albumin level <4g/L, body mass index (BMI) >25.5kg/cm^2, and female gender were associated with unfavorable response. This was further confirmed using multivariate logistic regression analysis. A model including these five variables was significantly associated with failure of response ***(Table 1)*** with sensitivity 0.66, specificity 0.71, PPV 0.62 and NPV 0.75($P<0.01$).
Table(1): Scoring system to predict response to interferon/ribavirin according to number of unfavourable variables.

Number of unfavorable factors	Response	Non response	Total	P value
0-2	1097(75.2%)	361(24.8%)	1458 (100%)	<0.01 (S)
3	591(64.5%)	257 (30.3%)	848 (100%)	
4-5	182 (54.5%)	318 (45.5%)	500 (100%)	

CONCLUSION: The proposed model involving female gender, BMI>25.5kg/cm2, AFP≥4.7ng/ml, ALT>1.74 folds ULN, and serum albumin<4g/L was significantly related to unfavorable response and thus could identify difficult to treat among chronic HCV Egyptian population. This model has the prospective to support clinical decisions regarding the proper selection of patients for therapy (based on a possibility of response), without imposing extra costs.

P630 DIFFERENT PRACTICE IN THE PATIENTS MANAGEMENT OF HEPATITIS B VIRUS (HBV) IN EGYPT

E. F. Moustafa[1], S. M. Hassany[1,*]. [1]*Tropical Medicine & Gasroenterology, Assiut University- Egypt, Assiut, Egypt*

INTRODUCTION: Hepatitis B virus (HBV) infects more than 300 million people worldwide and is a common cause of liver disease and liver cancer. HBV infection leads to a wide spectrum of liver disease ranging from acute (including fulminant hepatic failure) to chronic hepatitis, cirrhosis, and hepatocellular carcinoma.
AIMS&METHODS: To assess the different patterns of Egyptian physicians practices in management of patients with HBV infection, and evaluate their knowledge about the disease from different aspects including; epidemiology, knowledge to screening and treatment guidelines. The study included 350 physicians of different age groups, specialties and from different hospitals which distributed all over Egypt that treat patients with HBV infection. All physicians have filled a questionnaire this questionnaire was specially prepared for Egyptian physicians to evaluate their practice and knowledge about management of patients with HBV.
RESULTS: ***Awareness to epidemiology of the disease***: There are significant difference with hospital type and knowledge of physicians in these hospitals about epidemiology of HBV ($P>0.05$). ***Availability of educational resources***

and awareness to national guidelines: There is a significant difference with physician specialty and availability of local guidelines for management of HBV infection, local records or registries of HBV cases under care of doctors and also, significant difference with specialty as regard awareness to national HBV treatment guidelines ($P<0.05$). ***Knowledge about HBV screening and coinfection:*** As regard physician specialty there are no significant differences between all groups (Internal medicine, Tropical& Gastroenterology and Family medicine, GP& others), there is no significant difference in testing the spouse for infection and screening for HBV infection. As regard hospitals type, there are no significant differences between all groups in testing the spouse for infection and screening for HBV infection. ***Investigations have been done before starting therapy:*** As regard physician specialty and Hospital types, there are no significant differences between groups in investigations done before starting therapy. ***Knowledge about treatment:*** There is a significant difference in routes of management of patient with decompnsated liver disease according to the type of hospital which doctor work in.

CONCLUSION: There is an accepted percent of knowledge to the epidemiology of the disease, national guidelines, with better knowledge to doctors who work in university hospitals. Most of the Egyptian physicians don't have local guidelines in their hospitals.

P631 CLINICAL SIGNIFICANCE OF CO-INFECTION WITH HEPATITIS B.VIRUS AND HUMAN T-CELL LYMPHOTROPIC VIRUS TYPE 1

K. Michitaka[1,*], R. Fujikata[2], K. Kitoh[2], T. Tsuruoka[2], A. Hiraoka[1], Y. Kazatani[3], K. Nakamura[3]. [1]*Gastroenterology Center, Ehime Prefectural Central Hospital, Matsuyama,* [2]*Ehime Prefectural Minamiuwa Hospital, Minamiuwa-gun,* [3]*Ehime Prefectural Central Hospital, Matsuyama, Japan*

INTRODUCTION: Little information is available on the co-infection with hepatitis B virus (HBV) and human T-cell lymphotropic virus type1 (HTLV-1).

AIMS&METHODS: The purpose of this study was to determine the clinical significance of co-infection with HBV and HTLV-1. Data of 9838 patients screened for both HBV and HTLV-1 were extracted from a database at a hospital in South-West Japan, where both HBV and HTLV-1 are prevalent. Screening of HBV and HTLV-1 was performed with hepatitis B surface antigen and anti-HLTV-1, respectively. Laboratory data of patients in relation to these viral markers, especially data of patients co-infected with HBV and HTLV-1 and those infected with only HBV, were studied. Data were shown as median and range (min-max). This study was conducted respectively.

RESULTS: Among 9838 patients, 44 (0.4%) were positive for both viruses (group A). 305 (3.1%) were positive for HBV alone (group B), 833 (8.4%) were positive for HTLV-1 alone (group C), and 8656 (88.0%) were negative for both (group D). Group C included patients with a higher age than in the other groups, however, no significant age difference was found between group A (median age, 60 years; range, 37-93 years) and B (median age, 60 years; range 19-94 years). No difference in the aspartate aminotransferase (AST; IU/L) and alanine aminotransferase (ALT; IU/L) levels were found between groups A and group B (AST: 25, 6-208 vs. 24, 9-2966; ALT: 20, 9-391 vs. 23, 4-4079, respectively). The albumin, white blood cells, and platelet count did not differ between groups A and B. Among the 44 patients in group A, 5 patients died of diseases not associated with HBV or HLTV-1 infection. Hepatitis B e antigen (HBeAg), HBV-DNA, and HBV genotype were tested in small numbers of patients. In groups A and B, the number of patients positive for HBeAg (1/18 vs. 0/13) and HBV-DNA levels (2.6 log copies/mL, 0-8.1 log copies/mL, and 2.7 log copies/mL, 0-7.3 log copies/mL) did not differ significantly. The HBV genotype was similar between groups A and B (genotype A:B:C = 0:1:9 and 1:1:11, respectively).

CONCLUSION: No significant differences were found in the laboratory data between patients co-infected with HBV and HTLV-1 and those with HBV infection alone. A limited clinical significance of co-infection with HBV and HTLV-1 was found.

P632 ANTIHBS TITERS AFTER HEPATITIS B VIRUS VACCINATION DETERMINES THE DURATION OF THE IMMUNIZATION IN CHRONIC KIDNEY DISEASE PATIENTS

S. Aoufi Rabih[1,*], R. García Agudo[2], H. F. Guzmán Ames[3], P. González Carro[4], F. Pérez Roldán[4], E. Trinidad[3], J. M. Tenías Burillo[5], Working Group of the Spanish Association of Liver and Kidney. [1]*Hepatorenal Unit, Gastroenterology and Hepatology Department,* [2]*Hepatorenal Unit, Nephrology Department, Complejo Hospitalario La Mancha Centro,* [3]*Asyter Hemodialysis Unit,* [4]*Hepatorenal Unit, Gastroenterology and Hepatology Department,* [5]*Investigation Unit, Complejo Hospitalario La Mancha-Centro, Alcázar de San Juan, Ciudad Real, Spain*

INTRODUCTION: The response to vaccination against the hepatitis B virus (HBV) is poor in chronic kidney disease (CKD) patients.

AIMS&METHODS: The aim of this study was to evaluate the response to vaccination against HBV and the duration of the immunization in CKD patients after two cycles of 40 mcg doses of conventional vaccine and a cycle of 20 mcg doses of adjuvanted vaccine in non-responders at 0, 1, 2 and 6 months. AntiHBs titers were analyzed one month after each dose and at 3, 6 and 12 months of the end of each cycle.

RESULTS: We recruited 301 patients (221 patients in predialysis and 80 on hemodialysis). The 56.7% of patients responded to the first vaccination cycle, rising to 78.8% to 97.6% after the second and the third. Age and CKD were significantly associated with the response to vaccination. Immunization remained in 96.3% at 3 months, 87.9% at 6 months and 66% at 12 months after the first cycle; after the second cycle, it remained at 100% at 3 and 6 months and at 50% at 12 months; and at 100% at 12 months after the third cycle. Correlation was found between antiHBs titers and the immunization achieved and maintained at 3, 6 and 12 months. Only patients reaching antiHBs titers of 500-600 mIU/ml maintained immunization at 3 and 6 months; patients with antiHBs greater than 800 mIU ml were immunized at 12 months.

CONCLUSION: HBV vaccination with two cycles of four double doses of conventional vaccine and a cycle of four doses of adjuvanted vaccine achieves immunization for most CKD patients. Higher antiHBs titers after vaccination determines a more durable immunization.

P633 THE HLA-G 14-BASE PAIR DELETION ALLELE AND THE DELETION/DELETION GENOTYPE ARE ASSOCIATED WITH DIFFERENT FORMS OF EVOLUTION OF CHRONIC HEPATITIS B INFECTION

S. D. C. Ferreira[1,*], S. G. F. Chachá[1,2], F. F. Souza[1], A. C. Teixeira[1], N. H. S. Deghaide[1], R. D. C. Santana[1], C. T. Mendes-júnior[3], S. Zucoloto[4], E. A. Donadi[1], A. D. L. C. Martinelli[1]. [1]*Department of Internal Medicine, Faculty of Medicine of Ribeirão Preto - University of São Paulo, Ribeirão Preto,* [2]*Department of Internal Medicine, Federal University of São Carlos, São Carlos,* [3]*Departamento de Qúimica, Faculdade de Filosofia Ciências e Letras de Ribeirão Preto - FFCLRP - USP,* [4]*Department of Pathology, Faculty of Medicine of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil*

INTRODUCTION: *HLA-G* has well-recognized immunomodulatory properties, and the molecule is frequently expressed in the liver of hepatitis B virus (HBV) infected patients.

AIMS&METHODS: Since the *HLA-G* 14 bp-insertion/deletion polymorphism has been associated with the magnitude of *HLA-G* expression we evaluated the association between this polymorphism and different forms of evolution of chronic HBV infection and susceptibility to chronic HBV infection**.** We studied 196 chronic HBV infected patients (118 HBeAg-negative, 53 HBeAg-positive and 25 inactive carriers) followed at the University Hospital, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil, and 201 healthy controls from the same geographic area. *HLA-G* typing was performed using PCR-amplified DNA hybridized with specific primers. It was considered as inactive carriers those patients showing low levels of serum HBVDNA (<2000 UI/ml, b-DNA, Bayer) and persistently normal ALT levels.

RESULTS: The frequencies of I/D and I/I genotypes were not different comparing HBV patients to healthy controls ($P> 0.05$). On the other hand the frequency of allele D was significantly higher in HBeAg-positive chronic hepatitis compared to HBeAg-negative chronic hepatitis; [P=0.0460; OR=1.26; 95%CI=1.01-1.45]. Similarly the frequency of genotype DD was significantly higher in HBeAg-positive chronic hepatitis compared to HBeAg-negative chronic hepatitis; [P=0.0356; OR=2.08; 95%CI=1.05-4.09]. No differences were observed when HBV inactive carriers were compared to HBeAg-negative chronic hepatitis.

CONCLUSION: We showed an association between the presence of allele D and genotype DD of 14 bp of the*HLA-G* and HBeAg-positive chronic hepatitis B. The 14bp deletion allele has been associated with increased HLA-G production and in this way may influence the host immune response to the viral infection and the natural history of the infection.

P634 A META-ANALYSIS ON THE EFFICACY OF TENOFOVIR IN THE TREATMENT OF HEPATITIS B IN HIV CO-INFECTED PATIENTS

S. J. C. Bellido[1,*], I. H. Y. Cua[1]. [1]*Institute of Digestive and Liver Diseases, St. Luke's Medical Center, Quezon City, Philippines*

INTRODUCTION: *Patients with Hepatitis B coinfected with HIV have significantly more elevated serum HBV DNA levels with accelerated fibrogenesis and decompensation, giving them poorer prognosis. Studies on the efficacy of Tenofovir in Hepatitis B and HIV coinfection are mostly retrospective and observational, while existing randomized controlled studies are few with small sample size. This meta-analysis aims to study the efficacy of Tenofovir in the treatment of HIV-HBV coinfection by consolidating the results of the small trials.*

AIMS&METHODS: *This meta-analysis aims to study the efficacy of Tenofovir in the treatment of HIV-HBV coinfection by consolidating the results of the small trials.We selected randomized controlled studies comparing efficacy of Tenofovir versus control in the treatment of Hepatitis B-HIV coinfection, measuring the following outcomes: mean change in the HBV DNA level, number of patients with undetectable HBV DNA level, normalization of ALT and HBeAg seroconversion at the end of 48 weeks. The quality of each study included was assessed by two independent reviewers and data was analyzed using Review Manager version 5.*

RESULTS: *Fifteen studies from the search were collected. Three studies, with a total of 79 patients, met the inclusion and exclusion criteria, as well as the quality scale assessment. The studies included were homogenous. The results show a trend favoring the use of Tenofovir in the treatment of Hepatitis B-HIV coinfection, with a mean difference of -1.74 log_{10} copies/ml (CI 1.30 - 2.18, p-value < 0.00001) from baseline in the HBV DNA level. HBV DNA levels were found to be undetectable in*

42 (53%) patients using Tenofovir [RR 3.19 (CI 1.42 – 7.2, p-value = 0.005)]. Normal ALT levels were found in 15 patients after 48 weeks [RR 1.85 (CI 0.66 – 5.15, p-value = 0.52)], while no difference was observed in the HBeAg seroconversion.

CONCLUSION: *The use of Tenofovir as treatment of Hepatitis B infection among subjects coinfected with HIV showed a trend towards better efficacy compared to control in decreasing the mean HBV DNA and ALT levels.*

P635 EFFECTS OF THE CHEMOKINE RECEPTOR 5 (CCR5)-DELTA32 MUTATION ON HEPATITIS C VIRUS-SPECIFIC IMMUNE RESPONSES AND LIVER TISSUE PATHOLOGY IN HCV INFECTED PATIENTS

A. Yilmaz[1,*], H. Alagozlu[1], O. Ozdemir[2], S. Arici[3]. [1]*gastroenterology, cumhuriyet universty, sivas,* [2]*genetics, 18 Mart University Medical Faculty, Canakkale ,* [3]*Pathology, cumhuriyet universty, sivas, Turkey*

INTRODUCTION: The specific antiviral T cells provide CC chemokine receptor 5 (CCR5) for the immune response during the hepatitis C virus (HCV) infection. Heterogenous and/or homozygous 32 base pair deletion in CCR5 gene(CCR5Δ32 bpdel) leads to reduced protein expression. In the current case control study, we aimed to compare the histopathological findings of liver to the CCR5Δ32bpdel mutation profiles, expression and some other clinical findings in patients with chronic HCV infection.

AIMS&METHODS: Multiple StripAssay reverse hybridisation and Real Time PCR techniques were used to determine the germline CCR5 mutations and immunohistochemical technique was used to evaluate the gene expression in targer tissue biopsies.

RESULTS: Target CCR5 WT/WT, WT/Δ32, and Δ32/Δ32 genotypes were observed in 91.4%, 8.6%, and 0.0% for HCV positive patients and 98.3%, 1.7%, and 0.0% for control group respectively. The histologic activity indices (HAI) was significantly lower (4.0±1.0) in the mutated group than the non-mutated group (5.7±1.0). Decreased fibrosis levels were detected in HCV positive mutated group.

CONCLUSION: Results showed that CCR5 polymorphism was more frequent in HCV positive patients than in healthy population in Turkish population. Current resuls also showed that mutated CCR5 signalling pathway due to CCR5-Delta32 may potentially result in subtle reduction of HCV specifity to the drug responses due to the positive impact on liver inflammation, fibrosis levels and liver destruction in HCV infection.

P636 ADHERENCE AND LIFE IMPACT OF TRIPLE THERAPY IN PATIENTS WITH CHRONIC HEPATITIS C

A. I. Suceveanu[1,*], A.-P. Suceveanu[1], L. Mazilu[2], I.-R. Parepa[2], F. Voinea[3], A. Cenusa[4], R. Constantinescu[5], A. Catinean[6]. [1]*Gastroenterology,* [2]*Internal Medicine,* [3]*Surgery, EMERGENCY HOSPITAL , Constanta,* [4]*Gastroenterology, CF ,* [5]*Gastroenterology, Gastroenterology and Hepatology Institute, Iasi,* [6]*Gastroenterology, UMF Iuliu Hatieganu, Cluj-Napoca, Romania*

INTRODUCTION: Triple therapy with Peg-IFNs, Ribavirin and protease inhibitors is the new gold-standard treatment for hepatitis C in relapsers or nonresponder patients raising the treatment success up to 83%. In front of a new treatment challenge is now the low adherence, the new combination regimens bringing together with the significantly higher rates of sustained virologic response (SVR) more side effects interfering with patient's quality of life and work productivity.

AIMS&METHODS: This study aimed to analyze the adherence and life impact of triple therapy using Peg-IFNs, Ribavirin and protease inhibitors (Telaprevir vs. Boceprevir) in 50 patients from different counties from Romania diagnosed with chronic hepatitis C with failure to first line therapy. Multivariate Cox proportional hazards regression was used to analyse determinants of re-treatment initiation and compliance during treatment according to patient features.

RESULTS: This observational study identified as major drivers of retreatment initiation in patients with chronic infection with C virus the young age (2-3 medical visits vs. 4-8 visits, p=0.031), the female gender (28 vs. 22), the urban provenience and the high income (p=0.0337, 95% CI 4.66-44.56), the psychiatric and the alcohol or drugs abuse history (p=0.0351, CI 11.98-44.51). The adherence and the life impact of therapy during the retreatment were similar despite the regimen used and obvious lower in patients with history of previous abandon (p=0.0228 95% CI 2.47-39.01), drugs and alcohol abuse (p=0.0283, CI 95% 12-45, respectively p=0.0117 CI 95% 1-38), hematologic and psychiatric decompensation (p=0.0447, 95% CI 9.66-34.86). The bad capacity of work and temporary drop of job to continue the therapy was seen in 12.5% of patients (2pts) taking Telaprevir and 8.82% of patients (3pts) taking Boceprevir. Abandon of therapy without any known reason was more frequent in males (p=0.0345), with alcohol and drugs intake history (p=0.0221), from rural region and with low income (p=0.0119, respectively, p=0.0371), with psychiatric disturbances in personal history(p=0.0290).

CONCLUSION: Having as the principal end-point the sustain viral response (SVR), our study results, next to other similar literature information, should focus the researchers and physicians to discover molecules with fewer side effects or to improve the medical strategies in order to raise the quality of life in chronic hepatitis C patients following triple therapy.

P637 BUPRENORPHINE MAINTENANCE ACHIEVES A HIGHER COMPLIANCE RATE THAN METHADONE IN PATIENTS CHRONICALLY INFECTED WITH HCV TREATED WITH PEGYLATED INTERFERON AND RIBAVIRIN COMBINATION

D. Dimitroulopoulos[1,*], E. Petroulaki[2], S. Kollia[3], A. Tsantilas[2], D. Kypreos[1], N. Ziogas[1], P. Katerinis[1], K. Tsamakidis[1], D. Xinopoulos[1]. [1]*Gastroenterology, Agios Savvas Cancer Hospital,* [2]*National Greek Organization Against Drugs (OKANA) , National Greek Organization Against Drugs (OKANA) , Athens,* [3]*National Greek Organization Against Drugs (OKANA), National Greek Organization Against Drugs (OKANA), Halkida, Greece*

INTRODUCTION: Chronic HCV infection (HCV) is the most common infectious disease among intravenous drug users.

AIMS&METHODS: To determine and compare compliance rates between two groups of chronic HCV patients from the National Greek Organization Against Drugs (OKANA) in substitution programs with buprnorphine or methadone, treated with pegylated interferon plus ribavirin during 24 or 48 weeks of therapy and 24 weeks of follow up. Also, to evaluate the efficacy of treatment in each group. 97 consecutive chronic HCV infected patients, members of the OKANA program, were treated with pegylated interferon α-2α (180 μg/wk administered subcutaneous) in combination with oral ribavirin (1000 or 1200 mg/day depending on baseline body weight $\leq$ or $>$ 85 Kg, respectively, divided in two doses), for 24 or 48 weeks according to their genotype. 45 were in buprnorphine maintenance (Group A, 36 males, 9 females) and 65 in methadone maintenance (Group B, 52 males, 13 females). During the study, all patients were followed up periodically by hepatologists, internists and psychiatrists.

RESULTS: Baseline characteristics were similar between the two groups. 34/45 patients (75,6%) from group A and 31/65 (47,7%) from group B completed therapy (p=0.006). Thirty-two (71,1%) patients from group A and 27 (41,5%) from group B were followed up until the end of the follow-up period (p=0.004). At the end of the follow-up, sustained virologic response (SVR) was achieved in 23/45 (51.1%) patients from group A and 21/65 (32.3%) from group B (p= 0.075).

CONCLUSION: Buprenorphine maintenance achieves a significantly higher compliance rate than methadone in patients with chronic HCV infection treated with pegylated interferon and ribavirin. After 24 weeks of follow-up, response rates were similar for patients who were compliant to treatment for both groups.

P638 EVALUATION OF PREDICTORS OF SUSTAINED VIROLOGICAL RESPONSE (SVR) TO INTERFERON THERAPY AND HEPATIC PROGENITOR CELLS (HPCS) IN CHRONIC HEPATITIS C VIRUS (HCV) INFECTED PATIENTS

E. F. Moustafa[1,*], E. M. Muhammed[2]. [1]*Tropical Medicine & Gasroenterology, Assiut University- Egypt, Assiut,* [2]*Departments of Pathology, Sohag University, Sohag, Egypt*

INTRODUCTION: Studying the predictors of SVR to pegylated interferon (PEG-INF) alfa-2a and ribavirin (RBV) therapy in chronic HCV infected patients is crucial for selecting those who would benefit most from therapy. Increased HPCs in HCV-infected patients were shown to be correlated with increasing fibrosis and response to treatment. HPCs could be detected in the liver by immunohistochemical expressions of cytokeratin (CK) 7 and CK19.

AIMS&METHODS: a. Evaluate the response rate to interferon based treatment in chronic HCV patients. b. Detect the predictors of SVR to treatment. c. Study the correlations between CK7 and CK19 expressions and treatment response.
This study included 483 chronic HCV infected patients who fulfilled the study criteria who underwent clinical, biochemical and virological assessments before treatment and at 12, 24, 48 and 72 weeks post-treatment. Only 330 patients; 193 male and 137 completed the course and were included in the statistical analysis. Only 50 specimens were examined for CK7 and CK19 expression using avidin, biotin, peroxidase technique.

RESULTS: End of treatment virologic response (ETVR) was achieved in 70% of patients, while 30% were non responders. SVR was higher in females whereas most of male patients didn't achieve SVR ($P < 0.01$). Patients with SVR were significantly younger ($P < 0.004$) and had lower body weight ($P < 0.001$). There was significant inverse relation between SVR and aspartate aminotransferase (AST) and alpha feto-protein (AFP); $P < 0.000$ for each. The independent predictors of SVR were younger age and lower AST ($P < 0.02$ for each). There was significantly positive correlation between the grade of necro-inflammatory activity, AST and AFP and the stage of hepatic fibrosis ($P < 0.003$, $P < 0.000$ & $P <$

0.000 respectively). There was significant association between CK7 and/or CK19 expressions and grade of necro-inflammation ($P<0.033$, 0.026 respectively), and/or advanced stage of fibrosis ($P<0.001$, 0.000 respectively). There were significant inverse relations between SVR and stage of hepatic fibrosis ($P<0.001$), and CK19 expression ($P<0.000$).

CONCLUSION: Forty % of patients with chronic HCV who completed the course of combination therapy achieve SVR. Younger age and lower pre-treatment AST are independent predictors of SVR. HPCs as assessed by CK7 and CK19 expressions may be incorporated in assessment of treatment response of these patients.

P639 ABT-267 COMBINED WITH PEGYLATED INTERFERON ALPHA-2A/RIBAVIRIN IN GENOTYPE 1 HCV-INFECTED TREATMENT-NAÏVE PATIENTS: EFFICACY AND SAFETY UPDATE

J. G. Sullivan[1,*], M. Rodriguez-Torres[2], E. Lawitz[3], F. Poordad[3], M. Kapoor[4], L. Rodrigues[4], A. Campbell[4], C. Setze[4], W. Xie[4], A. Khatri[4], E. Dumas[4], P. Krishnan[4], T. Pilot-Matias[4], L. Williams[4], B. Bernstein[4]. [1]*Parkway Medical Center, Birmingham, United States,* [2]*Fundación de Investigación, San Juan, Puerto Rico,* [3]*The Texas Liver Institute, University of Texas Health Science Center, San Antonio,* [4]*AbbVie, North Chicago, United States*

INTRODUCTION: ABT-267 is a novel hepatitis C virus (HCV) NS5A inhibitor being developed for use in combination with other anti-HCV agents. This double-blind, randomized study evaluated ABT-267 combined with pegylated interferon+ribavirin (P/R) in genotype 1 (GT1) HCV-infected treatment-naïve patients.

AIMS&METHODS: Non-cirrhotic patients with HCV RNA >50,000 IU/mL received ABT-267 (5, 50 or 200mg once-daily) or matching placebo (PBO) in combination with P/R (pegylated interferon alpha-2a 180μg/week + weight-based ribavirin 1000-1200mg/day) for 12 weeks. After week 12, patients received P/R for 36 weeks and were followed post-treatment for 48 weeks. RVR, cEVR, SVR_{12} and SVR_{24} were assessed in the intent-to-treat population (flanking imputation and non-completer=failure to handle missing data). Adverse events (AE) and laboratory abnormalities were recorded.

RESULTS: 37 patients received ABT-267+P/R (n=28) or PBO+P/R (n=9): 60% male, 16% black, 30% Latino, 73% GT1a infection, 33% IL28B CC genotype, mean age 48 years, BMI 27 kg/m^2, baseline HCV RNA 6.6 $\log_{10}$ IU/ml. Virologic efficacy is shown in the table. There were no serious AEs during ABT-267/PBO + P/R treatment; AEs and laboratory abnormalities were similar for the PBO and ABT-267 groups and were consistent with the safety profile of P/R. Two patients discontinued ABT-267 prematurely (1 withdrew consent, 5mg group; 1 had virologic failure, 200mg group.) No patient discontinued ABT-267 due to an adverse event.

	PBO	ABT-267 5mg	ABT-267 50mg	ABT-267 200mg	ABT-267 Total
N	9	9	9	10	28
RVR, n (%)	2 (22)	7 (78)	7 (78)	8 (80)	22 (79)
cEVR, n (%)	6 (67)	9 (100)	8 (89)	8 (80)	25 (89)
SVR_{12}, n (%)	3 (33)	6 (67)	6 (67)	6 (60)	18 (64)
SVR_{24}, n (%)	2 (22)	5 (56)	4 (44)	5 (50)	14 (50)
Reasons for non-response (SVR_{24}):					
On-treatment virologic failure*	1	0	2	2	4
Relapse	4	3	0	0	3
Lost to follow-up	2	1	3	3	7

*HCV RNA value at the end of P/R treatment was ≥ LLOQ.

CONCLUSION: The proportion of patients achieving SVR_{12} and SVR_{24} was greater among patients who received ABT-267+P/R compared with P/R alone (64% and 50% versus 33% and 22%, respectively). ABT-267 was well tolerated in this study. These findings support exploring the combination of ABT-267 with other direct acting antiviral agents for interferon-free treatment of chronic HCV GT1 infection.

P640 THE SUBGROUP GENOTYPE AND RAPID VIRAL RESPONSE PREDICT SUSTAINED VIRAL RESPONSE IN PATIENTS WITH MIXED GENOTYPE CHRONIC HEPATITIS C

J.-J. Chen[1,*], H.-D. Tung[1]. [1]*Gastroenterology, Chi Mei Medical Center, Liouying, Tainan, Taiwan, Province of China*

INTRODUCTION: It is unclear whether the rapid virological response (RVR) influences the probability of achieving a sustained virological response (SVR) in patients with mixed genotype (mix-GT) infection of chronic hepatitis C.

AIMS&METHODS: The aim of this study is to clarify the influence of genotypes and other factors in mix-GT patients on RVR and SVR. Data were retrospectively analyzed from treatment-naive patients who received peginterferon alfa-2a (180μg/week) or 2b (15 mg/kg/wk) plus ribavirin 15 mg/day for 24 or 48 weeks according to RVR response. Sixty-nine mixed genotype(GT) 1 and 2 or mix-GT 1a+1b patients with evaluable HCV RNA at baseline and week 4 were grouped according to RVR status: RVR (HCV RNA <14 IU/ml) or no RVR. The proportion of patients with undetectable HCV RNA at week 12 (EVR) and the proportion with an SVR was calculated.

RESULTS: Overall, 78.2% achieved SVR and 95.7% had EVR. All patients in RVR group and 76.9% non-RVR group had EVR. There are 85.7 % (48/56) of RVR and 46.2 % (6/13) of non-RVR patients achieved SVR ($p<0.0001$). Among non-RVR patients, only twenty percent (1/5) achieved SVR when 1a including in their GT population (e.g. 1a+1b, 1a+2a, or 1a+2b). High viral load and elder patients are significantly more in non-RVR patients. The type and dosage of interferon, dosage of rivabirin, adherence of medication and clinical manifestations are no difference between non-RVR and RVR patients.

CONCLUSION: The probability of achieving SVR is depending on subgroup of genotype, viral load, and age in patients with mix-GT chronic hepatitis C. When the patients can get RVR, the SVR rate is equal to mono-GT infection patients.

P641 CLINICAL IMPACT OF OCCULT HBV INFECTION IN PATIENTS WITH CHRONIC HEPATITIS C

M. Simonova[1,*], S. Pavlova[2], T. Hadzhiolova[2], D. Takov[1], K. Katzarov[1]. [1]*Clinic of Gastroenterology,* [2]*Laboratory of Molecular Diagnostic in Liver Diseases, Military Medical Academy, Sofia, Bulgaria*

INTRODUCTION: Occult HBV infection is more frequently found in HCV–positive subjects than in healthy subjects, but its clinical impact remains still controversial.

AIMS&METHODS: The aim of this study is to determine clinical impact of occult HBV infection in subjects with chronic hepatitis C.

From March 2004 to January 2013 the study prospectively included 152 subjects with chronic hepatitis C, all HbsAg-negative (mean age 45±8,1 years), 95 males/57 females. Sera of all subjects were tested for the presence of HBV DNA by real-time PCR Cobas TaqMan ® Test with detection limit of 6 IU/ml (35 copies/ml) (Roche Molecular Systems, Inc.). Liver biopsy was performed in all patients. Two consecutive liver biopsies were preformed in 77 subjects and the rate of fibrosis progression was calculated. 85 subjects received antiviral treatment.

RESULTS: Occult HBV infection, defined in this study as positive serum HBV DNA, was found in 15% (23/152) of the subjects with chronic hepatitis C. Positive HBV DNA significantly associates with positive antiHBc Ab ($P<0.0001$). Positive HBV DNA associates with more severe grade of necro-inflammation changes in the liver (P=0,001). No association was found between positive HBV DNA and stage of liver fibrosis (P=0,570). Positive HBV DNA was found in 32% of subjects with progression of fibrosis and in 6,7% of the patients without fibrosis progression (P=0.010). Occult HBV infection didn't affect efficacy of antiviral treatment (P=1,000). No association between positive HBV DNA gender (P=0,116), age (P= 0,248), HCV genotype (P=0,501) and serum HCV RNA (P=0,641) was found.

CONCLUSION: Occult HBV infection is found in 15 % of the patients with chronic hepatitis C and associates with more severe necro-inflammatory changes in the liver and more rapid progression of liver fibrosis

P642 PEGYLATED THERAPY IN ELDERLY PATIENTS WITH CHRONIC HEPATITIS C : WHAT'S THE RESULTS?

O. Lasri[1,*], N. KABBAJ[1], L. AMRANI[1], M. SALIHOUN[1], I. SERRAJ[1], M. ACHARKI[1], M. NYA[1], N. AMRANI[1]. [1]*EFD-Hepatogastroenterology, UM5S, Hôpital ibn Sina, Rabat, Morocco*

INTRODUCTION: Chronic hepatitic C (CHC) is particular in elderly patients by the infection itself and the physiological state
AIMS&METHODS: The aims are to compare CHC patients treated by Pegylated therapy younger and older than 65 years concerning their virological, histological and to compare also their early virological response (EVR) and the sustained virological response (SVR).All cases of CHC treated with combination therapy were recruited from 2005 to 2012. All clinical, biological, virological and histological data were collected and analyzed. Patients were divided in 2 groups according to their age, Group 1: Patients younger than 65 years, Group 2: Patients older than 65 years. We compared the groups regarding their epidemiological, virological and histological characteristic as well as the EVR and the SVR. Statistical analysis was performed by chi 2 test
RESULTS: 200 patients were included, 130 patients (52%) in group 1 and 70 patients (48%) in group 2. The mean age was 50 years in Group1 and 67.4 years (range 65-83) in Group 2 with female predominance (77%) in Group 2. Genotype 1 was predominant in both groups: 53% in Group 1 and 67% in Group 2. The viral load was $\geq$ 600 000 IU/ml in 65% in Group 2 and 55% in Group 1. Severe fibrosis and cirrhosis were frequent (58%) in Group 2 ($p = ns$). Concerning the virological response, EVR was 80% in Group 1 and 65% in Group 2 ($p = ns$) and SVR was 84% in Group 1 and 52.7% in Group 2 ($p = ns$).
CONCLUSION: The most prevalent profile in CHC-patients older than 65 years was women infected by HCV-Genotype 1 and high viral load. EVR was achieved in most of cases (65%) and SVR in 52.7% without significant difference of these results in CHC-patients younger than 65 years.

P643 HIV PREVALENCE AMONG HCV EGYPTIAN INFECTED PATIENTS AND ITS IMPACT ON THE RESULT OF HCV TREATMENT

R. M. Salama[1,*], R. Fouad[1], O. Shaker[2], H. Abd El Hafez[1], M. Elraziky[1], S. Marzouk[2], W. El Akel[1], G. Esmat[1], M. Abd El Ghany[3]. [1]*Endemic medicine , [2]Biochemistry, Kasr Al Aini hospital- Faculty of Medicine - Cairo University, [3]Hepatogastroenterology, Ahmed Maher Hospital, Cairo, Egypt*

INTRODUCTION: HCV infection is the most common co-infection in HIV patients so we aimed to determine the prevalence of HIV infection in chronic HCV patients and its impact on chronic HCV patients treatment response.
AIMS&METHODS: A retrospective study performed on 1852 chronic HCV patients subjected to anti HCV treatment with alpha 2a, alpha 2b or standard interferon and Ribavirin and tested and confirmed for HIV co infection by ELISA twice. Upon HIV testing, two groups were generated, **Group1**: 1840 HCV patients, positive for HCV RNA and **Group 2**: 12 HIV positive patients and positive also for HCV. Informed consents were obtained from patients. Proper hematological biochemical investigations and other causes of hepatitis rather than HCV were carried out and excluded.
RESULTS: The prevalence of HIV among HCV infected Egyptian patients was 0.64%. We found male gender predominance; the hematological and biochemical parameters were similar in both groups with mild elevations in liver enzymes in group II. High rates of failure to treatment (77.8%) with lower SVR (22.2%) were in group II compared to group I (59.9%) as SVR was 22.1% in group II vs. 34.1% in group I, however with no statistical significance.
CONCLUSION: Despite the lower prevalence of HIV in Egyptian patients with HCV infection, still it affects their response to treatment .Therefore; we must screen HIV in all HCV patients and recommend its test to routine investigations before starting HCV therapy.

P644 SHOULD WE INVESTIGATE RETINOPATHY IN CHRONIC HEPATITIS C PATIENTS RECEIVING TREATMENT WITH INTERFERON?

S. Aoufi Rabih[1,*], L. B. Alfaya Muñoz[2], A. Fidalgo Broncano[2], R. Villanueva Hernández[1], P. González Carro[1], F. Pérez Roldán[1]. [1]*Gastroenterology and Hepatology, [2]Ophthalmology, Complejo Hospitalario La Mancha Centro, Alcázar de San Juan, Spain*

INTRODUCTION: Retinopathy secondary to interferon (IFN) was described in 1990. Its incidence is uncertain. Published studies include short series of patients. There seems to be a direct relationship between the dose of IFN and the duration of treatment. It may appear from week 8 of treatment initiation. It is usually asymptomatic and doesn't associate loss of visual acuity. It disappears completely in most patients after the discontinuation of treatment. There have also been some cases caused by hepatitis C virus with the formation of a variety of thrombogenic antibodies, causing retinal damage.
AIMS&METHODS: The aim of this study was to determine the prevalence of retinopathy in a cohort of chronic hepatitis C patients receiving or not antiviral treatment with IFN and ribavirin. We consecutively enrolled chronic hepatitis C patients from the Hepatology Consultation. We excluded patients with ocular pathology caused by other diseases (arterial hypertension, diabetes, etc.). Patients underwent a fundus of the eye performed by a single ophthalmologist.
RESULTS: We recruited 219 chronic hepatitis C patients of all genotypes, of which 81 were excluded due to concomitant eye diseases. We performed a fundus of the eye to 138 patients, 18 were receiving treatment with pegylated IFN and ribavirin for at least three months before the test. The 63.4% of patients were male, with a mean age of 54 years (18-74). None of the patients studied showed visual symptoms. Pathological eye changes were found in a patient treated with IFN (5.5%); the characteristics of the lesions were attributed to antiviral treatment by the ophthalmologist.
CONCLUSION: The prevalence of ophthalmic disorders in patients with chronic hepatitis C is very low and especially present in those receiving antiviral treatment with IFN. As the fundus of the eye is an inexpensive, noninvasive, easy to perform and accessible test at all sites, it seems advisable to indicate it in patients undergoing treatment with IFN. This retinopathy screening study contains the largest series of patients with chronic hepatitis C and interferon therapy.

PANCREAS II - Poster Area

P645 VALIDATION OF THE ORIGINAL ULTRASOUND SCALE FOR STRATIFICATION OF SEVERITY OF ACUTE PANCREATITIS

A. V. Popov[1], A. I. Ershova[1,*], D. A. Mineev[2], N. N. Popova[2], N. G. Stepanyan[2]. [1]*Hospital Surgery, [2]General surgery, Perm State Medical Academy, Perm, Russian Federation*

INTRODUCTION: An increasing number of cases and severity of acute pancreatitis (AP) guides the necessity of early identification of cases that require an intensive care and/or operation. There exist different complex scoring systems that are used for stratification of severity of AP, i.e. Balthazar–Ranson (B-R) & SOFA, but they have some limitations. According to the classification that was proposed by M.S. Petrov & J.A. Windsor [1] we devised a new scale for stratification of severity of AP that is based on the ultrasound (US) signs of inflammation or destruction processes in pancreas.
AIMS&METHODS: To compare the value of original scale with well-known B-R & SOFA scales in stratification of severity of AP. For US scale we analyzed the following parameters in points: US signs of oedema of pancreas (1), dilatation of Virsung (1), infiltration of parapancreas adipose tissue (2), parapancreatic abscess (3), fluid in parapancreatic adipose tissue and/or upper level of the abdominal cavity (3), fluid in the other parts of abdominal cavity (4); necrosis of pancreas: $<$ 30% (2), 30-50% (5), $>$ 50% (8); dilatation of choledochus (1); enlargement of gallbladder or cholelythiasis (1), dilatation of intrahepatic bile ducts (1).
RESULTS: There were 158 patients with AP (mean age 50.2±17.8, 72.4% male), of which 31.6% were classified as mild, 20.3% as moderate, 30.4% as severe & 17.7% as critical AP. The comparison of the scales depending on the severity of AP is shown in the table.

	Categories of acute pancreatitis (Petrov & Windsor)				P value		
Scales (points)	Mild	Moderate	Severe	Critical	mild vs moderate	moderate vs severe	severe vs critical
SOFA	3.89±0.10	9.12±1.16	9.71±1.92	12.29±1.73	<0.001	0.28	<0.001
B-R	1.22±0.42	2.43±1.05	7.31±1.83	9.71±1.78	<0.001	<0.001	<0.001
US scale	4.32±1.13	12.20±2.25	16.48±5.48	21.32±3.87	<0.001	<0.001	<0.001

We received well-known correlations between SOFA scale & B-R scale (Rs=0.69; $p<0.001$). US scale correlated also with SOFA scale (Rs=0.79; $p<0.001$) & B-R scale (Rs=0.88; $p<0.001$).
One of the prognostic factors of the severe AP is more than 14 points according to US scale (sensitivity 73%, specificity 87%, positive predictive value 65%, negative predictive value 90%).

CONCLUSION: Prognostic value of a new US scale is high for stratification of severity of AP. The best efficiency in the early prediction of severe AP could be achieved with the measurements of the B-R & US scales.

P646 CLINICAL CHARACTERIZATION OF HYPERTRIGLYCERIDEMIC SEVERE ACUTE PANCREATITIS: OUR EXPERIENCE DURING THE LAST DECADE

A. Santos[1,*], P. Amaro[1], M. Ferreira[1], J. Romãozinho[1], C. Sofia[1]. [1]*Hospitais da Universidade de Coimbra, Coimbra, Portugal*

INTRODUCTION: Hypertriglyceridemia is the third most common non iatrogenic cause of Acute Pancreatitis (AP), accounting for 1 to 38% of cases. This entity is defined by the presence of high triglyceride levels (> 1000mg/dL) in the absence of other etiological factors for acute pancreatitis.

AIMS&METHODS: Clinical characterization of inpatients with Hypertriglyceridemic Severe Acute Pancreatitis (HTG SAP) in a Gastroenterology Intensive Care Unit.

Retrospective analysis between 2002 and 2012; 185 cases of Severe Acute Pancreatitis (SAP); 13 patients with SAP and Triglycerids (TG) ≥ 1000mg/dL (7,3%). Other etiologies were excluded. We considered demographic and clinical variables with diagnostic and prognostic value. Medical and surgical management was reviewed.

RESULTS: Male: 92,3%; Mean age: 42,8 years (23-68); Time of evolution: 27 hours (3-72); Known dyslipidemia: 84,6%; Diabetes mellitus: 42,9%; Body Mass Index > 30Kg/m 2: 46,2%; Chronic alcoholism: 69,2%; Mean TG level at admission: 4805mg/dL (1011-11442); Ranson score at admission ≥ 3: 57,1%; C reactive protein level at 48 hours > 15mg/dL: 85,7%; Shock 7,7%; Renal failure 15,4%; Respiratory failure 84,6%; Pancreatic necrosis 30,8%; Infected pancreatic necrosis 7,7%; Fluid collections 38,5%; Plasmapheresis: 61,5%; mean TG level for these patients: 4926mg/dL; mean number of sessions: 1,9; mean reduction of TG level after first plasmapheresis session: 5496mg/dL (1194-11056); mean duration of stay: 7 days; mortality: 7,7%; statistically significant difference between HTG SAP mortality ans lithiasic SAP (p=0.042).

CONCLUSION: HTG is a rare cause of SAP, mainly affecting young adult male patients, most of which with a known past history of dyslipidemia. In about half of the cases it is associated with Diabetes mellitus and in two thirds with chronic alcoholism. The most frequent complications in this setting are respiratory failure and pancreatic necrosis. Plasmapheresis is an effective tool for rapid reduction of TG level. HTG SAP has a favourable outcome when compared with more frequent lithiasic aetiology.

INTRODUCTION: Acute pancreatic fluid collection and pseudocyst formation are the most frequent complications of acute pancreatitis.

AIMS&METHODS: The aims of this study were to evaluate the incidence, risk factors, and clinical course of pancreatic fluid collections and pseudocyst formation following acute pancreatitis. A prospective multicenter study was conducted with five participating centers from January 2011 to July 2012. A total of 302 patients diagnosed with acute pancreatitis were collected.

RESULTS: The incidence of pancreatic fluid collections and pseudocyst was 42.7% and 6.3%, respectively. Patients with fluid collection were significantly younger, compared to those without fluid collection (51.5±15.9 vs. 60.4±16.5 years, p = 0.000). Alcohol showed a higher proportion (54.3%) of etiology in patients with fluid collection, compared to other etiologies. CRP (48 hr) was significantly higher in patients with fluid collection, compared to patients without fluid collection (39.2±77.4 vs 15.1±36.2 mg/dL, p=0.016). LDH (48 hr) was significantly higher in patients with pseudocyst formation, compared to patients with complete resolution (1317.6±706.4 vs 478.7±190.5 IU/L, p=0.000). Pancreatic fluid collection showed spontaneous resolution in 69.8% (90/129) and 84% of the pseudocysts disappeared or decreased in size during follow up.

CONCLUSION: Age, CRP (48 hr), and alcohol etiology are risk factors for pancreatic fluid collection. LDH (48 hr) appears to be a risk factor for pseudocyst formation. Most pseudocysts showed a decrease in size or spontaneous resolution.

P649 LOW PLASMA CALCIUM LEVELS PREDICT SEVERE ACUTE PANCREATITIS AT ADMISSION WITH EQUAL ACCURACY AS SOPHISTICATED ORGAN FAILURE SCORES

J. A. Scheiber[1,*], A. A. Aghdassi[1], C. Nitsche[1], C. Budde[1], N. Hahn[1], P. Simon[1], G. Fluhr[1], F.-U. Weiss[1], M. M. Lerch[1], J. Mayerle[1]. [1]*Department of Medicine A, University Medicine, Ernst-Moritz-Arndt-University, Greifswald, Greifswald, Germany*

INTRODUCTION: Acute pancreatitis is one of the leading causes of hospitalization for gastrointestinal disorders. While 80% of patients develop mild acute pancreatitis, the remaining 20% develop severe acute pancreatitis (SAP) associated with significant morbidity and mortality. To ensure adequate clinical management and distribution of resources early prediction of the disease course is essential.

AIMS&METHODS: The objective of this study was to evaluate the use of several organ dysfunction scores (APACHE II, SAPS II, SOFA, LODS, MODS) and the pancreatitis specific scores (Ranson, Glasgow) for the prediction of SAP in patients admitted to the university hospital of Greifswald. 114 patients were prospectively enrolled in this study during 2004 and 2010, of which 22 developed SAP. Data for the calculation of the organ dysfunction scores was obtained at admission, data for calculating Ranson and Glasgow score during the following 48 hours. Subsequently, receiver operator curves were generated for each score. Area under the curve (AUC) estimates were interpreted as a comparative measure of the potential usefulness and test accuracy was compared at visually optimal thresholds.

RESULTS: The organ dysfunction scores showed a similar performance in predicting SAP at admission (AUC for: APACHE II 0.75 (95% confidence interval, 0.62-0.87); SAPS II 0.66 (0.54-0.79), SOFA 0.71 (0.57-0.85), LODS 0.77 (0.68-0.86), MODS 0.72 (0.58-0.86)), but none of these was adequate accurate to be used for clinical decision making. Ranson score performed better and Glasgow

score similar (AUC for: Ranson 0.89 (0.57-0.85), Glasgow 0.74 (0.67-0.85)) compared to the organ dysfunction scores, however these scores are only available 48 hours after admission. Hypocalcemia seemed to correlate well with SAP and prompted us to analyse its potential as a single predictive parameter. The predictive value of low plasma calcium levels for SAP was at least equivalent to that of the sophisticated organ dysfunction scores and to the pancreatitis specific scores (AUC for plasma calcium: at admission 0.78 (0.67-0.9); at 48 hours 0.92 (0.84-0.99)).
CONCLUSION: This study showed that several organ dysfunction scores are only of limited value for predicting SAP. The pancreatitis specific scores partially showed better performance, but their use is limited because of their delayed availability. Surprisingly, evaluation of hypocalcemia as predictor for SAP was at least equivalent to organ dysfunction scores and to the pancreatitis specific scores and thus could be a simple alternative for predicting SAP in clinical routine.

P650 ACUTE PANCREATITIS IN THE ELDERLY: ETIOLOGY AND CLINICAL FEATURES

M. Eusébio[1,*], A. G. Antunes[1], A. L. Sousa[1], B. Peixe[1], P. Caldeira[1], H. Guerreiro[1]. [1]*Gastroenterology, Hospital de Faro, Faro, Portugal*

INTRODUCTION: The incidence of acute pancreatitis has increased in recent years. With prolonged life expectancy the number of elderly patients affected by this pathology has consequently risen, becoming an important concern in this group of patients. The influence of age in the severity and clinical course of acute pancreatitis has been a subject of debate.
AIMS&METHODS: The purpose of our study was to evaluate the clinical features and the outcome of elderly patients with acute pancreatitis. We studied retrospectively all patients admitted with the diagnosis of acute pancreatitis at our Service between January 2010 and December 2010. Demographic data and clinical characteristics of elderly (≥65 years-old) and non-elderly (<65 years-old) were registered. The severity of pancreatitis was stratified according to the BISAP score (Bedside Index for Severity in Acute Pancreatitis).
RESULTS: 114 patients were included, being 67 elderly and 47 non-elderly. The former presented a higher Charlson co-morbidity index (mean of 1,96 *versus* 0,87, p=0,003). Biliary etiology was more common in the elderly group (82% *versus* 55%, p=0,000) and alcoholic etiology was more frequent in the younger group (30% *versus* 6%; p= 0,000). The BISAP score was significantly higher in the elderly (p=0,000). In regards to systemic complications related to this disease, they were more common in the elderly (58,21% *versus* 29,79%, p=0,003) namely renal insufficiency (29,85% *versus* 6,38%, p= 0,002) and hypocalcemia (32,8% *versus* 12,8%, p= 0,014). Nevertheless, the presence of local complications (10,4% *versus* 14,9%, p=0,477), medium hospital stay (10,97 ± 9,282 days *versus* 8,77 ± 9,418 days, p=0,108) and hospital mortality (7,5% *versus* 2,1%, p= 0,209) did not differ between groups.
CONCLUSION: Although clinically more severe and more frequently associated with concomitant diseases, acute pancreatitis in the elderly patients did not determine a higher mortality rate in our study.

P651 THE ROLE OF PSMAD2,3L-THREONINE IN THE MURINE PANCREATITIS MODEL

M. Sakao[1,*], Y. Sakaguchi[1], R. Suzuki[1], T. Okazaki[1], Y. Takahashi[1], K. Yoshida[1], T. Fukui[1], K. Uchida[1], K. Matsuzaki[1], A. Nishio[1], K. Okazaki[1]. [1]*Kansai Medical University, Hirakata , Osaka, Japan*

INTRODUCTION: Pancreatic exocrine acinar cells have regenerative ability from acute pancreatitis in mice and increase expression of several genes associated with undifferentiated pancreatic progenitor cells. In our previous report, we showed that, in small intestines,colons and Helicobacter-associated gastritis, pSmad2/3L-Threonine (pSmad2/3L-Thr) immunostaining-positive cells were detected in specific epithelial cells where the respective putative stem cells are thought to exist. We observed pSmad2,3L-Thr expression in pancreas to elucidate the location of progenitor cells in the pancreas after caerulein-induced pancreatitis.
AIMS&METHODS: The aims of this study are to characterize cell proliferation and differentiation during regeneration after caerulein-induced pancreatitis and to evaluate the role of pSmad2,3L-thr positive cells. Male C57BL/6 mice received 7times hourly intraperitoneal injections of caerulein, each consisting of 50μg/kg of body weight, and were analized on the day 1,2,4,7 after induced pancreatitis. Tissue sections were immunostained for pSmad2,3L-Thr with Ki67, amylase and CK-19 to determine the functions of pancreatic progenitor cells.
RESULTS: Immunohistochemical analysis revealed pSmad2/3L-Thr immunostaining-positive cells increased in acinar cells(co-localization with amylase), duct-like tubular complexes and duct cells(co-localization with CK-19) in the process of the pancreatitis, this phenomenon was observed during acinar-to-ductal metaplasia (ADM). Furthermore, pSmad2/3L-Thr positive cells significantly increased on the day2 simultaneously with Ki67 positive actively proliferating cells. However, immunohistochemical co-localization of pSmad2/3L-Thr with Ki67 was never observed at any points. These results suggest that pSmad2/3L-Thr positive cells within the proliferating lesions may remain in the quiescent and undifferentiated state.
CONCLUSION: pSmad2,3L-Thr expression occurs during acinar-to-ductal metaplasia(ADM) following induced caerulein pancreatitis and may contribute to the differentiation of the pancreatic progenitor cells.

P652 EFFECT OF CIGARETTE SMOKING ON THE PRODUCTION OF ADVANCED OXIDATION PROTEIN PRODUCTS (AOPP) IN PLASMA OF PATIENTS WITH ACUTE PANCREATITIS

M. Topola[1,*], M. Śliwińska-Mossoń[1], S. Milnerowicz[2], H. Milnerowicz[1]. [1]*Department of Biomedical and Environmental Analysis, Faculty of Pharmacy, Wroclaw Medical University, Wroclaw, Poland,* [2]*Department of Gastrointestinal Surgery and General Surgery, Wroclaw Medical University, Wroclaw, Poland, Wroclaw Medical University, Wrocław, Poland*

INTRODUCTION: Cigarette smoking is one of the many factors inducing oxidative stress. As a result of oxidation modifications may be formed advanced oxidation protein products (AOPP) in the blood - different forms of proteins in terms of structure, function and physicochemical properties.
AIMS&METHODS: The study was aimed to determine the relationship between cigarette smoking and AOPP production in patients with acute pancreatitis (AP). Materials were plasma and serum obtained from 30 patients with AP and 39 persons from control group. The study population was divided into subgroups of smokers and non-smokers based on the serum cotinine determination (ELISA method). AOPP concentration was determined by spectrophotometric method developed by Witko-Sarsat et al. (1996r.) and based on the reaction of plasma AOPP and potassium iodide in an acidic medium. In order to express the amount of AOPP production for 1 gram of albumin, the plasma albumin concentration by colorimetric method using bromocresol purple (BCP) was determinated.
RESULTS: It was shown a reduced albumin concentration in the group of non-smoking patients with AP (35.53±8.14 g/l) and smoking (38.69±8.98 g/l) compared to non-smoking control group (44.94±10.52 g/l) (p=0.0123 and p=0.0294). The difference in albumin concentration between the smoking control group (51.63±9.37 g/l) and smoking patients was demonstrated (p=0.0307). It was noted a higher AOPP concentration in the group of non-smoking patients (39.71±14.71 umol/l) compared to non-smoking control group (33.18±5.64 umol/l) (p=0.0385). A difference between the group of smoking patients (45.25±9.52 umol/l) compared to non-smoking (p<0.0001) and smoking control group (33.04±5.52 umol/l) (p=0.0434) was shown. It was observed an increased AOPP/albumin coefficient in the group of patients: non-smokers (1.14±0.45 umol/g) and smokers (1.20±0.53 umol/g) compared to non-smoking control group (0.74±0.21 umol/g) (p=0.0003 and p<0.0001).
CONCLUSION: Acute pancreatitis is an important factor causing a decrease in albumin concentration and an increase in AOPP formation and cigarette smoking can intensify this process.

P653 IMPACT OF CLINICAL PATHWAY ON TREATMENT OUTCOME IN PATIENTS WITH ACUTE PANCREATITIS

M. Vujasinovic[1,*], A. Marolt[1], J. Makuc[1], Z. Kikec[1], N. Robac[1], B. Tepes[2]. [1]*Department of Internal Medicine, General Hospital Slovenj Gradec, Slovenj Gradec,* [2]*Abakus Medico Diagnostic Centre, Rogaska Slatina, Slovenia*

INTRODUCTION: Acute pancreatitis (AP) is one of the most common reasons for hospitalization among all gastrointestinal diseases, and is associated with high mortality and costs of treatment.
AIMS&METHODS: To determine the impact of clinical pathway (CP) and control of indicators of quality (IOQ) on the outcome of treatment in patients with AP. All medical records after the introduction of CP are analyzed monthly and are discussed at the departmental meeting with emphasis on the most common deficiencies of the treatment. A retrospective analysis of medical records was performed and the following data were analyzed: demographic features of patients, etiology of AP, severity of acute pancreatitis, diagnostic procedures performed during hospitalization, antibiotic therapy prescribed, outcome of AP. We compared results of two periods in our centre: before (2006-2007) and after (2010-2012) implementation of CP.
RESULTS: There were 139 patients treated in the three-year period after introduction of CP: 81(58.3%) male and 58 (41.7%) female, mean age 59.6±17.3 years. The most common etiologies were alcoholism and gallstones (38.8% each), followed by unexplained (11.5%), drug-induced, hypertriglyceridemia, post ERCP (2.9% each) and tumors (2.2%). Antibiotic therapy was prescribed in 72 (51.8%) of patients.
The most frequent morphological condition was interstitial edematous pancreatitis in 60.4% of patients, followed by acute peripancreatic fluid collection (25.9%), necrotizing pancreatitis (12.2%) and pancreatic pseudocysts (1.4%). Abdominal US was performed in all patients in the first 24 hours. CE CT was performed in 57 (41%) of patients. Thirty-two (23.0%) patients were treated in ICU. Four patients died (2.9%). We found an increase in the number of alcoholic and gallstone pancreatitis on the account of a decrease in unexplained etiology in 2010-12, compared to 2006-7. The differences in the structure are statistically significant (Chi-square =39.398, df= 3, p=0.000). The use of antibiotics significantly decreased after implementation of CP (from 70.3% to 51.8%; p=0.003). There was no statistically significant difference in mortality (1.8% vs. 2.9%). Length of stay in Slovenj Gradec General Hospital is significantly shorter compared to Slovenian average (p=0.018).

CONCLUSION: Introduction of CP and control of IOQ has improved the treatment of patients with AP in all observed parameters: reduced length of stay,reduced percentage of unexplained cases, reduced use of antibiotic therapy (without changes in total mortality)

P654 EVALUATION OF NGAL AS A BIOMARKER IN PREDICTING PERSISTENT AKI AND SEVERE ACUTE PANCREATITIS(SAP)

P. K. Siddappa[1,*], J. B. Medaprapelam[1], M. Manrai[1], S. Appasani[1], V. Gupta[2], V. Jha[3], K. Singh[1], R. Kochhar[1]. [1]*Gastroenterology,* [2]*Surgery,* [3]*Nephrology, Postgraduate Institute of Medical Education and Research(PGIMER), Chandigarh, India*

INTRODUCTION: Acute kidney injury (AKI) in severe acute pancreatitis (SAP) causes high mortality and serum creatinine is an insensitive biomarker for these acute changes. Neutrophil gelatinase-associated lipocalin (NGAL), is a glycoprotein secreted by activated neutrophils, and has been used to predict AKI.
AIMS&METHODS: To study the role of plasma and urinary NGAL in predicting acute kidney injury (AKI) and severity (classified as per Atlanta criteria) in patients with acute pancreatitis (AP).
Fifty consecutive patients with AP within 3 days of symptom onset and age matched healthy controls were studied. Patients were treated as per a uniform protocol. Patients were tested for urinary and serum NGAL levels (ELISA) within 24 hours of admission and after 72 hours. Serum and urine NGAL were tested once in controls. Urine and serum NGAL levels were correlated with severity of AP and development of AKI.
RESULTS: Pancreatitis patients were aged 13-85 yrs (males 60%), with 31 age and sex matched controls. The mean serum-NGAL levels (587.66±251.5ng/ml [day1], 573.98±259.86ng/ml[day3]) and mean urine-NGAL levels (252.84±165.89ng/ml [day1], 202.36±132.46ng/ml[day3]) were significantly higher in patients with AKI ($p<0.05$). Mean serum and urine NGAL levels in controls were 15.10±6.29 and 4.26±4.57 ng/ml respectively. Both serum NGAL (cut off day1-705ng/ml & day3-650 ng/ml, AUC-0.77) and urine NGAL (cut off day1-293ng/ml&day3-205ng/ml, AUC-0.89) predicted persistent AKI with good sensitivity and specificity (p=0.000). Serum and urine NGAL levels at admission correlated with severity (4-tier and Atlanta classification), APACHE and BISAP score and mortality ($p<0.05$). Patients who had high urine-NGAL on day1(n=36) had significantly higher mortality(11 patients had persistent AKI(5 expired) while 7 patients had transient AKI(4 expired); this was statistically significant (p=0.001)).Of the patients who had lower urine-NGAL on day1(n=14), none had persistent AKI and 3 had transient AKI . Day1 urine-NGAL had a high probability to predict persistent AKI as well as mortality. At a cut off of 221ng/ml, urine-NGAL had a sensitivity and specificity of 65% in predicting severe pancreatitis (AUC=0.755,p=0.013). NGAL levels were significantly higher in AP than in controls both in serum and urine on both days(p=0.00).
CONCLUSION: NGAL(both serum and urinary) predicts AKI and severity in acute pancreatitis. Day1 urine-NGAL can be used to predict AKI, both its occurrence and persistence and can be used to monitor renal failure in patients with AP.

P655 CIRCULATING LEVELS OF FGF21 ARE ELEVATED DURING THE COURSE OF ACUTE PANCREATITIS IN PATIENTS

R. M. Nijmeijer[1,*], A. E. Kremer[2], H. G. Gooszen[3], C. Wijmenga[4], K. J. Van Erpecum[5], P. L. Jansen[2,6], F. G. Schaap[2], the Dutch Pancreatitis Study Group. [1]*Department of Internal Medicine, Rijnstate Hospital, Arnhem,* [2]*Tytgat Institute for Liver and Intestinal Research, Academic Medical Center, Amsterdam,* [3]*Department of OR, University Medical Center St. Radboud, Nijmegen,* [4]*Department of Genetics, University Medical Center Groningen, Groningen,* [5]*Department of Gastroenterology, University Medical Center Utrecht, Utrecht,* [6]*Department of Gastroenterology and Hepatology, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Fibroblast Growth Factor 21 (FGF21) is a stress-induced hepatokine that affects glucose and lipid homeostasis via effects on white adipose tissue and possibly other tissues. Moreover, FGF21 reduces severity of cerulein-induced acute pancreatitis (cAP) in mice. Pancreatic expression of FGF21 is transiently induced in the early phase of cAP, and may evoke autocrine signalling in acinar cells that express the relevant (co)receptors for FGF21. It is currently unknown how FGF21 limits pancreatic damage during cAP, and if a similar protective effect exists in humans. As an initial step to address the role of FGF21 in human AP, we determined FGF21 serum levels during the course of AP and studied the contribution of genetic variation in the FGF21 locus.
AIMS&METHODS: FGF21 levels were determined by ELISA in a total of 219 sera from AP patients at 0-9 days after onset of symptoms, and in 61 healthy controls. In addition, over 400 patients with AP and 1080 healthy controls were genotyped for three SNPs with predicted loss of FGF21 function and for one promoter variant with predicted impairment of stress-induction of FGF21.
RESULTS: Relative to healthy controls (median 0.11 ng/mL, range 0.02-0.49 ng/mL), circulating FGF21 levels increased from the first day after onset of AP symptoms, becoming significantly elevated after 3 (median: 0.23 ng/mL, range 0.018-18.0 ng/mL, $P<0.01$) and 4 days (median 0.29ng/mL, range 0.02-1.3 ng/mL, $P<0.01$) before levelling off. Drastic elevation (>2.5 ng/mL, *i.e.* >5 times higher than the maximum level in healthy controls) of serum FGF21 levels was noted in several patients, mostly after 1-3 days of symptom onset. Genetic analysis failed to detect minor alleles of three of the studied SNPs in both patients and controls. The fourth SNP did not show association to acute pancreatitis.
CONCLUSION: Serum FGF21 levels become elevated during the course of AP. The stimulus for this elevation and the source of FGF21 are unknown. Elevated FGF21 levels may counteract inflammation-induced lipolysis in white adipose tissue, and prevent lipotoxicity in the already compromised pancreas in AP patients. The large interindividual variation of FGF21 levels in AP patients, and a possible pancreatoprotective action of FGF21 require further study.

P656 FACTORS ASSOCIATED WITH SEVERE OUTCOME OF ACUTE PANCREATITIS – LARGE MONOCENTRIC EXPERIENCE

S. Bota[1,*], I. Sporea[1], R. Sirli[1], A. Popescu[2], M. Danila[1], M. Strain[1], D. Chisevescu[1], O. Gradinaru-Tascau[1], M. Popescu[1], M. Sendroiu[1], D. Suseanu[1], A. Martie[1], T. Moga[1], F. Bende[1], C. Popescu[1]. [1]*Gastroenterology and Hepatology,* [2]*Gastroenterolog and Hepatology,* "*Victor Babes*" *University of Medicine and Pharmacy, Timisoara, Romania*

INTRODUCTION: Acute pancreatitis (AP) is an acute inflammation of the pancreas with an unpredictable evolution. There are several scales and markers which try to predict its evolution.
AIMS&METHODS: Aim: to retrospectively assess the factors associated with severe evolution of AP.
Material and method: Between January 2006 and December 2012, 822 patients with AP were admitted in our Department. According to the Atlanta criteria we classified AP as mild or severe. We performed univariant and multivariate analysis to evaluate the correlation of the following parameters with a severe outcome of AP: age, body mass index (BMI), gender, etiology of AP, serum lipase, hematocrit, white blood count, serum creatinine, aspartat-aminotransferase (AST), alanine-aminotransferase (ALT), total bilirubin, alkaline phosphatase, gamma-glutamyl transpeptidase (GGT) and C reactive protein (CRP). All biological tests were performed at admission, excepting CRP which was collected 48-72 hours from the onset of AP symptoms.
RESULTS: From the entire cohort of patients, 62.5% had mild AP and 37.5% severe AP, while the mortality rate was 4.2%. The etiology of AP was: alcoholic - 31.9%, biliary – 46.5% and non-alcoholic, non-biliary-21.6%.
In univariant analysis, the following factors were correlated with severe evolution of AP: CRP (r=0.458; $p<0.0001$), white blood count (r=0.291; $p<0.001$), creatinine (r=0.279; $p<0.001$), age (r=0.219; $p<0.0001$), AST (r=0.102, p=0.01), ALT (r=0.098, p=0.01), BMI (r=0.096; p=0.007), alkaline phosphatase (r=0.085; p=0.04), serum lipase (r=r=0.076, p=0.007); and the following factors were not correlated with severe AP: etiology (r=0.005, p=0.88), gender (r=0.024, p=0.48), hematocrit (r =-0.021, p=0.54), total bilirubin (r=0.044, p=0.27), GGT (r=0.083, p=0.06).
In multivariate analysis only the following factors were associated with severe outcome of AP: white blood count ($p<0.0001$), age (p=0.001), serum creatinine (p=0.002) and CRP (r=0.002).
CONCLUSION: In univariant analysis, CRP was the factor best correlated with a severe outcome of AP, while in multivariate analysis, besides CRP, serum creatinine, age and white blood count were the only parameters correlated with a severe outcome of AP.

P657 MYRIADS OF MARKERS AND SCORING SYSTEMS FOR MULTIPLE EVENTS IN ACUTE PANCREATITIS . . .. WHICH DO WE MIX AND WHEN DO WE MATCH . . .

S. Appasani[1,*], R. B. Thandassery[1], J. Basha[1], U. Dutta[1], T. D. Yadav[1], K. Singh[1], R. Kochhar[1]. [1]*Gastroenterology, PGIMER, Chandigarh, India*

INTRODUCTION: Pancreatitis includes a plethora of events and markers for risk stratification.
AIMS&METHODS: *AIMS*
To prospectively evaluate the role of serum biochemical parameters, clinical scoring systems and computerized tomography(CT) severity scoring systems in determination of severity & hospital course of acute pancreatitis at different time frames during hospitalization.
MATERIALS AND METHODS Patients with acute pancreatitis from January2009-June2011 were stratified into mild & severe pancreatitis as per Atlanta criteria. CT scan was done in all patients after & was graded as per CT severity index(CTSI) and Mortele's modifiedCTSI(mCTSI). RANSON, Acute Physiology and Chronic Health Evaluation II(APACHE) score,Bedside Index for Severity in Acute Pancreatitis score (BISAP), Modified Organ Failure Score(MOFS)were calculated along with C – ReactiveProtein(CRP), coagulation

parameters, renal functions, liver functions and blood gases. All of them were repeated as required &correlated with clinical course and outcome.
RESULTS: 250 consecutive patients with acute pancreatitis (66%males, age13–84yrs) were analyzed. CRP($p<0.001$), urea ($p<0.001$), creatinine ($p=0.002$), arterial pH($p=0.004$), bicarbonate ($HCO3^-$) ($p<0.001$), D-Dimer ($p<0.001$) were found to correlate with severity of pancreatitis on multivariate analysis along with all scoring systems.When analyzed on ROC, D-Dimer (AUC=0.970, $p<0.001$)& BISAP scores (AUC=0.976, $p<0.001$) ranked best in predicting severe pancreatitis. Need for intervention was best assessed by CTSI (AUC=0.910, $p<0.001$)& mCTSI(AUC=0.890, $p<0.001$). APACHE and MOFS were repeated weekly in hospital and the highest score amongst them correlated along with initial score in predicting organ failure (AUC=0.989,0.966, $p<0.001$), infected necrosis (AUC=0.950,0.966, $p<0.001$) & final outcome (AUC=0.886,0.905, $p<0.001$).
CONCLUSION: Different parameters are required at different time frames.Emergency teams need not concentrate on complex scores & multiple markers which can be used if the patient requires prolonged hospitalization.
At admission simple parameters like BISAP and serum D-Dimer could be valuable in stratifying pancreatitis**. Need for interventions** could be predicted better with CTSI either at onset or during hospital course**. For clinical follo-wup**in patients with prolonged hospital stay, scoring systems APACHE and MOFS are useful to predict organ failure, infected necrosis and final outcome.

P658 ARTERIAL BLOOD GAS ABNORMALITIES IN ACUTE PANCREATITIS

S. Appasani[1,*], R. B. Thandassery[1], J. Basha[1], U. Dutta[1], T. D. Yadav[1], K. Singh[1], R. Kochhar[1]. [1]*Gastroenterology, PGIMER, Chandigarh, India*

INTRODUCTION: Blood gas anomalies are common in patients with acute pancreatitis and its multifactorial in origin
AIMS&METHODS: *AIMS*
To study arterial blood gas abnormalities(ABG) at admission in acute pancreatitis and correlate them with various outcome.
MATERIALS AND METHODS
Patients with acute pancreatitis from January 2009-June 2012 were included into study after informed consent. They were stratified into mild & severe pancreatitis as per Atlanta criteria. ABG was obtained at admission prior to oxygen supplementation. Relevant biochemical and radiological investigations were done and institutional protocol for management of pancreatitis was followed. Outcome measures included occurrence of organ failure, infected necrosis, hospital course and mortality.
RESULTS: 450 consecutive acute pancreatitis patients(67% males, mean age-42.8±12.4yrs) were analyzed. There was no difference in arterial pH, pAo2, pCO2, $HCO3^-$ and SaO2 amongst males and females and various etiologies of acute pancreatitis. ArterialpH($p<0.001$), pAO2($p<0.001$), pCO2($p=0.007$) and SAO2($p=0.001$) correlated with severity of pancreatitis at admission. pAO2($p=0.004$) and pCO2($p=0.009$) correlated with incidence of necrosis while pH($p<0.001$) correlated with infected necrosis. Mortality correlated significantly with pH ($p<0.001$), pAO2($p<0.001$), $HCO3^-$($p=0.041$) and SpO2($p=0.043$). Arterial pH($p<0.001$), pAO2($p=0.035$), $HCO3^-$($p=0.016$) and SAO2($p=0.004$) correlated with occurrence of cardiovascular failure and hypotension. The mean pH and pCO2 in patients with respiratory failure (7.27±0.12, 33.75±5.7) were significantly lower than those without (7.35±0.06, 40.24±5.6, $p<0.001$) signifying the presence of mixed acid base disorder contributed by metabolic acidosis and alkalosis. Arterial pH correlated with all these parameters with significance even after excluding renal failure ($p<0.001$).
CONCLUSION: Arterial pH at admission is an important predictor of severity, mortality, organ failure and necrosis. Mixed acid base disorders exist in acute pancreatitis which need keen observation and correction.

P659 EFFICACY OF RECOMBINANT HUMAN SOLUBLE THROMBOMODULIN ON THE TREATMENT OF SEVERE ACUTE PANCREATITIS

T. Eguchi[1,*], H. Koga[1], M. Kurosawa[1], T. Fukuchi[1], H. Yamashita[1], D. Itou[1], K. Ashida[1]. [1]*Department of Gastroenterology and Hepatology, Osakafu Saiseikai Nakatsu Hospital, Osaka, Japan*

INTRODUCTION: Severe acute pancreatitis (SAP) is a subgroup of acute pancreatitis with poor prognosis which is characterized by systemic inflammatory responses. The pathogenesis of SAP remains unclear, but recent studies revealed that inflammatory cytokines in SAP triggered the development of systemic inflammatory responses, including disseminated intravascular coagulation (DIC). Thus, a therapeutic agent with anti-inflammatory and anti-coagulatory effect seems to be practical for the treatment of SAP. Recombinant human soluble thrombomodulin (rTM) is an anti-coagulatory agent which was recently approve for the treatment of DIC in Japan. Furthermore, increasing numbers of reports revealed its anti-inflammatory effect through binding to cleave high mobility group box 1 (HMGB1).
AIMS&METHODS: To investigate the efficacy of rTM on the treatment of SAP. We reviewed the medical records of 12 patients who were treated with rTM for SAP in our department between 2009 and 2012. All of them were accompanied by DIC and 380U/kg of rTM was administrated once daily until resolution of DIC in addition to the other therapeutic agents, such as anti-bacterial agents and protease inhibitors (rTM group). The efficacy of rTM was evaluated by comparing the clinical outcome with that of 12 patients who were treated without rTM for SAP (Control group). Diagnosis of SAP was based on the Japanese severity scoring for acute pancreatitis.
RESULTS: As expected, SAP was more severe in rTM group than Control group at day 0 (day 0 is just before initiation therapy) (average age: 73.7 *v.s* 57.5, APACH II score: 13.6 *v.s* 7.3, CRP level: 21.9mg/dL *v.s* 15.0mg/dL, $P<0.05$). And, the ratio of patients with infected pancreatic necrosis was 50% for rTM group and 25% for Control group. In rTM group, the resolution of DIC was observed in 100% of cases. And the average level of CRP at day 7 was 8.31mg/dl, which was significantly lower than CRP level at day 0 ($P<0.05$). Negative conversion days in CRP were 20.7 days, and oral intake period were 9.9 days, and hospitalization days were 40.8 days. In addition, HMGB1 level was a tendency to decrease from 22.8ng/mL (at day 0) to 15.3ng/mL (at day 7). In Control group, there were no patients accompanied by DIC at day 0. And, the average level of CRP at day 7 was 4.51mg/dL, Negative conversion days in CRP were 18.5 days, oral intake period was 9.5 days, and hospitalization days were 30.6 days. Of note the clinical outcome of rTM group was not inferior to that of Control group. Moreover, HMGB1 level at day 7 in Control group (25.6ng/mL) was not decreased as compared with 20.2ng/mL at day 0.
CONCLUSION: rTM might be a novel therapeutic agent for the treatment of SAP.

P660 CLINICAL COURSE OF HEREDITARY PANCREATITIS IN CHILDREN.

G. Oracz[1,*], J. Kierkus[1], M. Dadalski[1], J. Ryzko[1]. [1]*Dep. of Gastroenterology, Hepatology and Feeding Disorders, The Childrens Memorial Health Institute, Warsaw, Poland*

INTRODUCTION: Hereditary Pancreatitis (HP) is a rare inherited condition. The reported pediatric experience with HP is small. We reviewed our experience over the last 20 years.
AIMS&METHODS: The aim of our study was to evaluate the clinical course of HP in children.
209 children with chronic pancreatitis, hospitalized since 1988 to 2012, were enrolled into the study. The medical records of these patients were reviewed for data on the presentation, diagnostic findings and endoscopic treatment. All children were screened for the PRSS1 gene mutations.
RESULTS: Hereditary pancreatitis was diagnosed in 28 patients (13.4%) (20 girls and 8 boys). PRSS1 gene mutations were found in 24 patients. We detected R122H/- in 13, R122C/- in 5, N29I/- in 5 and E79K/- in 1 patient. Family history was positive in all children with HP except one. In 4 patients without mutations diagnosis of HP was made when the patients satisfied the requirements of the family history. In one patient we found SPINK1 mutation (N34S/-). In 2 children CFTR mutation (IVS8-5T(TG)11/-) was present. There was no difference in age of the disease onset between HP group and non-HP group (7,4 vs. 9.08 years; NS). In children with PRSS1 mutation ERCP had mean 2,5° Cambridge grade, vs. 1.6°, $p<0.05$. 19 patients with HP had calcifications in the imagine studies (68% vs. 31%, $p<0.05$). Therapeutic intervention, including both surgical and endoscopic intervention, was more frequent in the HP group (75% vs. 35%; $p<0.05$). Pancreatic duct stenting was done in 16 children with HP (58% vs. 26%; $p<0.05$). ESWL was performed more frequent in HP group (20% vs. 3%; $p<0.05$). Endocrine pancreatic insufficiency was observed in 7 patients (25% vs. 17,6%, NS).
CONCLUSION: Hereditary pancreatitis in children has worse clinical course than CP in children without PRSS1 mutations.

P661 REVIEW OF PANCREATITIS IN CHILDREN - A TERTIARY CENTRE EXPERIENCE OVER 6 YEARS

V. M. Sivaramakrishnan[1,*], C. Godavitarne[1], M. Davenport[2], P. Harrison[3], B. Vadamalayan[1], A. Dhawan[1]. [1]*Paediatric Liver, GI & Nutrition Centre,* [2]*Department of Paediatric Surgery,* [3]*Institute of liver studies, Kings College Hospital NHS Foundation Trust, London, United Kingdom*

INTRODUCTION: Paediatric pancreatitis is relatively uncommon & the aetiology is diverse compared to adults. Due to heterogeneous symptoms in children it is often misdiagnosed.
AIMS&METHODS: To evaluate clinical presentation, aetiology, management & outcome of pancreatitis in children. This study reports a tertiary centre cohort of 60 children aged 0 yrs to 18 yrs with pancreatitis in the last 6 years. Diagnosis was made on clinical information with biochemical and/or radiological evidence. Demographic & clinical data were collected.
RESULTS: Sixty cohort (males 30) - Median age (yrs) was 10.5 (range: 2 to 17). Abdominal pain was the predominant symptom (86%) & in one third it was the only symptom. Thirty eight (63%) had acute pancreatitis **(AP)** of which 5 had recurrent acute pancreatitis. Twenty two (37%) had chronic pancreatitis **(CP).** In AP the predominant aetiology was Biliary disease in 36.8% half of them had associated Pancreato-biliary anatomic (PBA) anomalies and trauma in 23.7%. In CP the predominant aetiology was hereditary (27.3%) and idiopathic (27.3%). In hereditary group: PRSS1 & SPINK1 gene mutations in 86% & 14% respectively. Table 1: Aetiology (Top five) of AP and CP

	AP		CP	
	Aetiology	% Of AP	Aetiology	% Of CP
1	Biliary	36.8	Hereditary	27.3
2	Trauma	23.7	Idiopathic	27.3
3	Idiopathic	10.5	Biliary	13.6
4	Multisystem including infections	7.9	Autoimmune	13.6
5	Metabolic	7.9	PBA Anomalies	9.0

Other causes: AP - Isolated PBA anomalies in 5.4% and 2.6% each of autoimmune, hereditary & drug induced. CP - Multisystem & metabolic in 4.6% each. MRCP & ERCP were done in 73% and 65% respectively. In the entire cohort - PBA anomalies were identified in 11/60 (18.3%) and aetiology was idiopathic in 10/60 (16.6%).
One-third (36.7%) was medically managed, 26.6% had therapeutic ERCP (stent insertion), 25% had surgical intervention (cystogastrostomy -2, hepaticojejunostomy - 9, distal pancreatectomy -2 & Puestow procedure - 2) and 11.7% had ERCP & surgery. Mean number of inpatient admissions - 4.6 (range 1 to 14). Mean cumulative hospital stay for each patient - 21.5 days (range 1 to 81 days). Complications (25%) of which Pseudocyst in 9 (15%). One (1.6%) died due to systemic illness.
CONCLUSION: In our centre acute pancreatitis in children is predominantly associated with Biliary disease and trauma. One-fourth of chronic pancreatitis was hereditary. Extensive investigation including genetic testing is required to determine aetiology, as the outcome is dependent on it. Paediatric Pancreatitis has significant morbidity. Children with pancreatitis need to be referred to a tertiary centre where paediatric ERCP facility is available.

P662 MANAGING CYSTIC PANCREATIC LESIONS. THE EXPERIENCE AT A REGIONAL CANCER CENTRE IN THE UK

A. Olivares[1,*], B. BABURAJAN[2]. [1]*GASTROENTEROLOGY, HOSPITAL SEVERO OCHOA, MADRID, Spain,* [2]*GASTROENTEROLOGY, MAIDSTONE HOSPITAL, MAIDSTONE, United Kingdom*

INTRODUCTION: Cystic pancreatic lesions are increasingly recognised due to higher detection rate afforded by current CT technology. Concerns about malignant transformation have led to many attempts at stratifying this risk. Our regional protocol involves CT followed by EUS and fluid analysis. High risk lesions are resected if patients tolerate surgery, medium risk lesions are followed with CT and patients with low risk lesions are reassured and discharged.
AIMS&METHODS: To review the success of the risk stratification strategy and to assess the predictive capability of the various indicators.
All cases of pancreatic cysts that underwent EUS at our referral centre between August 2009 and February 2013 were included. All patients underwent CT with a pancreatic protocol and EUS with FNA. Amylase, CEA and CA 19-9 were estimated in the fluid at a single laboratory. Cyst characterisation was done at EUS by a single operator. An experienced cytopathologist reported on all smears. Surgery was performed at the Pancreatic-biliary Cancer unit at King's College Hospital, London.
RESULTS: We included 99 patients with average age of 68 years (53.5 % female and 46.46 % male). All patients had EUS within 2.65 months of the index CT. 59 % of the cysts were in the head, 17 % in the body and the rest were in the neck, uncinate and tail. The average cyst area was 6.59 cm^2 [0.27-100]. The EUS diagnosis was of mucinous cystadenoma in 24 %, pseudocysts in 19 %, serous cystadenoma in 12 % and IPMN in 14 %. Of these, 11 were branch IPMN, the rest were main duct IPMNs. Three patients had an associated mass. Although cytology was productive in 83 cases, diagnostic information was obtained in 49 (50%) with positive mucin stain, 4 with atypical cells (2 were malignant), 3 with papillary and 1 with neuroendocrine. A sample adequate for fluid biochemical analysis was obtained in 48 cases. Positive cytology or suspicious CT influenced the decision to operate. Nine patients underwent surgery. Of these 3 had mucinous cystadenoma, 1 IPMN, 3 pseudocysts, 1 papillary neoplasia and one neuroendocrine tumor. Another patient had an adenocarcinoma with cyst degeneration, not candidate for surgery. None of the cases surveyed developed malignancy during the surveillance period. None of the patients discharged developed malignancy but information on this group is not universally available.
CONCLUSION: The risk stratification protocol for pancreatic cysts reliably detects individuals with high risk lesions. CT and cytology are most useful in identifying high risk lesions and EUS and cyst fluid analysis identify low risk lesions. Overall, the risk of malignancy in this group is low and an expectant approach as practiced in the majority appears appropriate.

P663 DIAGNOSTIC ACCURACY OF CONTRAST-ENHANCED COMPUTED TOMOGRAPHY IN ASSESSING EXTRA-REGIONAL LYMPHADENOPATHY IN PANCREATIC CANCER: A SYSTEMATIC REVIEW

D. S. J. Tseng[1,*], H. C. van Santvoort[1], S. Fegrachi[1], M. G. Besselink[2], I. H. Borel Rinkes[1], M. S. van Leeuwen[3], I. Q. Molenaar[1]. [1]*Dept. of Surgery, University Medical Center Utrecht, Utrecht,* [2]*Dept. of Surgery, Academic Medical Center, Amsterdam,* [3]*Dept. of Radiology, University Medical Center Utrecht, Utrecht, Netherlands*

INTRODUCTION: Pancreatoduodenectomy is the only potentially curative option for patients with pancreatic cancer. One of the contra-indications for curative resection is extra-regional lymph node (ELN) metastases. Although computed tomography (CT) quality improved over the last decade, pre-operative evaluation of ELN may be difficult. This is the first systematic review that focuses on the CT in assessing ELN metastases in pancreatic or peri-ampullary cancer.
AIMS&METHODS: The aim of this study was to determine the diagnostic accuracy of CT in assessing ELN metastases in pancreatic cancer.
We performed a systematic review in PubMed/Embase/Cochrane according to the PRISMA guidelines of studies published up to March 22nd 2013. Studies reporting on the CT assessment of ELN in patients undergoing pancreatoduodenectomy were included. We excluded studies that did not report the number of suspected ELN on CT and number of ELN metastases during histopathological investigations; i.e. if it was not possible to construct a 2×2 contingency table. Data on baseline characteristics, CT-investigations and histopathological outcomes were extracted. Diagnostic accuracy, positive predictive value (PPV), negative predictive value (NPV), sensitivity and specificity were calculated for individual studies and pooled data.
RESULTS: After screening 4.030 studies, 4 cohort studies reporting on CT-findings and histopathological outcome in 157 patients with pancreatic cancer were included. Histopathologically proven ELN metastases were present in 28/157 (18%) patients, which had been diagnosed pre-operatively on CT in 7 (25%) patients. Of the remaining 129 patients without ELN metastases, CT falsely suggested presence of ELN metastases in 18 patients. Overall diagnostic accuracy varied from 63-81% and specificity, PPV and NPV ranged from 80-100%, 0-100% and 67-90% respectively. However, sensitivity was poor with ranges from 0-38%. Pooled accuracy, sensitivity, specificity, PPV and NPV were 75%, 25%, 86%, 28% and 84% respectively.
CONCLUSION: CT has a low diagnostic accuracy in assessing ELN metastases in patient suspected of pancreatic cancer. We therefore propose that – in absence of other signs of irresectability, e.g. liver metastases, arterial encasement – the suspicion of ELN metastases on CT should not be a contra-indication for explorative laparotomy and, when possible, pancreatoduodenectomy.

P664 RESECTION MARGIN CLEARANCE IN PANCREATIC CANCER AFTER IMPLEMENTATION OF THE LEEDS PATHOLOGY PROTOCOL (LEEPP): CLINICALLY RELEVANT OR JUST ACADEMIC?

F. Gebauer[1,*], M. Tachezy[1], Y. Vashist[1], A. Marx[2], E. Yekebas[1], J. R. Izbicki[1], M. Bockhorn[1]. [1]*General, Visceral and Thoracic Surgery,* [2]*Dept. of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

INTRODUCTION: Applying rigorous standardized histopathological protocols in the examination of resection specimens of PDAC of the pancreatic head reveals microscopic incomplete (R1) resection rates of up to and greater than 80%. Aim of this study was to assess oncological outcome in patients after R0/R1 resections in a homogenous cohort suffering from ductal adenocarcinoma (PDAC) of the pancreatic head.
AIMS&METHODS: Between January 2007 and May 2011, 125 consecutive patients underwent surgical pancreaticoduodenectomy (PD) or pylorus-preserving PD because of PDAC of the pancreatic head. These patients were histopathologically examined according to a standardized protocol (Leeds Pathology Protocol *LEEPP*). The oncological outcome and clinicopathological data were compared to a matched patient group before implementing the abovementioned protocol (n = 108).
RESULTS: The R1 rate increased significantly after implementing the LEEPP from 13 to 52%. A difference in overall survival (OS) could not be detected between R0 and R1 resections. The median OS in patients with a tumor clearance

of less than 2 mm from the resection margin was 15.1 months (12.1 to 18.1 months) vs. 22.2 months (7.8 - 36.7 months) (P = .046). Multivariate analysis revealed a margin clearance or 2mm and more as independent prognosticator for OS.
CONCLUSION: With applying a standardized histopathological protocol, there was still no correlation between the R-status and OS in patients with PDAC. However, since a margin clearance of 2 mm or more is a predictive factor for OS the R1 definition might have to be changed in PAC.

P665 EFFICACY OF EUS-IMPLANTED FIDUCIAL MARKERS TO DIMINISH MARGINS IN RADIATION OF PANCREATIC CANCER

J. Van Hooft[1,*], A. van der Horst[2], G. van Tienhoven[2], R. Davila Fajardo[2], P. Fockens[1], A. Bel[2]. [1]*Department of Gastroenterology and Hepatology,* [2]*Department of Radiotherapy, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Radiation treatment of pancreatic tumors uses target volume margins to correct for the substantial day-to-day position variation of the pancreas. Modern linear accelerators (linacs) are equipped with Cone-Beam CT (CBCT), a CT device with reasonable image quality enabling imaging during treatment. Fiducial markers in the pancreas are well visible on CBCT. These markers can help diminish the error in daily patient treatment, thereby reducing the large margins. Consequently the radiation exposure of surrounding healthy tissue can be reduced. The aim of our study is to study the feasibility of EUS-guided placement of fiducial markers and to quantify interfractional position variation using these markers.
AIMS&METHODS: Eleven consecutive patients with borderline-resectable pancreatic cancer were included in our study. Each patient had 2 or 3 flexible gold fiducials (Visicoil; 10–20 mm, 0.35mm diameter; 27 in total) implanted under EUS-guidance using a 22-gauge needle. Daily CBCTs were obtained before each of 25 radiation fractions and registered with the reference CT on bony anatomy and on each of the fiducials. From this, the position variation of the fiducials relative to the vertebrae was measured as well as the distance between the markers.
RESULTS: In 10 out of 11 patients fiducial markers could be detected on the treatment planning CT, 0 to 5 (average 3.4) days after implantation, as well as on all 242 CBCTs obtained during treatment. A clear shift in the distance between markers that would indicate marker migration was not seen for any of the 20 pairs. Position variations (displacements) were largest in the cranio-caudal direction. For 51/242 (21%) of fractions, the variation in at least one direction was >10mm.
CONCLUSION: The large position variation and its range between patients strongly supports the benefit and
necessity of EUS-implanted fiducial markers for better focusing the radiation to the pancreas tumor, enabling
smaller safety margins

P666 DAXX/ATRX AND MEN1 GENES ARE STRONG PROGNOSTIC MARKERS IN PANCREATIC NEUROENDOCRINE TUMOR

J. Park[1,*], W. H. Paik[1], B. J. Song[1], J. K. Ryu[1], J. M. Park[1], S. H. Lee[1], Y.-T. Kim[1], S. Y. Yang[1]. [1]*INTERNAL MEDICINE, GASTROENTEROLOGY, SEOUL NATIONAL UNIVERSITY HOSPITAL, SEOUL, Korea, Republic Of*

INTRODUCTION: The incidence and prevalence of pancreatic neuroendocrine tumors (PNET) are increasing; these tumors represent approximately 1.3% of all cases of pancreatic cancer in incidence and 10% of cases in prevalence. PNET has usually better prognosis compared to that of pancreatic ductal adenocarcinoma, however, some of PNETs are diagnosed as in advanced stage with distant metastasis. Accurate prediction of its prognosis and the proper treatment may be very important in patients with PNETs.
AIMS&METHODS: The aim of this study was to explore prognostic markers based on genetic basis of PNETs and they were known as the most frequently mutated genes MEN1, DAXX/ATRX. The pathologically confirmed 111 patients with PNETs were enrolled and the following clinical and pathologic factors were evaluated; AJCC stage, treatment modalities, differentiation and mitosis. Also, immunohistochemical staining of MEN1, DAXX/ATRX genes, Ki-57, chromogranin, synaptophysin, CD56, somatostatin, insulin and glucagon were done.
RESULTS: The median age of study patients was 55 yrs and AJCC staging of the patients were as follows: IA; 41 patients, IB; 30 patients, IIA; 13 patients, IIB; 8 patients, IV; 19 patients. The median OS was 55.5 months and 81 patients underwent R0 resection. There were 23 patients (27%), 17 patients (20%) and 27 patients (31%) were positive for MENIN, ATRX and DAXX respectively. In addition, DAXX and ATRX are known to be mutually exclusive genes. Mutations in the MEN1 and DAXX/ATRX genes were resulted in negative immunohistochemical staining and it was significantly associated with longer DFS () and OS (33 mo. vs. 65 mo., $p < 0.01$; 63 mo. vs. 124 mo., $p < 0.001$ respectively). AJCC staging and grade of differentiation were the statistically significant prognostic factors among other clinical variables.
CONCLUSION: Mutations in the MEN1 and DAXX/ATRX genes (negative immunohistochemical staining results) were associated with better clinical prognosis. This study was the first one to investigate prognostic markers based on genetic basis of PNETs.

P667 POSTOPERATIVE RECURRENCE IN PATIENTS OPERATED ON FOR BENIGN INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS (IPMN)

O. Roux[1], M.-P. Vullierme[2], J. Cros[3], S. Dokmak[4], S. Gaujoux[4], B. Aussilhou[4], V. Rebours[1], O. Hentic-Dhomé[1], F. Maire[1], M. Palazzo[1], L. Palazzo[1], A. Aubert[1], A. Couvelard[5], A. Sauvanet[4], P. Hammel[1], P. Ruszniewski[1], P. Lévy[1,*]. [1]*Service de Pancreatologie,* [2]*Service de Radiologie,* [3]*Service d'Anatomo-Pathologie,* [4]*Service de Chirurgie Hépato-biliaire, Hopital Beaujon, APHP, Université Denis Diderot, Clichy,* [5]*Service d'Anatomo-Pathologie, Hopital Bichat, APHP, Université Denis Diderot, Paris, France*

INTRODUCTION: Risk of postoperative recurrence in patients operated on for benign IPMN has not been extensively studied. Benign and malignant IPMN were often considered together, and recurrence not always distinguished from lesions not resected at time of surgery.
AIMS&METHODS: To evaluate the recurrence rate of IPMN and the occurrence of non IPMN-related pancreatic adenocarcinoma after partial pancreatectomy for benign IPMN; to assess the need for reoperation; to look for predictive factors of relapse. Clinical, imaging and pathological data were collected for all consecutive patients operated on in a single centre between 1998 and 2008. Recurrence of IPMN was evaluated on MRI performed at intervals depending on the stage of resected lesions. Recurrence was defined as new cystic lesions communicating with main pancreatic duct. The evolution of IPMN cysts not resected during surgery was documented but not considered as a recurrence. A minimal 2-yearpostoperative follow-up was necessary.
RESULTS: The data for 125 patients (63 males, median age at surgery 60 (20-77) yrs, low (LGD), moderate (MGD), high (HGD) grade dysplasia in 47, 43 and 35 pts, respectively) were analysed. IPMN involved branch ducts (BD, n=69), main pancreatic duct (MPD, n=5) or mixed-type, n=51. Examination of pancreatic section showed no IMPN lesion in 83 pts, LGD in 42 pts, MGD or HGD in no pts. Median postoperative follow-up was 4(2-13) years. 83 pts had no residual lesion after surgery (group 1, median F/U: 4yrs (2-13)), while 42 had some lesions deliberately not resected in order to avoid extensive pancreatectomy (group 2, median F/U: 4 yrs (2-8)). 3 recurrences were observed in Group 1 pts, all of them were invasive recurrence leading to total pancreactectomy. In group 2 pts, no new lesion occurred in any pt but 1 or more changes in existing lesions were observed in 5 pts (increase in size, mural nodule, MPD involvement, occurrence of symptoms in 3, 1, 2 and 1 pts, respectively, leading to total pancreatectomy in 4 pts (LGD and MGD in 2 and 2 pts respectively, 1 inoperable pt).
CONCLUSION: Postoperative relapse rate of benign IPMN is low (3.6%) after a 4-year follow-up. Detection of invasive recurrence prompts to carefully follow all operable patients. Residual lesions should be followed like de novo IPMN

P668 PROGNOSTIC SIGNIFICANCE OF QUALITY OF LIFE IN PANCREATIC CANCER

T. G. Oh[1,*], M. J. Chung[1], J. Y. Park[1], S. Bang[1], J. B. Chung[1], S. Y. Song[1], S. W. Park[1]. [1]*Division of Gastroenterology, Yonsei Institute of Gastroenterology, Seoul, Korea, Republic Of*

INTRODUCTION: We only use tumor marker (CA19-9) and imaging method for evaluating chemotherapy response. But, there might be several factors for predicting chemotherapy response. We evaluated quality of life (QoL) as the factor for predicting chemotherapy response.
AIMS&METHODS: Between November 2005 and April 2013, 243 patients with locally advanced or metastatic pancreatic adenocarcinoma who had favorable response at the time of first follow-up were enrolled. We defined 5 categories of QoL as ECOG, pain scale, ascites, jaundice, weight loss. We evaluate whether worsening of QoL influence to predictability for chemotherapy response.
RESULTS: 55 of 243 patients had worsening of QoL which is related to cancer. We defined these patients as group B, while rest of them defined as group A. When we accessed chemotherapy response evaluation second time, in group A, 49 (26.2%) of 188 patients had disease progression, but, in group B, 47 (85.5%) of 55 patients had disease progression ($p < 0.001$). There also be significant difference in overall survival between group A and B patients (median OS; group A : 14.3 months vs. group B : 8.8 months, $p < 0.001$). If we divided groups according to increment of CA19-9, the group who had increment of CA 19-9 at the first follow-up had poor survival outcome compared to the group who had decrease of CA 19-9 (median OS; 11.3 months vs. 13.9 months, $p = 0.012$). But, it seemed that QoL was more powerful factor for predicting chemotherapy response compared to CA19-9 (HR (hazard ratio) = 2.483 for QoL, $p < 0.001$ vs 1.277 for CA19-9, $p = 0.243$).
Table 1. Comparison of disease progression rate at the time of second follow-up and survival outcome according to worsening of QoL

	Group A*	Group B*	Total	p-value
Total, n	188	55	243	
Disease progression at the time of second follow-up, n (%)	49 (26.2%)	47 (85.5%)	96 (39.5%)	<0.001
Overall Survival (months)	14.3	8.8	13.2	<0.001
Progression-free survival (months)	7.9	4.9	6.9	<0.001

CONCLUSION: We suggest that worsening of QoL should be considered as important factor for predicting chemotherapy response. Objective measurement system for evaluating QoL will be needed for validation of QoL as the factor for predicting chemotherapy response.

P669 EVALUATION OF THE ROLE OF SURGERY FOR METASTATIC PANCREATIC CANCER: A SINGLE CENTER EXPERIENCE

T. Takayashiki[1,*], H. Yoshitomi[1], H. Shimizu[1], M. Ohtsuka[1], A. Kato[1], K. Furukawa[1], S. Kuboki[1], D. Okamura[1], D. Suzuki[1], N. Sakai[1], M. Nakajima[1], M. Miyazaki[1]. [1]*Department of General Surgery, Graduate School of Medicine, Chiba University, Chiba, Japan*

INTRODUCTION: Metastasectomy has become standard treatment for some malignancies. However, the role of surgery for metastatic pancreatic cancer remains unclear because these tumors are uncommon.
AIMS&METHODS: A retrospective study during the period between April 2000 to March 2013 was designed to evaluated the surgical treatmetn and prognosis of metastatic pancreatic cancer in our institution.
RESULTS: Nine patients with metastatic pancreatic cancer were identified. Of these 9 patients, 4 were men and 5 were women with a mean age was 62 (49-76) year-old. Primary cancer were renal cell carcinoma (RCC) in 7 and lung cancer (LC) in 2. The tumor was located in the head in 2, in the body in 2, in the tail in 2, and the other 3 cases were multiple metastasis. Surgical method included pancreaticoduodenectomy in 2, distal pancreatectomy in 2, total pancreatectomy in 2, pancreaticoduodenectomy with partial resection in 1, partial resection in 1, and laparoscopic distal pancreatectomy in 1. Median desease free survival after metastasectomy of RCC was 2.8 years. All patients of RCC except 2 cases (died of other illness) were alive at follow up period and 5-year survival rate was 75.0%. All the recurrent cases of RCC were treated molecular target therapy such as sorafenib or sunitinib. In the LC group, one patinet who was diagnosed pleomorphic carcinoma died of local recurrence only 3 months after metastasectomy. In contrast, the other patinent who underwent laparoscopic surgery is alive more than 1 year after metastasectomy without any recurrence.
CONCLUSION: An aggressive surgical resection combined with molecular target therapy contributes long-term survival of the patients of pancreatic metastasis from RCC. However, usefulness of the pancreatic metastasectomy of LC is still unclear and their prognosis may depend on pathological diagnosis. Laparoscopic surgery should be considered in the cases of isolated pancreatic metastasis with neither local invasion nor lymph node metastasis.

P670 TREATMENT STRATEGIES AFTER CURATIVE RESECTION OF PANCREATIC ADENOCARCINOMA: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

W.-C. Liao[1,2,*], Y.-K. Tu[2], K.-L. Chien[2], M.-S. Wu[1], J. Lin[3]. [1]*Medicine, National Taiwan University Hospital,* [2]*Graduate Institute of Epidemiology and Preventive Medicine, National Taiwan University, Taipei,* [3]*School of Medicine, Fu Jen Catholic University, New Taipei City, Taiwan, Province of China*

INTRODUCTION: Major adjuvant therapies for pancreatic cancer include 5-fluorouracil, gemcitabine, chemoradiation, and chemoradiation plus 5- fluorouracil or gemcitabine. The optimal therapy remains elusive, and opinions on chemoradiation are divisive.
AIMS&METHODS: We conducted a random-effects Bayesian network meta-analysis to compare observation and these adjuvant therapies in terms of overall survival. We systematically reviewed randomised controlled trials comparing the above 6 treatment strategies. For meta-analysis of overall survival, hazard ratios (HRs) and survival durations were combined in a single network meta-analysis, and the influences of prognostic factors on effects of adjuvant therapies were evaluated with meta-regression.
RESULTS: Compared with observation, the HR (95% credible interval) for death was 0.62 (0.42-0.88) with 5-fluorouracil, 0.68 (0.44-1.07) with gemcitabine, 0.91 (0.55-1.46) with chemoradiation, 0.54 (0.15-1.80) with chemoradiation plus 5-fluorouracil, and 0.44 (0.10-1.81) with chemoradiation plus gemcitabine. The HR for death of adjuvant therapies vs observation increased by 2.5% (95% credible interval 0% to 5.3%) per 1% increase in the percentage of patients with positive lymph nodes. After adjustment for this factor, 5-FU and gemcitabine provided a significant survival benefit over observation alone [HR 0.65 (0.49-0.84) and 0.59 (0.41-0.83), respectively], whereas chemoradiation was associated with worse overall survival compared with 5-FU [HR 1.69 (1.12-2.54)] and gemcitabine [HR 1.86 (1.04-3.23)].

Table 1. Included randomised controlled trials

Author, year	Trial	Treatment arms
Kalser, 1985	GITSG	ChemoRT plus 5-FU/observation
Neoptolemos, 2001	ESPAC-1	Observation/5-FU/chemoRT
Neoptolemos, 2004	ESPAC-1	Observation/5-FU/chemoRT/ chemoRT plus 5-FU
Oettle, 2007	CONKO-001	Observation/gemcitabine
Smeenk, 2007	EORTC 40891	Observation/chemoRT
Regine, 2008	RTOG 9704	ChemoRT plus 5-FU/chemoRT plus gemcitabine
Ueno, 2009	JSAP-02	Observation/gemcitabine
Neoptolemos, 2009	ESPAC-1+/3 (v1)	Observation/5-FU
Neoptolemos, 2010	ESPAC-3 (v2)	5-FU/gemcitabine

ChemoRT: chemoradiation.
CONCLUSION: Compared with observation and chemoradiation, adjuvant 5-FU and gemcitabine prolonged overall survival after resection. Adding chemoradiation to 5-FU or gemcitabine did not provide significant additional survival benefit. Lymph node positivity adversely affected the overall survival advantage of adjuvant therapy over observation.

P671 OBJECTIVE ASSESSMENT OF SURGICAL RESTAGING AFTER CONCURRENT CHEMORADIATION FOR LOCALLY ADVANCED PANCREATIC CANCER

Y.-T. Kim[1,*], W. H. Paik[1], J. K. Ryu[1], S. H. Lee[1], S. W. Kim[2], J.-Y. Jang[2]. [1]*Department of Internal Medicine,* [2]*Department of Surgery, Seoul National University Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: The role of neoadjuvant chemoradiation therapy in locally advanced pancreatic cancer (LAPC) is still controversial, and previous studies did not provide objective improvements after neoadjuvant treatment.
AIMS&METHODS: The aim of this study was to evaluate surgical downstaging after concurrent chemoradiation therapy (CCRT) for LAPC by measuring the objective changes after treatment. From January 2003 through July 2011, 54 patients with LAPC underwent neoadjuvant CCRT. CT findings about tumor size, major vessel invasion before and after CCRT were analyzed.
RESULTS: Fourteen patients had borderline resectable and 40 patients had unresectable disease before CCRT. After CCRT, partial response was achieved in 4 patients. Stable disease and progressive disease were noticed in 36 and 14 patients, respectively. Tumor size showed no significant difference before and after CCRT (3.6 ± 1.1 vs. 3.6 ± 1.0 cm, $P = 0.61$). Vessel invasion was improved in 2 patients, while aggravated in 13 patients. Thirty-nine patients with unresectable and 11 patients with borderline resectable state at initial diagnosis still had unresectable and borderline resectable state after CCRT, respectively. Four borderline pancreatic cancers were aggravated to unresectable pancreatic cancer, whereas 1 unresectable pancreatic cancer was improved to borderline resectable after CCRT. Only 1 patient with borderline resectable disease underwent operation after CCRT, however curative resection was failed due to CA invasion and peritoneal seeding. The adverse events associated with CCRT were tolerable.
CONCLUSION: Preoperative CCRT in LAPC rarely leads to surgical downstaging, and it could make resectability rate become lower.

P672 CUX1 – A MARKER OF INVASIVE PHENOTYPE IN NEUROENDOCRINE TUMORS OF THE PANCREAS

S. Krug[1,*], B. Kühnemuth[1], H. Griesmann[1], M. Schober[1], B. Sipos[2], A. Schulze[3], T. M. Gress[1], P. Michl[1]. [1]*Department of Gastroenterology and Endocrinology, University Hospital, Philipps-University, Marburg, Marburg,* [2]*Department of Pathology and Neuropathology, University Hospital, Eberhard Karls University, Tübingen, Germany., Tübingen, Germany,* [3]*Cancer Research UK London Research Institute, Gene Expression Analysis Lab, London, UK., London, United Kingdom*

INTRODUCTION: Previously, we identified the transcription factor CUX1 as a mediator of proliferation, resistance to apoptosis, invasiveness and angiogenesis

in neuroendocrine tumor cells. However, the molecular signaling pathways driving CUX1 effects in neuroendocrine neoplasias (NEN) remain to be elucidated.
AIMS&METHODS: The aim of this study is to characterize CUX-dependent signaling pathways mediating its tumor-promoting effect in-vitro and in-vivo.
We used an RNA profiler comprising 84 key genes involved in neoplastic transformation, invasion and angiogenesis. The target genes were validated on protein level via Western Blot. In addition, CUX1 was also evaluated in-vivo by xenograft experiments of CUX1 overexpressing Bon1 cells in nude mice. Furthermore CUX1 expression was assessed in a human micro tissue array (MTA) of 63 human insulinomas.
RESULTS: Several target genes mediating tumor invasion and metastasis were upregulated by CUX1 on mRNA level, among them MMP2, MMP9, TGFß, HIF-1α and integrin-α-5. CUX1-dependent regulation of MMP9 and HIF-1α was further validated on protein level. In vivo, CUX1 overexpression led to an increased tumor volume which was accompanied by a significantly higher proliferation index and increased microvessel density, as assessed by Ki-67 and CD31 immunostaining. Under hypoxic cell culture conditions, CUX1-expressing tumor cells showed increased HIF-1α levels, suggesting a role of CUX1 in mediating HIF-dependent escape mechanisms in tumor hypoxia. Immunohistochemically, CUX1 expression was evaluated in 63 human insulinomas using a multiple tissue array: In this series, malignant insulinomas expressed higher CUX1 levels compared to those with benign behavior, with a trend towards higher expression in metastatic versus primary tumors.
CONCLUSION: These data identify CUX1 as important mediator of an invasive proangiogenic phenotype in malignant pancreatic neuroendocrine tumors in-vivo and suggest a role for CUX1 in mediating HIF-1α-dependent escape mechanisms to antiangiogenic strategies.

ENDOSCOPY AND IMAGING II – Poster Area

P673 PNEUMATIC BALLOON DILATATION IN ACHALASIA: A COMPARISON STUDY OF SAFETY AND EFFICACY WITH WITZEL DILATOR AND RIGIFLEX BALLONN

A. Tebaibia[1,*], M. A. Boudjella[1], M. Lahcene[1], F. Benmediouni[1], N. Oumnia[1].
[1]*internal medicine department, kouba hospital, Algiers, Algeria*

INTRODUCTION: Several studies have shown that the use of the Witzel dilator or Rigiflex balloon is an effective and safe treatment for achalasia. But there is no consensus on the optimal method for performing pneumatic dilation (PD) and there is no comparison between these dilators.
AIMS&METHODS: to compare efficacy and safety in untreated patients with achalasia of graded PD with Witzel dilator and Rigiflex balloon. Between 1999 and 2012, two operators treated 192 patients with achalasia. They were 103 (54%) females and 87 (46%) males; mean age: 40 ± 18, 7 years (10-86), mean symptoms duration: 38±28 months (6 -190). Achalasia was diagnosed according to manomertric criteria. The dilatation was performed in the group A (n: 94) with Witzel balloon (diameter: 40 with an initial inflation pressure of 150 mm Hg during the first session. In case of relapse, dilatation was repeated with an incremental pressure (200 and 300 mm Hg) during the second and the third session. In the group B (n:96), we used the graded method with Rigiflex balloon (balloon 30 mm diameter inflated with 5 PSI pressure during 30 minutes at first session, 35 mm at the second and 40 mm at the third session). In two groups, PD was performed ambulatory, under endoscopic control, after simple premedication by diazepam. The PD was carried out every week until remission (1-3 sessions). Clinical results were evaluated according to Eckardt score.
RESULTS: The mean oesophageal diameter was 5 cm in group A vs 4.6 cm in group B , the mean lower oesophageal sphincter pressure was 33±10 mm Hg VS 33.5+/-11 mmHg and mean lower oesophageal relaxation was 49±23 VS 46.5±20. A total of 276 dilatation (152 sessions in Group A vs 124 Group B) were performed (mean: 2±1 per patient). Pneumatic dilatation was effective (immediate success) in 81 of 94 patients in group A (87%) and in 89 of the 96 in group B (93%). The difference was not statistically significant ($p < 0,3$). No perforations occurred in Witzel group and none in Rigiflex group. The rate of gastro-oesophageal reflux with esophagitis was 6% in group A vs 17% in group B, the difference was statistically significant ($p < 0.025$)
CONCLUSION: Pneumatic dilatation performed with Witzel dilator or Rigiflex balloon is an effective and safe treatment of achalasia. In the short term, the therapeutic results with both dilators are identical. Reflux is more common with Rigiflex.

P674 PNEUMATIC DILATATION FOR THE TREATMENT OF ACHALASIA IN PATIENTS YOUNGER THAN 20 YEARS : ABOUT 90 PATIENTS

A. Tebaibia[1,*], M. A. Boudjella[1], M. Lahcene[1], F. Benmediouni[1], N. Oumnia[1].
[1]*internal medicine department, kouba hospital, Algiers, Algeria*

INTRODUCTION: achalasia is a rare motor disease, seen in all ages but rarely reported before age of 20 years. Pneumatic dilation (PD) efficacy and safety in large series has not been assessed.
AIMS&METHODS: to study the profile of achalasia in this slice of age and to assess efficacy and safety of pneumatic dilatation in a large series. over a period of 10 years, from January 2000 to December 2009, all symptomatic achalasia patients younger than 20 years who referred to our centre were enrolled consecutively. They were 49 females and 41 males; mean age: 14.57 ± 4.88 years (5 months- 20 years). All patients underwent a standardized symptoms questionnaire, a barium esophagogram, an upper endoscopy and an esophageal manometry. Achalasia was diagnosed according to manomertric criteria. The dilatation was performed with a Witzel balloon or Rigiflex balloon, ambulatory, under endoscopic control, after simple premedication by diazepam (10 mg IM) . The PD was carried out every week until remission (1-3 sessions). After complete dilatation, patients were controlled at 6 month and 12 month. Clinical results were evaluated according to Vantrappen classification.
RESULTS: Achalasia was associated with Allgrove syndrome in 23 cases. A total of 252 dilatations were performed (mean: 2.8 ± 1.5 per patient). Only one session was performed in 19 patients, two in 16 patients, three in 15 patients and more than three sessions in 28 ones. Immediate success was obtained in 63 (70%) patients whereas it declined to 39% at 12 months. The final rate of failure at 12 months was 61%. 25 patients took isosrbid dinitrate, 15 (60%) of them improved. No perforation occurred in this study.
CONCLUSION: Allgrove syndrome is frequently observed in patients with achalasia before age of twenty. At short term, pneumatic dilatation is effective and safety. However, the long term success rate is rather low, resulting in permanent successful treatment of achalasia in only 39% of patients after the first sessions of dilatation.

P675 ASSESSMENT OF DUODENAL VILLOUS MORPHOLOGY USING MAGNIFICATION NARROW BAND IMAGING: A PROMISING TECHNIQUE FOR OPTIMISING DUODENAL BIOPSY PROCEDURE

A. K. Dutta[1,*], S. K. Gangadharan[1], G. Shah[2], A. B. Pulimood[1], E. G. Simon[1], A. J. Joseph[1], A. Chacko[3]. [1]*Gastrointestinal Sciences , [2]Pathology, CHRISTIAN MEDICAL COLLEGE , Vellore, [3]Institute of Gastroenterology and Liver Disease, The Madras Medical Mission, Chennai, India*

INTRODUCTION: Narrow band imaging (NBI) with magnification enables detailed assessment of the duodenal villi and may be useful in predicting the presence of villous atrophy or normal villi.
AIMS&METHODS: We aimed to assess the morphology of duodenal villi using magnification narrow band imaging and correlate it with the histology findings in patients with clinically suspected malabsorption syndrome. Patients were prospectively recruited and underwent upper gastrointestinal endoscopy using white light followed by magnification narrow band imaging. The mucosa in second part of duodenum was carefully assessed initially using white light without magnification for presence of features like scalloped mucosal folds, mucosal nodularity, atrophic mucosal folds and mosaic pattern. On NBI, presence of numerous finger or leaf shaped villi denoted a normal pattern while shortened or stubbed villi, villi in gyriform configuration or complete absence of villi suggested villous atrophy. The villous morphology on NBI in the second part of duodenum was assessed independently by two endoscopists and the presence of normal or atrophic villi was recorded. Biopsy specimen was obtained from the same area and was examined by two pathologists together. The sensitivity and specificity of magnification narrow band imaging in detecting the presence of duodenal villous atrophy was calculated compared to the histology.
RESULTS: The study included 100 patients with clinically suspected malabsorption. Their mean age was 37.5+12.4 years and 42% were females. Sixteen patients had histologically confirmed villous atrophy. The sensitivity and specificity of narrow band imaging in predicting villous atrophy was 87.5% and 95.2% respectively for one endoscopist. The corresponding figures for the second endoscopist were 81.3% and 92.9% respectively. The inter-observer agreement was very good with a kappa value of 0.87. The duodenal white light examination showed abnormal features in only two patients and hence had a very poor sensitivity of 12.5%. The final diagnosis in the sixteen patients with villous atrophy was celiac disease in 7, tropical sprue in 3, giardiasis in 2, strongyloidosis in 1, AIDS enteropathy in 1, Crohn's disease in 1 while the diagnosis could not be established in one patient with villous atrophy.
CONCLUSION: Magnification narrow band imaging performed very well in predicting duodenal villous morphology. This may help in performing targeted biopsies and avoiding unnecessary biopsies in patients with suspected malabsorption.

P676 DETECTION OF GASTRIC CANCER BY HYPERSPECTRAL IMAGING

A. Goto[1,*], J. Nishikawa[1], T. Okamoto[1], J. Nishimura[1], M. Nakamura[1], I. sakaida[1]. [1]*Department of Gastroenterology and Hepatology, Yamaguchi university, Ube, Japan*

INTRODUCTION: Esophagogastroduodenoscopy is widely used for the screening of gastric cancer, however, skill is required to detect small gastric cancer. Image enhancement endoscopy developed in recent years, but the modality which is useful for the detection of gastric cancer has not been established yet. The hyperspectral imaging (HSI) is the new technology that obtains spectroscopic information and renders it in image form. This study examines the difference of the spectral reflectance (SR) in the gastric tumor and the normal mucosa recorded by hyperspectral camera (HSC) equipped with HSI technology and tries the specifying of the wavelength, which is useful for the diagnosis of gastric cancer.

AIMS&METHODS: A total of 104 gastric tumors removed by endoscopic submucosal resection from 96 patients at Yamaguchi University Hospital, were recorded using a HSC1701. SR was obtained from 10 samples of tumors and 10 samples of normal mucosa for each case. Because the SR varied in each case, corrected SR which was defined as subtracting mean SR of normal samples from mean SR of tumor samples was used. 104 cases are randomly divided into 54 training cases and 50 test cases. To determinate the optimal wavelength and the cutoff point for differentiating tumors from normal mucosa, we established a diagnostic algorithm with training samples and evaluated it with test samples. And we tried highlighting tumors by image processing using HSC analysis software at the optimal wavelength and the cutoff point. Also we examined correlation between the SR at the optimal wavelength and the clinicopathological characteristic of tumors.
RESULTS: Especially in the range of 600 to 800 nm, the SR in the tumors tended to be higher than that in normal mucosae. The diagnostic algorithm used the 770-nm wavelength, with a cutoff point established from training samples. The sensitivity, specificity, and accuracy rates of the algorithm's diagnostic capability in the test samples were 70%, 99%, and 84% respectively. It was possible to enhance tumors by image processing using HSC analysis software at 770-nm wavelength. The tumor-emphasized areas and the histopathologically determined tumorous areas are almost identical. And also the SR at 770-nm wavelength admitted correlation with the microvessel density of tumors.
CONCLUSION: The result of recording the removal specimen of gastric tumors by HSC, the wavelength to identify tumors and normal mucosa could be specified. Differences in SR between tumors and normal mucosa suggested that tumors can be clearly distinguished from background mucosa with HSI technology.

P677 PROSPECTIVE LONG TERM ASSESSMENT OF SEDATION-RELATED ADVERSE EVENTS AND PATIENT SATISFACTION FOR GASTROINTESTINAL ENDOSCOPY

B. Kilgert[1,*], M. Vieth[2], M. F. Neurath[1], H. Neumann[1]. [1]*Department of Medicine I, UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen,* [2]*Institute of Pathology, Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: Fear and sedation-related adverse events are supposed barriers for patients to attend endoscopic screening or surveillance programs.
AIMS&METHODS: In this prospective, double-blind controlled trial we investigated the long term effect of different sedation protocols in patients undergoing upper gastrointestinal endoscopy and colonoscopy. Therefore, consecutive patients undergoing screening or surveillance endoscopy were included. Before and after the endoscopic procedure patient satisfaction was assessed with a standardized clinical interview by using a visual analogue scale (VAS). In addition, sedation recovery times, recall of pain and clinical parameters including blood pressure, pulse rate and oxygen saturation were evaluated. Two weeks after the procedure, the patient was contacted again, to either repeat the clinical interview and to assess any potential adverse events which may have occurred after the endoscopic procedure.
RESULTS: 102 patients were prospectively included (44% female, mean age 51 years; mean BMI 25). Fear and concerns regarding the endoscopic procedure were not different between patient groups. Upon full recovery, patient satisfaction was highest if propofol sedation or a combination of propofol and pethidine was used. Combination of benzodiazepines and pethidine yielded high satisfaction rates while combination of propofol and benzodiazepines resulted in poorest patient satisfaction rates. Blood pressure and pulse rate were significantly reduced if propofol sedation was used while mean oxygen saturation levels were lowest for combination of propofol and pethidine. On follow up, patient satisfaction was highest if propofol monosedation was used. Major side effects occurred in no cases. Minor side effects including nausea, vomiting and pain at the injection side occurred in 15% of patients and were mostly due to propofol sedation.
CONCLUSION: Monotherapy with propofol has the best long term outcome regarding patient satisfaction for upper endoscopy and colonoscopy and should therefore preferable be used for sedation in order to increase acceptance rates for endoscopic procedures.

P678 THE INCIDENCE AND COST OF UNEXPECTED HOSPITAL ATTENDANCE FOLLOWING ELECTIVE OUTPATIENT OESOPHAGO-GASTRO-DUODENOSCOPY

H. Gordon[1,*], J. Brindley[1], J. Graby[2], M. A. Abdullah[2], C. Zheng[2], J. Mawdsley[1], I. Beveridge[1], K. Monahan[1]. [1]*Gastroenterology,* [2]*West Middlesex University Hospital, London, United Kingdom*

INTRODUCTION: Elective outpatient Oesophago-gastro-duodenoscopy (OGD) is an increasingly common diagnostic and therapeutic procedure, with 10% annual growth in the UK. It is considered a safe procedure, with an overall complication rate traditionally quoted at 0.13% (1). However, a recent American study has suggested almost a 10 fold higher rate of hospital attendances post-procedure (2).
AIMS&METHODS: The aim of this study was to identify the true morbidity and related healthcare costs following elective outpatient OGD within a UK population. We conducted a retrospective observational study to identify all Accident & Emergency (A&E) attendances and hospital admissions within 14 days of all outpatient OGDs performed at West Middlesex University Hospital London in 2011. Of these, post-OGD related attendances were identified and associated healthcare costs calculated. Attendance data were collated from the hospital's electronic records system, enterpriseCAMIS®.
RESULTS:
Of the 1,977 outpatient OGDs performed, 44 patients (2.26%) presented to A&E within 14 days post OGD. However, only 6 re-attendances were procedure-related (0.3%), most commonly for pain. 4 patients required hospital admission, all of whom had undergone therapeutic interventions. 1 patient required a 3 day admission for vomiting post stent insertion. 1 patient required a 16 day admission following bleeding post variceal banding. 1 patient required a 5 day admission due to pain following stent removal. The final 5 day admission was precipitated by haematemesis following stent insertion. The total cost of hospital admissions and A&E attendances was £10,075, equating to £5.10 per endoscopy.

	A&E Attendances (cost)	Hospital Admissions (cost)
Related to Procedure	6, 0.3% (£870)	4, 0.2% (£9,205)
Unrelated to Procedure	38	5

CONCLUSION:
REFERENCES:
1. Silvis SE, Nebel O, Rogers G, Sugawa C, Mandelstam P. Endoscopic complications. Results of the 1974 American Society for Gastrointestinal Endoscopy Survey. JAMA 1976;235:928.
2. Leffler D A, Kheraj R, MD; Garud S, Neeman N, Larry A, Nathanson A, Kelly C P, Sawhney M, Landon B, Doyle R, Rosenberg S, Aronson M; The Incidence and Cost of Unexpected Hospital Use After Scheduled Outpatient Endoscopy, *Arch Intern Med.* 2010 Oct 25;170(19):1752-7
The rate of procedure related hospital reattendance demonstrated by this study was substantially less than that recently identified in America (1.07%) (2). However it is still significantly in excess of that traditionally quoted. All patients within our cohort who experienced substantial morbidity had undergone therapeutic interventions; the likelihood of therapeutic intervention should be considered when estimating morbidity and budgeting for post procedure costs.

P679 EVALUATION OF WHITE OPAQUE SUBSTANCE WITHIN GASTRIC NEOPLASIA AS VISUALIZED BY NONMAGNIFYING AND MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING

H. Ueyama[1,*], K. Matsumoto[1], A. Nagahara[1], Y. Nakagawa[1], K. Matsumoto[1], T. Yao[2], S. Watanabe[1]. [1]*Gastroenterology,* [2]*Human Pathology, Juntendo University School of Medicine, Tokyo, Japan*

INTRODUCTION: White opaque substance (WOS) within gastric neoplasia is a unique finding visualized in magnifying endoscopy with narrow-band imaging (M-NBI) and represents intramucosal accumulation of lipid droplets. The clinical features of WOS within gastric neoplasia are not well known.
AIMS&METHODS: Our aim was to study whether the presence and morphology of WOS can be used to discriminate between adenoma and early carcinoma. One hundred fifty-six patients with 164 gastric neoplasias (17 adenomas and 147 early carcinomas) who underwent nonmagnifying endoscopy with NBI (N-NBI) and M-NBI before endoscopic resection in our hospital between January 2010 and December 2012, were retrospectively investigated. We studied the frequency of the presence of WOS within gastric neoplasia and the clinicopathological findings of WOS-positive gastric neoplasias. We also studied the morphology of WOS and the presence of WOS on narrow-band imaging with or without magnifying endoscopy.
RESULTS: WOS was more frequently seen in adenomas (6/17: 35.3%) than in early carcinomas (31/147: 21.1%). Among the 6 WOS-positive adenomas, 4 cases (66.7%) were clearly visualized by N-NBI and 2 cases (33.3%) by M-NBI. Among the 31 WOS-positive carcinomas, 19 cases (61.3%) were visualized by only M-NBI and 12 cases (38.7%) by N-NBI. Regarding the morphology of WOS, WOS within adenoma demonstrated a symmetrical distribution with a regular reticular pattern because the intervening part between the crypts is wide and has no severe structural abnormalities; in contrast, WOS within carcinoma demonstrated an asymmetrical distribution with an irregularly dotted, speckled, or reticular pattern because the intervening part between the crypts is narrow and has severe structural abnormalities. WOS-positive gastric neoplasias tended to locate in the middle to lower third of the stomach [35/37 (94.6%): U2/M14/L21], represent superficial elevated type [25/37 (67.6%): 0-I:1/0-IIa:25/0-IIb:2/0-IIc:9] macroscopically, and indicate well differentiated adenocarcinoma [29/37 (78.4%): adenoma:6/pap:1/tub1:29/tub2:1/por:0/sig:0] histologically.
CONCLUSION: In cases in which the WOS is observed, WOS within adenoma tends to be clearly visualized by N-NBI and has a regular pattern, whereas WOS within carcinoma tends to be visualized by M-NBI and has an irregular pattern. The presence of WOS on N-NBI or M-NBI and the morphology of WOS may be useful to discriminate between adenoma and early carcinoma.

P680 THE SENSITIVITY AND SPECIFICITY OF CONVENTIONAL ENDOSCOPY FOR THE DIAGNOSIS OF GASTRIC ATROPHY IN PATIENTS WITH DECREASED PEPSINOGEN TESTS.

I. Kikuste[1,*], A. Lapina[2], K. Funka[1,2], A. Rutkis[2], H. Kurs[2], V. Saule[2], P. Janovics[1,2], M. Leja[1,2]. [1]*University of Latvia,* [2]*Riga East University Hospital , Riga, Latvia*

INTRODUCTION: The aim of the study was to assess the sensitivity and specificity of conventional endoscopy for the diagnosis of gastric atrophy in patients with decreased pepsinogen tests (high risk group) based compared to histological diagnosis of atrophy.
AIMS&METHODS: The study was a subanalysis of a larger randomly selected cross-sectional sample of the general population in Latvia recruited from November 2008 to July 2009 with the primary objective of exploring cardiovascular risk factors. The selected individuals underwent a structured interview and blood sample collection. From the total number of 6000 invitees, in 3807 cases pepsinogen I (PgI) and pepsinogen II (PgII) was measured in plasma by Eiken (Eiken Chemical Co., Tokyo, Japan) pepsinogen test systems and PgI/PgII ratio was calculated. Patients with PgI level <70 ng/ml and PgI/PgII ratio <3 (indicating any degree of gastric mucosal atrophy) were invited for upper gastrointestinal conventional white light endoscopy from January 2012 to July 2012. For adequate staging and grading of gastric mucosa atrophy, at least four non-targeted biopsies of two topographic sites (at the lesser and greater curvature, from both the antrum and the corpus) were taken and clearly labelled in separate vials; additional target biopsies of lesions were also taken.
RESULTS: 100 patients (39 male, mean age 61) with changed pepsinogen tests, showing gastric mucosa atrophy underwent conventional white light gastroscopy (Olympus GIF-Q165 gastroscope). In 17/19(90%) patients endoscopic signs of atrophy were confirmed by histology: 14/17 patients (74 %) had mild (OLGA stage I) and 3/17 (16%) patients - moderate (OLGA II) atrophy. However, among 81 endoscopically negative patients (without endoscopic signs of atrophy) gastric mucosa atrophy by histology was diagnosed in 54/81 (67%) patients: 47/54 (87%) had OLGA stage I, 6/54 (11%) - OLGA stage II and 1/54 (2%) patient had OLGA stage III gastritis. The overall sensitivity and specificity of conventional endoscopy for the diagnosis of atrophy based on histological diagnosis of atrophy were **56.7%** and **93.3%,** respectively. The accuaracy was higher in patients with atrophy in both corpus and antrum: sensitivity - **60.9%**, specificity - **95.2%**. The negative predictive value (NPV) of conventional gastroscopy was 34%; positive predictive value (PPV) - 97%.
CONCLUSION: Conventional white light endoscopy cannot accurately diagnose atrophic gastritis in patients with changed serum pepsinogen tests (high risk group).

P681 ENDOSCOPIC REMOVAL OF PARTIALLY MIGRATED INTRA-GASTRIC BANDS FOLLOWING SURGICAL GASTROPLASTY: A PROSPECTIVE CASE SERIES DEMONSTRATING SAFETY AND EFFICACY

I. Khamaysi[1,*], I. Gralnek[1], K. Yassin[1], A. Suissa[1]. [1]*Gastroenterology, Rambam Medical center, Haifa, Israel*

INTRODUCTION: Introduction: Laparoscopic gastric banding is a popular surgical technique for morbid obesity. However, the intra-gastric partial migration of bands is a well-recognized complication. Intra-gastric band partial migration usually necessitates repeat surgery. Endoscopic band removal is reported to be effective, yet reports are sporadic and scarce. We report on the efficacy and safety of endoscopic removal of partially migrated intra-gastric bands in a prospective case series.
AIMS&METHODS: Methods: From 1/1/2011 to 15/11/2012, we prospectively collected data on patients referred to a tertiary-care university hospital for endoscopic removal of migrated intra-gastric bands. Under endoscopic visualization, using a standard gastroscope, the partially migrated band was visually identified within the gastric lumen; a Jagwire was introduced, looped through the band and withdrawn to the mouth using a grasper. A mechanical lithotriptor was then threaded over the Jagwire and under fluoroscopic guidance slowly advanced. By twisting the handle of the lithotripter, the band was readily cut by strangulation. The cut edge of the band was then grasped using a snare and with gentle traction extracted from the gastric wall and then removed per os.
RESULTS: Results: There were n=7 patients (4F/3M, mean age 38.4 years). Mean time from laparoscopic gastric band placement to endoscopic intra-gastric band removal was 6.2 years. The migrated intra-gastric bands were all successfully removed in a mean of 1.3 sessions. No patient required subsequent surgical intervention. There were no immediate or delayed adverse events.
CONCLUSION: Conclusion: Endoscopic removal of partially migrated intra-gastric bands appears feasible, effective, safe, and may prevent repeat surgery.

P682 ENDOSCOPIC MANAGEMENT OF FISTULAE AFTER SLEEVE GASTRECTOMY

I. Khamaysi[1,*], I. Gralnek[1], K. Yassin[1], A. Suissa[1], Y. Chowers[1]. [1]*Gastroenterology, Rambam Medical center, Haifa, Israel*

INTRODUCTION: Background: Treatment of gastric fistulas after sleeve gastrectomy is difficult, and is often associated with additional surgery, sepsis, and prolonged non-oral feeding.
Objective: To assess an endoscopic strategy for management of gastric fistulas.
Design: Observational study.
AIMS&METHODS: Patients: All consecutive patients from July 2007 to December 2011.
