Intervention: Endoscopic management involved successive procedures for endoscopic diversion of the fistula with a stent and/or closure of the residual orifice with surgical clips or sealant.
Main Outcome Measurements: Technical success, fistula closure, mortality and morbidity, stent migration.
RESULTS: Results: twenty patients (12 males, mean-age 36.5 years, range 18-60 years) with gastric fistulas after sleeve gastrectomy underwent multiple endoscopic procedures (1-6) for the fistula treatment. Most fistulas (90%) were located just distal to gastro-esophageal junction. Two patients (10%) had distal sleeve fistula. Sixteen patients (80%) were managed successfully with endoscopic treatment. Two patients were re-operated. Two patients were treated by over-the-scope-clips (OTSC), 9 patients- by stent insertion (one or more), 7 patients-by stents and OTSC combination and 2 patients- by OTSC and glue application. Two patients still have a minor draining fistula. Stent migration occurred in 88% of patients. The mean time to fistula closure from the start of endoscopic management was 6.6 weeks (range 1-16 weeks) with a mean of 3 endoscopic procedures per patient.
CONCLUSION: Conclusion: An endoscopic approach to the management of gastric fistulas that develop after sleeve gastrectomy using sequential stent insertion and closure of the residual orifice achieved resolution of the fistulas with minimal morbidity in the majority of patients.

P683 IS IT POSSIBLE TO PERFORM GASTRIC ESD ONLY AFTER SEEING EXPERT'S TECHNIQUES?

J. Hamanaka[1,1,*], S. Komiyama[1], H. Yamada[1], S. Nishigori[1], M. Terada[1], A. Kotani[1], H. Okazaki[1]. [1]*gastroenterology, YOKOHAMA MINAMI KYOSAI HOSPITAL, Yokohama, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has become established as a minimally invasive treatment for gastric neoplasms in Japan. We reported the validity of our training system for gastric neoplasms at DDW 2012. As you know, gastric ESD is considered difficult compared with endoscopic mucosal resection (EMR). Although high en bloc resection rate has been reported and a few papers were known about the training for gastric ESD under the mentorship of the specialist in Japan. Experience in Europe, however, is still limited and ESD is only performed in a few selected centers with low volumes of cases. This study examines if only seeing an expert's technique is effective for trainee to perform gastric ESD or not.
AIMS&METHODS: Between April 2012 and March 2013, a total of 152 ESD procedures in 140 patients (104 gastric ESD, 30 colorectal ESD and 16 esophageal ESD) were seen by one trainee who is not specialist in endoscopy. He graduated from medical school six years ago and his major was hepatology. He performed 1200 cases of gastroscopy and 700 cases of total colonscopy examinations during 6 years.
RESULTS: Fifteen cases treated with gastric ESD from April 2013 to May 2013 were investigated. They consist of 8 lesions in the antrum; 5 lesions in the angle or the lesser curvature in the body; 2 lesions in other locations. The En block R0 Resection rate was 100% (n=15) and the perforation rate was 0%. Delayed hemorrhage was seen in one case which was controlled by endoscopic treatment. The mean procedure time was 102.5min and the mean tumor size was 14.5mm. The trainee could complete the whole ESD procedures in 15 cases.
CONCLUSION: This study suggested that only seeing expert's ESD procedure enabled ESD trainees to perform gastric ESD without decline the treatment outcome.

P684 AETIOLOGY OF ANAEMIA IN HOSPITALIZED PATIENTS: A PROSPECTIVE SINGLE-CENTRE CROSS-SECTIONAL STUDY

J. Gerada[1,*], E. Carachi[1], J. Pocock[1]. [1]*Gastroenterology, Mater Dei Hospital, Msida, Malta*

INTRODUCTION: Anaemia is a common finding in patients admitted to hospital, resulting in a number of gastroenterology referrals for consideration of endoscopy. Various studies have evaluated the aetiology of anaemia in the elderly population and its burden on the endoscopy service, however very few studied this across all adult age groups.
AIMS&METHODS: To evaluate the aetiology of anaemia in adult patients of all age groups admitted to hospital.
Methods
Adult ($\geq$15 years) patients, with incidental/ symptomatic anaemia, admitted unselectedly between May 2010 and May 2011, under a gastroenterology firm, forming part of the unselected medical take rota in a secondary care hospital, were prospectively studied. Anaemia was defined as below the lower limit of normal of our laboratory's reference range ($<$13g/dl males, $<$11.5g/dl females). History and physical examination, together with a complete blood count, iron studies, vitamin B12/folate levels and renal profile were carried out in all patients. Additional blood tests, imaging and GI endoscopy were requested at the physician's discretion, guided by the mean corpuscular volume. Causes of anaemia were classified as anaemia of inflammation, iron-deficiency anaemia, overt blood loss, other causes and unexplained.

RESULTS: A total of 505 patients were admitted during the study period, of which 132 (26.1%) had anaemia. 14 were excluded as had incomplete data. 118 patients were included for analysis (mean age 69.9 ±16.1 years, males n=73 (61.9%)). The mean haemoglobin was 10.0 ±1.8g/dl (normocytic 64.5%, microcytic 28.8%, macrocytic 5.9%, pancytopenia 0.8%). 16.9% (n=20) had 2 or more causes for anaemia. The frequency of the different diagnosis can be seen in Table 1. Age, gender or mean corpuscular volume did not show statistical significance in predicting malignant or non-malignant GI lesions (*p value* 0.61, 0.92, 0.11 respectively).

Table 1: Frequency of the different diagnoses obtained following appropriate investigations

	n	%
Anaemia of inflammation	**49**	**41.5**
- sepsis	25	51
- non-haematological/non-GI malignancy	15	30.6
- haematological malignancy	8	16.4
- autoimmune disease	1	2
Fe-deficiency anaemia	**22**	**18.7**
- GI malignancy	7	31.8
- non-malignant GI lesion	6	27.3
- undetermined	4	18.2
- menstruation	3	13.6
- non-GI malignancy	2	9.1
Overt blood loss	**10**	**8.5**
- upper GI	6	60
- lower GI	2	20
- respiratory	1	10
- urinary	1	10
Other causes	**25**	**21.2**
- renal disease	17	68
- liver disease	3	12
- thalassaemia	3	12
- thyroid disease	1	4
- folate deficiency	1	4
Unexplained	**12**	**10.2**

CONCLUSION: Sepsis, non-GI malignancy and GI lesions (malignant and non-malignant) were the primary causes of anaemia in this cohort of patients, each comprising about 20% of the cases. Gastrointestinal endoscopy is thus only required in one fifth of adult patients with anaemia.

P685 A LARGE-SCALE MULTICENTER PROSPECTIVE STUDY VALIDATING THE CRITERIA FOR PERIENDOSCOPIC ANTITHROMBOTIC THERAPY CESSATION: THE SAPPORO CONSENSUS

K. Mabe[1,*], S. Nakagawa[2,3], H. Seki[4], S. Katsuki[5], K. Yamashita[6], M. Kato[1], N. Sakamoto[3]. [1]*Endoscopy, Hokkaido University Hospital,* [2]*Nakagawa ichoka,* [3]*Gastroenterology, Hokkaido University Graduate School of Medicine,* [4]*Gastroenterology, KKR Sapporo Medical Center, Sapporo,* [5]*Gastroenterology, Otaru Ekisaikai Hospital, Otaru,* [6]*First Department of Internal Medicine, Sapporo Medical University, Sapporo, Japan*

INTRODUCTION: It is common practice to shorten the duration of anticoagulant (AC) and antiplatelet (AP) therapy cessation during endoscopic procedures to minimize the risk for thrombosis. In its guidelines for periendoscopic AC/AP therapy published in 2006, the Japan Gastroenterological Endoscopy Society (JGES) recommended a longer duration of AC/AP cessation than that recommended in Europe.

AIMS&METHODS: This multicenter prospective study aimed at determining and validating an optimal duration of periendoscopic AC/AP cessation. Endoscopists and various specialists prescribing AC/AP therapy participated to develop a consensus on the criteria for AC/AP cessation (Sapporo consensus) based on the JGES guidelines with the risk for thrombosis in mind, and followed up all institutions that had jointed in the consensus for adherence to the consensus practice as well as for post-procedural events. All but except for emergency endoscopic procedures performed during follow-up were included for analysis. All procedural events were analyzed, based not only on reports from participating institutions but also on patient questionnaires.

RESULTS: A total of 5,331 patients (mean age:72.3 years; male:female=13:7) were enrolled from 16 participating institutions. Of these, 202 patients (3.8%) had a longer duration of AC/AP cessation than that defined in the consensus. Questionnaires on post-procedural events were collected from 77.3% of patients and all procedural events were reported from all participating institutions. Post-procedural events included thrombosis in 2 patients (0.04%) and post-procedural hemorrhage in 42 patients (0.8%), which was significantly higher in incidence in those receiving 2 or more AC/AP (1.3%), those receiving clopidogrel (1.7%), high-risk patients with AC/AP cessation (3.5%), those receiving therapeutic endoscopy (4.9%), and those undergoing heparin-bridging (14%). Of those undergoing therapeutic endoscopy, high-risk patients with AC/AP cessation and those undergoing heparin-bridging were associated with a significantly higher incidence of hemorrhage.

CONCLUSION: Data showed generally high adherence to the consensus practice, with no marked increase in post-procedural events compared to those reported in previous studies. The consensus practice calls for further examination to identify and manage those potentially at risk of hemorrhage with the approach.

P686 DEVELOPMENT OF NEW ANESTHESIA PROCEDURE USING PROPOFOL FOR THERAPEUTIC ENDOSCOPY

K. Matsumoto[1,*], A. Nagahara[1], H. Ueyama[1], Y. Nakagawa[1], Y. Tajima[1], K. Matsumoto[1], H. Sasaki[1], Y. Shimada[1], D. Asaoka[1], M. Hojyo[1], S. Watanabe[1]. [1]*gastroenterology, JUNTENDO UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan*

INTRODUCTION: In recent years, the use of Propofol has been attracting attention to use as a sedative medicine during endoscopic therapeutic procedure, but its complications and cumbersome administration method have become problems. However, there is no standard protocol for Propofol so far. To use Propofol safe and effective, standardized protocol should be necessary.

AIMS&METHODS: Our aim was to establish a simple and safe way of using Propofol during therapeutic endoscopic procedures. Patients who were scheduled to undergo endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR) were recruited and after obtain the informed consent, following anesthesia induction procedure were performed. At the time of anesthesia induction, we injected Propofol 0.05 ml/kg for 10 seconds by power injector after pethidine hydrochloride 0.5mg/kg iv. After that, 1.0ml of Propofol was added every minute until sedation was achieved. As a maintenance dose, 0.25ml/kg/hr of Propofol was continuously administered. If patient getting awake, 1.0ml additional injection was repeated for every minute until sedation was obtained and added 5ml/hr to maintenance dose. SpO2 and blood pressure were monitored. Anesthesia depth was monitored by BIS monitor and maintained as Ramsay anesthetics depths scores 6 (it does not awake in an irritation). Propofol was stopped temporally under these patients' conditions, that is, SpO2 < 90, BP < 80mmHg or BIS under 60 (5 seconds or more). After recovered, Propofol was resumed. We evaluated the number of doses of Propofol at the time of anesthesia induction and maintenance phase, and the number of patients who need to stop temporarily.

RESULTS: There were 31 patients (mean age70.9yr, men/women; 24/7) with upper gastrointestinal neoplasms. ESD was 29cases and EMR was 2 cases. Mean procedure time was 109.7min (range; 30-410). All patients achieved sufficient anesthesia and underwent successful endoscopic procedure. Average number of doses at anesthesia induction was 3.0 times (range; 0-11). Average number of doses at maintenance phase was 1.9 times (range; 0-4). The number of patients who need to stop temporarily were 2 cases (3.2%) because of hypotension. However, there was no case of cessation of Propofol due to decreased SpO2 or low BIS score.

CONCLUSION: This newly developed Propofol anesthesia protocol is effective and well tolerated for longtime therapeutic endoscopy. Therefore, this protocol could be used as standard protocol for various kind of therapeutic endoscopic procedures.

P687 A PROSPECTIVE, RANDOMIZED CONTROLLED TRIAL OF SOFT-COAGULATION VERSUS HEATER PROBE THERMAL COAGULATION FOR ENDOSCOPIC HEMOSTASIS OF BLEEDING PEPTIC ULCERS

K. Hamada[1,*], R. Takenaka[1], T. Nunoue[1], N. Okazaki[1], D. Kawai[1], K. Takemoto[1], H. Tsugeno[1], S. Fujiki[1]. [1]*Digestive Endoscopy Center, Tsuyama Central Hospital, Tsuyama city, Japan*

INTRODUCTION: Thermal coagulation is the most common method in endoscopic hemostasis for bleeding peptic ulcer. Recently, the efficacy and safety of soft-coagulation for treatment of bleeding peptic ulcer has been reported.

AIMS&METHODS: The aim of this study was to compare the efficacy of soft-coagulation with that of thermal coagulation in patients with bleeding peptic ulcers. Patients who visited our hospital with hematemesis or melena were considered for the study and randomized to receive soft coagulation or heater probe thermal coagulation. Soft-coagulation was performed with a 70 W current. Heater probe unit was used with a pulses of 20 to 30 J. Initial hemostasis was declared when the hemostasis was obtained by the single allocated method. When the second-look endoscopy revealed hemostasis, primary hemostasis was declared to be achieved. Specialists were defined as endoscopists who had over 5 year experience with special endoscopic qualification in Japan. Primary endpoint was the primary hemostasis rate and secondary endpoints were the procedure time, rebleeding rate, and complications. The factors associated with primary hemostasis was analyzed with regard to clinical characteristics.

RESULTS: Between May 2010 and February 2012, there were 111 patients enrolled in the study, 56 patients in the soft coagulation group (group S) and 55 patients in the heater probe group (group H). Primary hemostasis were achieved in 54 patients (96%) in the S group and in 37 patients (67%) in the

H group ($p < 0.001$). The duration of endoscopic therapy was less in the S group than in the H group, but not significant ($p = 0.10$). Rebleeding occurred in 7 patients (13%) in group H and none in group S ($p < 0.01$). Minor perforation occurred in two patients in group H. In the subanalysis, primary hemostasis rate achieved by trainee was 96% in the group S, and 60% in the group H ($p < 0.001$), while primary hemostasis rate achieved by specialist was 100% in both groups ($p = 1.00$). When the diameter of exposed vessel on ulcer bed was over 1 mm, primary hemostasis rate was significantly higher in the S group than in the H group (96% vs. 64%, $p < 0.001$).
CONCLUSION: Soft-coagulation was more useful than heater probe thermal coagulation on endoscopic hemostasis for bleeding peptic ulcer. It may provide a promising hemostasis irrespective of endoscopic experience or diameter of exposed vessel on ulcer bed.

P688 PREDICTIVE FACTORS OF MORTALITY AFTER PERCUTANEOUS ENDOSCOPIC GASTROSTOMY PLACEMENT

M. Barbosa[1,*], J. Magalhaes[1], C. Marinho[1], J. Cotter[1]. [1]*Gastroenterology, Centro Hospitalar do Alto Ave, Guimaraes, Portugal*

INTRODUCTION: Percutaneous endoscopic gastrostomy (PEG) is considered one of the preferred routes for long-term enteral feeding.
AIMS&METHODS: To determine predictive factors of an increased mortality risk after PEG insertion. Retrospective study which included patients who underwent PEG placement between May 2007 and January 2013. Variables analyzed: sex, age, Charlsońs co-morbidity index, previous aspiration pneumonia, indication for PEG, follow-up period, 30-, 90-, 180-day mortality rates after PEG insertion and analytic variables: hemogram, ionogram, urea, creatinine, albumin and C-reactive protein. Exclusion criteria: absence of follow-up. Statistical significance was established at $p<0.05$.
RESULTS: One-hundred ninety patients were evaluated, 135 were included: 69 women, mean age of 73 years-old, Charlsońs index of 4 (mode and median), 71% with past history of aspiration pneumonia. Indications for PEG: cerebrovascular disease (50%), dementia (18%), cancer (10%) and others (22%). The mean follow-up time was 320 days, the overall mortality rate was 62% and previous aspiration pneumonia (p=0.006), higher levels of C-reactive protein (p=0.002) and leucocytosis (p=0.005) are among the predictive factors of mortality found. The 30-day mortality rate was 19% and the only predictive factor of mortality found was higher urea levels (p=0.046). Ninety-six percent of patients had a follow-up period superior to 90-days and 91% superior to 180-days: mortality rates were 30% and 43%, respectively, and the predictive factors of mortality observed were: diabetes mellitus (90-days:p=0.013;180-days:p=0.040) and higher levels of C-reactive protein (90-days:p=0.002; 180-days:p=0.008).
CONCLUSION: The mortality rate after PEG placement is high. Past history of aspiration pneumonia, presence of diabetes mellitus and higher levels of C-reactive protein significantly influenced the prognosis of these patients. These factors should be considered in the decision making of PEG insertion.

P689 FEASIBILITY, EFFICACY AND SAFETY OF A PURE NATURAL ORIFICE TRANSLUMENAL ENDOSCOPIC GASTROJEJUNAL BYPASS IN A GASTRIC OUTLET OBSTRUCTION SURVIVAL ANIMAL MODEL

J.-M. Gonzalez[1], E. A. Bonin[1], G. Vanbiervliet[2], S. Berdah[3], M. Barthet[1,*]. [1]*Gastroenterology, North Hospital, Marseille,* [2]*University Hospital, Nice,* [3]*Digestive surgery, North Hospital, Marseille, France*

INTRODUCTION: Natural orifice translumenal endoscopic surgery (NOTES) gastrojejunal anastomosis (GJA) may be a less invasive surgical technique for creating a gastrojejunal bypass without incisions. This approach may be useful for bariatric procedures and for the treatment of gastric outlet obstruction.
AIMS&METHODS: The aim is to determine feasibility, efficacy and safety of a pure NOTES gastrojejunal bypass using a simulated gastric outlet obstruction in a porcine survival animal model.This prospective animal study was performed on nine 20 to 30 kg domestic pigs, with a double-channel gastroscope (Karl Storz GmbH). The procedure steps were: 1) gastric incision with a needle-knife, 2) transgastric peritoneal access, 3) jejunal loop selection and mobilization into the stomach, 4) incision of the jejunum and creation of a stoma within the stomach wall, 5) full thickness suturing using an endoscopic T-tag suturing prototype (Brace Bar, Olympus, Japan). To create a gastric outlet obstruction model, we closed the pylorus with T-tag sutures. The animals were assessed clinically during the three weeks survival period. Weight gain was assessed by comparison of baseline and final weight at the end of the study. Patency of GJA was assessed at the post-mortem examination.
RESULTS: We successfully performed nine pure NOTES gastrojejunal bypass procedures with a mean operative time was 108 ± 26 minutes [65-142]. Each GJA was endoscopically sutured using four to seven T-tag sutures (mean of 5.55 ± 1.30). Two T-tags were used for the pyloric closure. There were no intra-operative complications. Five out of nine pigs were survived for three weeks. The mean weight was 29.5 kg at baseline versus 27.7 kg at three weeks follow-up. By comparing our series with a control group, we found a significant difference in the weight curves: a loss of 3.2 kg in the study group in comparison to 5.2 kg in the control group. We observed an incomplete closure of the pylorus in two animals. On post-mortem examination, the diameter of the GJA was about 20 mm [8-250 mm]. Four pigs died from anastomotic dehiscence complicated with septic peritonitis.
CONCLUSION: Gastrojejunal bypass with pyloric closure is technically feasible using a pure NOTES approach. This procedure is techlinically efficient resulting in a patent anastomosis and a weight loss in surviving animals. Anastomotic dehiscence is a major a concern since it carries a high mortality rate. Further improvements for this model for reducing the risk of anastomotic dehiscence may be creation of a two-step procedure in separate occasions.

P690 USEFULNESS OF OVER-THE-SCOPE (OTSC) CLIPS FOR CLOSING DIGESTIVE FISTULAS

P. Mercky[1], E. A. Bonin[1], O. Emungania[2], J.-M. Gonzalez[1], J. Brunet[2], J.-C. Grimaud[1], M. Barthet[1,*]. *[1]Gastroenterology, [2]Digestive Surgery, North Hospital, Marseille, France*

INTRODUCTION: Therapeutic endoscopy has recently evolved into treatment of complex gastrointestinal (GI) postoperative leakages. New endoluminal devices such as Over-The-Scope (OTSC) clips may facilitate the closure of large defects. The aim of this study was to describe our 3-year experience on 28 patients treated for digestive fistulas using this OTSC clipping device.

AIMS&METHODS: This is a retrospective study conducted on patients referred for GI fistulas in two French teaching hospitals. Technical aspects, clinical outcomes and closure rate were recorded.

RESULTS: Twenty-eight patients were treated for GI leaks: eighteen (60%) had a gastric fistula after laparoscopic sleeve gastrectomy (LSG), the others where distributed into recto-vaginal, urethro-rectal, recto-vesical, gastro-gastric, gastro-cutaneous, esophago-jejunal fistulas and colo-rectal anastomotic leak. The average follow up was 10.4 months. Out of the 28 patients treated, eighteen (64.2%) had undergone a previous endoscopical or surgical treatment. The orifice size was 3 mm to 20 mm (average 7.2 mm). Successful OTSC clip placement was achieved in 30 out of 34 attempts. There were four intraoperative undesired events (14.2%) but successfully managed and without any clinical consequences. Overall success rate was 71.4% and fourteen patients (50%) recovered with primary efficacy. Six patients (21.4%) required a subsequent endoscopic treatment. Eight patients (28,5%) required surgery for endoscopic treatment failure. In nine cases, we used one or more additional endoscopic procedures concomitantly with the OTSC combining SEMS, standard clips and glue injection. Healing rate after LSG fistula was 88.9% was and significantly higher than overall rate (p=0.01).

CONCLUSION: OTSC placement seems to be safe and effective for treatment of GI fistulas, as primary or as adjuvant endoscopic therapy. Better results were seen in early fistulas, and leaks after LSG rather than chronic fistulas.

P691 CLINICAL IMPACT OF WHITENESS OF GASTRIC MUCOSAL CRYPT OPENING OBSERVED BY MAGNIFYING ENDOSCOPY

M. Kawamura[1,*], H. Sekine[1], T. Kikuchi[1], Y. Sakai[1], F. Nagasaki[1].
[1]*Gastroenterology, Sendai City Hospital, Miyagi, Japan*

INTRODUCTION: Several studies have reported a relationship between the micromucosal structure observed by magnifying endoscopy (ME) and *Helicobacter pylori*-induced gastritis. However, there has been no report on the relationship between *H. pylori* gastritis and whiteness of gastric mucosal crypt opening (CO) observed by ME.
AIMS&METHODS: One hundred and seventy-five consecutive patients (including 86 patients with gastric cancer) were enrolled. We observed mucosal microsurface at the lesser and greater curvature in the gastric corpus by ME. Whiteness of CO was subclassified as "white-edged dark spot (WED)" type, consisting of a dark spot bordered by white color; "white" type, consisting of no dark spot and only white color; and "dense white pit (DWP)" type, consisting of a dense white color with the appearance of a snow-ball. Histological gastritis was also evaluated according to the updated Sydney System.
RESULTS: In a total 249 areas with round CO observed by ME, histological findings showed mononuclear cell and neutrophil infiltration were significantly higher in "white" and "DWP" type than in "WED" type CO ($P<0.0001$). Whiteness of CO were significantly differences between *H.pylori*-positive (n=139) and -negative (n=36) patients (WED, 16.7% *vs* 77.8%; White, 60.7% *vs* 22.2%; DWP, 22.6% *vs* 0%). There were significant differences between whiteness of CO in patients with gastric cancer and patients with no gastric cancer (WED, 19.8% *vs* 36.2%; White, 53.8% *vs* 46.3%; DWP, 26.4% *vs* 17.5%). DWP were frequently observed in patients with undifferentiated-type gastric cancer (45.7%).
CONCLUSION: ME observation of CO whiteness was associated with histological gastritis and may identify patients at high-risk of *H. pylori*-associated gastric diseases.

P692 THE UTILITY OF ULTRATHIN ENDOSCOPY AS A DIAGNOSTIC TOOL FOR BARRETT'S OESOPHAGUS (BO). SYSTEMATIC REVIEW AND META-ANALYSIS

S. Sami[1,*], V. Subramanian[2], J. Ortiz-Fernández-Sordo'[1], A. Saeed[3], K. Ragunath[1]. [1]*Nottingham Digestive Diseases Centre, University of Nottingham, UK, Nottingham,* [2]*Department of Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom,* [3]*Department of Medicine, University of Jordan, Amman, Jordan*

INTRODUCTION: Screening for BO in patients with multiple risk factors is increasingly recommended by gastrointestinal (GI) societies. Standard Endoscopy (SE) is not suitable for population screening. Unsedated Ultrathin Endoscopy (UE) has been proposed as a more cost-effective alternative. However, reports on the performance characteristics of this tool vary among different studies.
AIMS&METHODS: The aim of this study was to estimate the pooled diagnostic accuracy, technical success rate and tolerability of UE (via trans-nasal or trans-oral insertion route) for the diagnosis of BO in adult patients with upper GI symptoms.
A systematic literature search and meta-analysis was performed of all primary studies evaluating UE (index test). We only included studies which used SE as the gold standard. Studies were excluded if data on accuracy or BO presence were not extractable; or if they used fibreoptic endoscopy as this technology is obsolete in current practice.
Data extraction was undertaken by three reviewers independently of each other and who then cross-checked the consistency of their findings. The quality of included studies was assessed using a validated tool (QUADAS-2). Data analysis was performed using the Meta-DiSc (version 1.4) software.
RESULTS: Five studies including 439 patients met the inclusion criteria. The pooled sensitivity, specificity, diagnostic odds ratio (DOR), and area under the curve (AUC) for the diagnosis of BO were 0.91 (95% confidence interval [CI] 0.84-0.96), 0.96 (95% CI 0.94-0.98), 353.9 (95% CI 56.8-2204.7) and 0.97 (Standard error [SE] 0.03) on a per-protocol analysis.
Success rate for both UE and SE was 0.86 in the smallest study using unsedated trans-oral route, while all the other studies reported success rates ranging from 0.95 to 1.0 for UE (including unsedated trans-nasal route) and from 0.98 to 1.0 for SE. The majority (0.57-0.71) of patients preferred UE compared to SE and said they were willing to have UE again in the future if necessary. The mean tolerability scores for unsedated UE were significantly better in two studies, similar in one study and not reported in the rest of the studies.
CONCLUSION: These data suggest that UE in general and unsedated trans-nasal UE in particular is accurate in detecting BO and more acceptable to patients compared to SE. However, the current available UE devices require a dedicated endoscopy suite and decontamination facilities adding to the cost and complexity as well as limiting their access to the general population. There is a clear need for more simple, portable and disposable device to screen for BO in the community setting.

P693 ANALYSIS OF 25,000 CASES INVOLVING TRANSNASAL ENDOSCOPIC SCREENINGS IN THE WORLD'S FIRST DEDICATED VEHICLE FOR TRANSNASAL ENDOSCOPY AND OUR HOSPITAL FOR 7 YEARS.

S. Ikeda[1,*], H. Okamura[2], M. Iino[1], R. Nakagawa[3], T. Ohki[3], M. Ikeda[1].
[1]*Gastrointestinal Surgery,* [2]*Medicine, IKEDA HOSPITAL, Shizuoka,* [3]*Surgery, Institute of Gastroenterology, Tokyo Women's Medical University, Tokyo, Japan*

INTRODUCTION: Transnasal endoscopy (TNE) has been widely available as less painful and more easy and safe method than peroral endoscopy (POE) in gastrointestinal (GI) tract screening, especially a checkup of the upper GI tract in Japan. In our hospital, we have started to use TNE systems since 2005, and performed approximately 4,000 tests a year for cases that asymptomatic subjects who mainly underwent health screenings and checkups. Furthermore, we introduced the world's first dedicated vehicle for TNE to conduct checkups for employees on company property in 2008 as reported at 2011 UEGW Stockholm. Subsequently, 4,500 tests (about 1,300 cases per year) were performed for employees in the vehicle on company property. We report the increasing importance of TNE for the upper GI tract in a hospital and on company property.
AIMS&METHODS: The results, characteristics of detected cancer and optical images from TNE were compared with POE in 25,000 cases that asymptomatic subjects who underwent screenings for 7 years since the introduction of TNE.
RESULTS: In the 25,000 cases, we pointed out that a total of 35 subjects had malignant lesions, of which 1, 5, 27 and 2 were hypopharyngeal, esophageal, gastric and duodenal cancer, respectively. Subjects with early gastric, esophageal and duodenal cancer were treated by endoscopic submucosal dissection. Epistaxis was seen in 1% or less of 25,000 cases, and any severe procedural accidents did not occur. Cases that subjects who underwent POE switched from TNE because of inability to insert the endoscopes for TNE was 0.3%. There was no significant difference between TNE and POE, and the optical images were similarly clear.
CONCLUSION: We have recommended and performed endoscopic screenings for workaholic employees without enough time to visit a hospital in the world's first dedicated vehicle for transnasal endoscopy on company property. Radiation exposure and discomfort from gag reflex are issues in barium contrast x-ray and POE as a screening, respectively. With TNE, the detection accuracy of lesion seems to be higher than barium contrast x-ray, and it is less painful and more easy and safe than POE. Moreover, TNE has not only a good compliance, but also allows better risk management of sedation.

P694 THERAPEUTIC STRATEGY FOR RESIDUAL/RECURRENT LESIONS AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION: PREVENTION AND SALVAGE BY ENDOSCOPIC SUBMUCOSAL DISSECTION

S. Hoteya[1,*], D. Kikuchi[1], T. Iiuka[1], M. Kaise[1]. [1]*Gastroenterology, Toranomon Hospital, Tokyo, Japan*

INTRODUCTION: Several years have passed since the development of Endoscopic Submucosal Dissection (ESD), and its spread has enabled therapies with a higher R0 rate and lower local recurrence rate. However, the fact that ESD is now also carried out for more difficult lesions has caused the new, though infrequent, problem of post-ESD local residual/recurrence. With repeat ESD for a post-ESD recurrent lesion, because far more severe and extensive fibrosis is present in the submucosa, the technical difficulty of submucosal dissection is very high, and both safety and radical curability must be assessed. On the other hand, it is important to prevent post-ESD residual/recurrent tumor that would be difficult to treat by ESD.
AIMS&METHODS: The aims of this study were to clarify the clinical features of the post-ESD residual/recurrent lesion and compare the outcomes between early additional ESD (addESD) and repeat ESD (reESD) after initial ESD to establish the treatment strategy for cases of the LM+ that causes post-ESD residual/recurrence. The short-term results (tumor size, resection size, treatment time, complete en bloc resection rate, complication rate) and long-term results (local recurrence rate, distant metastasis) were retrospectively studied in addESD and reESD for 2,042 lesions subjected to ESD between April 2005 and March 2013.
RESULTS: 53 lesions were determined to be post-ESD LM+ with suspected regional residue of the tumors. Of the 53 LM+ lesions, 11 underwent addESD immediately after initial ESD, 15 lesions had additional surgery, and 38.5% (10/26) had regional residual lesions. A total of 27 lesions did not undergo addESD or additional surgery; in follow-up, 29.6% (8/27) had local recurrence (mean time to recurrence, 806 days) and most recurrences were discovered within three years after initial ESD. A total of 15 lesions with post-ESD local recurrence underwent reESD, including the 5 recurrent lesions and 10 lesions referred from another hospital. Of the reESDs, 73.3% (13/15) involved curative resections and also

have not shown local recurrence or distant metastasis. AddESD showed significantly higher performance in dissection speed than reESD.
CONCLUSION: Both sESD and reESD had favorable short-term and long-term results. About 32% of cases that consequently tested LM+ after ESD developed local residual/recurrent disease, so implementing addESD as soon as possible, before complete scarring of the ulcer makes reESD difficult, is useful for preventing residual/recurrent disease. If a residual/recurrent lesion occurs, reESD is useful.

P695 COMPARISON OF TWO DOSES OF INTRAVENOUS PROTON PUMP INHIBITOR FOR THE PREVENTION OF BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION: A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

S. J. Kim[1,*], C. W. Choi[1], S. B. Park[1], B. J. Song[1], D. H. Kang[1], H. W. Kim[1]. [1]*Gastroenterology, Pusan National University Yangsan Hospital, Yangsan, Korea, Republic Of*

INTRODUCTION: Intravenous bolus loading followed by continuous infusion of proton pump inhibitor (PPI) is the standard treatment of choice for the prevention of gastric ulcer rebleeding. But the optimal dose of proton pump inhibitor (PPI) for the prevention of bleeding after endoscopic submucosal dissection (ESD) is unclear.
AIMS&METHODS: Our aim is to compare the effects of continuous infusion and bolus injection of PPI for the prevention of recent bleeding after ESD.
273 patients with gastric epithelial neoplasm were enrolled. All patients who underwent ESD were randomly assigned to either the continuous infusion (n=136) or bolus group (n=137). For both groups, initial pantoprazole 80mg bolus loading infusion for 30 min before ESD. In continuous infusion group, 8mg/hr continuous infusion for 72 hours, totally 576mg is done after initial loading. For bolus group, pantoprazole 40mg is injected twice a day for 72 hours, totally 240mg. Follow-up endoscopy is performed the next day after ESD routinely. Indication of additional EGD is melena, hematemesis, Hb loss $>$ 2g/dL. Primary outcome measure is the bleeding related to ESD. Secondary outcome is risk factors of the bleeding after ESD.
RESULTS: Clinical characteristics were not different between the two groups. The bleeding rate of the continuous infusion group was not significantly lower compared with the bolus group (6.6 % vs 5.8 %, p = 0.79). No significant difference of bleeding incidence was found for the factors of tumor location, gross type, invasion depth, histology, ulcer or fibrosis presence. On multivariate analysis, the specimen size (relative hazard : 1.855, 95% CI : 1.083 – 3.179, p = 0.24) was independent factors predictive of bleeding after ESD. Subgroup analysis according to tumor size, there was no significant difference of bleeding rate between two group.
CONCLUSION: A continuous infusion of high-dose pantoprazole does not show the superiority compared to pantoprazole bolus in the prevention of bleeding after ESD. So bolus of PPI (pantoprazole 40mg twice a day) is more cost-effective dose for the prevention of bleeding after ESD.

P696 EFFICACY OF FAMOTIDINE OR PANTOPRAZOLE FOR THE HEALING OF ENDOSCOPIC SUBMUCOSAL DISSECTION-INDUCED ULCER: A PROSPECTIVE RANDOMIZED TRIAL

T.-H. Oh[1,*]. [1]*Internal medicine, SANGGYE PAIK HOSPITAL, Seoul, Korea, Republic Of*

INTRODUCTION: Currently acid suppressing agents are routinely prescribed to heal the iatrogenic ulcer, however, it is still controversial that which treatment of proton pump inhibitor or H2 receptor antagonist is more effective regimen. Although several reports showing similar efficacy in the bleeding prevention and healing of EMR induced ulcer, to date there have been no controlled study in patient with ESD induced ulcer which had larger ulcer size. Therefore, we prospectively compared famotidine and pantoprazole for the healing of relatively larger ESD-induced ulcers.
AIMS&METHODS: Following ESD, all patients were given intravenous infusion of pantoprazole 40 mg once daily for two consecutive days, starting from the day of ESD. From the third day after ESD, all patients were allocated to famotidine (40 mg/day) or pantoprazole (40 mg/day) group for 8 week and instructed not to take other antisecretory drugs or possible ulcerogenic drugs. At 4 weeks, all enrolled subjects underwent follow-up endoscopy to compare the degree of healing including ulcer size and stage, and ulcer related symptoms between the two groups.
RESULTS: A total of 85 patients were randomized to each group according to the category of initial ulcer size; group 1 (ulcer size $<$ 3cm), group 2 (3 $\leq$ ulcer size $<$ 4), group 3 (ulcer size $\geq$ 4). Four patients were excluded following reasons; follow-up loss (two) and follow-up endoscopy at 5 weeks after ESD (two).
Finally, forty one patients in famotidine group and forty patients in pantoprazole group were compared. The two groups were comparable in terms of baseline characteristics such as age, sex, comorbidity, history of previous peptic ulcer, history of NSAID medications, social history including smoking and alcohol, final diagnosis, *H. pylori* status, location of lesion, injection materials, immediate complications and initial ulcer size. Four weeks after ESD, the two groups were not different with respect to ulcer stages (P = 0.35) or ulcer related symptoms (P = 0.38). The ulcer reduction ratios were no significant difference between the famotidine and pantoprazole group (0.274 ± 0.253 vs. 0.24 ± 0.187, $P = 0.72$). In subgroup analysis for patients according to the category of initial ulcer size, the three groups were comparable with the baseline characteristics. In comparing ulcer stages, ulcer related symptoms and ulcer reduction ratios were not significantly different among the three groups.
CONCLUSION: Our results demonstrate that the effects between the famotidine and pantoprazole therapy are similar in terms of the ulcer healing for the iatrogenic following ESD.

P697 EX VIVO PILOT STUDY FOR CONFOCAL ENDOMICROSCOPIC IMAGING OF GASTROINTESTINAL STROMAL TUMORS.

T. R. Ohya[1,*], K. Sumiyama[1], M. Kobayashi[2], J. Takahashi-Fujigasaki[3], A. Dobashi[1], H. Tajiri[1,2]. [1]*Department of Endoscopy,* [2]*Department of Internal Medicine, Division of Gastroenterology and Hepatology,* [3]*Division of Neuropathology, The Jikei University School of Medicine, Tokyo, Japan*

INTRODUCTION: Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the gastrointestinal (GI) tract arising from the deeper layers hidden by the overlying normal mucosa, and therefore it is difficult to sample tissues for histologic analysis and even endoscopically observe the tumors. Probe based confocal laser endomicroscopy (pCLE) is a newly established endoscopic method providing in vivo histology at a subcellular resoloution. Our preceding animal experiments demonstrated that the muscularis propria could be visualized with pCLE within an artificial submucosal space.
AIMS&METHODS: Aims of this study was to evaluate the technical feasibility of visualization of GIST tumor cells with pCLE after topical application of neuronal stains. Surgically removed full-thickness wall of 4 stomachs and 1 duodenum containing GISTs were studied. First, the overlying normal mucosa and the submucosa was removed approximately 5mm^2 until the tumor surface was exposed. A neuronal fluorescent molecular probe (NeuroTrace500/525, Invitrogen) was topically sprayed onto the exposed submucosal tumor and pCLE (Cellvizio, Mauna Kea Technologies, Paris) observation of the exposed portion of the GIST were performed. Cresyl violet was additionally sprayed for 3 gastric tumors. Standard histologic analysis was then performed after formalin fixation and the recorded pCLE images were capered with the corresponding histology.
RESULTS: pCLE succeeded to visualize the morphology of GIST tumor cells demonstrating each spindle shaped cell with image quality identical to bench microscopic images. NeuroTrace visualized the cell body and the nuclei of tumor cells. Meanwhile, the Cresyl violet selectively stained cell body and cytoplasm including a gastric GIST that NeuroTrace failed to visualize.
CONCLUSION: The results of this pilot ex vivo study showed the technical feasibility of the morphology based histologic analysis of GISTs using pCLE following topical application of the neuronal stains successfully visualized tumor cells. We believe that this minimally invasive endoscopic histology would overcome existing technical limitations currently associated with needle or forceps based biopsies.

INTRODUCTION: Endoscopic submucosal dissection (ESD) for esophageal squamous cell carcinoma (SCC) has been developed in Japan as a standard endoscopic resection technique. Recently, we have used a combination of an IT knife nano for peripheral incision and a SB knife for submucosal dissection. The aim of this study is to examine the usefulness and safety of the combined use of the SB knife and IT knife nano in ESD for esophageal SCC.
AIMS&METHODS: Esophageal ESD was performed on 414 lesions of 338 patients at Hiroshima University Hospital between April 2006 and March 2013. Lesions were divided into 3 groups: Group A, 235 lesions in 186 patients dissected with only a Hook knife between April 2006 and October 2010; Group B, 131 lesions in 110 patients dissected with the Hook knife and SB knife between November 2010 and June 2012; and Group C, 48 lesions in 42 patients dissected with the IT knife nano and SB knife between July 2012 and March 2013. We retrospectively examined mean procedure time, procedure time per unit area, rate of en bloc resection, and rate of complications (perforation, delayed bleeding) between the 3 groups.

RESULTS: There were no significant differences in tumor location, macroscopic type, invasion depth, or degree of fibrosis among the 3 groups. Tumor size was significantly larger in Group C than in Group A ($P < 0.05$). Mean procedure time was 68.5 ± 46.8 min (15–300 min) in Group A, 92.9 ± 48.3 min (20-300 min) in Group B, and 103.0 ± 42.1 min (35–180 min) in Group C. Procedure time per unit area in Group C was significantly shorter than that in Group A (7.8 ± 3.7 min in Group C vs. 11.7 ± 8.0 min in Group A, $P < 0.05$). The rate of en bloc resection was 93.2% (219/235) in Group A, 97.7% (128/131) in Group B, and 100% (48/48) in Group C. The rate of perforation was 6.0% (14/235) in Group A, 6.1% (8/131) in Group B, and 2.1% (1/48) in Group C. The rate of delayed bleeding was 1.7% (4/235) in Group A and 0.8% (1/131) in Group B; no delayed bleeding occurred in Group C.
CONCLUSION: The combination use of SB knife and IT knife nano showed possible potential for shortening of procedure time and increasing the safety of ESD for patients with esophageal SCC.

P699 PRELIMINARY STUDY ON USE OF CARBON DIOXIDE SUBMUCOSAL INJECTION CUSHION IN ESOPHAGEAL AND GASTRIC TUMOUR ENDOSCOPIC SUBMUCOSAL DISSECTIONS

T. Uraoka[1,*], Y. Kawahara[2], N. Ohara[3], K. Hori[2], H. Okada[2], N. Yahagi[1], K. Yamamoto[4]. *[1]Division of Research and Development for Minimally Invasive Treatment, Cancer Center, Keio University School of Medicine, Tokyo, [2]Department of Endoscopy, Okayama University Hospital, [3]Department of Pathology, Japanese Red Cross Okayama Hospital, [4]Department of Gastroenterology and Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) can be used for the successful *en bloc* resection of early stage gastrointestinal tumours including large lesions, but requires a satisfactory facilitative submucosal (sm) injection agent for safety and efficacy. We previously reported on the effectiveness of carbon dioxide (CO_2) as an sm injection agent using isolated and live pig models (*Dig Endosc* 2011), but this novel technique had not previously been assessed clinically.
AIMS&METHODS: The aim of this preliminary clinical study was to assess the safety and feasibility of this technique in esophageal and gastric ESDs.
Nine consecutive patients with 9 lesions including for 4 superficial esophageal and 5 early gastric cancers were enrolled for outcome analysis. The study protocol was approved by the ethics committee of our institution and informed consent was obtained from each patient. A gastroscope with a distal attachment was used along with a syringe filled to 50ml with CO_2 and connected to a 23-gauge injection needle catheter. CO_2 was then injected by hand into the sm layer followed by a circumferential incision and sm dissection using an electrosurgical knife. Standard sm injection with a glycerin solution (glycerol) was allowed for case of insufficient sm cushion. All resected specimens were examined histopathologically.
RESULTS: Mean resected specimen and tumour sizes were 35.0±13.0mm and 10.4±8.0mm, respectively. Median procedure time was 40 minutes (range, 20-70). Partial physical sm layer dissections were observed in all cases from the pressure of the CO_2 sm injections resulting in easier dissection of the sm layer using the electrosurgical knife with current and the distal attachment manually. Additional injections of glycerol were required in each case because of rapid CO_2 absorption. All tumours were successfully resected *en bloc* endoscopically and histologically without any complication enabling for precise histopathological assessment. Eight patients could be followed up for more than 22 months with no recurrences in any of those cases.
CONCLUSION: This study demonstrated the safety and efficacy of using CO_2 sm injections during esophageal and gastric ESDs despite the need for additional glycerol injection although further investigation of the technique will be needed prior to extensive clinical use.

P700 USEFULNESS OF ENDOSCOPIC EXAMINATION UNDER GENERAL ANESTHESIA IN THE DETECTION OF SUPERFICIAL CANCERS OF THE OROPHARYNX AND HYPOPHARYNX

Y. Takaki[1,*], Y. Ono[1], S. Ishikawa[1], K. Yao[2], Y. Yano[1], T. Matsui[1], H. Tanabe[3], K. Ikeda[3], S. Haraoka[3], A. Iwasita[3], T. Yamano[4], T. Sakata[4], T. Hirai[5], S. Shono[5]. *[1]Department of Gastroenterology, [2]Department of Endoscopy, [3]Department of Pathology, [4]Department of otolaryngology, [5]Department of anesthesiology, FUKUOKA UNIVERSITY CHIKUSHI HOSPITAL, Chikushino-city, Japan*

INTRODUCTION: The concept of field cancerization indicates that the possibility of multicentric cancer should be considered when superficial squamous cell carcinomas (SCCs) of the oro- and hypopharynx are detected. However the complex structure and the gag reflex make it difficult to adequately examine.
AIMS&METHODS: In this study, we compared the ability to detect superficial pharyngeal SCCs endoscopically with and without general anesthesia (GA). The subjects were 22 patients (male:female = 21:1, average age 68.1 years) who underwent endoscopic resection (ER) of 33 superficial SCCs of the oro- and hypopharynx at our Department between January 2005 and February 2013. Both preoperative endoscopies and endoscopies under GA were performed using non-magnifying white light imaging (WLI), narrow-band imaging (NBI) and magnifying NBI. Endoscopies under GA were performed just before ER. We exposed the larynx with the assistance of a curved laryngopharyngoscope (Sato-style, Nagashima Medical Instruments) in 14 cases. We determined the number of newly detected lesions under GA and compared the clinicopathological findings in the lesions detected preoperatively (A group) and the newly detected lesions under GA (B group).
RESULTS: The numbers of detected lesions by preoperative endoscopies and endoscopies under GA were 26 and 33, respectively (P=0.016, binomial test). Accordingly, 7 lesions were newly detected. As shown in Table 1, examination under GA was useful in the detection of small lesions white in color or the same color as the background mucosa. There is no significant difference in macroscopic appearance and depth of invasion between A group and B group.
Table 1. The size and endoscopic appearance

	A group (n=26)	B group (n=7)	P value
Mean diameter (SD) mm	17.9 (10.8)	7.7 (4.2)	0.02*
Coloration			0.04**
Red	20	1	
White / same as sorrounds	6	6	

*: Student's t-test, **: Fisher's exact test
CONCLUSION: WLI + NBI examination under GA markedly improves the detection rate for multicentric cancers of the oro- and hypopharynx, and is essential for endoscopic treatment.

P701 THE STUDY REGARDING FEASIBILITY OF REPEATED ENDOSCOPIC RESECTION FOR METACHRONOUSLY MULTIPLE SUPERFICIAL HEAD AND NECK SQUAMOUS CELL CARCINOMA

Y. Takeda[1,2,*], T. Yano[1], Y. Yoda[1], T. Odagaki[1], Y. Oono[1], H. Ikematsu[1], K. Kaneko[1]. *[1]Department of Gastroenterology, Endoscopy Division, National Cancer Center Hospital East, Kashiwa, [2]Department of Gastroenterology, Ishikawa Prefectural Central Hospital, Kanazawa, Japan*

INTRODUCTION: Progress of endoscopic instrument has led to early detection of superficial cancer and has allowed for endoscopic resection (ER) in head and neck (HN) region. In contrast, metachronously superficial cancers often occur in patients with head and neck squamous cell carcinoma (HNSCC) during followed up periods. Although it is reported that ER as an initial treatment is safe and effective, the feasibility of repeated ER (R-ER) for metachronously superficial cancers has not been clarified.
AIMS&METHODS: The aim of this retrospective study was to analyze the feasibility of R-ER for superficial HNSCC. Between June 2002 and December 2010, a total of 151 consecutive patient received initial ER (I-ER) for naive superficial HNSCC in our Hospital. Endoscopic mucosal resection using the cap (EMR-C) or endoscopic subepithelial dissection (ESD) was performed in all patients under general anesthesia. We have comparatively evaluated fasting period, hospital staying and early (within a week after ER) and late (1 week to 3 months) complications in same patients.
RESULTS: I-ER was performed for 196 lesions in 151 patients. Of 151, 48 (32%) had metachronously multiple HNSCC with median follow up period of 43 months (range: 2-124) from I-ER. R-ER was performed for 122 lesions in 48 patients. Patient characteristics of 48 patients included median age of 64 years (45-82), male/female: 46/2, 44 (92%) had history of synchronous or previous esophageal cancer. Median times of R-ER were twice (2-7 times). Median tumor size was 15 mm in diameter (2-50) of 196 lesions for I-ER, and 10 mm (2-43) of 122 lesions for R-ER. While local recurrence developed in 8 (5.2%) of 151 patients with median follow up period of 43 months (2-124), no local recurrence was found in 48 patients received R-ER with median follow up period 40 months (3-95), respectively. Fasting period during hospital staying was 3 days (1-14) of 7 (4-23) for R-ER, and 3 (1-20) of 8 (3-58) for I-ER. Early complication rates of R-ER and I-ER were 9.8% and 7.9%, respectively (bleeding: 1.6%vs1.3%, subcutaneous emphysema: 3.3%vs2.6%, mediastinal emphysema: 0.8%vs0%, pneumonia: 1.6%vs 2.6%, laryngeal edema requiring tracheostomy: 2.5%vs1.3%). Late complication rates of R-ER and I-ER were 1.6% and 2.6%, respectively (delayed bleeding: 1.6%vs1.3%, percutaneous endoscopic gastrostomy with dysphagia: 0%vs1.3%). Overall complication rates were 11.5% in R-ER and 10.6% in I-ER. There was no significant difference at any events.
CONCLUSION: These results indicate that R-ER may be almost same the feasibility compared with I-ER.

INTRODUCTION: Endoscopic submucosal dissection (ESD) for superficial esophageal neoplasms (SENs) is a promising procedure that enables en bloc resection regardless of the tumor size. Despite of its technical difficulties, recently good outcomes have been reported from high-volume centers as a single-center study, but safety and efficacy have not been evaluated in a multicenter survey including municipal hospitals.
AIMS&METHODS: This is a multicenter retrospective study from May 2005 to October 2012 in 11 hospitals attending the Osaka Gut Forum. Of 295 consecutive patients with 354 esophageal lesions treated by ESD, a total of 349 SENs in 290 patients (239 male, median age 69 yrs) were analyzed. The incidence of complications was estimated. In addition, we compared the results between before and after December 2009, or between 4 high-volume centers (HVC) that experienced more than 30 cases and 7 low-volume centers (LVC) that experienced less than 30 cases.
RESULTS: Mean tumor size was 20.9mm. Over half SENs were located in the middle thoracic esophagus (60%) and depressed type (54%). The pathological diagnoses were as follows; dysplasia/intraepithelial neoplasia 100 (29%); SCC 230 (66%); adenocarcinoma 10 (3%); undetermined 9 (3%). The invasion depth of SCC was EP 73; LPM 79; MM 45; SM1 11; SM2 ($>200\mu$m) or deeper 22. Two hundred and ninety five lesions (85%) were completely resected with negative margins and 259 lesions (76%) were curatively resected. Procedure times were 100±66 mins. Perforation including mediastinal emphysema, postoperative pneumonia, bleeding, and esophageal stricture occurred in 22 (6.5%), 6 (1.8%), 0 (0%), and 23 (6.8%), respectively. Outcome survey showed that the rates of perforation and long procedure time (≧2 hrs) were significantly decreased in the later period compared with the prior period [10.3% vs. 4.0%, p=0.025, 48.5% vs. 25.7%, $p<0.001$, respectively]. There were, however, no significant differences of short-term outcomes between HVC and LVC.
CONCLUSION: This multicenter survey indicated that esophageal ESD had a high risk of perforation and required long procedure time at first, but was becoming more feasible as a standard treatment with acceptable complication risks.
Disclosure of Interest: None Declared

P703 PRETREATMENT FACTORS CONTRIBUTING TO NON-CURATIVE ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER

Y. Ohara[1,*], N. Toshikuni[1,2], H. Mori[1], K. Matsueda[1], H. Yamamoto[1]. [1]gastroenterology, Kurashiki Central Hospital, Kurashiki, [2]gastroenterology, Kanazawa Medical University, Kanazawa, Japan

INTRODUCTION: Endoscopic submucosal dissection (ESD) is established as a curative treatment for early gastric cancer (EGC). Although the expansion of the criteria for ESD permits an increase in the number of patients who benefit from ESD, it may also increase the number of cases wherein ESD results in non-curative resection.
AIMS&METHODS: We conducted this study to clarify pretreatment factors for non-curative ESD. Between January 2008 and December 2012, 364 patients (276 males and 88 females; median age, 71 years) with 401 EGC lesions underwent ESD. In case of EGC lesions with suspected submucosal invasion, endosonography was performed before treatment. Curative ESD was defined as complete ESD meeting the criteria described in the Japanese gastric cancer treatment guidelines or the expanded criteria proposed by Gotoda et al. Pretreatment factors for non-curative ESD were examined using multiple logistic regression analysis. Variables included age (>70 years vs. <=70 years), gender, tumor size (>20 mm vs. <=20 mm), tumor location (upper vs. middle and lower), morphological classification (superficial elevated and depressed type vs. others), ulceration, and histological differentiation (differentiated type vs. undifferentiated type).
RESULTS: Non-curative ESD was observed in 63 (15.7%) lesions. The reasons for non-curative ESD were positive horizontal/vertical margins for 15 lesions, lymphatic and/or venous invasion for 23 lesions, sm2 invasion for 12 lesions, and others for 13 lesions. Multivariate analysis revealed that tumor size >20 mm [odds ratio (OR), 3.6; p = <0.0001], superficial elevated and depressed type (OR, 5.2; p = 0.0002), ulceration (OR, 5.3; p = 0.0007), and undifferentiated type (OR, 8.2; p = 0.0001) were significant factors for non-curative ESD. The reasons for non-curative ESD in superficial elevated and depressed lesions were sm2 invasion for 9 lesions, lymphatic and/or venous invasion for 3 lesions, and another for 1 lesion.
CONCLUSION: This study suggested that EGC lesions with large sizes, ulceration, or undifferentiated type have an increased risk for non-curative ESD, even if they satisfy the eligibility criteria for ESD. Furthermore, superficial elevated and depressed type was found to be an important factor influencing the curability of ESD.

P704 RISK FACTORS OF DELAYED HEALING OF IATROGENIC GASTRIC ULCER AFTER ENDOSCOPIC RESECTION

Y. W. Chang[1,*], J. Y. Jang[1], J.-W. Kim[1], W.-J. Ko[1]. [1]gastroenterology, Kyung Hee University Hospital, Seoul, Korea, Republic Of

INTRODUCTION: Endoscopic resection is safe, and applicable to a wide variety of clinical situations. However, endoscopic submucosal dissection (ESD) may cause large and deep defects after the procedure. Iatrogenic ulcers after endoscopic resection were thought to heal faster and to recur less often than peptic ulcers. About 10% of iatrogenic gastric ulcers after ESD were still remained as incomplete healing state at 8 weeks. So, we conducted a retrospective cohort analysis to clarify the contributing factors of delaying gastric ulcer healing after endoscopic resection and review the optimal duration of proton pump inhibitor (PPI) after endoscopic resection.
AIMS&METHODS: We analyzed retrospectively total 629 lesions in 533 patients who performed endoscopic resection due to gastric adenoma or early gastric cancer (EGC) between January, 2007, and December, 2011, at Kyung Hee University Hospital in Seoul, Korea. First post-ESD follow-up endoscopy was performed at the 8 weeks after ESD/EMR in the *Helicobacter pylori* (*H. pylori*) negative group and at the 12 weeks after ESD/EMR in the *H. pylori* positive group. Standard dose of PPI were administered for the treatments of iatrogenic ulcers after ESD/EMR in all patients.
RESULTS: After ESD/EMR, 77 in 629 lesions (12%) were healed incompletely at the first follow-up endoscopy. In univariate logistic regression analysis, the following factors were significantly associated with incomplete healing of iatrogenic ulcers: (1) the presence of depression [hazard ratio, 2.322 (95% CI, 1.270-4.245)], (2) the presence of ulcer or erosion [hazard ratio, 2.926 (95% CI, 1.531-5.590)], (3) the histologic type (high grade dysplasia or EGC) [hazard ratio, 2.661 (95% CI, 1.501-4.719)], and (4) the removed specimen size after ESD [hazard ratio, 3.066 (95% CI, 1.425-6.341)]. And, the use of antiplatelet agents showed borderline significance [hazard ratio, 1.844 (95% CI, 0.921-3.693)]. In multivariate logistic regression analysis, three factors were significantly associated with incomplete healing of iatrogenic ulcers: the presence of ulcer or erosion [hazard ratio, 2.210 (95% CI, 1.115-4.381)], the histologically high grade dysplasia or early gastric cancer [hazard ratio, 2.157(95% CI, 1.115-4.381)], and the removed specimen size (≥ 3.0 cm) [hazard ratio, 2.285 (95% CI, 1.042-5.011)].
CONCLUSION: Delayed healing of iatrogenic ulcers in ESD/EMR was associated with the presence of ulcer or erosion before ESD/EMR, the histologic type (high grade dysplasia or EGC) and the removed specimen size.

P705 LONG DECOMPRESSION TUBE PLACED BY TRANSNASAL ULTRATHIN ENDOSCOPY WITH HYDROPHILIC GUIDEWIRE FOR SMALL BOWEL OBSTRUCTION: SAFE METHOD AND RAPID INSERTION

Y. Muta[1,*], S. Yazumi[1]. [1]Digestive Disease Center, The Tazuke Kofukai Medical Research Institute, Kitano Hospital, Osaka, Japan

INTRODUCTION: Placement of a long intestinal decompression tube is a common option for the nonoperative management of small bowel obstruction (SBO). However, there is sometimes a great difficulty in intubating small bowel with conventional technique using fluoroscopy and guidewire manipulation, which could cause prolonged procedure time and severe patient distress.
There have been some reports regarding the usefulness of long tube intubation method assisted with endoscopy, however still some problems remain. A novel technique was developed using a combination of transnasal endoscopy and hydrophilic guidewire.
With this method, the tube can easily advance through the jejunum benefit by the stiffness of the guidewire, and hydrophilic guidewire can be easily controlled through the tube thanks to the minimal striction.
We performed a retrospective study in patients with SBO treated by long decompression tube to compare the new method with conventional method.
AIMS&METHODS: The aim of this study is to evaluate the safety and efficacy of this new technique.
We analyzed a total of 141 patients with long tube intubation performed in our institution from October 2010 to March 2013. Tubes were inserted either with our new method or with conventional method, and patients were categorized in 2 groups accordingly; endoscopy group and conventional group.
We evaluated the cause of the obstruction, success rate of the placement, the total procedure time, and adverse events.
We used transnasal gastrointestinal videoscopes with diameter of 5.0 mm at the distal end (GIF-XP260N, Olympus Medical Systems, Japan). Hydrophilic guidewires and hydrophilic long tubes with 16 Fr diameter and 300 cm length were used in both groups.
RESULTS: Subjects comprised 80 men and 61 women, and median age was 68 years. There were no significant differences in background characteristics between the 2 groups. The most common cause of SBO was postoperative adhesion followed by malignancy and herniation.
The success rate was significantly higher in endoscopy group (99.1%) as compared to 85.1% in conventional group ($p = 0.01$). The mean procedure time was significantly shorter in endoscopy group (42 minutes) compared with 68 minutes in conventional group ($p < 0.01$)
In endoscopy group, 63.6% of the patients could avoid surgery during hospitalization and 73.3% in conventional group respectively, though there was no significant difference between them. No major adverse events such as perforation were observed in either group.
CONCLUSION: Using a combination of transnasal ultrathin endoscopy and hydrophilic guidewire is a safe and efficient method for patients with SBO to place long decompression tubes, and is superior to conventional intubation methods.

P706 CONFOCAL LASER MICROSCOPY FOR THE EVALUATION OF NEW MORPHOMETRIC PARAMETERS OF NEOANGIOGENESIS AND TARGETED PANENDOTHELIAL MARKERS IN HUMAN COLORECTAL CANCER

A. Ciocâlteu[1,*], A. Săftoiu[1], L. Gruionu[2], D. Pirici[3], C. Georgescu[4], G. Gruionu[1,5]. [1]*Research Center of Gastroenterology and Hepatology, University of Medicine and Pharmacy of Craiova,* [2]*Department of Mechanical Engineering, University of Craiova,* [3]*Department of Histology, University of Medicine and Pharmacy of Craiova,* [4]*Department of Pathology, Emergency County Hospital , Craiova, Romania,* [5]*Steele Laboratory of Tumor Biology, Department of Radiation Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, United States*

INTRODUCTION: Tumor microcirculation is characterized by an abnormal vascular network with dilated, tortuous, saccular vessels. Imaging the tumor vasculature and determining its morphometric characteristics represent a critical goal for optimizing the development of antiangiogenic therapy.
AIMS&METHODS: In this study we evaluated vascular morphometric parameters in colorectal cancer by using a minimally-invasive imaging technique, confocal laser endomicroscopy (CLE). Fresh biopsies from tumor and normal tissue were collected during colonoscopy from five patients with T3 colorectal carcinoma without metastasis, and were marked with fluorescently labeled anti-CD31 antibody. The imaging was performed using a dedicated endomicroscopy system (Pentax Inc). ImageJ NIH software was used for image processing. To account for directional variability, the parameters of vascular segments from two equal perpendicular rectangles (50 microns wide in the horizontal and vertical direction) were averaged for each sample. Vessel diameters, vessel density, vessel lenght, tortuosity index and daughter/mother ratio were expressed as the average±standard deviation. Statistical differences were calculated using the Student's t-test, considering p-values $\leq$0.05 significant.
RESULTS: The average diameter of vessels in the normal sample was 7.6±0.3μm, the vessel density was 988.8±51.4vessels/mm^2, whereas in the tumor sample the vessel diameter was 9.4±0.4μm and the vessel density 1511.1±69.3vessels/mm^2 ($p<0.05$). The tortuosity index (ratio of segmented and straight line lengths) and vessel length were 1.06±0.02 and 28.7±3.2μm in normal tissue, 1.07±0.01 and 24.6±3.1μm in tumor tissue respectively. The daughter/mother ratio (ratio of the sum of the squares of daugther vessel radia over the square of the mother vessel radius, considerind the mother as the largest vessel at a branching point) was 1.11±0.09 in normal tissue, while in tumor tissue we obtained a similar average value of 1.10±0.08 ($p>0.05$).
CONCLUSION: Our study found no significant difference in the tortuosity index and daughter/mother ratios between normal and tumor microvasculature in contrast to the conventional perception that the blood vessels are more tortuous in colorectal cancer. Provided new contrast agents will be clinically available, future *in vivo* use of CLE could lead to identification of novel biomarkers based on the morphometric characteristics of tumor vasculature.

P707 POLYP RESECTION RATE AND POLYPECTOMY SUCCESS RATE – TWO NEW COLONOSCOPY QUALITY ASSURANCE PARAMETERS. – POLYPECTOMY IS A YOUNG MANS' GAME!

A. Staicu[1,*], R. Jha[1], B. Rembacken[1]. [1]*Gastroenterology, St James University Hospital, Leeds, United Kingdom*

INTRODUCTION: One of the core purposes of colonoscopy is to detect and remove polyps. Incomplete resection of polyps is associated with an increased risk of subsequent cancer. In spite of this, no Quality Assurance (QA) benchmarks have been developed to assess the ability of endoscopists to competently deal with polyps.
AIMS&METHODS: We retrospectively analysed the colonoscopy database from 3 British endoscopy units over a 5 year period (2008-2012 inclusive). Colonoscopies carried out with therapeutic intent were excluded. Screening and surveillance examinations were included.
RESULTS: Data from 4393 polyps (average size 6.3mm) found during 17060 colonoscopies carried out by 15 colonoscopists was analysed. Removal of 4121 polyps was attempted (1981 by snare polypectomy and 938 by EMR, the remainder removed by hot biopsy or cold snare). In 559 cases the polypectomy "failed", either due to incomplete resection (121 polyps) or failure of retrieval of the polyp (438 polyps). Most failures were in removing larger sessile lesions (avg size 14.7mm) found in the rectum, sigmoid or caecum.
By dividing the unsuccessful procedures with the total number of polypectomies, a "Polypectomy Success Rate" (PSR) was calculated. The median PSR was 82% (std 11.5%). Two endoscopists had Polypectomy Success Rates (PSR) 2 standard deviations below median at (51% and 62%, minimum standard Polypectomy Success Rate: 62%). There was no significant association between the PSR and the caecal intubation rate (P=0.83), the total number of polyps removed (P=0.25) or the total number of colonoscopies carried out (P=0.37). However, there was a significant association with the age of the endoscopist (P=0.002, $r^2 = 0.53$)!
1946 polyps were in the size range for removal at the initial examination (up to 2cm on the left side and 1cm on the right). However, 475 eligible polyps were not removed, giving a median Polyp Resection Rate (PRR) of 71%. Reasons for not removing a polyp included finding a more significant nearby lesion (26%), comorbidities (20%), patient uncomfortable (12%), inadequate bowel prep (11%), difficult polyp position requiring deferral to a dedicated session (8%) and lesion not found on extubation (5%). One endoscopist was 2 STD below the median at 35% (STD 11.6% giving a minimum quality standard of 48%).
CONCLUSION: We propose two new, important QA benchmarks and propose minimal standards for Polyp Resection Rate (62%) and Polypectomy Success Rates (48%).

P708 30 DAYS HOSPITALIZATION RATE AFTER SCREENING COLONOSCOPY – CASE-CONTROL STUDY NESTED IN PROSPECTIVE RANDOMIZED CONTROLLED STUDY

A. M. Pietrzak[1,*], M. Kaminski[1], E. Kraszewska[1], M. Rupinski[1], J. Regula[1]. [1]*Medical Centre for Postgraduate Education, Warsaw, Poland*

INTRODUCTION: In the past few years it have been proven that screening, including primary colonoscopy, reduces colorectal cancer incidence and mortality. Few studies have addressed the risk of 30 day hospitalization rates following screening colonoscopy.
AIMS&METHODS: The aim of our study was to compare the 30 day hospitalization rates after screening colonoscopy with the age and sex matched control groups and then to identify definite and possible serious adverse events leading to these hospitalizations.
The study was approved by the institutional ethical committee.
Methods: This study was nested in a randomized controlled trial in which 55-64 year old individuals living in one geographical area between 2009-2011 were drawn from population registries and randomly assigned in a 1:2 ratio to either colonoscopy group (COL; offered screening colonoscopy via mail invitation) or control group (CON; not contacted). Each subject randomized to the screening group was matched to two subjects from the control group with the same sex and birth year and assigned an identical screening and virtual screening dates. We have followed screening participants and their matched controls for deaths and causes (ICD 10 coding) of hospitalizations within 30 days from the date of actual or virtual screening, using the Ministry of Interior and National Health Service databases (covering over 98% of all insured population), respectively.
Adverse events leading to hospitalization in both groups were divided for definitely related (bleeding, post-polypectomy syndrome, perforation) and possibly related (cardiovascular (CVS), central nervous system (CNS), other gastrointestinal, infectious and deaths) to colonoscopy. Any other causes were assessed as unrelated.
RESULTS: 12,033 participants were included, 4,011 to the COL group and 8,022 to the CON group; hospitalization for any reason within 30 days occurred in 93 (2.32%) and 183 (2.28%), respectively ($p>0.1$). We identified 3 definitely and 13 possibly (9 CVS, 1 CNS, 2 infectious and 1 death) related complications in the COL group. There were 21 possibly (15 CVS, 3 CNS, 1 infectious and 2 deaths) related hospitalizations in the CON group ($p>0.1$). In the COL group there were no statistically significant differences in the rates of sedations, total exams, bowel preps, tolerance, polypectomies and diverticulosis between patients with and without possibly related adverse events.
CONCLUSION: The study shows no difference in the 30 day hospitalization rates between both groups. Serious adverse events were uncommon (4/1000) and no risk factors of hospitalizations were identified. Screening colonoscopy carries no additional risk for hospitalization.

P709 RANDOMIZED CONTROLLED TRIAL OF ULTRA-THIN VERSUS PEDIATRIC INSTRUMENTS FOR COLONOSCOPY IN OLDER FEMALE PATIENTS

D. Nemoto[1,*], K. Utano[1], S. Endo[1], N. Isohata[2], T. Otani[1], D. G. Hewett[3], K. Togashi[1]. [1]*Coloproctology,* [2]*AIZU MEDICAL CENTER, FUKUSHIMA MEDICAL UNIVERSITY, Aizuwakamatsu, Japan,* [3]*School of Medicine, University of Queensland, Brisbane, Australia*

INTRODUCTION: Pediatric colonoscopes with 11 mm diameter are often used to negotiate the female colon. Gastroscopes, which are thinner than pediatric colonoscopies, are occasionally required to negotiate angulated sigmoid colons. However, the use of ultra-thin colonoscopes (6.8 mm diameter, standard length) for such difficult cases has not been studied.
AIMS&METHODS: Study aims: To compare the use of ultra-thin instrument with a pediatric instrument for colonoscopy in older female patients.
Methods: Following approval from Institutional Review Board, we commenced a randomized controlled study in August 2012. Female patients aged 70 years or older were enrolled and randomly allocated to colonoscopy with an ultra-thin scope (UTS) or a pediatric scope (PDS). Patients with a history of colonic resection were excluded from the study. Three board-certified endoscopists performed colonoscopy with carbon dioxide insufflation and no fluoroscopic guidance. Patients did not receive any sedation. Conventional insertion techniques, including clockwise torque shortening technique, were used with position change and abdominal pressure when necessary. We measured cecal intubation rate, ileal intubation rate, time to cecum and adenoma detection rate and degree of pain experienced (using a numerical rating scale, NRS). Patients were blinded to the instrument used until after measurement of the NRS. We used the Fischer's exact test or Mann-Whitney test to compare outcomes between groups.
RESULTS: Seventy-three patients enrolled into the study and 3 patients withdrew after randomization: 38 patients were allocated to the UTS group and 35 patients to the PDS group. The median age was 77 years (range 70 to 92 years). Cecal intubation rates were 97% in UTS and 94% in PDS (p=0.60). Ileal intubation rates were 81% in UTS and 88% in PDS (p=0.52). Median times to cecum

were 15.2 minutes (range 4.3 to 44.1) in UTS and 9.8 minutes (range 4.6 to 30.0) in PDS. There was a significant difference in insertion time (p=0.0085). Adenoma detection rates were 32% in UTS and 26% in PDS (p=0.62). There was a significant difference in pain experienced during colonoscopy ($p<0.0001$) between UTS (NRS 1/11, range 0 to 9) and PDS (NRS 4/11, range 1 to 8).
CONCLUSION: In older female patients undergoing unsedated colonoscopy, use of an ultra-thin instrument was associated with significantly less pain although insertion time was longer, compared with a pediatric instrument.

P710 INCIDENCE, TREATMENT AND OUTCOME OF ADVERSE EVENTS OF 100.000 SCREENING COLONOSCOPIES PERFORMED BY QUALITY CERTIFIED ENDOSCOPISTS IN AUSTRIA

E. Waldmann[1,2,*], P. Salzl[1,2], M. Britto-Arias[1,2], I. Gessl[1,2], D. Sallinger[1,2], M. Trauner[1], W. Weiss[2], M. Ferlitsch[1,2]. [1]*Department of Internal Medicine III, Div of Gastroenterology and Hepatology, Medical University of Vienna,* [2]*Quality Assurance Working Group, Austrian Society of Gastroenterology and Hepatology (OEGGH), Vienna, Austria*

INTRODUCTION: In Austria screening colonoscopy is part of the preventive health checkup since 2005. Since screening colonoscopy is an invasive examination performed on a potentially healthy population, it is essential that adverse events occur as seldom as possible. In this study we evaluated incidence, treatment and outcome of adverse events in screening colonoscopies.
AIMS&METHODS: This retrospective cohort study included all patients who underwent screening colonoscopy by one of 204 quality certified endoscopists in Austria between November 2007 and March 2013.
RESULTS: In total 102.328 patients were included in this study. 53.286 (51.1%) women and 50.042 men (48.9%). The mean age in women was 61.2 years, in men it was 61.1 years. 86.8% received sedation. Cecal intubation rate was 95.5%. In 0.3% (n=264) of all colonoscopies adverse events were reported. 39% of them were cardiopulmonary events, 62% in women and 38% in men; followed by bleeding (46.2%; 30.3% vs 69.6%), perforation (4.5%; 42% vs 58%) and others (10.2%). 58.3% of perforations and 97.5% of bleedings occurred in colonoscopies with polypectomy. Colon perforation rate was 1:8527, post-polypectomy bleeding rate was 1:328. Further risk factors are polypectomy of multiple (>4; 0.04%), big (>2cm; 0.23%) and pedunculated polyps (0.04%) using snare (0.07%). 62.1% of all adverse events were treated conservatively, 19.3% in an ambulant setting, 13.6% were hospitalized and 4.5% required operative intervention. Out of the 12 perforations, 9 were treated in an operative setting, 2 as inpatients, 1 conservatively. 11 patients reached institution ad integrum, in one case we had no information about the outcome.
CONCLUSION: Colon perforation and postpolypectomy bleeding rates of 1:8527 and 1:328 were rarer than recommended in current guidelines (perforation rate should not exceed 1:1000 and bleeding rate 1:200). The results of our study show an internationally comparable adverse event rate in colonoscopies, performed within the ''Quality certificate screening colonoscopy''. Screening colonoscopy in Austria corresponds to highest requirements in regard to safety and quality.

INTRODUCTION: Endoscopic Submucosal Dissection (ESD) allows monobloc and complete resections of digestive superficial tumors with high rate. The aim of this study was to evaluate the feasibility of ESD and the complete resection rate at 1 year. Preliminary results were available.
AIMS&METHODS: Patients with superficial medium or distal rectal tumors, more than 1 cm in size, were prospectively included in 9 expert French centres between February 2010 and June 2012.Follow-up was one year. The study was temporary stopped from September 2010 to June 2011 because of the high complications rate. Inclusions have resumed after remedial action.
RESULTS: 45 patients were retained for analysis (67 years, 24 males). Median procedure time was 110 [30, 280] minutes and median diameter was 35 [10-100] mm. Perforations rate was 17% (n=8), immediately detected with none salvage surgery. 6 (13%) patients had immediate bleeding treated during ESD and 6 (13%) had late bleeding treaded endoscopically for 5 and surgically for 1 patient who needed red blood transfusion. Mortality was zero. Total monobloc resection rate was 29 (65%) with 5 (11%) monobloc ESD finalised by a snare. Macroscopic complete resection rate was 95% and curative R0 resection rate was 54%. 3 (6%) patients had an invasive tumour (2 sm1: 1 with curative criteria and 1 requiring surgery, 1 T2 requiring surgery). At 3 months, there was 93% compliance to endoscopic control and complete resection rate was 86%. 1 patient needed a complementary mucosectomie. At 1 year, 33 (73%) patients had an endoscopic control and complete resection rate was 31 (69 %). Monobloc resection was significantly associated with less tumour diameter (37 +/- 21 cm monobloc versus 52 +/- 27 piecemeal, p=0 .04) and RO resection was significantly associated with less than 3cm diameter (84% R0 versus 60% R1, p=0.05). At the end of the study, after the remedial action, there was more monobloc resection (74% vs 52%), less procedure duration/tumour size (2.2 vs 4.1) and less perforations (0% vs 34%).
CONCLUSION: Superficial rectal tumours can be treated safely and effectively by ESD with a high complete resection rate. Experience in ESD is low in Europe and curative RO resection should increase and complications rate decrease with experience and corrective actions.

P712 HIGH-DEFINITION ENDOSCOPY WITH VIRTUAL CHROMOENDOSCOPY ALLOWS ACCURATE PREDICTION OF FOOD ALLERGY IN REAL-TIME – AN OBSERVATIONAL STUDY

H. Neumann[1,*], M. Vieth[2], M. F. Neurath[1], Y. Zopf[1]. [1]*Department of Medicine I, UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen,* [2]*Institute of Pathology, Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: Food allergy is an adverse immune response to food antigens involving the immune system via IgE and non-IgE mediated mechanisms. Previously it was shown that standard white-light endoscopy may reveal discrete mucosal alterations in patients with severe food allergy. Of note, these findings were mostly unspecific for the underlying disease.
AIMS&METHODS: Study objective was to access the value of high-definition colonoscopy with virtual chromoendoscopy (i-scan) for prediction of mucosal changes in patients with suspected food allergy. Therefore, consecutive patients suffering from recurrent abdominal pain and diarrhea were included. First, the patients underwent a clinical interview in order to contain the diagnosis. Afterwards, ileocolonoscopy was performed using high-definition endoscopy with i-scan. The mucosa of the terminal ileum, caecum and at the rectosigmoid junction was carefully inspected with i-scan. Than a diagnostic lavage was performed at these locations and analyzed by measuring 13 different allergic markers, including TNF-alpha and IgE. Subsequently, biopsies were obtained for additional histopathological analysis.
RESULTS: 26 patients (19 female, mean 46 age years; Range 50-68 years) were prospectively included. Based on the clinical presentation and the lavage diagnosis intestinal food allergy was diagnosed in 60% of patients. High-definition endoscopy with i-scan visualized lymphoid hyperplasia, slight mucosal edema and blurred mucosal vascular pattern. Based on these findings i-scan could predict food allergy with a sensitivity, specificity and accuracy of 85%, 89%, and 86%, respectively. Positive and negative predictive value of i-scan for prediction of food allergy was 92% and 80%, respectively.
CONCLUSION: High-definition endoscopy with virtual chromoendoscopy could mimic slight mucosal changes in patients with intestinal food allergy which were highly predictive for the disease.

P713 DEVELOPMENT OF A NEW CLASSIFICATION SYSTEM FOR CONFOCAL LASER ENDOMICROSCOPY IN INFLAMMATORY BOWEL DISEASES

H. Neumann[1,*], E. Coron[2], K. Mönkemüller[3], M. F. Neurath[1], M. Vieth[4]. [1]*Department of Medicine I, UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen, Germany,* [2]*Centre Hospitalier Universitaire, Nantes, France,* [3]*Basil Hirschowitz Endoscopic Center of Excellence, University of Alabama at Birmingham, Birmingham, United States,* [4]*Institute of Pathology, Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: Probe-based confocal laser endomicroscopy (pCLE) allows in vivo histology during ongoing colonoscopy and assessment of mucosal and submucosal alterations in real time. Here, an international collaboration of five experts proposed a new and unique pCLE classification for the use in patients with inflammatory bowel disease (IBD).
AIMS&METHODS: Main study objective was to establish a pCLE classification for IBD. Second study objective was to assess accuracy, interobserver and intraobserver agreement of the new classification. Therefore, consecutive patients with known IBD underwent screening or surveillance colonoscopy and were evaluated using pCLE. First, a post hoc review of 25 pCLE video sequences was performed in order to accomplish the new classification system which is based on different vessel and crypt categories. Accordingly, all observers scored an additional set of 100 pCLE video sequences, using the new classification. In all cases, histopathology served as the reference standard.
RESULTS: Based on different vessel and crypt categories a new pCLE classification for IBD was developed. Interobserver agreements for vessel and crypt architecture were substantial with kappa values of 0.77 (95% confidence interval: 0.65-0.90) and 0.63 (95% confidence interval: 0.48-0.79), respectively. Intraobserver agreements for vessel and crypt architecture were substantial with kappa values of 0.75 (95% confidence interval: 0.49-1) and 0.68 (95% confidence interval: 0.38-0.97), respectively. Overall, sensitivity, specificity and accuracy for predicting histological inflammation in macroscopically non-inflamed mucosa were 94%, 81%, and 87%, respectively. Positive and negative predictive values were 82% and 94%, respectively.
CONCLUSION: Here, a panel of international experts developed and validated a new and unique classification for pCLE in IBD. The classification allows

prediction of microscopic inflammation even in macroscopically non-inflamed mucosa. Final results will be reported at UEGW.

P714 I-SCAN IMPROVES THE DETECTION OF RIGHT SIDED COLON ADENOMAS IN COMPARISON TO HIGH-DEFINITION WHITE LIGHT ENDOSCOPY

H. Neumann[1,*], M. Vieth[2], C. Günther[1], R. Atreya[1], J. Siebler[1], M. F. Neurath[1]. [1]*Department of Medicine I, UNIVERSITY OF ERLANGEN-NUREMBERG, Erlangen,* [2]*Institute of Pathology, Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: Colonoscopy remains the gold standard for colorectal cancer surveillance. Nevertheless, population based studies have shown, that 20-50% of colorectal lesions may be missed during colonoscopy and that colonoscopy has only limited effects on the occurrence of proximal colon neoplasms. i-scan is a newly introduced virtual staining technique that provides an improved tissue contrast.
AIMS&METHODS: Main study objective was to assess if i-scan improves the detection of proximal colon adenomas in comparison to high-definition white light endoscopy (HD-WL). Therefore, consecutive patients undergoing surveillance colonoscopy were prospectively included. The right colon was first investigated with HD-WL followed by a repeat examination with i-scan.
RESULTS: Overall, 300 patients (40% female; mean age 61 years) were prospectively included. In the HD-WL group 76 polyps (mean diameter 9.2mm, range 2-40mm) were detected within the right colon. i-scan detected 62 additional polyps (mean diameter 3.7mm, range 2-10mm) within the right colon. Histopathological analysis revealed 22 hyperplastic lesions and 54 adenomas in the HD-WL group. Additionally, 12 carcinomas were found. i-scan detected additional 12 hyperplastic lesions, 48 adenomas and 1 tumor (schwannoma of 2mm in the caecum). Overall, i-scan detected significantly more colorectal lesions and more adenomas (both $p < 0.001$). The median additional time exposure for i-scan was 157 seconds.
CONCLUSION: Additional investigation of the right colon with i-scan requires less than 3 minutes and yields in an increased adenoma detection rate. Therefore, i-scan has the potential to significantly enhance the quality of screening and surveillance colonoscopy.

P715 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL NEOPLASIA DURING THE CLINICAL LEARNING CURVE

H. Shiga[1,*], K. Endo[1], M. Kuroha[1], H. Nagasawa[1], R. Moroi[1], K. Matsushita[1], T. Tadano[1], Y. Kakuta[1], Y. Kinouchi[1], T. Shimosegawa[1]. [1]*Division of Gastroenterology, TOHOKU UNIVERSITY GRADUATE SCHOOL OF MEDICINE, Sendai, Japan*

INTRODUCTION: The efficacy of endoscopic submucosal dissection (ESD) for en bloc resection of colorectal neoplasia has been reported. However, even in Japan, colorectal ESD has not yet been widely spread because of the technical difficulty and higher risk of complications, especially for novices of colorectal ESD who have little experience in gastric ESD. The same is also true of skilled endoscopists in western countries that have smaller number of early gastric neoplasia. We report here the results of colorectal ESD during the clinical learning curve. We also discuss ways to reduce the difficulties of colorectal ESD, especially for novices.
AIMS&METHODS: Colorectal ESD was performed at Tohoku University Hospital between July 2009 and April 2013 by 4 endoscopists with experience in fewer than 5 cases of gastric ESD. The first 20 cases of each endoscopist were investigated. The dual knife (standard tip-type knife; Olympus Optical Co., Tokyo, Japan) or the SB knife junior (small scissors-type knife; Sumitomo Bakelite Co., Tokyo, Japan) was used as a knife for mucosal incision and submucosal dissection. From among the clinicopathological factors (location, macroscopic types, tumor size, histological types and knife types), the factors that affected the co-primary outcomes (the procedural time, the en bloc resection rate and the complication rate) were identified.
RESULTS: (Clinicopathological characteristics) A total of 80 cases (54 males, 26 females; 56 colonic and 24 rectal lesions; 29 IIa, 30 IIa+Is, 9 IIa+IIc and 12 Is) were included in this study. The mean age of the patients was 68.1 (30-87) years. The mean tumor diameter was 35.2 (20-95) mm. The histological analysis showed 39 adenocarcinomas (48.8%) and 41 adenomas (51.2%). (Outcomes) The mean procedural time was 108.8 (37-329) minutes. The en bloc resection rate with tumor-free margins was 75.0% (60/80). Perforation occurred in 6 patients (7.5%) who were managed by conservative medical treatment after the endoscopic closure. Postoperative hemorrhage occurred in 3 patients (3.8%) who were treated by endoscopic hemostasis. Multivariate analyses revealed that colonic lesions and larger lesions (40mm or more) were significantly associated with longer procedural time (90min or more). The use of SB knife junior was significantly associated with higher en bloc resection rate. Colonic lesions were also associated with perforations.
CONCLUSION: Colorectal ESD is technically challenging for novices. The use of the SB knife junior may increase the en bloc resection rate. It may be better to begin from rectal and smaller lesions (less than 40mm) in order to reduce complications.
Disclosure of Interest: None Declared
Keywords: colorectal neoplasia, Complication, en bloc resection, endoscopic submucosal dissection (ESD), learning curve

P716 EFFICACY AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR RECTAL NEOPLASIA CLOSE TO THE DENTATE LINE

H. Shiga[1,*], K. Endo[1], M. Kuroha[1], H. Nagasawa[1], R. Moroi[1], K. Matsushita[1], T. Tadano[1], Y. Kakuta[1], Y. Kinouchi[1], T. Shimosegawa[1]. [1]*Division of Gastroenterology, TOHOKU UNIVERSITY GRADUATE SCHOOL OF MEDICINE, Sendai, Japan*

INTRODUCTION: Although colonic endoscopic submucosal dissection (ESD) is difficult and has a higher risk of perforation, rectal ESD is relatively easy and has lower risk of perforation. However, the ESD procedure for rectal lesions close to the dentate line may be difficult, because such lesions have a higher risk of bleeding from rectal venous plexus. Moreover, the working space in the anal canal is very narrow. We report here the results of ESD for rectal neoplasia close to the dentate line.
AIMS&METHODS: ESD was performed at Tohoku University Hospital between January 2011 and April 2013 by an endoscopist with experience in more than 50 cases of colorectal ESD. Because of sensory nerves, the ESD procedure for squamous epithelium is usually accompanied by pain. Therefore, local lidocaine injection was used on the occasion of incision of the dentate line. Clinicopathological characteristics (tumor size, macroscopic types, histological types and existence of hemorrhoids) were investigated. Co-primary outcomes were the procedural time, the rate of en bloc resection and the rate of complications.
RESULTS: (Clinicopathological characteristics) A total of 15 cases (7 males, 7 females; 1 female with 2 lesions close to the dentate line) were included in this study. The mean age of the patients was 63.2 (40-83) years. The mean tumor diameter was 59.8 (21-122) mm. Among the 15 cases, 11 were laterally spreading tumors of the granular type, and 4 were large protruding tumors. Twelve cases (80.0 %) had hemorrhoids. The histological analysis showed 8 cases (53.3 %) of adenocarcinomas and 7 cases (46.7 %) of adenomas. (Outcomes) The mean procedural time was 121.1 (38-224) minutes. The en bloc resection rate was 100.0% (15/15) and the en bloc resection rate with tumor-free margins was 80.0% (12/15). Two cases required another knife, a hook knife. No case required a snare. Postoperative hemorrhage occurred in two cases (13.3%), which were treated by endoscopic hemostasis. Two cases complained of anal pain for about a week after ESD, which were treated by oral loxoprofen. One case (6.7%) had low grade fever for several days after ESD, which may be due to sepsis and was treated by antibiotics. Anal-stenosis occurred in one patient (6.7%) who was treated by endoscopic balloon dilation.
CONCLUSION: The procedure of ESD for rectal lesions close to the dentate line is feasible and safe, only if it is performed by endoscopists with sufficient experience. The pain can be well-controlled using local lidocaine injection. However, in order to reduce complications, further devices are required.
Disclosure of Interest: None Declared

P717 A NOVEL BALLOON-COLONOSCOPE IS SAFE & EFFECTIVE IN ADENOMA DETECTION - A PROSPECTIVE HUMAN STUDY

I. M. Gralnek[1,2,*], A. Suissa[2], S. Domanov[1]. [1]*Gastroenterology, Elisha Hospital,* [2]*Gastroenterology, RAMBAM HEALTH CARE CAMPUS, Haifa, Israel*

INTRODUCTION: Colonoscopy is the "criterion standard" for detecting colorectal adenomas & cancers. However, multiple studies show adenomas (20% > 30%) are missed. This is primarily due to inadequate visualization of the proximal aspect of colonic folds and flexures. The NaviAid™ G-EYE™ (SMART Medical Systems Ltd, Ra'anana, Israel) is a novel, balloon-colonoscope comprising a standard colonoscope with a reprocessable, permanently integrated, inflatable balloon at the colonoscope tip. The balloon is inflated (endoscopist controlled) through the endoscope internally, without external accessories. The balloon-colonoscope is advanced by the endoscopist with the balloon deflated. At the cecum, the balloon is inflated to engage the colon walls and the balloon-colonoscope is then withdrawn by the endoscopist. Withdrawal of the inflated balloon-colonoscope causes mechanical straightening of colonic folds & flexures.
AIMS&METHODS: To establish the feasibility of use and safety of a novel balloon-colonoscope. This was a prospective cohort study in human subjects (ages 40-75 years) referred for CRC screening, polyp surveillance or diagnostic evaluation. The primary study endpoint was cecal intubation, additional endpoints included: time to cecal intubation, withdrawal time, total procedure time, polyp detection rate (PDR), adenoma detection rate (ADR), success of polypectomies, and adverse events. Telephone follow up with subjects was performed 24-72 hours post-colonoscopy. This study was Helsinki committee approved.
RESULTS: From 15/11/12 - 30/1/13, n=50 consecutive subjects (mean age 59.0 years, range 40-74 years, 27 female) were enrolled. Three subjects were excluded due to inadequate colon prep, technical problem, and hernia, thus 47 subjects analyzed. A 47/47 (100%) cecal intubation rate was achieved. Mean time to cecum was 4.3 mins, withdrawal time 7.4 mins, and total procedure time 16.5 mins. We identified a total of 44 polyps in 25/47 subjects, a 53.2% PDR. There were 36 (81.8%) polyps (1-5mm), 4 (9.1%) polyps (6-9mm) and 4 (9.1%) polyps (≥10mm) in size. We found that 36/44 (81.8%) polyps were "adenomas", and 21/47 subjects had at least one adenoma, yielding an ADR=44.7%. All polyps were removed by cold / hot snare polypectomy. There were 2 subjects with minor adverse events: diarrhea & abdominal pain.
CONCLUSION: The NaviAid™ G-EYE™ balloon-colonoscope appears feasible, usable, and safe. There was 100% cecal intubation, a 53% PDR, a 45% ADR, and no serious adverse events. Comparative human studies are now in progress.

P718 THE INCIDENCE AND COST OF UNEXPECTED HOSPITAL ATTENDANCE FOLLOWING ELECTIVE OUTPATIENT FLEXIBLE SIGMOIDOSCOPY

J. H. Brindley[1,*], H. Gordon[1], E. Barrow[1], L. O'Kane[1], R. Dancey[1], C. Collins[1], K. Sundaram[1], K. Monahan[1]. [1]*Gastroenterology, West Middlesex University Hospital NHS Trust, London, United Kingdom*

INTRODUCTION: Outpatient flexible sigmoidoscopy is an increasingly utilised investigation shown to be effective in the detection and prevention of bowel cancer. The procedure is thought to entail a low risk of complications. However, recent literature suggests the complication rate of other endoscopic procedures may be up to 10 fold that traditionally quoted (1). The true complication rate of flexible sigmoidoscopy is of particular importance as the UK is introducing the Bowel Cancer Screening Programme (BCSP) by which all citizens will be offered the procedure at age 55.
AIMS&METHODS: The aim of this study was to identify the morbidity and related healthcare costs of unexpected hospital attendance following outpatient flexible sigmoidoscopy. An observational study of A&E attendances and admissions occurring within 14 days of all outpatient flexible sigmoidoscopies which took place in 2011 was conducted. All procedures took place at West Middlesex University Hospital, London. Data was collected using the hospital's electronic records system, enterpriseCAMIS®. Cases were analysed to assess whether reattendance could be attributed to the procedure, and healthcare costs were determined.
RESULTS: Of the 1137 outpatient flexible sigmoidoscopies performed, 18 patients (1.58%) presented to A&E within 14 days. Only 2 of these attendances were thought to be related to the procedure (0.18%). 1 case resulted in a 5 day admission due to bleeding post polypectomy. The second A&E attendance was also due to bleeding. The cost of the above admission was £4,682. Including the related A&E attendance, the total financial burden of related reattendance following flexible sigmoidoscopy was approximately £4,827 in 2011. This equates to an additional cost of £4.25 per procedure.
CONCLUSION: This study suggests outpatient sigmoidoscopy is relatively safe, with complications necessitating reattendance occurring following 0.18% procedures. The financial burden of hospital reattendance within our UK based study population was minimal, supporting the cost effectiveness of extending services for National bowel cancer screening programs.

P719 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY COLORECTAL NEOPLASM WITH SEVERE FIBROSIS

K. Sasajima[1,*], R. Chinzei[1], M. Takahashi[1], Y. Koushima[1]. [1]*Gastroenterology, SAITAMA RED CROSS HOSPITAL, Saitama, Japan*

INTRODUCTION: Colorectal endoscopic submucosal dissection(ESD), has not been widely spread because of technical difficulty and high incidence of perforation. The first aim of study is to evaluate clinical outcome of colorectal ESD. Of colorectal ESD cases, submucosal severe fibrosis is the most difficult situation. To overcome severe fibrosis is so important to improve clinical outcome. Secondary aim was to evaluate the feasibility of ESD for severe fibrotic lesions in comparison with non-severe fibrotic lesions.
AIMS&METHODS: 250 colorectal consecutive lesions were enrolled in this study. Flush knife was used in all cases. We defined that submucosal layer like screen was not lifted by injection liquid even with sodium hyaluronate use. In dissecting severe fibrosis, we minutely dissected the expected line just above the muscle layer after dissection of both sides horizontally. The comparison was done in the two groups for operative time, en bloc resection rate, curative resection rate, the rate of ancillary device use, the delayed bleeding rate, and perforation rate. A P value $< .05$ was considered statistically significant.
RESULTS: The average diameter of lesions was 34.0mm. Sixty-eight lesions were located in the rectum, 61 in left colon, and 121 in the right colon. For morphological type, 113 lesions were LST-NG, 86 LST-G, 32 protruded, 13 depressed and 6 recurrent lesions. By histological examination, 161 intramucosal cancers, 45 slightly invasive submucosal cancers, 17 massively submucosal invasive cancers, and 27 tubular adenomas. The average operative time was 85.4 minutes, and the en bloc resection rate was 97.6% (244/250). With regard to complications, postoperative bleeding was observed 1.2% (3/250). Microperforation which occurred in only 1 case was conservatively repaired with endoscopic clipping. Severe fibrotic lesions were detected in 19 including 6 recurrent lesions. The tumor size was significantly larger for the severe fibrotic lesions (45.3mm) than non-severe fibrotic lesions (33.1mm). Operative time was significantly longer for the severe fibrotic lesions (180min) than non-severe fibrotic lesions (77.6min). En bloc resection (100%:97.4%) and curative resection rates (89.5%:91.3%) were respectively similar between two groups. The rate of ancillary device use tended to be higher for the severe fibrotic lesions (10.5%) than non-severe (7.4%). The perforation (0%:0.4%) and delayed bleeding (0%:1.3%) rates were also similar between two groups.
CONCLUSION: Our study showed ESD with severe fibrosis was much more time-consuming and difficult than non-severe fibrosis. However, we managed to obtain equivalent safety and curability for severe fibrotic lesions compared to non-severe.

P720 ENDOCYTOSCOPY CAN PREDICT THE VENOUS AND LYMPHATIC VESSEL INVASION: A RETROSPECTIVE STUDY

K. Takeda[1,*], S.-E. Kudo[1], K. Wakamura[1], K. Ichimasa[1], M. Kutsukawa[1], Y. Mori[1], M. Misawa[1], T. Kudo[1], T. Hayashi[1], H. Miyachi[1], S. Ryozawa[1], E. Hidaka[1], S. Okoshi[1], F. Ishida[1], H. Inoue[1], S. Hamatani[1]. [1]*Showa University Northern Yokohama Hospital, Yokohama city, Japan*

INTRODUCTION: Endocytoscopy (EC) , which enables observation of *in vivo* cells and nuclei at about 400-fold magnification, provides more detailed information about the lesions.
AIMS&METHODS: The aim of our study is to evaluate the possibility of EC with regard to prediction of venous and lymphatic vessel permeation.The subjects were 86 colorectal tubular adenocarcinomas (36 Tis, 27 T1 carcinomas, 13 T2 carcinomas, nine T3 carcinoma and one T4 carcinomas) from 86 patients treated by endoscopic or surgical resection after observation with EC at Showa University Northern Yokohama Hospital from February 2009 to March 2013. In observing EC images, we defined the average scale of four vessels as ''vessel diameter'' and proportion between maximum portion and minimum portion of the vessel as ''vessel caliber variation''. We analyzed the correlationship between these parameters (''vessel diameter'' and ''vessel caliber variation'') and venous or lymphatic vessel permeation. Then, we predict the cutoff value from ROC curve with consideration of tumor invasion depth.
RESULTS: In confirming the association between vessel diameter and venous permeation, ROC curve (AUC 0.776) suggested that 47μm could be a cutoff value of vessel diameter correlated to venous permeation (sensitivity 64.0%, specificity 85.2%). And in confirming the association between vessel caliber variation and lymphatic vessel permeation, ROC curve (AUC 0.689) suggested that 50% vessel caliber variation could be cutoff value correlated to lymphatic vessel permeation (sensitivity 61.5%, specificity 68.4%). Odds ratio of venous permeation was 5.30 in T1 carcinoma, 8.00 in T2 carcinoma and 1.00 in T3 and T4 carcinoma, while that of lymphatic vessel permeation was 1.18 in T1 carcinoma, 1.11 in T2 carcinoma and 5.00 in T3 and T4 carcinoma.
CONCLUSION: EC could evaluate the venous and lymphatic vessel invasion by measuring the vessel formation.

P721 MANDATED ENDOSCOPY SAFETY CHECKLISTS: A TICK-BOX EXERCISE OR A USEFUL CLINICAL INTERVENTION?

M. K. Matharoo[1,2,*], A. Haycock[1], N. Sevdalis[2], S. Thomas-Gibson[1]. [1]*Endoscopy, The Wolfson Unit for Endoscopy, St. Mark's Hospital, Harrow,* [2]*The Centre for Patient Safety and Service Quality (CPSSQ) Department of Surgery and Cancer, Imperial College, London, United Kingdom*

INTRODUCTION: Errors in endoscopy are common but often inconsequential, and therefore go uncorrected. A series of minor errors however, may culminate in a significant adverse event. This is un-surprising given the volume and complexity of cases and shift-working patterns.
Surgical safety checklists (SSC) can prevent errors thus reducing morbidity and mortality[1]. Consequently, SSC are now mandatory. Many UK hospitals are mandating use of the World Health Organisation (WHO) SSC for endoscopy without an evidence base. It is unknown if checklists are applicable to Endoscopy.
AIMS&METHODS: - Develop, implement and provide training for an endoscopy specific safety checklist
- Evaluate compliance with the checklist
A checklist was developed to address common and significant patient safety issues in endoscopy. Sequential multidisciplinary expert focus groups were convened to draft the initial checklist and revise subsequent versions following feedback from team-members. The checklist was designed to be concise, practical and used by the endoscopist and assisting nurses just prior to the procedure.
A training programme including workshops and video examples of appropriate and poor checklist usage was delivered to endoscopists and nurses. Hands-on training and in-room support was provided by a clinical researcher during the first week of checklist implementation.
Errors prevented by the checklist were prospectively recorded. Factors affecting compliance were assessed 11 months post implementation. Prospective data collection for a 7-day period included:
1. Degree of checklist completion
2. Time of procedure
3. Endoscopist grade
4. Case mix: Routine / Emergency / Bowel Cancer Screening (BCS).

RESULTS: Provisional data shows the checklist identified 8 potential errors in the first 32 procedures. When errors were reported, the checklist was incomplete. 106 (53%) checklists were fully completed, 73 (37%) partially completed and 20 (10%) not completed. Compliance was greatest for morning than afternoon lists (60%) vs. (43%) $p=<0.05$. Registrars were least likely to complete the checklist (35%) compared to consultants (64%) and nurse endoscopists (62%) $p=<0.001$). BCS cases were most likely to have a checklist completed (82%) compared to routine (45%) and emergency (63%) cases $p=<0.01$.

CONCLUSION: Checklists avert errors by sharing vital information and enhanced teamwork. For checklists to have a meaningful impact on patient safety, considerable investment in effective implementation and compliance is required. This can be achieved by a multi-disciplinary education programme and strong clinical leadership. Further studies to establish if errors are reduced by use of an endoscopy checklist are underway.

P722 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M. Iwabuchi[1,*], M. Sugimura[1], H. Suzuki[2], H. Takahashi[1], H. Yoshida[1], H. Kikuchi[1], K. Shishikura[1], K. Ukai[1], K. Tadokoro[1]. [1]*Gastroenterology,* [2]*Pathology, Sendai Medical Center, Sendai, Japan*

INTRODUCTION: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathologic features are still unclear and need further exploration.

AIMS&METHODS: The aim of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and surgical pathology files of 1874 polypectomy specimens performed during January 2007 and December 2011 at our institution. A total of 131 serrated lesions resected were classified into three categories : HP (hyperplastic polyp), SSA/P (sessile serrated adenomas/ polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases.

RESULTS: Of these 131 lesions, a total of 70 (53.4%) were HP, 28 (21.4%) SSA/P, and 33 (25.2%) TSA. Mean age of patients with each polyp was 62.0 years old for HP, 64.1 for SSA/P, and 59.9 for TSA. Male to female ratio (M/F) was 1.92 for HP, 1.0 for SSA/P, and 1.75 for TSA. Mean size of SSA/P (10.2mm) and TSA (9.6mm) were significantly larger than that of HP (6.7mm). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 75% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Incidences of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 70), 7.1% (2 out of 28), and 6.1% (2 out of 33), respectively.

CONCLUSION: Though SSA/P and TSA have distinct clinical features, both are premalignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.

P723 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR RECTAL CARCINOID TUMORS

N. Ishii[1,*], Y. Fujita[1]. [1]*Gastroenterology, St. Luke's International Hospital, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) was developed for en bloc resection of mucosal tumors of the gastrointestinal tract. In addition, recently, rectal carcinoid tumors have been treated using ESD[1]. However, only a small number of patients with rectal carcinoid tumors have been treated using ESD, and long-term outcomes have not been reported to date.

AIMS&METHODS: We investigated the efficacy, safety, and long-term outcomes of ESD for the resection of rectal carcinoid tumors. From September 2005 to March 2013, 45 patients (30 males, 15 females, age range, 31-81 years) were included in the study, and 47 rectal carcinoid tumors were treated using ESD. All the tumors were limited to the submucosal layer on endosonography. We retrospectively evaluated the size of the tumors and the resected specimens, the rate of en bloc resection, the rate of pathological free margin resection, the procedural time, and the complications (bleeding and perforation). Colonoscopy and computed tomography were performed every year after ESD. Informed written consent for ESD was obtained from all the patients.

RESULTS:

Median size of the tumors (range) (mm)	5 (1.5-11)
Median size of the resected specimens (range) (mm)	19 (7-33)
Median procedural time (range) (min)	31 (12-117)
Rate of en bloc resection (%)	100 (47/47)
Rate of pathological free margin resection (%)	100 (47/47)
Lymph vascular involvement (%)	9 (4/47)
Postoperative bleeding (%)	4 (2/47)
Perforation (%)	0 (0/47)
Recurrence (%)	0 (0/47)

The results of ESD for the tumors were presented in Table. All the tumors were resected en bloc, and free pathological margins were confirmed. Although lymph vascular involvement was histopathologically demonstrated in 4 patients (9%), additional surgery was not performed at the patients' request. Postoperative bleeding occurred in 2 patients (4%), and both these patients were successfully managed by endoscopic hemostasis with hemoclips; no recurrence was observed during the median follow-up period of 31 (range, 1-80) months.

CONCLUSION: ESD was time consuming but effective for rectal carcinoid tumors and led to favorable long-term outcomes.

P724 EFFECT OF CHROMOENDOSCOPY ON ADENOMA DETECTION IN THE COLON: A META-ANALYSIS

N. Mohammed[1,*], V. Subramanian[1]. [1]*Gastroenterology, Leeds Institute of Molecular Medicine, Leeds, United Kingdom*

INTRODUCTION: Early adenoma detection reduces mortality from colorectal cancers. Advances in endoscopy are aimed at improving adenoma detection. Contrast enhancement using dye spray is reported to improve the detection of subtle mucosal changes.

AIMS&METHODS: We aim to perform a meta-analysis to look at the effect of chromoendoscopy on adenoma detection in the colon.

Various electronic databases were searched for articles reporting on detection of polyps comparing conventional colonoscopy and chromoendoscopy. The pooled mean difference in total number of adenomatous polyps, number of right and left sided polyps, advanced and flat adenomas, total number of polyps and number of <5mm polyps detected was calculated. A fixed effects model was used unless there was significant heterogeneity. Publication bias was assessed using Funnel plots and Egger's test and heterogeneity was assessed using Cochran's Q and the I^2 test.

RESULTS: 3714 number of patients from 14 studies were included in the analysis. 7 studies were randomized controlled trials and 7 had tandem study design. Chromoendoscopy detected significantly higher number of adenomas, advanced adenomas, right and left sided adenomas (Table 1). A significantly higher number for hyperplastic and small ($<$ 5mm) polyps were detected by chromoendoscopy but no differences were noted for detection of flat adenomas. A random effects model was used due to significant heterogeneity between the studies mainly because of differences in patients included in the study and the study design. Sensitivity analysis for publication bias using the trim and fill method which conservatively imputes hypothetical negative unpublished studies to mirror the positive studies in the funnel plot did not change the statistical significance of the pooled analysis.Table 1

Variable	Pooled mean difference	P value
Adenoma detection	0.139 (95% CI 0.082 to 0.195)	0.0001
Right sided adenomas	0.137 (95% CI 0.048 to 0.226)	0.003
Left sided adenomas	0.117 (95% CI 0.007 to 0.227)	0.036
Advanced adenomas	0.105 (95% CI 0.017 to 0.194)	0.019
Flat adenomas	0.154 (95% CI -0.084 to 0.393)	0.205
Hyperplastic polyps	0.364 (95% CI 0.281 to 0.447)	0.001
$<$ 5mm polyps	0.271 (95% CI 0.172 to 0.369)	0.001

CONCLUSION: Chromoendoscopy improves detection rate of adenomatous polyps compared to conventional colonoscopy. This seems greater for advanced as well as right sided adenomas, but significantly higher number of hyperplastic and small ($<$5mm) polyps were detected by chromoendoscopy. Future work needs to focus on the cost effectiveness of chromoendoscopy taking into account the increased time and cost of chromoendoscopy and long term outcomes like reduction in colorectal cancer rates between chromoendoscopic and conventional colonoscopy surveillance.

P725 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTROINTESTINAL NEOPLASMS: INITIAL CLINICAL EXPERIENCE IN A TERTIARY MEDICAL CENTER IN BRAZIL.

O. Meirelles-Santos[1,*], N. Miyajima[1], M. G. Camargo[2], J. C. V. Dias[1], C. S. R. Coy[2]. [1]*Endoscopy,* [2]*Colon and Rectal Surgery, State University of Campinas, Campinas, Brazil*

INTRODUCTION: The endoscopic submucosal dissection (ESD) is a technique developed in Japan for *en bloc* resection of early gastrointestinal epithelial neoplasms. It is considered technically challenging and only performed in a few specialized centers. Although ESD has been popular in Japan, clinical experience has been rarely reported in Brazil.

AIMS&METHODS: For the esophageal lesions, the indications by Higuchi *et al.* and Makuuchi *et al.* were adopted; the guidelines of the Japanese Association of Gastric Cancer were used as criteria for gastric lesions; for the colorectal lesions, the recommended standards by Uraoka *et al.* and Saito *et al.* were employed. The feasibility of the method, complications and histological analysis of the specimens were evaluated at the Endoscopic Unit of the Gastrocentro at the State University of Campinas.

RESULTS: Fifty-two patients were submitted to ESD from June 2010 to April 2013: five esophageal, twenty-three gastric and twenty-four colorectal lesions. Regarding the esophageal neoplasms, the average diameter was of 27mm,

mean duration of resection was 91min and all specimens presented free-margins. There was one esophageal perforation, managed by endoscopic clips. In regard to the gastric lesions, the mean size was 30 mm and the average procedure time was 126min. There was one case of bleeding after eight days of the procedure, managed endoscopically. There was one single case with focal positive margins. Finally, for the colorectal lesions, the mean size was 29.8mm, average time of procedure was 151min. One procedure in the transverse colon was interrupted for technical difficulties. Two complications occurred in the rectal resections: a perforation managed with endoscopic clips and a bleeding during the procedure, also controlled endoscopically. Three patients presented positive margins, one of them was adenocarcinoma. All depth margins were negative.

CONCLUSION: In our service, the initial experience with endoscopic submucosal dissection achieved high success with few complications, allowing appropriate staging of lesions.

P726 PROPOFOL SEDATION DURING COLONOSCOPY: BACK TO THE FUTURE!

P. Tresin[1,*], A. Della Rocca[2], E. Rosa-Rizzotto[2], A. Scatto[3], E. Guido[2], L. Peraro[2], D. Caroli[2], F. De Lazzari[2]. [1]*Anesthesiology Unit, St Anthony Hospital,* [2]*Gastroenterology Unit, St Anthony Hospital,* [3]*Intensive Care Unit, Azienda Ospedaliera, Padova, Italy*

INTRODUCTION: Midazolam plus Meperidine (M+M) is the most common recipe for endoscopy sedation utilized in Europe. Propofol has some advantages over narcotics and benzodiazepines, but it is generally limited to anesthesiologists using manual titration.

AIMS&METHODS: To demonstrate that propofol infusion via target-controlled infusion(TCI) pump is just as safe and effective as M+M for sedation during colonoscopy. Four types of sedation were utilized in this trial: Propofol TCI(PTCI), M+M, Midazolam alone,Propofol titration(PT). Propofol was administered by non-anesthesiologists using a TCI pump(Syramed®µSP6000, Arcomed) and by anesthesiologists in the titration model. Blood pressure was measured during colonscopy at least every 5 minutes,and continuous oximetry, electrocardiography and capnography were performed.No exclusion criteria were stipulated.All the pts were evaluated at the end of the procedure using the Observer's Assessment of Altertness/Sedation(OAA/S) scale, their satisfaction was established by Numeric Visual Scale(NVS), and they were discharged when the ALDRETE score was >8.

RESULTS: 439 consecutive pts were included in the study. 200 pts(45.6%) received PTCI at an average drug dosage(ADD) of 156.8±69.6 mg; 184 pt received M+M(41.9%) at an ADD,respectively,of 4.18±1.3 mg and 47.5±5.5 mg; 40 pt(9.1 %) received PT at an ADD of 212.50±85.70 mg; 15 pt(3.4%) received Midazolam alone.All four groups were clinically homogeneus. Adverse events were: hypoxemia(So2$<$90%):PTCI 0 pt, M+M 7 pt, PT 2 pt ($p<0.05$); apnea: PTCI 0 pts, M+M 8 pts PT 16 pts($p<0.001$); hypotension (SBP$<$90mmHg): PTCI 20 pts, M+M 21 pts PT 4 pts(p=ns); bradycardia ($<$40 bpm) PTCI 2 pts, M+M 5 pts, PT 1 pts (p=ns).Apnea was treated successfully with neck extension. Pts outcome and satisfaction: mean ALDRETE score: PTCI 9.98±0.12 vs M+M 9.77±0.4 ($p<0.001$) vs PT 9.97±0.15(p=ns). Mean NVS(pain) PTCI 0.61±1.62 vs M+M 1.33±2,22 ($p<0.001$). Mean Procedure length: mean cecal intubation time (intubation rate was 98.4%) PTCI 6.38±3.59 min vs M+M 7.92±5.29 min($p<0.05$) vs PT 7.47±4.43(p=ns). Mean time for the entire procedure: PTCI 39.43±16.2 min vs M+M 53.82±15.31 min($p<0.001$) vs PT 52.10±16.9 min($p<0.001$). Mean post sedation recovery time PTCI 16,5±12,3 min vs M+M 26.5±9,4 min(P=0,0001) vs PT 24,8±9,1 min($p<0,0001$). At univariate analysis less total propofol(adjusted for BMI, Sex, Age, Endoscopist, Abdominal surgery) was administered using TCI than the titration method: 156.85±69.63 vs 212.50±85.70($p<0.0001$).

CONCLUSION: Propofol sedation using TCI pump will be the future standard of care during colonoscopy: less pain, less adverse events, faster discharge

Disclosure of Interest: None Declared

Keywords: colonoscopy, Propofol sedation, target-controlled infusion

P727 LARGE COHORT STUDY EVALUATING THE ROLE OF HYBRID ESD (H-ESD) AND CONVENTIONAL PIECEMEAL EMR TECHNIQUE IN THE RESECTION OF LARGE AND CHALLENGING COLONIC POLYPS DEMONSTRATES NO OUTCOME BENEFIT OF H-ESD OVER EMR.

R. Bhattacharyya[1], P. Bhandari[1,*], P. Basford[1], S. Tholoor[1], G. Longcroft-Wheaton[1]. [1]*Gastroenterology, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*

INTRODUCTION: The learning curve for ESD in the west is very long, so a hybrid technique has been proposed. The impact of Hybrid ESD (H-ESD) technique on clinical outcome is unclear. We aim to compare the outcome benefits of Multi-piece EMR and H-ESD in the resection of challenging colonic polyps.

AIMS&METHODS: A Prospective cohort study of endoscopic resection of difficult colonic polyps. Patients were tertiary referrals from experienced endoscopists. EMR was defined as submucosal injection followed by piecemeal snare resection. H-ESD involved submucosal injection before mucosal incision with an ESD knife followed by snare resection. Endoscopic follow up was arranged. Multiple linear regression analysis was performed.

RESULTS: 347 flat/sessile polyps >20 mm were resected between 2007-12. Mean follow-up was 1004 days. ***H-ESD Cohort:*** N= 110/347(32%). Mean size 45mm(range 10-170). 25/110(23%) were salvage procedures for scarred lesions due to failed EMR attempts by other endoscopists. Endoscopic clearance was achieved in 95.5%. Need for surgery (n=4): 1 for perforation and 3 for unexpected cancer. 98.6% had no recurrence at endoscopic follow up.

EMR cohort: N=237/347(68%). Mean size 42mm(range 20-150). 11/237(4.6%) were salvage procedures for scarred polyps. Endoscopic clearance was achieved in 93%. Need for surgery(n=21): 1 patient for incomplete resection & 20 for suspicion of cancer in EMR specimen. At endoscopic follow up 98% had achieved complete clearance.

Recurrence risk was higher with lesion size >50mm & scarring due to previous EMR attempts. This was unaffected by technique (EMR or H-ESD). Perforation/microperforation was more likely in the H-ESD Cohort, but the overall complication rates were similar for both cohorts.

	SIZE		TECHNIQUE		PREV EMR		SITE	
COMPLICATIONS (25)	≤50mm 15/271 (5.5%)	>50mm 8/76 (10.5%)	ESD 11/110 (10%)	EMR 12/237 (5%)	Yes 3/36 (8%)	No 20/311 (6%)	LC 20/250 (8%)	RC 3/97 (3%)
	P=0.016		P=0.11		P=0.521		P=0.201	
RECURRENCE (35)	≤50mm 19/271 (7%)	>50mm 16/76 (21%)	ESD 12/110 (11%)	EMR 23/237 (10%)	Yes 10/36 (28%)	No 25/311 (8%)	LC 31/250 (12%)	RC 4/97 (4%)
	P=0.0001		P=0.156		P=0.0001		P=0.105	

CONCLUSION: Both techniques achieved an excellent overall cure rate for large & challenging polyps. This is the first large series comparing the two techniques and demonstrates that polyp cure rate was equally good with both techniques. H-ESD technique was used more commonly for polyps with significant scarring & was associated with slightly higher perforation rates. Our data does not demonstrate any significant outcome benefit of H-ESD technique over the conventional EMR technique.

P728 THE CHALLENGES OF IMPLEMENTING EVIDENCE INTO ENDOSCOPIC PRACTICE: A QUALITATIVE STUDY

P. T. Rajasekhar[1,*], S. R. Brown[2], C. Nixon[2], M. G. Bramble[3], J. E. East[4], M. D. Rutter[5], B. P. Saunders[6], C. J. Rees[7], The Quality Improvement in Colonoscopy Study Group. [1]*Gastroenterology, NORTHERN REGION ENDOSCOPY GROUP, South Shields,* [2]*Evaluation Research Development Unit,* [3]*School of Medicine and Health Science, Durham University, Stockton-on-Tees,* [4]*Gastroenterology, John Radcliffe Hospital, Oxford,* [5]*Gastroenterology, University Hospital North Tees, Stockton-on-Tees,* [6]*Gastroenterology, St Marks Hospital, London,* [7]*Gastroenterology, South Tyneside NHS Foundation Trust, South Shields, United Kingdom*

INTRODUCTION: The Quality Improvement in Colonoscopy (QIC) study was a region wide service improvement study that aimed to improve adenoma detection rate (ADR) by implementation of measures into routine colonoscopy practice. They were: withdrawal time of $\geq$ 6 minutes; hyoscine butylbromide use; supine position for examination of the transverse colon; rectal retroflexion. Each has been shown to improve lesion detection. The implementation of evidence into clinical practice can be challenging.

AIMS&METHODS: We aimed to evaluate factors influencing implementation of the 'bundle' in the QIC study. Twelve endoscopy units participtaed who are members of the Northern Region Endoscopy Group (NREG), a clinical research network in England. The study team held training sessions at each unit to introduce the "bundle", supported by a nominated local lead colonoscopist and nurse. Posters were supplied for each endoscopy room to aid promotion. Following study completion, units and individuals were purposively sampled for the qualitative study to ensure a range of units (by size, bundle uptake) were included. Semi-structured interviews were conducted until saturation was reached. Data were evaluated using thematic analysis to code and categorise interviews.

RESULTS: 118 colonoscopists participated in the QIC study. Interviews were conducted with 11, 8 lead colonoscopists, 1 lead nurse and 3 non-lead colonoscopists. Increased emphasis on examination time, increased awareness of ADR as a quality marker and empowerment of endoscopy nurses to encourage use of quality measures were seen as positive outcomes of the study. The simple, highly visible posters were also reported as useful in aiding study promotion. Challenges included difficulty in arranging set up meetings and engaging certain speciality groups.

CONCLUSION: Implementation of evidence into clinical practice can be challenging. During the QIC study, challenges included arranging staff meetings and engaging all team members. Positive outcomes included increased awareness of colonoscopy quality, particularly slower withdrawal times, and empowerment of endoscopy nurses to promote quality measures. We demonstrate that emphasis on timing of meetings and strategies to engage speciality groups should be given consideration when planning implementation of evidence or guidelines into clinical practice.

INTRODUCTION: Chromo-endoscopy (CE) increases the detection of neoplasia longstanding ulcerative colitis (UC). Kudo pit pattern (KPP) I/II have been suggested to be predictive of benign polyps in UC, however its' accuracy in non-magnified high definition (HD) CE or if it can be applied to HD Narrow Band Imaging (NBI) is unknown.
AIMS&METHODS: We aimed to assess inter- and intraobserver agreement and diagnostic accuracy of KPP in UC surveillance endoscopy with CE or NBI. 50 images of lesions (13 neoplastic)identified in 27 UC patients either with classical CE (methylene blue 0.1%) (n=24) or NBI (n=26), were selected and mounted in a Powerpoint file in a standardized way in two different sets. 10 endoscopists with experience in NBI/CE had to indicate the KPP, the neoplastic nature and how sure they were about the diagnosis. The interval between set 1 and 2 was at least 10 weeks to minimize recall bias. Kappa statistics were performed (SPSS Statistics 20.0). Kappa results are expressed as median ± range. Mann Whitney U test was performed to assess differences in interobserver agreement between different techniques.
RESULTS: Median sensitivity, specificity, negative predictive value and positive predictive value for diagnosing neoplasia based on the presence of KPP I/II was 77% (54-85%), 68% (51-84%), 88% (84-94%) and 46% (36-61%) resp. Similarly, based on the overall endoscopic appearance, this was 77% (31-100%) 69% (43-92%), 90% (79-100%) and 48% (37-67%) resp. The overall agreement for any KPP was only fair (Kappe = 0.291) , with CE being significantly better than NBI (0.339 vs 0.246 $p < 0.001$). Agreement for differentiation between non-neoplastic KPP (I,II) and neoplastic KPP (III l, IIIs, IV, V) was moderate (kappa= 0.584) and even substantial and significantly better for NBI (kappa= 0.683 , 0.497 resp $p < 0.001$). Similar kappa-values were found for the overall assessment for the neoplastic nature of a lesion. Intra-observer agreement was moderate for KPP assessment (0.517) and substantial to differentiate neoplastic from non-neoplastic lesions (0.665).
CONCLUSION: Among experts, assessment of KPP I or II with non-magnified HD CE or NBI has a good NPV to rule out neoplasia. Differentiation between non-neoplastic and neoplastic KPP shows a moderate to substantial agreement and is significantly better for NBI.

P730 IN VITRO EVALUATION OF DNA DAMAGE IN HUMAN COLONIC EPITHELIAL CELL LINES EXPOSED TO METHYLENE BLUE AND WHITE LIGHT

R. Alessandro[1,*], M. Gerloni[2], C. Rosette[2], C. Ciscato[1], M. Wallace[3], P. Sharma[4], R. Kiesslich[5]. [1]*U.O. Endoscopia Digestiva, Istituto Clinico Humanitas, Rozzano (MI), Italy,* [2]*Cosmo Bioscience, San Diego,* [3]*Mayo Clinic Florida, Jacksonwille,* [4]*Veterans Affairs Medical Center and University of Kansas School of Medicine, Kansas City , United States,* [5]*Medizinische Klinik, St Marienkrankenhaus , Frankfurt., Germany*

INTRODUCTION: Methylene Blue (MB) is a vital dye commonly used during chromoendoscopy. Although this procedure is generally considered safe, some concerns have been raised about its potential genotoxicity. However, the results of tests with mouse micronuclei exposed to high concentration of injected MB suggest that genotoxic effects should not occur *in vivo*.*
AIMS&METHODS: To support the clinical use of Methylene Blue-MMX® tablets as a diagnostic tool during endoscopic examinations, experiments were conducted *in vitro*, using HT-29 cell line to ascertain the level of DNA damage in cells exposed to white light for different time periods, in order to determine if photoexcited methylene blue damages DNA.
To simulate chromoendoscopy *in vitro*, a monolayer of cultured HT-29 cells was incubated with 1 mL of 0.5% MB. Thereafter, the cells were exposed to white light of the same wavelength to different durations of light exposure (from 5 to 60 minutes) and conditions (presence or absence of oxidative conditions). MB-induced DNA breaks were evaluated on histone H2A variant (H2AX) that is phosphorylated (H2AX) in response to DNA double strand damage. In additional tests, the same exposure times were repeated with and without a redox protective factor (N-acetyl cysteine). H2AX determination required fixation and permeabilization of cells, followed by incubation with a fluorescent labeled antibody to H2AX. Fluorescence intensity was quantified by flow cytometry.
RESULTS: HT-29 cells treated with MB and continuously exposed to white light for 5 and 10 minutes did not show statistically significant levels of DNA damage. Prolonged exposure to light from 15 to 60 minutes led to a proportional increase of DNA damage. We also demonstrated that the presence of a redox agent (N-acetyl cysteine) completely prevented the DNA damage
CONCLUSION: These tests show that the potential genotoxic effect of MB on HT-29 cells is closely related to the duration of the light exposure, with a cut-off time of at least 10 minutes of continuous exposure. Such exposure times i.e. continuous white light for >10 minutes on gastrointestinal mucosa is not typically reached during a normal colonoscopy procedure. Moreover, in cases of longer exposure times, the presence of a reducing agent was able to prevent completely the DNA damage.

P731 INTESTINAL BARRIER DYSFUNCTION IDENTIFIED BY CONFOCAL ENDOMICROSCOPY IN MACROSCOPICALLY NORMAL TERMINAL ILEUM PREDICTS REQUIREMENT FOR TREATMENT ESCALATION IN INFLAMMATORY BOWEL DISEASES

R. Leong[1,2,*], M. Yang[1], B. Wong[1], K. Liu[2], C. Hillemand[1], V. Kariyawasam[2], C. Selinger[2], J. Chang[1,3], M. Danta[3], M. Arshi[3], T. Phan[3]. [1]*Bankstown Hospital,* [2]*Concord Hospital,* [3]*Garvan Institute, Sydney, Australia*

INTRODUCTION: Intestinal mucosal epithelial barrier dysfunction (IMEBD) is increasingly recognised as the antecedent event in inflammatory bowel diseases (IBD) because microbial antigen entry into the lamina propria may incite a chronic inflammatory response. Confocal endomicroscopy (CEM), which images *in vivo histology* under real time, may identify and quantitate IMEBD and predict IBD course.
AIMS&METHODS: This study evaluated IMEBD using CEM (EC-3870FK, Pentax) and correlated its severity with IBD course defined by the need for treatment escalation (TE). TE included drug dose increase, class step-up or surgery.
IBD subjects and controls were prospectively recruited for CEM using IV fluorescein contrast given dynamically. Blinded assessment of the uninflamed terminal ileum was performed. A composite 'confocal leak score' (CLS) of IMEBD was calculated from the summation of individual validated CEM features of 'fluorescein leak' (FL), 'cell junction enhancement' (CJE) and 'cell drop out' (CDO). Area under the curve (AUC) of receiver operating characteristic (ROC) analysis was used to define thresholds separating IBD from controls and for TE requirement. Primary endpoint was time (in days) to TE from date of CEM. Kaplan Meier survival, categorical and non-parametric statistics were performed.
RESULTS: A total of 63 consecutive subjects underwent prospective CEM (59% F, 34 CD, 13 UC, 16 controls) yielding 18,280 images. Sex, age and follow up time were not different (all $P > 0.05$). Median follow up was 50 days (1-1,120). There were 13 TEs (3 ASA, 2 steroid, 2 immunomodulator, 5 biological, 1 surgery). Median CLS for CD, UC and controls were 15.3, 8.2 and 5.3 respectively ($P=0.006$) and predicted for TE for both CD ($P=0.024$) and UC ($P=0.035$). On ROC, CLS of 8.8 differentiated IBD from controls (AUC=0.76, sens 70%, spec 81%; OR 10.2 [95% CI: 2.5-42]) and CLS of 14.7 predicted for TE (AUC=0.76, sens 92%, spec 59%; OR 17.1 [95% CI: 2.0-147]). The composite CLS ($P=0.004$) and its 3 components (all $P < 0.030$) all predicted for TE. Nine patients had repeat CEM after a median of 546 days of whom 56% needed TE. TE significantly decreased CLS ($P=0.043$) at follow up CEM.
CONCLUSION: Confocal endomicroscopy can identify and quantitate IMEBD in IBD. IMEBD predicts for need for treatment escalation and significantly improves following treatment escalation indicating reversibility of mucosal barrier dysfunction.

P732 COLONOSCOPY FOR CHRONIC CONSTIPATION SHOULD NOT BE UNDERTAKEN AS THE YIELD IS POOR!

S. Butt[1,*], K. Besherdas[1]. [1]*CHASE FARM HOSPITAL, Enfield, United Kingdom*

INTRODUCTION: Colonoscopy is accepted as the gold standard imaging modality for colonic symptoms of altered bowel habit, anaemia, rectal bleeding and for the detection of colorectal cancer. Chronic constipation is a common condition seen within secondary care. The role of colonoscopy in chronic constipation, however, remains controversial. The ASGE guidelines recommend colonoscopy in those over 50 years of age who have not undergone prior colorectal cancer screening if they present with chronic constipation as it is thought that chronic constipation is associated with an increased risk of colon cancer. Others believe that the yield of colonoscopy in chronic constipation is low and comparable with asymptomatic patients who undergo colonoscopy for cancer screening.
AIMS&METHODS: The aim of the study was to clarify the yield of colonoscopy in patients with chronic constipation. A single centre, retrospective analysis of patients undergoing colonoscopy for chronic constipation in a district general hospital from north London was performed. The patients were identified using the Unisoft Endoscopy reporting software over a period between June 2006 and April 2013. Data obtained during the study period was scrutinized for findings of procedure and if abnormal for assessment of additional symptoms.
RESULTS: During the study period 242 patients had a colonoscopy for chronic constipation, age range 17- 96 years, Male : Female 65: 177. The findings at colonoscopy included: normal in 130 (54%), divertculosis in 52 (21%),

diverticulitis in 2, haemorroids in 31 (13%), adenomatous polyps in 16 (7%), lipoma in 1, anterior rectal prolapse 2, indeterminent colitis in 1.
There were no patients with colorectal cancer. The 16 patients with adenomatous polyps were scrutinized further: 11 had rectal bleeding in addition to constipation, 1 had left iliac fossa mass, 4 patients had adenomatous polyps and chronic constipation as the sole presenting symptom.
CONCLUSION: No patients undergoing colonoscopy for chronic constipation had colorectal cancer. In this study, adenomatous polyp was detected in 7% and is comparable to detection in asymptomatic individuals. The finds from this study do not advocate colonoscopy in patients presenting with chronic constipation alone as the yield of pathology detection is poor.

P733 ENDOSCOPIC SUBMUCOSAL DISSECTION OF RECTAL CARCINOID TUMORS USING THE CLUTCH CUTTER

S. Hamada[1,*], K. Akahoshi[2], Y. Motomura[1], M. Kubokawa[2], J. Gibo[2], K. Kanayama[2], F. Shinichirou[2], Y. Otsuka[2], T. Hosokawa[2], T. Miyazaki[2], N. Tomoeda[2], A. Miyagaki[2], R. Utsunomiya[2], M. Oya[3]. [1]*Aso Iizuka Hospital, Iizuka, Japan,* [2]*gastroenterology,* [3]*pathology, Aso Iizuka Hospital, Iizuka, Japan*

INTRODUCTION: ESD shows high tumor eradication rates in early colorectal tumor but substantial risks during the procedure. To reduce the risk of complications related to ESD using conventional knives, we developed the Clutch Cutter (CC), which can grasp and incise the targeted tissue using electrosurgical current.
AIMS&METHODS: The aim of this study was to evaluate the efficacy and safety of ESD using CC for the removal of rectal carcinoid tumors. Between June 2008 and December 2012, we prospectively enrolled consective 12 patients (Seven men, five women; mean age 65 years) with rectal carcinoid tumors less than 10mm in diameter and within the submucosal layer without lymph node involvement shown by EUS. We performed single device ESD using CC for all lesions. The CC can grasp and cut a piece of tissue with electrosurgical current. It has a thin serrated cutting edge to facilitate grasping the tissue. The outer side of the forceps is insulated so that electrosurgical current energy is concentrated at the blade to avoid burning the surrounding tissue. Furthermore, the forceps can be rotated to the desired orientation. After marking and injection of a solution into the submucosa, each lesion in our study was separated from the surrounding normal mucosa by complete incision around the lesion using the CC. A piece of submucosal tissue was grasped and cut with the CC using electrosurgical current to achieve submucosal exfoliation.
The therapeutic efficacy and safety were assessed.
RESULTS: All lesions were treated simply without unintentional incision. The mean size of the tumors and resected specimens was 7.5±2.1mm (range: 5-11) and 25±8.3mm (range: 12-40), respectively. The en-bloc resection rate was 100%. The histologically complete resection rate was 100% (12 of 12) in the horizontal margin and 92% (11 of 12) in the vertical margin. The mean operating time was 68.2±32.5 minutes (range: 20-124). No delayed hemorrhage and perforation occurred.
CONCLUSION: ESD using CC appears to be an easy, safe, and technically efficient method for resecting rectal carcinoid tumors.

P734 LOCAL RECURRENCE AFTER EMR FOR NON-PEDUNCULATED COLORECTAL LESIONS: SYSTEMATIC REVIEW AND META-ANALYSIS

T. Belderbos[1,*], M. Leenders[1], L. Moons[1], P. Siersema[1]. [1]*Gastroenterology and Hepatology, University Medical Center Utrecht, Utrecht, Netherlands*

INTRODUCTION: Endoscopic mucosal resection (EMR) is a safe and effective technique for removal of non-pedunculated colorectal adenomas and minimally invasive carcinomas. However, local recurrence is sometimes observed after EMR. It is currently unclear in which cases follow-up colonoscopy is necessary and what the optimal time interval is for this re-examination.
AIMS&METHODS: We aimed to perform a systematic review on the risk of local recurrence after EMR, to identify risk factors for recurrence and to provide a recommendation for the interval of follow-up colonoscopy.
A literature search was performed in Pubmed, Embase and Cochrane. EMR was defined as endoscopic snare resection after submucosal fluid injection for removal of non-pedunculated adenomas and mucosal or superficial submucosal (Sm1) carcinomas. Local recurrence, as defined by the Higaki criteria,[1] was subdivided into early recurrence, found at the first follow-up colonoscopy, and late recurrence, found after at least one previous normal colonoscopy. To calculate the pooled estimate of the recurrence risk after EMR, a random effects meta-analysis was performed. Paris classification, size, localization, histopathology, piecemeal resection and additional use of argon plasma coagulation (APC) were assessed for a possible association with recurrence.
RESULTS: Our search yielded 1833 unique articles, of which 33 were ultimately selected. Overall mean recurrence risk after EMR was 15% (95% confidence interval (CI) 12% - 19%). Recurrence risk was higher after piecemeal resections (20%, CI 16% - 25%) than after en-bloc resections (3%, CI 2% - 5%; $p<0.0001$). In fifteen studies differentiating between early and late recurrences, 152/173 recurrences (88%) were found during first follow-up colonoscopy and 21 (12%) after at least one previous normal colonoscopy. In only four studies patients underwent follow-up at 3, 6 and ≥12 months. Nineteen (76%) of 25 recurrences were detected at three months, increasing to 24 (96%) at six months. Size, piecemeal resection and non-tumorfree resection margins were found to be associated with local recurrence in a majority of the studies performing univariable analysis. In multivariable analysis, only piecemeal resection remained associated with recurrence (in 3 of 3 studies).
CONCLUSION: Local recurrence after EMR for non-pedunculated colorectal adenomas and early carcinomas occurs in 3% of en-bloc resected lesions and in 20% of piecemeal resected lesions. Piecemeal resection is the only independent risk factor for recurrence. Most recurrences are found during first follow-up colonoscopy. As more than 90% of recurrences are detected within 6 months after EMR, we propose that 6 months is the optimal follow-up interval.

P735 ENDOSCOPIC PIT PATTERN FOR DIFFERENTIAL DIAGNOSIS OF COLORECTAL SERRATED POLYPS: CAN IT DISTINGUISH SESSILE SERRATED ADENOMA FROM HYPERPLASTIC POLYP?

T. Kihara[1,*], Y. Kubota[1], K. Konishi[1], Y. Yano[1], A. Katagiri[1], T. Muramoto[1], K. Konda[1], K. Shinmura[1], T. Tagawa[1], T. Yamochi[2], H. Yoshida[1]. [1]*Division of Gastroenterology, Department of Medicine,* [2]*Department of Pathology, Showa University School of Medicine, Tokyo, Japan*

INTRODUCTION: Sessile serrated adenomas (SSAs) have been thought to be the precursors of colorectal cancers. However, a low diagnostic accuracy of the endoscopic techniques for differentiating and conventional hyperplastic polyp (HP) has been reported. Recently, Kimura, *et al.* (Am J Gastroenterol 2012; 107:460) have identified a novel mucosal crypt pattern, type II open-shape pit pattern (Type II-O), that is specific to SSAs The aim of this study is to clarify the ability to distinguish between SSA and HP by the mucosal crypt patterns.
AIMS&METHODS: We examined 134 serrated polyps (SPs), which were histologically diagnosed at the Showa University Hospital from June 2010 to May 2012. Three experienced colonoscopists reviewed the chromoendoscopic pictures using magnifying colonoscopy. Type II-O crypt patterns were determined according to the definition previously described by Kimura, *et al.* Briefly, this crypt pattern was similar to hyperplastic (stellar or papillary pits), but the pits were wider and more rounded in shape, reflecting dilatation of the crypts. The shapes of the Type II-O pits also differed from those of normal mucosa, in that they were larger in size with serrations surrounding the pit.
RESULTS: Although 134 SPs were enrolled in this study, 15 SPs were excluded from this study because the quality of endoscopic images was insufficient. A total of 119 SPs (73 SSAs and 46 HPs) were evaluated the mucosal crypt patterns. Of 119 SPs, 52 lesions (45 SSAs and 7 HPs) were identified Type II-O. Our data of the Type II-O showed that the interobserver and intraobserver agreement of three colonoscopists was $k = 0.61$ (range, 0.57 to 0.65) and $k = 0.68$ (range, 0.52 to 0.94) The positive predictive value (PPV), negative predictive value (NPV), sensitivity and specificity of Type II-O for differentiating between SSA and HP were 87% (45/52), 58% (39/67), 62% (45/73) and 85% (39/46), respectively.
CONCLUSION: Our results indicate that the Type II-O mucosal crypt pattern may be useful for differential diagnosis of serrated polyps. However, there is a need to identify more specific features of SSA.

P736 NEW HIGH DEFINITION NARROW BAND IMAGING VERSUS CONVENTIONAL WHITE LIGHT COLONOSCOPY FOR DETECTION OF COLORECTAL ADENOMAS IN SYMPTOMATIC PATIENTS: A RANDOMIZED CONTROLLED TRIAL WITH TANDEM COLONOSCOPY

W. K. Leung[1,*], O. S. Lo[2], K. S. Liu[1], T. Tong[1], S.-Y. Wong[1], W.-K. W. Seto[1], I. F. Hung[1], W.-L. Law[2]. [1]*Department of Medicine,* [2]*Department of Surgery, University of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: It remains unclear whether the narrow band imaging colonoscopy (NBI-C) is superior to white light colonoscopy (WLC) for detection of colorectal adenoma. The recently available new high definition (HD) NBI system provides more than two-time brighter images than the previous version. We tested whether the new NBI-C would improve detection of colorectal adenoma as compared to WLC in a randomized study with tandem colonoscopy.
AIMS&METHODS: We recruited patients who were scheduled to have colonoscopy for bowel symptoms or surveillance purpose. Patients were aged ≥40 years and without history of inflammatory bowel disease, previous colonic resection or familial colorectal cancer syndrome. Eligible patients were randomized to receive either the new NBI-C (CF-HQ 190; Olympus, Tokyo, Japan) or conventional HD WLC (CF-H260). NBI was used on withdrawal of colonoscope in the NBI-C and WL was used on withdrawal for the WLC. Tandem colonoscopy was immediately performed after the first examination in all patients by using the same assigned colonoscope and withdrawal method. Lesions detected on second-pass examination were considered to be missed lesions. The primary endpoint was the proportion of patients with at least one adenoma detected.

RESULTS: 272 patients (136 in each group) were available for this interim analysis, including 133 (48.9%) men with a mean age of 62 years. The proportion of patients with adenomas was 55.9% in the NBI-C and 42.7% in the WLC (Difference = 13.2%; 95% CI = 1.4 to 24.6%; P = 0.039). There was no significant difference in the proportions of patients with adenoma ≥1cm (NBI-C 8.1 vs WLC 8.8%; P = 1.0) and serrated/hyperplastic polyps (NBI-C 24.3% vs WLC 21.3%; P= 0.67). The mean number of adenomas detected per patient was 1.27 (SD = 1.81) in NBI-C and 1.06 (SD = 1.93) in WLC (P = 0.35). The missed rate for adenoma ≥ 5mm found on tandem colonoscopy was 2.9% in NBI-C and 5.1% in WLC (P = 0.38). There was a significant association between the quality of bowel preparation and missed adenoma rates (poor preparation 38.5%, fair 22.6%, good 17.7% and excellent 7.4%; P = 0.03). The mean withdrawal time between both groups was comparable (NBI-C 10.3 min vs WLC 10.1 min; P = 0.72).
CONCLUSION: Our data suggested that the new NBI-C was superior to the conventional HD WLC in detecting colorectal adenoma. Missed adenoma rate however correlated with the quality of bowel preparation rather than the imaging methods.

P737 OUTCOMES OF ENDOSCOPIC MUCOSAL RESECTION (EMR) OF LARGE POLYPS (≥ 20 MM) DETECTED IN A COLORECTAL CANCER SCREENING PROGRAM.

X. Bessa[1,2,*], A. Diaz-Gonzalez[3], M. Pellisé[3], C. Alvarez[1], J. Villaverde[1], I. de Lemos[1], C. Hernández[4], F. Macià[4], J. Grau[5], A. Serradesanferm[3], M. A. Pozo[3], J. Llach[3], L. E. Barranco[1], A. Castells[3], M. Andreu[1]. [1]*Gastroenterology Department,* [2]*Hospital del Mar,* [3]*Gastroenterology Department, Hospital Clínic,* [4]*Epidemiology Unit, Hospital del Mar,* [5]*Epidemiology Unit, Hospital Clínic, Barcelona, Spain*

INTRODUCTION: Large polypoid lesions have a higher risk of malignancy, and a complete resection followed by an adequate surveillance is required.
AIMS&METHODS: Aim: To evaluate the treatment and outcomes of large polyps detected in an average-risk population undergoing colorectal cancer screening programm.
Methods: All polyps ≥ 20 mm detected in the first round of a CRC screening program (50 to 69 years) were evaluated retrospectively. We collected data about clinical and endoscopic characteristics (size [20-29 vs >30 mm], location [rectal, left and right colon], morphology [sessile or flat vs pedunculated] and lateral extension), histopathology, resection technique (en bloc vs piecemeal), and presence of residual/recurrent neoplasia at follow-up.
RESULTS: 483 polyps ≥ 20 mm (444 adenomas, 8 hyperplastic, 10 serrated polyps and 21 adenocarcinomas [9 in situ and 13 invasive tumors]) were diagnosed. Regarding non-invasive (n=470) polyps, globally 444 (95%) polyps were treated endoscopically (77.8% en bloc / 22.2% piecemeal) and 26 (5.5%) polyps were surgically resected (15 [57.7%] after a first endoscopic resection, in all cases fragmented). Piecemeal resected polyps were significantly larger, sessile or flat and with lateral extension. A surveillance colonoscopy was performed (median time: 5.4 months) in 154 (34.6%) of the endoscopically resected polyps. Residual/recurrent neoplastic tissue was identified in 30 (6.8%) of the resected polyps at the polypectomy site, and specifically in 22 (31%) out of the 71 piecemeal resected polyps . Regarding those sessile-flat polyps (n=139) submitted to EMR, 113 (81.3%) polyps were treated endoscopically (43.4% en bloc /56.6 % piecemeal) and 26 (18.7%) polyps were surgically resected (15 [57.7%] after a first endoscopic resection, in all cases fragmented). Residual adenoma was detected in 15.7% and significantly in the piecemeal resected polyps (34% vs. 4%, p <0.004).
CONCLUSION: Most large polyps can be successfully eradicated endoscopically. A relatively high rate of residual/recurrent neoplasia, specifically in piecemeal-resected polyps, confirms the importance of follow-up colonoscopy.

INTRODUCTION: Recently, it has been published the first international guideline for surveillance of patients with serrated polyps (Gastroenterology 2012, 143:844-857).
AIMS&METHODS: Aim: To evaluate the impact of the surveillance protocol of serrated polyps in the surveillance of colorectal adenomas in a population screening program
Methods: Individuals belonging to the Colonprev study undergoing screening with colonoscopy. Clinical guidelines evaluated for colorectal adenomas: European Union 2011, British Society Gastroenterology 2010 and Spanish Gastroenterological Association (AEG)/AGA 2009. Definitions: Serrated polyp (SP) : hyperplasic, sessile serrated polyp and traditional serrated adenoma. Advanced SP (ASP): proximal to splenic flexure, size >= 10 mm or dysplasia. Surveillance at three years for individuals with advanced adenomas (AA) or >= 3 non-advanced adenoma (NAA) for adenomatous lesions and for those patients with ASP.
RESULTS: After excluding 27 individuals with CRC, 5,032 individuals were included. A total of 493 (9.8%) had AA and 182 (3.6%) had >= 3 NAA. A total of 1048 (20.8%) individuals had SP, 374 (7.4%) of these, ASP. In 274 out of the 5032 individuals (5.4%) with ASP, no simultaneously AA or >= 3 NAA coexists. Of these 274 ASP, 43 (0.8% of all individuals) and 218 (4.3% of all individuals) corresponded to hyperplasic polyps >= 10 mm or proximal to the splenic flexure, respectively, while 34 (0.7% of all individuals) were a non-hyperplasic proximal SP. The additional absolute percentage of patients, who should have been included in the monitoring group of three years or less, was 5.4%.
CONCLUSION: The implementation of the monitoring protocol of SP, mainly at the expense of monitoring advanced hyperplasic polyps (proximal or size >= 10 mm), determines a moderate increase in the number of individuals requiring an endoscopic follow-up at three years or less, and therefore, needs should resize endoscopic screening programs.

P739 A RANDOMIZED, CONTROLLED, LARGE SCALE STUDY OF THE WATER-INJECTION COLONOSCOPY WITHOUT SEDATION IN BEGINNERS AND ENDOSCOPISTS

Y. Yang[1,*], H. Xu[1], A. Jiang[1], L. Shi[1], G. Song[1], X. Wang[1], G. Shang[1], P. Li[1]. [1]*Gastroenterology Department, The 1st Affiliated Hospital of Harbin Medical University, Harbin, China*

INTRODUCTION: Water-injection colonoscopy is now recognized by endoscopists in training the beginners.
AIMS&METHODS: To investigate the advantage of the water injection colonoscopy, we conducted a large-scale study.1960 patients were randomized into the air insufflation and water injection colonoscopy group. 600 colonoscopies were performed by 6 experienced endoscopists(100each).1360 colonoscopies were performed by 4 beginners(340each). All the patients were examined without any sedatives or analgesics. The cecal intubation time, the abdominal pain (evaluated by VAS pain score) were observed. The success standard:the cecal intubation time was within 15min.
RESULTS: 1355 and 599 cases performed by beginners and experienced endoscopists respectively were in the statistics.682 were in the water group and 673 in the air group of beginners, the success rate of the cecal intubation was 91.35% vs 74.15%(P<0.05), the cecal intubation time was 9.0±5.0 vs 12.0±4.0min, (P<0.001), the abdominal VAS pain score was 2.0±2.0 vs 4.0±2.0(P<0.001) in the water and air group respectively. For experienced endoscopists, 297 were in the water group and 303 in the air group, the cecal intubation time was 6.0±3.0 vs 4.0±3.0, (P<0.001), the abdominal VAS pain score was 1.0±2.0 vs 3.0±2.0 (P<0.001) respectively.
Table Comparison of the water and air colonoscopies

Beginners	Water group (n=623)	Air group (n=499)	Z value	P value
Cecal intubation time(min)	9.00±5.00	12.00±4.00	12.05	<0.0001
Abdominal VAS pain score	2.00±2.00	4.00±2.00	15.68	<0.0001
Experienced endoscopists	Water group (n=297)	Air group (n=302)	Z value	P value
Cecal intubation time(min)	6.00±3.00	4.00±3.00	10.39	<0.0001
Abdominal VAS pain score	1.00±2.00	3.00±2.00	-10.27	<0.0001

CONCLUSION: The water method could relieve the patients' abdominal pain obviously for both beginners and endoscopists, and it could shorten the cecal intubation time and increase the success rate for beginners. Why the intubation time for experienced colonoscopists was longer with the water method than the air method was worth further investigation.

P740 WATER-INJECTION COLONOSCOPY IS A MORE EFFECTIVE METHOD FOR TRAINING THE BEGINNERS

Y. Yang[1,*], X. Wang[1], G. Shang[1], P. Li[1]. [1]*Gastroenterology Department, The 1st Affiliated Hospital of Harbin Medical University, Harbin, China*

INTRODUCTION: Robert concluded a Mininal Competency Criteria(MCC) assessed by Mayo Colonoscopy Skill Assessment Tool(MCSAT) in his study of beginners performing the air colonoscopy.

AIMS&METHODS: We developed a water-injection colonoscopy for training the beginners to compare with the air colonoscopy in Robert's study.800 water-injection colonoscopy procedures without any sedatives and analgesics were performed by 2 beginners (400 each). Cecal intubation times and independent cecal intubation rates were recorded. The average score of the motor and cognitive skills were assessed by using a 4-point grading scale (1, novice; 2, intermediate; 3, advanced; 4, superior).These data were grouped based on the order of performance. An average of the beginners' parameter was calculated at each step of training to establish the learning curves.
RESULTS: Compared with the MCC that the average scores of 3.5, independent cecal intubation rates of 85% and cecal intubation times of 16 minutes or less were achieved at 275 procedures with the air method in Robert's study, in our study, the average cecal intubation times were 8.8min and 10.9min, the independent cecal intubation rates reached 100% and 85% at 275 procedures of the two beginners respectively. And the average scores of the two parameters were obviously better than those in each corresponding stage in Robert's study. The average score of the motor and cognitive skills reached 3.5 at less than 275 procedures in all the items except loop reduction
CONCLUSION: The water injection colonoscopy is superior than the air colonoscopy in reaching the MCC concluded by Robert when training the beginners.

P741 PREDICTION OF DIMINUTIVE POLYP HISTOLOGY AND THE NEXT SURVEILLANCE INTERVALS USING NARROW-BAND IMAGING DURING SCREENING COLONOSCOPY

Y. S. Kim[1,*], H. Y. Kang[1], S. H. Lim[1], S. Y. Yang[1], J. H. Song[1], K. E. Chung[1], S. J. Kang[1], J. S. Kim[1]. [1]*Internal medicine, Seoul National University Hospital Healthcare System Gangnam Center, Seoul, Korea, Republic Of*

INTRODUCTION: The American Society for Gastrointestinal Endoscopy (ASGE) recently developed a preservation and incorporation of valuable endoscopic innovations (PIVI) statement for the real-time endoscopic assessment of the histology of diminutive colorectal polyps.
AIMS&METHODS: The aim of this study was to assess performance of Narrow-Band Imaging (NBI) without magnification predicting diminutive polyp histology during real time screening colonoscopy, and whether NBI is able to predict colonoscopy surveillance intervals.
Consecutive asymptomatic subjects undergoing screening colonoscopy were enrolled. Histology of polyps was predicted at NBI and assigned a designation of high or low confidence by 6 board-certified staff endoscopists without prior experience with NBI. The predicted next surveillance interval using NBI was compared with those that would be recommended using pathologic findings according to ASGE criteria.
RESULTS: A total of 445 polyps $\leq$ 10 mm (351 polyps $\leq$ 5 mm, 218 adenoma $\leq$ 5mm) in 212 subjects were analyzed. Sensitivity, specificity, positive and negative predictive values, and accuracy of high confidence NBI predictions for adenoma $\leq$ 5 mm were 82.1%, 82.7%, 88.6%, 73.8%, and 82.3%, respectively. High confidence characterization of polyps $\leq$ 5 mm predicted the correct surveillance interval in 75% of cases. NPV of high confidence NBI for adenoma for the rectosigmoid colon lesions $\leq$ 5 mm was 87%.
CONCLUSION: Both the surveillance interval agreement and the negative predictive value for identifying adenoma by non-experts in NBI did not meet the ASGE recommended thresholds for optical biopsy. Better results should be achieved to use NBI as a real-time optical biopsy of diminutive colorectal polyps in colorectal screening of the general population.

P742 DIAGNOSTIC ABILITIES OF THREE ENDOSCOPIC MODALITIES FOR SMALL COLORECTAL POLYPS: WHITE-LIGHT ENDOSCOPY VS MAGNIFYING NBI VS ENDOCYTOSCOPY

Y. Yagawa[1,*], S.-E. Kudo[1], Y. Mori[1], K. Wakamura[1], M. Kutsukawa[1], M. Misawa[1], Y. Wada[1], T. Hayashi[1], H. Miyachi[1]. [1]*Digestive Disease Center, SHOWA UNIVERSITY NORTHERN YOKOHAMA HOSPITAL, yokohama-si, Japan*

INTRODUCTION: Narrow band imaging (NBI) system is a technology that enchances the visualization of surface mucosal and vascular patterns on the polyp1. Endocytoscopy (EC) enables observation of in vivo cells and nuclei with 450x ultra-magnification2. Both systems may allow acute optical diagnosis of small (1-10mm) polyps without histopathology.
AIMS&METHODS: This study assesses the diagnostic ability of white light endoscopy (WL), magnifying NBI , and EC for prediction of histopathology of small colorectal polyps for experienced and novice endoscopists.
94 small colorectal polyps (77 neoplastic lesions and 17 non-neoplasticones) were observed with both NBI with magnification and EC after performing conventional WL with the use of an integrated type EC scope (CF-Y0001 and CF-Y0020, Olympus, Tokyo). For each lesion, images of three endoscopic modalities (WL, NBI, and EC) were separately stored. By computer-based randomization, three types of test files of 94 subject lesions were created to evaluate each endoscopic modality; (1) WL alone, (2) WL + NBI, and (3) WL+EC. Three blinded experienced endoscopists (KW , MM and YM ; colonoscopy $>$ 3000 cases) and three blinded novice endoscopists (YS, KK and SK ; colonoscopy $<$ 500 cases) made the diagnosis (neoplastic or non-neoplastic) of them in each file. The diagnostic abilities for three test files were calculated with reference to the final histopathological diagnoses.
RESULTS: Of the 94 polyps, 77 were neoplastic and 17 were non-neoplastic. The average of sensitivities are experienced: (1) 91.3%, (2) 93.5%, (3) 96.1%, novice: (1) 87.0%, (2) 88.7%, (3) 88.3%. The average of specificities are experienced: (1) 74.5%, (2) 88.2%, (3) 86.3%, novice: (1) 62.7%, (2) 72.5%, (3) 62.7% . The average of accuracies are experienced: (1) 88.7%, (2) 92.6%, (3) 94.3%, novice: (1) 82.6%, (2) 85.8%, (3) 83.3%. For experienced endscopists, WL+NBI and WL+EC showed significantly higher specificity and accuracy than WL alone ($P < 0.05$).
CONCLUSION: Diagnostic ability of experienced endoscopists was superior to that of novice endoscopists in any tests. Using NBI or EC in addition to WL helped experienced endoscopists to predict the histopathology of small polyps, however they provided no additional diagnostic value for trainee endoscopists.

P743 CAN DESMOPLASTIC REACTION OF INVASIVE COLORECTAL CARCINOMAS BE INDICATED IN VIVO BY ENDOCYTOSCOPY?

Y. Sugihara[1,*], S.-E. Kudo[1], K. Wakamura[1], H. Miyachi[1], Y. Mori[1], M. Misawa[1], T. Kudo[1], T. Hisayuki[1], K. Kodama[1], T. Hayashi[1], S. Okoshi[1], E. Hidaka[1], H. Ishida[1], S. Hamatani[1]. [1]*Digestive disease center, Showa University Northern Yokohama Hospital, Yokohama, Japan*

INTRODUCTION: Background:In magnifying diagnosis during colonoscopy, the detection of desmoplastic reaction(DR) on the superficial layer is useful for predicting massively-invasive submucosal carcinomas. Although endocytoscopy, using an ultra-high magnification system, can observe cellular images in living colorectal lesions, there is no data concerning the diagnostic findings of DR with endocytoscopy.
AIMS&METHODS: Aims:The aim is to clarify the feature of endocytoscopic image of DR on the superficial layer in invasive colorectal carcinomas
Methods:From Apr. 2005 to Apr. 2013, a total of 19186 colorectal neoplasms, excluding advanced cancers, were resected endoscopically or surgically at our center. Using magnifying endoscopy and endocytoscopy, 502 lesions were observed and diagnosed according to Kudo's pit pattern classification and EC classification. Of these lesions, 53 lesions showed EC3b (defined as unclear gland formation and agglomeration of distorted nuclei strongly stained with methylene blue) by endoctyoscopy. According to the pathological findings, these lesions were divided into two groups: DR positive (DR+) group and DR negative (DR-) group, and investigated the distinctive feature of endocytoscopic image of DR.
RESULTS: Results:Of these 61 lesions showing EC3b, 30 lesions were included in DR+ group and 31 lesions in DR- group. In endocytoscopic images, 'fine granular structure' was found in 23(26.5%) of 61 lesions. There was significant difference in the observation rate of fine granular structure between DR+ group and DR- group (23/30(76.6%) vs 0/31(0%): $p < 0.01$). The sensitivity and specificity that the presence of fine granular structure predicted DR on the superficial layer was 76% and 100% respectively. And other features of endocytoscopic image had not significant difference.
CONCLUSION: Conclusions:Endocytoscopic image of ''fine granular structure'' have possibility to relate with DR on the superficial layer. Detection of DR by endocytoscopy would be useful for the diagnosis and treatment of massively-invasive colorectal cancers.

P744 RISK FACTORS AND ENDOSCOPIC TREATMENT OF RECCURENT CHOLELITHIASIS - DATA FROM A HIGHLY EXPERIENCED CENTER IN ERCP

A. Tantau[1,2,*], V. Mercea[3], D. Crisan[3], M. Tantau[1]. [1]*''Iuliu Hatieganu'' University of Medicine and Pharmacy,* [2]*4th Medical Clinic,* [3]*Regional Institute of Gastroenterology and Hepatology Cluj-Napoca, Cluj-Napoca, Romania*

INTRODUCTION: Endoscopic sphincterotomy and stone extraction are standard procedures for the removal of bile duct stones. Reccurence of common bile duct (CBD) stones can occur in these patients. Risk factors have been partly defined, some of them being related to bile stasis .
AIMS&METHODS: We aimed to explore the risk factors contributing to the recurrence of CBD stones after successful endoscopic stone clearance, focused on the anatomical factors of CBD.
Between 2002 and 2011, 2986 patients were evaluated in our department for a suspicion of CBD lithiasis. Of these patients, after excluding patients without sphincterotomy and those with remnant lithiasis, 2086 were followed up for the recurrence of CBD stones. Univariate and multivariate analyses for the risk factors including stone size, CBD dilation, choledocoduodenoanastomosis, gastric surgery with different types of anastomosys and the presence of diverticula were performed.
RESULTS: The recurrence of CBD stones was found in 92 (4.7%) patients. On univariate analysis, the presence of choledocoduodenoanastomosis (p=0.05), enlarged infundibulum (p=0.019), periampullary diveticulum (p=0.003) and stone size (p=0.006) were significant contributors for the recurrence of CBD stones. On multivariate analysis, the presence of periampullary diverticulum (p=0.004, OR=0.28), choledocoduodenoanastomosis (p=0.01, OR=2.86), and previous small size lithiasis (1-4mm) (p=0.002, OR=0.38) were independent risk factors for reccurent stones. Gender, age, dilated CBD, Billroth I and II anastomosis did not influence the recurrence rate.
CONCLUSION: The recurrence of CBD stones might be influenced by the presence of periampullary diverticulum, choledocoduodenoanastomosis and previous small size lithiasis. Patients with these risk factors could benefit from a regular follow-up of the lithiasic pathology.

P745 RESULTS OF REPEAT ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) AFTER INITIAL BILIARY CANNULATION FAILURE

D.-A. Benajah[1], B. Benyachou[1,*], N. Lazaar[1], M. El yousfi[1], I. Mellouki[1], N. Aqodad[1], M. El Abkari[1], A. Ibrahimi[1]. [1]*Gastroenterology, CHU Hassan II, FEZ, Morocco*

INTRODUCTION: The failure of biliary cannulation during endoscopic retrograde cholangiopancreatography (ERCP) can occur in 5-20% of cases. After this failure, ERCP can be repeated in clinically stable patients
AIMS&METHODS: Our aim was to report the results and determine the value of repeat ERCP after the first failure. Materials and methods: We reported results and success rate of repeat ERCP in a retrospective study including all patients who underwent repeated ERCP for the same purpose after the first failure.
RESULTS: During the study period, 1036 patients underwent ERCP with a primary success rate approaching 88%.One hundred and twenty-five patients [96 female (77%); mean age: 52 years; age range: 24-80 years] with previously unsuccessful biliary cannulation at previous ERCP. The main indications for biliary cannulation and therapeutic intervention (table1) were choledocholithiasis (70.4%), cholangitis in 12.8% of which 25% was severe cholangitis, and pancreatic malignancy (12.8%). The average time of the repetition of the procedure was 10 days (1 - 25j). No reason for the initial failed biliary cannulation was identified in 40% of cases. Unstable position (16%), periampullary diverticulum (32%).The papilla could not be identified at the initial procedure in12% of cases. Biliary cannulation was successful in 79 patients (63.2%) in a single procedure. The failure of the second ERCP was mainly due to an impassable biliary stricture in 33.2% of cases. The post-ERCP complications were repeated with minimal bleeding stopped spontaneously in 11% of cases, PEP in 4% of cases.
CONCLUSION: In our experience, the repetition of the ERCP after the first failure of procedure was associated with an acceptable success leading the overall success rate of this examination to 95.6%, without increasing the incidence of post-ERCP complications, and avoiding use another alternative to access the bile duct.

P746 SAFETY PROFILE OF ENDOSCOPIC RETROGADE CHOLANGIOPANCREATOGRAPHY IN VERY OLD PEOPLE

A. L. Sousa[1], D. Sousa[1,*], A. G. Antunes[1], M. Eusébio[1], A. Ramos[1], B. Peixe[1], T. Belo[1], H. Guerreiro[1]. [1]*Gastroenterology, Hospital de Faro, EPE, Faro, Portugal*

INTRODUCTION: The performance of Endoscopic Retrogade Cholangiopancreatography (ERCP) in the elderly population is particularly indicated for lithiasic or neoplastic disease. With longer life expectancy, invasive and therapeutic procedures are increasingly being performed on patients of advanced ages.
AIMS&METHODS: The aim of our study is analyse the results of ERCP in very old patients (aged ≥80 years) for lithiasic or neoplastic disease. Between 1st July 2011 and 30th June 2012, we evaluated patients of ≥60 years who underwent ERCP at a single center. Two groups of patients were compared: group I (GI) aged 60-79 years old and group II (GII) aged ≥80 years. We recorded demographic data, indications, comorbidities, blood analysis before the procedure, success of ERCP, complications, mortality and length of hospitalization. Statistical analysis: chi-quare and t-Student tests.
RESULTS: 154 ERCPs were performed in 132 patients (66 in each group). The procedure was successful in 97.4% of patients in GI and in 94.7% of patients of the GII. The most frequent indications in the GI were cholangitis and malignant obstructive jaundice (59.2%) and in the GII were cholangitis and choledocholithiasis (70.8%). Malignant strictures were more common in GI (40.8%). There were 5 complications (2.7%) - 2 severe pancreatitis in GI, 1 major bleeding in GII, 2 cholangitis (1 of moderate severity in GII and 1 of mild severity in GI). During the firsts 30 days, there were 6 deaths in the GI and 5 deaths in the GII, mainly related to the underlying pathology.
CONCLUSION: Our study shows that ERCP is safe in the very old. The decision to perform an ERCP should be taken based on clinical need. The age itself should not be a contraindication for endoscopic intervention, because even for the elderly patient population the benefits outweigh the risks.

P747 TEMPORARY PLACEMENT OF A FULLY COVERED SELF-EXPANDABLE METAL STENT IN THE PANCREATIC DUCT FOR AIDING EXTRACTION OF LARGE PANCREATIC DUCT STONES WITH PANCREATIC DUCT STRICTURES: PRELIMINARY DATA

E. Linghu[1,*], Z. Qin[1]. [1]*Department of Gastroenterology and Hepatology, the Chinese PLA General Hospital, Beijing, China*

INTRODUCTION: Placement of fully covered self-expandable metal stents (FCSEMSs) has not been reported to aid extraction of large pancreatic duct (PD) stones.
AIMS&METHODS: To evaluate the technical success and safety of temporary placement of a FCSEMS in the PD to aid extraction of large PD stones.
Four symptomatic patients with large (>10 mm) pancreatic duct stones, who could not be cleared of stones using a balloon catheter and basket using ERCP alone, were selected for FCSEMS placement. After placement of FCSEMS (10-mm diameter) in the pancreatic duct for 1 week to 5 months (mean duration: 77 days), standard endoscopic maneuvers cleared large pancreatic duct stones.Technical success and safety of temporary placement of a FCSEMS in the PD for aiding extraction of large PD stones. Technical success was defined as successful placement of stents and the ability to achieve PD clearance in two endoscopic encounters. Complications were assessed according to consensus criteria.
RESULTS: The procedure was technically successful in all 4 patients. At 6-month follow-up, no residual stones were seen on pancreatography, and all patients were doing well without any symptom recurrence.
CONCLUSION: Temporary placement of a FSCEMS in the PD for aiding extraction of large PD stones is a safe technique that facilitates the removal of large stones.

P748 SELECTIVE BILIARY CANNULATION USING THE DOUBLE GUIDE WIRE TECHNIQUE. SUCCESS RATE AND COMPLICATIONS.

F. GEORGOPOULOS[1,2,*], N. ATHANASOPOULOS[2], G. PENESIS[2], I. KABARNOU[2], S. SEVASTOPOULOS[2], J. K. TRIANTAFILLIDIS[2]. [1]*GASTROENTEROLOGY, AL ZAHRA HOSPITAL, DUBAI, DUBAI, United Arab Emirates,* [2]*GASTROENTEROLOGY, NIKEA GENERAL HOSPITAL, ATHENS, Greece*

INTRODUCTION: Difficult selective biliary cannulation during ERCP accounts for up to 10% of cases with naïve Vater papilla. Several techniques have been introduced like needle knife papillotomy or insertion of a guide wire or a pancreatic plastic stent into the main pancreatic duct to facilitate the selective bile duct cannulation described as double guide wire technique.
AIMS&METHODS: To retrospectively investigate the frequency use and complication rate of the double guide wire technique. This technique was compared to the standard selective cannulation technique. Difficult cannulation was defined if more than 15 minutes were necessary for selective cannulation or if the quide wire was inerted more than 5 times into the main pancreatic duct. Over a period of 57 months, 701 ERCPs were performed by a single operator, 523 (74.6%) of whom were performed on a naïve Vater papilla.
RESULTS: The overall selective cannulation rate was achieved in 512 patients (97.9%). Difficult cannulation requiring an alternative technique was required in 103 (20, 1%) patients. Double guide wire technique was successful in 48 out of 56 patients (85.7%), needle knife in 49 out of 50 patients (98%) and Rendezvous technique in 5 out of the 7 patients (71.4%). Overall complications occurred in 20 patients (3.8%), with 7 (1.34%) pancreatitis (2 severe, 5 mild), 1 (0.2%) bleeding, 2 (0.4%) perforation and 10 (1.95%) cholangitis. In the conventinal cannulation group 5 cases of pancreatitis (1 severe and 4 mild), 2 cases of perforation, 1 case of bleeding and 8 cases os cholangitis were observed. Two cases of cholangitis but no pancreatitis were observed in the double guide wire technique group. One mild and one severe pancreatitis were observed in the needle knife technique group.
CONCLUSION: Insertion of a guide wire into the pancreatic duct to facilitate the selective cannulation of the difficult bile duct is feasible in high rate and can be a safer alternative than other techniques.

P749 ENDOSCOPIC PAPILLARY LARGE BALLOON DILATION ALONE USING SHORT DOUBLE-BALLOON ENTEROSCOPE FOR THE TREATMENT OF DIFFICULT CHOLEDOCHOLITHIASIS IN PATIENTS WITH ROUX-EN-Y GASTRECTOMY

H. Kogure[1,2,*], A. Yamada[2], H. Watabe[2], H. Isayama[2], T. Tsujino[2], N. Takahara[2], R. Uchino[2], T. Hamada[2], K. Miyabayashi[2], S. Mizuno[2], D. Mohri[2], T. Sasaki[2], N. Yamamoto[2], Y. Nakai[2], K. Hirano[2], M. Tada[2], M. Fujishiro[1], K. Koike[2]. [1]*Endoscopy and Endoscopic Surgery,* [2]*Gastroenterology, The University of Tokyo, Tokyo, Japan*

INTRODUCTION: Endoscopic treatment of difficult common bile duct (CBD) stones in patients who have undergone Roux-en-Y gastrectomy can be challenging.
AIMS&METHODS: We evaluated the efficacy and safety of endoscopic papillary large balloon dilation (EPLBD) using short double-balloon enteroscope (DBE) for the treatment of difficult CBD stones in patients with Roux-en-Y gastrectomy. Between April 2006 and March 2013, we performed short DBE-assisted ERCP in 30 choledocholithiasis patients with Roux-en-Y gastrectomy (m/f: 27/3, mean age 77 years). The mean stone size was 11 mm (3–25 mm). Multiple (≥4) stones were found in 13 patients (43%). The size of balloon for papillary dilation was determined according to the size of stones, not exceeding the diameter of the distal CBD.

RESULTS: Access to the papilla was successful in 29 patients (94%). The mean time required to reach the papilla was 28 min (5–82 min). Successful biliary cannulation was achieved in 28 patients (93%), 5 of which required PTBD rendezvous technique. Finally, 25 patients underwent stone removal. EPLBD without EST (10–18 mm) and EPBD (8 mm) were performed in 23 and 2 patients, respectively. The overall complete stone removal rate was 96%. Mechanical lithotripsy and extracorporeal shock wave lithotripsy were required in 4 (16%) and 5 (20%) patients, respectively. Complications occurred in 4 (13%) patients, including retroperitoneal air (n = 1) and hyperamylasemia (n = 3), but all were asymptomatic.
CONCLUSION: EPLBD using short DBE appears to be an effective and safe treatment for difficult CBD stones in patients with Roux-en-Y gastrectomy.

P750 ERCP-RELATED PERFORATIONS: RESULTS FROM SINGLE CENTRE EXPERIENCE AT A DISTRICT GENERAL HOSPITAL IN JAPAN

H. Hisai[1,*], Y. Koshiba[1], T. Hirako[1], Y. Arihara[1], Y. Ikeda[1], E. Miyazaki[1]. [1]*Department of Gastroenterology, Japan Red Cross Date General Hospital, Date, Japan*

INTRODUCTION: Endoscopic retrograde cholangiopancreatography (ERCP) has become a common procedure worldwide for various pancreticobiliary diseases. It is available in most acute hospitals in Japan. Perforation after ERCP is rare but one of the most dreaded complications. The reported incidence of perforation is 0.08 to 2.2%, and the mortality rate is 12 to 25%. These data stems mainly from older studies or retrospective databases of tertiary referral centres, however, there are few reports about the incidence and the outcomes at a district general hospital.
AIMS&METHODS: The aim of this study was to assess the incidence of ERCP-related perforation and the clinical outcomes in the district general hospital setting. A review of all patients undergoing ERCP at our institution from April 1996 and April 2013 was performed to assess the ERCP-related perforations. Perforation following ERCP was divided, according to Stapfer classification, as follows: remote from the papilla (type I, lateral or medial wall), periampullary (type II), at the level of the distal bile duct (type III, related to wire or basket instrument) or retroperitoneal air alone (type IV).
RESULTS: Out of 5732 ERCPs that were performed (71.2% therapeutic interventions), a total of 15 perforations occurred, yielding an incidence of 0.26%. Of a total of 15 patients, males were predominant (11/15, 73%) and the mean age of the patients was 70.7 (range 50-87) years. The indications for ERCP were choledocolithiasis in 7 patients (47%), malignant biliary strictures in 4 (27%), cholecystitis in two (13%), intrahepatic bile duct stricture in one (7%) and gallbladder polyp in one. We identified 5 type I, 6 type II, and 4 type III perforations. In all patients, perforation was recognised during ERCP. Type II perforations were related to sphincterotomy or procedures following sphincterotomy. Three patients with Billroth II anatomy suffered from perforation of the afferent limb. Nine out of 15 (60%) were managed medically with endoscopic biliary drainage or percutaneous transhepatic biliary drainage. The remaining 6 patients (type I in all 5 patients and type III in one) underwent surgery. Endoscopic closure of the perforation site was not performed in any patients as most of them were not amenable to endoscopic intervention. There were two mortality cases with unstable general conditions (type I in one and type III in one).
CONCLUSION: Although most patients fully recovered from perforation after ERCP, however, some patients experienced life-threatening outcomes, including mortality. Scope-related perforation is a serious complication requiring surgery. Early recognition and appropriate management is crucial for optimal results.

P751 ASSESSMENT OF THE EFFECTIVENESS OF ERCP MECHANICAL SIMULATOR (EMS) EXERCISE ON TRAINEES' ERCP PERFORMANCE IN THE INITIAL LEARNING PERIOD: MULTICENTER RANDOMIZED CONTROLLED TRIAL

I. Hritz[1,*], Z. Dubravcsik[2], A. Szepes[2], Z. Szepes[3], I. Kruglikova[4], P. Funch-Jensen[4], L. Madacsy[2]. [1]*Department of Gastroenterology, Fejer County Szent György Hospital, Székesfehérvár,* [2]*Department of Gastroenterology, Bacs-Kiskun County Hospital, Kecskemet, Hungary, Kecskemét,* [3]*1st Department of Internal Medicine, University of Szeged, Szeged, Hungary,* [4]*Department of Surgery and Endoscopy, Aarhus University Hospital, Aarhus, Denmark*

INTRODUCTION: The ERCP computer-based simulator (ECS) is thought to be useful for teaching the endoscopic technique of side-viewing duodenoscopy. We have previously demonstrated that ECS can differentiate between endoscopists with lack or high level of ERCP competence. Furthermore, it has been suggested that simulator practice improves clinical performance of trainees in the initial learning period, however limited clinical information is available in terms of ECS practice.
AIMS&METHODS: The study aimed to evaluate the effect of ECS practice on trainees' clinical ERCP performance. Fifteen trainees who performed regularly esophago-gastroduodenoscopy and colonoscopy but were naive to side-viewing duodenoscopy and ERCP underwent clinical training in three different high volume endoscopy unit supervised by three ERCP experts. Trainees were randomized into two groups after a 2 hours long didactic seminar of ERCP teaching about basic duodenoscopy techniques and methods of Vater papilla cannulation. Study group (SG; n=6) participated first in ECS practice using the AccuTouch Endoscopy Simulator before starting on patients; control group (CG; n=9) did not undergo ECS practice. 59 patients were involved into the study (~3.93/trainee). ECS practice was made on 7 different computer simulated ERCP cases with 10 repetitions. The clinical performance of all participants was monitored and analyzed with different variables. Statistical analysis with Student's t-test and non-parametric Mann-Whitney test was performed.
RESULTS: Trainees who underwent ECS training intubated the pylorus and reached the papilla in significantly shorter period of time as compared to trainees without such practice (88.6 vs. 130.2 sec; $p<0.03$ and 129.4 vs. 179.4 sec; $p=0.03$, respectively). There was no statistical difference in pylorus intubation technique, proper orientation and positioning of the papilla as well as lack of unnecessary motions between the two study groups, however proper papillary cannulation control was superior in SG compared to CG (score 2.84 vs. 2.36; $p=0.04$). Additionally, reddening of the visual field was also significantly decreased in SG compared to CG (22.2 vs. 31.2 sec; $p<0.05$).
CONCLUSION: In our randomized, multicenter trial the ECS practice significantly enhanced trainees' clinical ERCP performance in the initial learning period. In conclusion, ECS has definite training potential in trainees' who are naive to side-viewing duodenoscopy and thus can be extremely useful in future ERCP training.

P752 PATIENTS RADIATION DURING INERVENTIONAL ERCP IS RELATED TO THE COMPLEXITY AND TECHNICAL DIFFICULTY OF THE PROCEDURES

K. D. Paraskeva[1,*], V. Tsapaki[2], A. Giannakopoulos[1], N. I. Mathou[1], E. Evgenidou[1], S. Papasavvas[1], N. Angelogiannakopoulou[2], C. Triantopoulou[2], J. A. Karagiannis[1]. [1]*Gastroenterology,* [2]*Radiology,* "*Konstantopoulio*" *Hospital, Athens, Greece*

INTRODUCTION: Interventional ERCP is a well-established endoscopic procedure either for treatment or palliation for a great variety of hepatobiliary and pancreatic diseases. However, patients and endoscopy staff radiation during these procedures consists an important, although not extensively studied, not to say neglected, issue.
AIMS&METHODS: To assess and correlate patients radiation dose according to the complexity and technical difficulty (and thus fluoroscopy time) of several interventional ERCP procedures. Data of 650 patients-procedures performed in a 42 months period in a single center were retrospectively recorded and analyzed. All procedures were categorized according to a validated (Cotton scale) three degree (1 to 3) technical difficulty and complexity grading scale as follows: 1. Simple and uncomplicated common bile duct (CBD) stones (1-2 stones <1 cm in diameter) and plastic stent placement for post-operative bile duct leaks and low CBD strictures. 2. Complex CBD stones (>2 stones and/or >10mm in diameter) or when large balloon papillary dilatation was performed, treatment of hilary or more proximal strictures, benign post-operative biliary strictures. 3.Pancreatic duct procedures, procedures in patients with Billroth II operation and procedures for intra-hepatic bile ducts stones. All procedures were performed by one senior endoscopist with more than 10 years of experience. Fluoroscopy time, number of films taken and patients radiation dose in terms of Kerma area product (KAP) were recorded and analysed in relation with the technical difficulty of ERCP according to the above grading scale.
RESULTS: Mean values for each Group are presented in the following table:

Grade of procedure	N pat's	Age	Time	Films	KAP
1	407	70.2	3.9	2.4	15.8
2	157	69.8	7	2.9	23.8
3	20	70.3	5.8	2.6	17.5

There was statistically significant difference between Groups 1 and 2 for all parameters (Mann-Whitney U, Wilcoxon W): Fluoroscopy time Z=-7,839 $p<0.001$, Films taken Z=-2,780 $P<0.005$ and KAP Z=-4,131 $p<0.001$, while there were no significant differences between all other groups. The relatively low KAP in Group 3 is presumably due to the small number of cases, compared with Groups 1 and 2, and that most of them were patients with Billroth II operations where most of the time was spent in cannulation rather than fluoroscopy.
CONCLUSION: Complexity and technical difficulty of interventional ERCP procedures increases both fluoroscopy time and KAP and thus patients radiation dose.

P753 THERAPEUTIC ERCP IN CHOLELITHIASIS – A TEN YEAR - EXPERIENCE OF A SINGLE CENTER

M. Tantau[1,2,*], V. Mercea[2], D. Crisan[2], G. Mester[2], S. Vesa[1], A. Tantau[1,3]. [1]*"Iuliu Hatieganu" University of Medicine and Pharmacy,* [2]*Regional Institute of Gastroenterology and Hepatology Cluj-Napoca,* [3]*4th Medical Clinic, Cluj-Napoca, Romania*

INTRODUCTION: Endoscopic Retrograde Cholangio-Pancreatography (ERCP) is the standard method of treatment of choledocholithiasis.
AIMS&METHODS: To evaluate the diagnostic success rate and the outcomes of therapeutic ERCP for bile duct stones, depending on the anatomical variants.

A total of 3097 consecutive ERCPs were performed in 2986 patients during a 9-year period (2002-2011) in our endoscopy department. The analysis of the results of therapy was performed depending on anatomic variants, age and opacification of the Wirsung duct.
RESULTS: The rate of successful cannulation was 98%. The patient's age and the diameter of the common bile duct were the factors influencing the probability of finding a gallstone (age over 74 years, AUC=0.547; $p<0.001$) and a CBD diameter larger than 12 mm (AUC=0.735, $p<0.001$). The number of cases with opacification of the Wirsung duct, the use of precut papillotomy and the inability of finding a stone significantly decresed with the increasing experience of operator ($p<0.001$). Stone removal was unsuccessful in 2.3%. Factors associated independently with unsuccessful extraction were previous surgical sphincteroplasty, stone size and Billroth I anastomosis. The precut sphincterotomy, required overall in 4.21% of cases, was significantly associated with the additional presence of an impacted stone ($p<0.001$), but did not correlate significantly with the other anatomical alterations. The use of the precut papillotomy technique decreased significantly with the increased expertise of the operators ($p<0.001$). The prevalence of pancreasum divisum in 866 patients with pancreatography was of 3.0%.
CONCLUSION: The endoscopic treatment of choledocholithiasis is highly effective, influenced partly by the experience of the operator; in experienced hands, however, the success rate is high even in case of anatomic variants and difficult calculi.

P754 ENDOSCOPIC OSTIUM INCISION AT NON-MALIGNANT POST-SURGICAL BILIOENTERIC ANASTOMOTIC STRICTURE AFTER COMPLEX ABDOMINAL SURGERY

M. Raithel[1,*], A. F. Hagel[1], A. Nägel[1], S. Raithel[1], M. F. Neurath[1], P. Konturek[2]. [1]*Medicine 1, University Erlangen, Erlangen,* [2]*Medizinische Klinik, Thüringen Kliniken, Saalfeld, Germany*

INTRODUCTION: Bilioenteric anastomotic stricture is a well-known complication after bile duct surgery or liver transplantation. This study reports our experience with endoscopic ostium incision of high-grade or subtotal stricture at the non-malignant biliary
AIMS&METHODS: Over a 7-yr period among more than 7500 ERCPs, 38 patients (0.50%) after complex abdominal surgery were identified with high-grade/subtotal bilioenteric anastomotic stricture with failed cannulation or inaccessible ostium.
RESULTS: DBE enteroscopy (n= 19), push enteroscopy (n=7) or transstomal endoscopy via jejunostomy (n=12) were used to reach the bilioenteric anastomotic stricture and to intervene at the postsurgical stricture by ostium incision, guidewire canulation or dilation.
Results: From 38 patients with endoscopically identified high-grade or subtotal bilioenteric anastomotic stricture ostium incision was necessary in 23 patients (60.5%) to access the biliary tree, while in the remaining 15 patients (39.4%) guidewire probing or blunt bouginage/dilation was successful.
The ostium incision in 23 patients was made by either snare, needle knife and/or papillotome in 4 (17.3%), 3 (13.0%) and 18 patients (78.2%), respectively. Sucessful ostium incision was achieved in 20 of 23 patients (86.9%), allowing all further ERCP interventions successfully. Major complications included 1 perforation (5.2%) and 2 cholangitis (10.5% after transstomal approach).
CONCLUSION: Ostium incision at the strictured bilioenteric anastomosis may be required in a minority of postop patients. It represents a somewhat risky procedure, which should be performed only in experienced centers to avoid percutaneous transhepatic biliary approaches or re-operation.

P755 THE UTILITY OF THE SECOND-GENERATION MULTIBENDING BACKWARDOBLIQUE VIEWING DUODENOSCOPE IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

M. Chiba[1,*], H. Imazu[1], K. Kanazawa[1], N. Mori[1], H. Toyoizumi[1], H. Tajiri[2]. [1]*Department of Endoscopy,* [2]*Division of Hepatology and Gastroenterology, The Jikei University School of Medicine, Tokyo, Japan*

INTRODUCTION: In the associated procedure for ERCP, the factors of patient's anatomy, or compressed tumor and all, make en face view of the papilla of Vater difficult. Those, also makes deep biliary cannulation and therapeutic techniques difficult. Therefore, we have developed multibending backwardoblique viewing duodenoscope (M-D scope) in conjunction with Olympus Medical Systems, Tokyo, Japan. Our pilot study of first-generation M-D scope showed (1); it allowed the endoscopic view "to look" up to the papilla while keeping a constant distance between the papilla and the endoscope tip, using swan-neck position. Especially, the M-D scope was useful for biliary cannulation in cases with Billroth I gastrectomy. However, biliary stenting was failed in a case of strong biliary stricture with Klatskin's tumor, and the M-D scope could not be inserted into duodenum in a case of duodenal stenosis due to pancreatic cancer. The reason of this technical failure was because the M-D scope with proximal bending portion did not get an adequate stiffness. To overcome this limitation, we newly developed the second-generation M-D scope (TJF-Y0022, Olympus Medical Systems, Tokyo, Japan).
AIMS&METHODS: The aim of the present retrospective study was to evaluate the utility of the second-generation M-D scope (S-M-D scope) in ERCP. To get an adequate scope stiffness, traction wire was strengthened, and proximal bending angle was changed from 70 degree of up/down to 45 degree. From July on 2012 to March on 2013, S-M-D scope was used in cases of biliary ERCP which were selected at random, or cases in which initial biliary cannulation with a conventional duodenoscope (JF-260V) was failed. Six endoscopists with various experience used S-M-D scope and were given questionnaire about when the proximal bending was used. Clinical and ERCP-related data such as serum amylase before and after the procedure, success of biliary cannulation were analyzed.
RESULTS: S-M-D scope was used in 53 cases of biliary ERCP related procedure including biliary stenting, sphincterotomy, stone removal and so on. The overall success rate of biliary cannulation with the M-D scope was 100%(53 /53), and all of the endoscopic procedures were successfully completed. Questionnaire showed proximal bending was used to obtain the ideal en face position for biliary cannulation in 9 cases (17%), and S-M-D scope was useful in 2 cases of 5 with Billroth I gastrectomy, In addition, stiffness of S-M-D scope never limited all procedures. Any complications were not found.
CONCLUSION: The S-M-D scope was very useful for therapeutic and diagnostic ERCP.

P756 ENDOSCOPIC SNARE AMPULLECTOMY(ESP) FOR AMPULLARY TUMOURS - SINGLE CENTRE STUDY

N. Dubale[1,*], P. Sonone[2], V. Bhide[2], A. Bapaye[1]. [1]*Department of Digestive Diseases & Endoscopy,* [2]*Department of Pathology, Deenanath Mangeshkar Hospial & Research Centre, Pune, India*

INTRODUCTION: Tumors of duodenal papillae may be malignant or premalignant. Endoscopic snare papillectomy (ESP) may be a minimally invasive solution to treat these lesions and can obviate the need for major surgical intervention. This retrospective single centre study evaluates the safety and outcome of ESP for ampullary tumors.
AIMS&METHODS: Patients with ampullary tumors treated with ESP during 6-years (Feb 2007 to Jan 2013) identified from our ERCP database. All underwent pre-ESP side-viewing duodenoscopy, EUS and relevant additional imaging to confirm localized disease and suitability for the procedure.
ESP was performed using a diathermy snare by fulcrum technique followed by biliary and pancreatic stenting –which were removed at 4 – 6 weeks with biopsies from the base for residual tumor. Patients with histology confirmed as adenocarcinoma were counseled for either close follow-up or surgical resection & with benign histology were closely followed up. Follow up done at 1, 3, 6, 12, 18, and 24 months& yearly thereafter.
RESULTS: 36 patients underwent ESP, mean age 63 years (33 – 83), males – 23. Initial presentation was abdominal pain 16(44%), obstructive jaundice 13(36%), anorexia 4 (11%) and cholangitis in 3(8%) patients. Mean tumor diameter was 18mm (7 – 37). Complications - 2 bleeds (managed with APC), one delayed biliary stenosis, stones & cholangitis (underwent ERCP & stenting) and one fatal pancreatitis after follow- up biopsy.
Histopathology: adenocarcinoma – 20(56%), adenoma – 15(41%), NET – 1.Margin positive 7 (19.4%) – adenocarcinoma– 4 (20%), adenoma – 3 (20%). Mean follow up 13.6 months (1 – 58).
4 (11%) lost to follow up – 2 each in carcinoma and adenoma group.
On follow up in adenoma group – patients without recurrence at mean 12-month (3 – 36) were – 10(67%),recurrence – 3 (treated by APC), NET 3-month no recurrence. Adenocarcinoma group –8(40%) underwent surgery. Of the remaining 12, 7(58%) – no recurrence at mean 26-month (14 – 58) ,recurrence -2 , fatal pancreatitis-1, lost to follow up- 2.
CONCLUSION: ESP for ampullary tumors is effective and safe. It can be curative for most ampullary adenomas.ESP for localized adenocarcinoma may be potentially curative in > 50% patients and may obviate need for major surgery. Negative resection margin status may be a predictor of improved ESP outcomes.

P757 SAFETY AND EFFICACY OF DEXMEDETOMIDINE SEDATION FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

T. Imai[1,*], O. Inatomi[1], S. Bamba[1], Y. Mochizuki[2], H. Ban[1], M. Shioya[1], Y. Saito[2], A. Andoh[1], Y. Fujiyama[1]. [1]*Division of Gastroenterology,* [2]*Division of Endoscopy, Shiga University of Medical Science, otsu, Japan*

INTRODUCTION: Endoscopic retrograde cholangiopancreatography (ERCP) often requires deep sedation because it is an invasive procedure. Although

propofol and midazolam sedation have been widely used and accepted for ERCP, occasionally these agents cause respiratory depression. Dexmedetomidine, a highly selective α2-adrenoreceptor agonist with sedative activity and minimal effects on respiration, has recently been widely used for patients in the intensive care unit. However, its utility for endoscopic procedures remains unclear. In this study, we retrospectively investigated the safety and efficacy of dexmedetomidine sedation during ERCP.
AIMS&METHODS: Of the patients who underwent ERCP between January 2013 and May 2013, 20 cases were selected, excluding the elderly or the patients with reduced cardiac function. The patients were sedated with dexmedetomidine, intravenously infused at 3.0 μg/kg/h for 10 min and then continuously at 0.4 μg/kg/h. In addition, pentazocine and midazolam were administrated when further sedation was required as a result of restlessness or body movement. To evaluate patient consciousness, Bispectral Index monitoring and the Richmond Agitation-Sedation Scale (RASS) were used. During ERCP, the level of sedation between RASS-2 and RASS-3 was maintained. The examination completion rate and complication rate associated with sedation were evaluated.
RESULTS: In our patient cohort, the mean age was 63.7 years and the male-to-female ratio was 5:3. The mean examination time was 47 min. The mean dose of additional midazolam and pentazocine was 9 mg and 5 mg, respectively. The examination completion rate for each examination was 100%. In one case, a transient reduction in blood pressure was observed. There was no case that SpO_2 was 90% or less throughout the whole observation period.
CONCLUSION: In this study, we safely performed ERCP using dexmedetomidine combined with a small amount of other sedative agents. In conclusion, dexmedetomidine can be used as an alternative to conventional methods for deep sedation during ERCP.

P758 DIRECT PERORAL CHOLANGIOSCOPY IN A LARGE PROSPECTIVE COHORT ANLAYSIS

V. C. Meves[1,*], C. Ell[1], J. Pohl[1]. [1]*Dr. Horst-Schmidt-Kliniken Wiesbaden, Wiesbaden, Germany*

INTRODUCTION: Direct cholangioscopy (DC) with ultraslim endoscopes and freehand cannulation of the common bile duct (CBD) is a promising technique for evaluating and treating cholangiopathy. However, its safety and success rates are as yet unclear.
AIMS&METHODS: Evaluation of the overall success rates and adverse events with the procedure in a single center academic tertiary referral center. Prospective cohort study with 100 DC procedures in 84 patients with biliary disease were evaluated prospectively.
RESULTS: In 34 cases with small or medium-sized sphincterotomies, sphincteroplasty was performed with a 10-mm dilating balloon before DC. The intraductal area of interest was successfully accessed in 87% of the procedures. The intended interventions were successfully carried out in 81 cases (93.1%), but failed in six (6.9%). In patients without significant strictures, intrahepatic exploration of the bile ducts beyond the level of the bifurcation was feasible in only 10.8% of cases. The mean total procedure time was 38.6 $\pm$ 12.2 minutes. Adverse events occurred in 12 procedures (12%) and were managed conservatively.
CONCLUSION: DC is safe and allows direct high-resolution examination and a wide range of therapeutic options in the bile ducts in the majority of patients with biliary disease. However, the range of access is limited to the main bile duct, and suspected pathology restricted to the proximal intrahepatic ducts beyond the bifurcation is therefore not a good indication for DC.

P759 A MULTI-CENTER RETROSPECTIVE STUDY OF PHOTODYNAMIC THERAPY WITH POLYHEMATOPORPHYRIN FOR MALIGNANT BILIARY OBSTRUCTION: RESULTS OF 76 CONSECUTIVE APPLICATIONS

W. Dolak[1,*], B. Hellmich[2], M. Fleischer[3], I. Hinterberger[4], L. Booz[1], M. Wasilewski[2], B. Stadler[3], W. Plieschnegger[4], F. Siebert[4], P. Knoflach[3], M. Gschwantler[2], M. Trauner[1], A. Püspök[1], Austrian PDT study group. [1]*Gastroenterology and Hepatology, Medical University of Vienna,* [2]*Internal Medicine IV, Wilhelminenspital, Vienna,* [3]*Internal Medicine I, Klinikum Wels-Grieskirchen, Wels,* [4]*Internal Medicine, Barmherzige Brüder St. Veit an der Glan, St. Veit an der Glan, Austria*

INTRODUCTION: Photodynamic therapy (PDT) is a treatment modality for malignant biliary obstruction.
AIMS&METHODS: The aim of the present study was to retrospectively analyze the experience with PDT using polyhematoporphyrin as a photosensitizer at different Austrian referral centers for biliary endoscopy. At the participating institutions charts of PDT patients were screened for their underlying diseases, anti-tumor co-therapies, interventional complications, adverse events within 30 days post PDT and follow-up.
RESULTS: 47 patients (34 male, 13 female, median age 70 years, range 46 to 86 years) underwent a total of 76 PDT applications at 4 referral centers in Austria. Polyhematoporphyrin was used as a photosensitizer in all cases (2mg/kg body weight). The underlying conditions included 41 Klatskin tumors, 4 cases of metastatic colorectal cancer (mCRC) and 2 cases of distal cholangiocarcinoma (CCa). Prior tumor treatment included chemotherapy in 12 cases, liver surgery in 5 cases, radiofrequency ablation in 2 cases and 1 case each of external radiotherapy, ethanol instillation and selective internal radiotherapy. PDT could be performed without any complication in all patients. Within 30 days after PDT the following adverse events were recorded: 13 cases of cholangitis, 2 cases of E. coli sepsis and 1 case each of non-ST-elevated myocardial infarction, transfusion dependent anemia, Clostridium difficile colitis and acute renal failure. 30-day and 90-day mortality (referring to the first PDT procedure) were 2% and 12%, respectively. The median survival after PDT was 15.1 months (95% CI 11.6 - 18.5 months).
CONCLUSION: PDT using polyhematoporphyrin as a photosensitizer proved to be feasible and safe in this retrospective study. The number of adverse events within 30 days after PDT (including the rate of cholangitis), mortality rates and survival time were comparable to previous publications on PDT with different photosensitizers. PDT seems to be a valuable therapeutic option for patients suffering from malignant biliary obstruction.

P760 WHAT IS THE BEST DIRECTION FOR USES OF THE NEW HISTOLOGY NEEDLE WITH REVERSE SIDE-BEVEL (ECHOTIP® PROCORE™) FOR EUS-GUIDED FINE NEEDLE BIOPSY? : AN EXPERIMENTAL STUDY.

A. Yamabe[1,*], A. Irisawa[1], G. Shibukawa[1], Y. Abe[1], A. Nikaido[1], K. Imbe[1], K. Hoshi[1]. [1]*Gastroenterology, Fukushima Medical University Aizu Medical Center, Aizuwakamatsu, Japan*

INTRODUCTION: Recently, ProCore as the EUS-guided histology needle was developed and widely used. The theoretical advantages of ProCore are 1) "core trap" within the needle which holds the core specimen, 2) "reverse side-bevel" which serves to cut the specimen, allow scraping away the tissue into the bevel and to gain a core tissue on withdrawal. In this regard, it is considered movement of the needle with whipping back may be able to obtain more tissue than movement at natural speed. In addition, the slow-pull technique which is performed with simultaneous minimal negative pressure provided by pulling the stylet slowly and continuously is recommended. Nevertheless, tissue yield with the ProCore is not consistent and no standard technique has been established.
AIMS&METHODS: The aim of this study is to determine what is the best direction for uses of the ProCore in experimental study. We performed fine-needle biopsy (FNB) with 22G ProCore for fresh chicken tenderloin and liver. Six techniques with moving back and forth 10 times of the needle per pass were evaluated: 1) needling with natural speed; without suction, with slow-pull technique, with 10ml suction, 2) needling with whipping back; without suction, with slow-pull, with 10ml suction. To perform whipping back, we made a handmade device attached stopper. The obtained tissue were entirely expressed onto a charta by reinsertion of the stylet, and measured total weight by electronic balance. In addition, the materials were evaluated whether a visible core for histology was obtained or not.
RESULTS: At FNB for tenderloin, the weight of obtaining tissue using natural speed technique was 0.36±0.07 (mean±SD, mg) in no suction group, 0.78±0.19 in slow-pull group, 2.59±0.68 in 10ml suction group, respectively. In using whipping back technique, the weight was 0.24±0.20 in no suction group, 0.44±0.22 in slow-pull group, 1.97±0.70 in 10ml suction group, respectively. At FNB for liver, in order of the above, 1.12±0.98, 5.2±2.13, 18.52±4.28, 2.2±0.82, 7.22±1.36, 16.98±3.74, respectively. In either target, many specimens were obtained with higher negative pressure, at any techniques ($P<0.001$). Moreover, visible core samples were constantly obtained in the groups with negative pressure.
CONCLUSION: Our experimental study indicates that EUS-FNB using ProCore should be performed with negative pressure (at least 10ml) in any needling techniques. Although ProCore has the reverse side-bevel, it is difficult to mention this mechanism was workable.

P761 ENDOSCOPIC ULTRASONOGRAPHY GUIDED-GALLBLADDER STENTING FOR PATIENTS SUFFERING FROM ACUTE CHOLECYSTITIS OR THOSE WITH LONG-TERM CHOLECYSTOSOTMY

A. Y. B. Teoh[1,*], P. W. Chiu[1], R. S. Tang[2], C. C. Chong[1], E. K. Ng[1], F. K. Chan[2], J. Y. Lau[1]. [1]*Surgery,* [2]*Medicine and Therapeutics, Chinese University of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: Acute cholecystitis is traditionally managed by cholecystectomy. The uses of endoscopic methods to treat the condition have been described but did not gain popularity. Recently, a lumen apposing stent (AXIOS, Xlumena, CA, USA) designed for EUS guided-transmural gallbladder stenting (EUS-GBS) has become available. In this study, we present our experience of performing EUS-GBS for patients suffering from acute cholecystitis or on long-term percutaneous cholecystostomies.
AIMS&METHODS: All patients admitted to the Prince of Wales Hospital with a diagnosis of acute cholecystitis who were unfit for surgery and those who were

on long-term cholecystomies were recruited. EUS-GBS was performed with a linear array echoendoscope (GF-UCT180 Olympus, Japan). The gallbladder was punctured from the dudoenum or antrum. After initial puncture, the track was then dilated with a 8.5 Fr cystotome or 6Fr needle knife and a biliary balloon. The AXIOS stent was then inserted and deployed under EUS and endoscopic guidance. Follow-up cholecystoscopy was performed 3 months after the procedure. The stent was then removed if cholecystoscopy showed no residue stones. Outcomes measurements included technical and clinical success rates, morbidities, mortalities and recurrent biliary events.
RESULTS: Between June 2012 to April 2013, 10 patients were recruited to the study. The mean (S.D.) age of the patients was 82.5 (7.23) years old. 7 patients suffered from acute cholecystitis and 3 were on long-term percutaneous cholecystostomies. 7 patients were of American society of Anaesthesiology grading 3 and 3 patients were grade 4. The mean (S.D.) temperature and white cell counts of patients who suffered from acute cholecystitis on admission were 38.44 (1.11) degrees Celsius and 22.5 (10.3) x 10^9/L. Technical success and clinical success was achieved on all patients. An additional covered metallic stent was required in 2 patients. The mean (S.D.) procedural time was 35.5 (11.4) minutes. Procedural complications occurred in 3 patients, 2 with mal-positioning of the stent and 1 with pneumoperitoneum. Follow-up cholecystoscopy was performed in 5 patients and 1 patient had residue stones that required laser lithotripsy. 2 patients suffered from common bile duct stones after removal of the stent.
CONCLUSION: EUS guided-gallbladdder stenting and intervetions were feasible with the lumen apposing stent. It is a technically demanding procedure requiring dedicated instruments. However, it is a promising technique for treatment of acute cholecystitis and gallstones with acceptable morbidities.

P762 COMPARATIVE STUDY IN 100 CASES BY AN EXPERT USING 22G STANDARD AND FENESTRATED ASPIRATION NEEDLES, IN ENDOSCOPIC ULTRASOUND-GUIDED BIOPSY OF SOILD PANCREATIC LESIONS.

A. Alatawi[1], F. Beuvon[2], S. LEBLANC[1], S. CHAUSSADE[1], B. TERRIS[2], F. PRAT[1,*]. [1]*gastroentrology,* [2]*histopathology, AP-HP Cochin hospital, Paris, France*

INTRODUCTION: Endoscopic ultrasound-guided fine-needle aspiration(EUS-FNA) using standard needles (SN) has proven to be of high diagnostic value in the evaluation of solid pancreatic masses (SPM), Fenestrated needles (FN) have been promoted to improve the histopathological quality of the EUS-FNA.
AIMS&METHODS: To compare the histological quality and diagnostic yield in FN versus SN.Over a 2y period,we included patients with SPM > 2cm in size,EUS-FNA performed by the same senior endoscopist by a 22 Gauge needles either SN or Procore® FN by aspiration method while using an EUS GF-UCT140 scope(Olympus, Japan).Each needle pass was treated by a independent histopathologist (blinded to the type of needle used).We developed a quality scale to evaluate the histopathological contents of each slide following a 4 category grading levels,(A)absent 0%,(B)Minimal surface area/slide(SA/S)< 25%,(C)Moderate SA/S< 25%>50%,(D)Significant SA/S>50%,these grades were applied to evaluate the contents of(blood, digestive contamination,normal pancreatic tissue,necrotic tissue and tumoral tissue),the cellularity load was evaluated by number of cells/SA(fair<100,good 100to1000,excellent >1000),presence of biopsy microframents(number and size),the diagnostic yield(definite group(begnin or malignant),suspect group (atypical, suspicous,normal tissue),group non-adequate for reporting(NAR)for lacking of histopathological content),patient clinical data and exam related complications were registered.
RESULTS: 100 patients,(SN 50%,FN 50%),males(63%),females(37%),median age(68,4 years +/- 12,5y SD).Median lesion size (32mm+/-4,6mm SD),location (head72%,body18%,tail10%), the median N° of needle passes (SN=3,FN=2), for SN content:blood (A=12%,B=56%,C=26%, D=6%), tumoral tissue (A=14%, B=64%, C=20%, D=2%), N° of cells/SA (fair 10%,good 36%, excellent 54%), 34microfragments present in 46% of slides with a median size of 0.6mm +/- 0.5 SD, diagnostic yield is 90%(definite in 84%,suspect in 6%)and 10%was NAR.For theFN 1stpass, blood content (A=2%, B=44%, C=36%, D=18%),tumoral tissue (A=18%, B=48%, C=22%, D=12%), N° of cells/SA (fair 4%, good 28%, excellent 68%), 76 microfragments present in 60% of slides with a median size of 0.96mm+/-0.7SD,diagnostic yield is 94%(definite 68%,suspect 26%) and 6% was NAR.Global diagnostic yield for FN needle(-median N° of passes of 2)is 98%(definite 88%, suspect 10%) and 2% was NAR.
CONCLUSION: As compared to SN, FN shows improved histopathological quality grades of obtained material in EUS-FNA but with a relatively similar diagnostic yield in the first pass, nevertheless the global outcome of FN passes seems superior to that of SN.

P763 ROLE OF ENDOSCOPIC ULTRASOUND (EUS) IN CHILDREN: A LARGE SINGLE CENTRE EXPERIENCE

J. Agarwal[1,*], S. Lakhtakia[1], R. Gupta[1], M. Ramchandani[1], K. Rakesh[1], D. Santosh[1], G. V. Rao[1], D. N. Reddy[1]. [1]*Asian Institute of Gastroenterology, Hyderabad, India*

INTRODUCTION: Experience in the use of endoscopic ultrasonography (EUS) in children is limited. The aim of this study was to determine its feasibility and efficacy in children at a tertiary care gastroenterology referral centre in India.
AIMS&METHODS: Consecutive patients aged ≤ 18 years who underwent EUS from January 2009 to December 2012 were retrospectively identified through a computer database search. EUS was done using radial GF-UCT160 or curvilinear GF-UCT140 echoendoscopes.Indications, findings, interventions and complications of the procedures in these patients were recorded.
RESULTS: A total of 350 EUS procedures were performed in 347 children (246 males, mean age 14.9 ± 2.6 years); of which 44(12.6%) cases underwent EUS guided interventions .The main indications for EUS were recurrent acute pancreatitis in 123 (35.4 %), chronic pancreatitis(CP) in 100 (28.8%), select cases of acute pancreatitis in 36(10.4%), pancreatic pseudocyst in 26 (7.5%), abdominal pain of suspected pancreatobiliary origin in 22(6.4%), suspected biliary obstruction in 19(5.5%), mediastinal mass/lymph nodes in 13 (3.7%), pancreatic mass in 6 (1.7%), upper gastrointestinal submucosal lesion in 1 (0.3%), periampullary mass in 1(0.3%). Findings included CP in 90 (26%), indeterminate CP in 88(25%), pseudocyst in 37(10.6%), acute resolving pancreatitis in 40 (11.5%), lymph nodes (mediastinal -13, abdominal- 4)in 17(4.9 %) , normal in 21(6%), gall stones with normal common bile duct in 16 (4.6%), acute on chronic pancreatitis in 14(4%), acute peripancreatic fluid collection in 8(2.3%), necrotizing pancreatitis in 6 (1.7%).Uncommon EUS findings were choledochal cyst in 3(0.8%), biliary microlithiasis in 2 (0.5%), biliary hydatid cyst in 1(0.3%), insulinoma in 1(0.3%), pseudopapillary tumor of pancreas in 1 (0.3%), duodenal duplication cyst in 1(0.3%), and internal hernia in 1(0.3%).
EUS-guided pseudocyst drainage was performed in 20 (5.8%), fine needle aspiration in 16 (4.6%), celiac plexus block in 6 (1.7%), pancreatic duct (PD) puncture and stenting in 2 (0.6%) cases. In all patients anesthesiologist administered ketamine with midazolam (50:1) for induction, followed by propofol for maintenance .The procedure was successful in all patients. Post procedure mild abdominal pain was encountered in 2 patients who had undergone intervention.
CONCLUSION: EUS and EUS guided interventions in children are feasible and safe. Procedure is well tolerated under propofol sedation when given by anaesthetist.

P764 DIAGNOSTIC ACCURACY OF CT, DW-MRI AND EUS IN RESECTABLE GASTRIC TUMORS: A RETROSPECTIVE STUDY

M. C. Petrone[1,*], C. Franzini[2], P. A. Testoni[1], P. G. Arcidiacono[1]. [1]*Vita-Salute San Raffaele University, Scientific Institute San Raffaele, Milan,* [2]*Fidenza Hospital San Secondo, Fidenza, Italy*

INTRODUCTION: Assessment of the preoperative T-N staging is of pivotal importance for the therapeutic strategy in gastric cancer(GC). Until recently, computerized tomography (CT) has been the mainstay of preoperative staging for GC, but accuracy in T and N staging were often inadequate. Among multiple imaging tests for GC staging, endoscopic ultrasound (EUS) has emerged as the most accurate tool for pre therapeutic loco regional tumor staging, while there are few data regarding the new concept of diffusion-weighted magnetic resonance imaging (DW- MRI).
AIMS&METHODS: The aim was to assess the accuracy of EUS, CT and DW-MRI in the preoperative staging of GC, and the ability to correctly select patients for neoadjuvant therapy. Gold standard was histologic specimens. All patients who underwent preoperative clinical assessment of T/N stage with EUS, CT and DW-MRI and subsequent resection for GC between 2009 and 2011 were collected. Staging results from preoperative tools were compared with postoperative pathologic results. Main outcome parameter was the diagnostic value of different imaging techniques in distinguishing between early stage (T1/2N0) and locally advanced (T3/4 or any N+) in order to establish the accuracy of the preoperative work-up in selecting patients who may benefit from neoadjuvant therapy.
RESULTS: Sixty-six patients with GC underwent EUS, CT and DW-MRI followed by resection, including patients treated with preoperative chemotherapy (n=20). The overall T staging accuracy was 38.3% for EUS, 57.4% for CT and 40.6% for DW-MRI, whereas for N stage accuracy were respectively of 60%, 48% and 64.1%. Sensitivity of EUS in selection of advanced T stage patients (T3-4 vs T1-2) was better compared to CT and DW-MRI (86.2% vs 78.9% and 75% respectively). Patients with advanced tumors (T3-4/N+) were globally best selected by EUS (sensitivity: 89% EUS, 75% CT, 76% MRI). EUS under staged patients in 11% of cases, CT in 25%, DW-MRI in 24% of cases.
CONCLUSION: The concordance between EUS and pathologic results was lower than expected for individual T and N stages. Similar data are achieved by using the new DW-MRI. Conversely EUS achieved the best results in correctly select patients who may benefit from neoadiuvant therapy. EUS should be still adopted as routine procedure in preoperative work-up.

P765 THE ROLE OF ENDOSCOPIC ULTRASONOGRAPHY IN THE ETIOLOGICAL EVALUATION OF IDIOPATHIC ACUTE PANCREATITIS

M. L. Bianchi[1,*], L. De Luca[1], M. T. Fabi[1], S. Fiori[1], A. de Leone[1], D. Baroncini[1]. [1]*Gastroenterology and Digestive Endoscopy Unit, A.O. "Ospedali Riuniti Marche Nord" - San Salvatore Hospital, Pesaro, Italy*

INTRODUCTION: Historically, no cause was identified in 10-30% of cases of acute pancreatitis and these patients were often labelled as suffering from idiopathic acute pancreatitis (IAP). Endoscopic ultrasonography (EUS) may play a significant role in the diagnostic evaluation of these patients.

AIMS&METHODS: The aim of this study was to evaluate the use of EUS in determining a probable etiology where conventional radiologic methods had failed to identify the cause of acute pancreatitis. Between June 2009 and June 2012 268 patients (158 male, 110 female; age range 47-78, mean age 67.5 years) were admitted to the emergency room of our hospital for biochemically proven acute pancreatitis. All patients were evaluated by conventional radiologic methods (transabdominal ultrasound, computer tomography and/or magnetic resonance cholangiography). The patients with no etiology established were considered affected by IAP and underwent EUS (Olympus linear echoendoscope Gf Type Uc140p-Al5; Olympus Co., Ltd., Tokyo, Japan) at Gastroenterology and Endoscopy Unit of "Ospedali Riuniti Marche Nord", Pesaro – Italy.
RESULTS: In 42/268 (15.7%) patients without prior colecistectomy (18 male, 24 female; age range 57-79, mean age 67 years) no etiology was found by conventional radiologic methods and diagnosis of IAP was done. A definitive diagnosis by EUS was done in 34/42 patients (80.9%). Cholelithiasis or microlithiasis (small gallbladder stones 1 to 5 mm) was identified in 24/42 patients (57.1%), choledocholithiasis (sludge and stones 2 to 4 mm) in 6/42 (14.3 %). All stones were confirmed by subsequent ERCP or cholecystectomy. 4/42 (9.5.%) patients were found to have chronic pancreatitis and in the remaining 8/42 (19%) patients no etiology was identified.
CONCLUSION: EUS provided additional diagnostic information in a large number of patients classified as having IAP by conventional radiologic examinations. In this study patients with IAP were reduced from 42/268 (15.7%) to 8/268 (3%) after EUS was done. Early identification of a biliary cause of acute pancreatitis, and early treatment, reduce the risk of recurrent pancreatitis, morbidity and mortality. EUS should be performed as first-line investigation in patients with acute pancreatitis especially when a biliary etiology is suspected.

P766 EUS IN PANCREATIC CANCER STAGING - A SINGLE CENTER PROSPECTIVE STUDY

M. Kliment[1,2,*], O. Urban[1,2], P. Falt[1,2], M. Lovecek[3], M. Straka[4].
[1]Gastroenterology, AGEL Research and Training Institute – Ostrava-Vítkovice Branch, Hospital Vitkovice, [2]Medical Faculty University of Ostrava, Ostrava, [3]Surgery, University Hospital, Olomouc, [4]Surgery, J.G.Mendel Oncology Center, Novy Jicin, Czech Republic

INTRODUCTION: Accurate preoperative staging of pancreatic cancer is important for proper treatment selection. EUS is considered an accurate tool in preoperative staging.
AIMS&METHODS: The aim of this prospective study was to evaluate the accuracy of preoperative EUS T- and N-staging of pancreatic cancer. Patients with histologically confirmed pancreatic carcinoma, that underwent preoperative EUS staging followed by surgery, were included in the study. The accuracy of EUS T-staging was evaluated by the comparison of EUS with final (histopathological or peroperative) T-staging and was calculated as a ratio of patients with agreement between EUS and final T-staging and total number of patients. Accuracy of all as well as each T-stage of pancreatic cancer were calculated. EUS-nodal staging was based on EUS image only. Two of four EUS signs of malignant lymph node involvement were necessary for an EUS diagnosis of malignant LN, with one beeing short axis diameter of≥10 mm. EUS and histopathological staging of LN were compared and accuracy of EUS N-staging was calculated.
RESULTS: A total of 87 patients (male: 62,1%, mean age±SD: 61,6±8,7 years) with pancreatic carcinoma, that underwent either surgical resection with histopathological staging (n=50) or exploration/paliative surgery with peroperative staging (n=37) were analysed. In the majority (76/87; 87,4%) of patients pancreatic carcinoma was localised within the head. In the wole study group, the agreement between EUS and final T-staging was 52,9% (46/87) with understaging occuring in 39,1% (34/87) and overstaging in 8% (7/87) of patients. The lowest agreement was in the T4- (6/22; 27%) and T3- (18/34; 52,9%) stage carcinoma groups, where understaging occured in 73% (16/22) and 47,1% (16/34), respectively. EUS-N-staging was analysed in 64 patients with the accuracy of 73,4% (47/64). EUS N-staging was false-negative in 11% (7/64) and false-positive in 15,6% (10/64) patients.
CONCLUSION: The overall accuracy of EUS T-staging of pancreatic cancer is inacceptably low, caused mostly by understaging of T4- and T3 pancreatic cancer. Therefore, a combination of EUS and CT/MRI is recommended in preoperative T-staging. EUS without FNA evaluates correctly 3/4 of lymph nodes in patients with pancreatic cancer.

P767 THE PROTOTYPE LONGER MINIATURE ULTRASOUND MINIPROBE "UM-3Y" DURING SINGLE-BALLOON ENTEROSCOPY (SBE) IN NEOPLASTIC LESIONS OF SMALL BOWEL

R. Cannizzaro[1,*], E. Orzes[1], S. Maiero[1], M. Tabuso[1], M. Fornasarig[1]. *[1]SOC Gastroenterology, CENTRO RIFERIMENTO ONCOLOGICO, Aviano, Italy*

INTRODUCTION: Single-balloon enteroscopy (SBE) is an endoscopic procedure useful for investigating patients suspected for having tumours, inflammatory bowel diseases or bleeding of small bowel with an anterograde or retrograde approach. The evaluation of neoplastic lesions of small bowel by an ultrasound miniprobe can be useful in spite of the difficulty to have a histological definition of these lesions.
AIMS&METHODS: The aim of the study was to evaluate the prototype longer ultrasound miniprobe UM-3Y (Olympus, Tokyo, Japan) in submucosal lesions of small bowel during SBE.
Between 2010 and 2012 we investigated a total of 15 patients (mean age 60), 6 males and 9 females for anaemia, radiological suspect of small bowel tumour, diarrhea and follow-up small bowel cancer. All patients after a negative esophagogastroduodenoscopy and colonoscopy underwent to capsule enteroscopy that showed a lesion of the small bowel. All patients underwent to SBE. For every patient histological samples were collected. During SBE a prototype longer miniature ultrasound miniprobe UM-3Y which incorporated a radial scanning system with a frequency of 20MHz was used, this was connected to an endoscopic ultrasonic observation unit (EU-M30; Olympus, Tokyo, Japan). The prototype has a length of 2700 mm and diameter 2.5 mm. After endoscopic examination of the small bowel and lesion detection with SBE, we inflated the overtube balloon to fix the endoscope in place and performed EUS-SBE.
RESULTS: In all cases we were able to insert EUS probe through the enteroscope channel and finally obtain a clear ultrasound image. In 2 of 3 patients the initial endoscopic diagnosis was a suspicion of submucosal mass and it has been characterized as neuroendocrine tumours by EUS-SBE and histology, in 2 of 2 patients adenocarcinoma was confirmed and in 2 patients we found respectively a GIST and a lymphoma. In the other cases ultrasonography allowed us to characterize duodenal cysts, an aggressive fibromatosis, an adenoma of the papilla of Vater and a jejunoileitis in this case excluding a lymphoma, in the other 4 cases EUS-SBE showed normal wall.
CONCLUSION: Endoscopic ultrasound with miniprobe UM-3Y is an important diagnostic tool for investigating with high accuracy small bowel lesions.

P768 LONG-TERM OUTCOMES FOLLOWING ENDOSCOPIC ULTRASOUND-GUIDED CELIAC PLEXUS NEUROLYSIS

S. Doi[1,*], I. Yasuda[1], M. Mabuchi[1], S. Uemura[1], T. Iwashita[1], M. Nakashima[2], T. Mukai[2], E. Tomita[2], H. Moriwaki[1]. *[1]First Dept. of Internal Medicine, Gifu University, [2]Dept. of Gastroenterology, Gifu Municipal Hospital, Gifu, Japan*

INTRODUCTION: Endoscopic ultrasound-guided celiac plexus neurolysis (EUS-CPN) is reportedly a safe and effective method for alleviating pancreatic cancer-related pain. However, previous studies have primarily reported only the short-term outcomes of this treatment.
AIMS&METHODS: To evaluate the long-term outcomes following EUS-CPN, we retrospectively reviewed patients who underwent EUS-CPN for alleviating pancreatic cancer-related pain between July 2003 and July 2012. The EUS-CPN described in the present study included both conventional EUS-CPN as well as EUS-celiac ganglia neurolysis (EUS-CGN). Only patients who were followed-up until death were included in the analysis. Pain was evaluated using the visual analog scale (VAS), and the initial evaluation was performed 7 days after the EUS-CPN. Patients who exhibited a reduction in the VAS score to ≤3 were considered to show an effective response, whereas those who exhibited a reduction in the VAS score to ≤1 were considered to show a complete response. The duration of the EUS-CPN effect was defined as the duration between which EUS-CPN was performed and the time at which a narcotic agent was first administered or its dosage was increased since EUS-CPN. Univariate and multivariate analyses of the prognostic factors associated with the long-term effects of EUS-CPN until death were performed.
RESULTS: We evaluated 133 patients who underwent EUS-CPN (only conventional EUS-CPN, 73 patients; only EUS-CGN, 44 patients; both conventional EUS-CPN and EUS-CGN, 16 patients) for pancreatic cancer-related pain. The effective response and complete response rate at the initial evaluation was 69% and 36%, respectively. The median (95% CI) duration of the effect was 61.0 (36.6–85.3) days. We found that the statistically significant prognostic factors of the long-term effect of EUS-CPN until death included a reduction in the VAS score by ≥4 at the initial evaluation, complete pain relief (VAS score of ≤1 at the initial evaluation), bilateral distribution of ethanol, and relatively short duration of pain prior to EUS-CPN (≤120 days); the hazard ratio (95% CI) of these factors were 2.0 (1.2–3.2), 1.9 (1.2–3.1), 2.8 (1.8–4.4), and 2.8 (1.7–4.5), respectively. The difference of CGN or CPN did not affect the long-term outcomes.
CONCLUSION: Our findings indicate that the treatment effect of EUS-CPN may last longer in patients who exhibited a better response at the initial evaluation. Moreover, we believe that EUS-CPN should be performed at an earlier stage for the appropriate management of pancreatic cancer-related pain.

P769 ENDOSCOPIC ULTRASOUND-GUIDED CHOLECYSTOSTOMY FOR ACUTE CHOLECYSTITIS IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION

T.-H. Kim[1,*], Y. W. Sohn[2]. *[1]Internal Medicine, Wonkwang University hospital , Iksan, [2]Internal Medicine, Wonkwang University hospital , Sanbon, Korea, Republic Of*

INTRODUCTION: Although early laparoscopic cholecystectomy is the treatment of choice for patients with acute cholecystitis, percutaneous cholecystostomy has been performed in patients unsuitable for cholecystectomy. EUS-guided transgastric/transduodenal gallbladder drainage by using a plastic stent or covered self-expandable metal stent (SEMS) may be an alternative effective treatment for these patients
AIMS&METHODS: To evaluate the technical feasibility and safety of EUS-guided transgastric/transduodenal gallbladder drainage with single-step placement of a pigtailed plastic stent or a fully covered SEMS in patients with acute cholecystitis who are unsuitable for cholecystectomy. This study involved 15 patients with acute cholecystitis who did not respond to initial medical treatment and were unsuitable for cholecystectomy. EUS-guided transgastric/

transduodenal gallbladder drainage with single-step placement of a pigtailed plastic stent or a fully covered SEMS.
RESULTS: EUS-guided gallbladder drainage (pigtailed plastic stents =7, SEMS = 8) were successfully placed in all patients through the stomach (n= 3) or duodenum (n= 12). Fourteen patients among 15 patients achieved functional success within 3 days of stent placement. Bile leakage occurred in 2 patients and pneumoperitoneum occurred in 3 patients during or after the procedure, but all patients improved with conservative management. During follow-up (median 124 days, range 30-250 days), one patient experienced recurrent cholecystitis.
CONCLUSION: Placement of pigtailed plastic stent and fully covered SEMS after EUS-guided transgastric/transduodenal gallbladder drainage may be a feasible and safe alternative to treatments such as percutaneous cholecystostomy in patients with acute cholecystitis.

P770 A RETROSPECTIVE COMPARATIVE STUDY OF SLOW PULL VS. SUCTION TECHNIQUE IN ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION OF PANCREATIC SOLID LESIONS

Y. Nakai[1], H. Isayama[1], N. Yamamoto[1], T. Hamada[1], N. Takahara[1], R. Uchino[1], S. Mizuno[1], K. Miyabayashi[1], K. Yamamoto[1], D. Mohri[1], K. Kawakubo[1], **H. Kogure**[1,*], T. Sasaki[1], K. Hirano[1], M. Tada[1], K. Koike[1]. [1]*Gastroenterology, The University of Tokyo, Tokyo, Japan*

INTRODUCTION: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) of pancreatic masses is an established procedure to obtain a pahthological diagnosis. However, the application of suction during EUS-FNA is still controversial due to increased blood contamination and the efficacy of slow pull technique, 10 to 20 to-and-fro movements with simultaneous minimal negative pressure provided by pulling the needle stylet slowly and continuously, was recently reported in new core biopsy needles. However, the efficacy of slow pull technique in EUS-FNA using a regular needle has not been fully elucidated.
AIMS&METHODS: Patients who underwent EUS-FNA for pancreatic solid lesions were retrospectively studied to compare suction and slow pull techniques using regular EUS-FNA needles. Primary endpoint was the diagnostic yield of malignancy. Secondary endpoints were cellularity and blood contamination on cytologic specimen. Subgroup analyses were performed based on the needle size (22- and 25- gauge). In addition, a multivariate logistic regression analysis for sensitivity of malignancy was performed, using tumor size (<25 mm vs. ≥ 25 mm), needle size (22- vs. 25- gauge), tumor location (head vs. body/tail) and FNA technique (suction vs. slow pull) as potential predictive factors.
RESULTS: A total of 389 passes (190 by suction and 199 slow pull technique) were performed during 103 EUS-FNA procedures in 98 patients with pancreatic solid lesions. Slow pull technique showed lower scores in cellularity (≥ 2 in 39.0% vs. 76.7%) but blood contamination scores were lower (≥ 2 in 27.1% vs. 66.7%) and sensitivity to diagnose malignancy was higher (90.6% vs. 67.9%) when a 25-gauge FNA needle was used. No significant differences were seen between two techniques when a 22-gauge needle was used. In a multivariate analysis of 86 cases with malignancy, slow pull technique (odds ratio [OR] 1.80, $p = 0.037$) as well as tumor size ≥ 25 mm (OR 3.70, $p < 0.001$) and tumor location in the body or tail (OR 2.82, $p < 0.001$) were associated with higher sensitivity.
CONCLUSION: Slow pull technique was associated with less blood contamination and can potentially increase the diagnostic yield compared with suction technique in EUS-FNA of pancreatic solid masses, especially with a 25-gauge FNA needle.

P771 THE BENEFITS OF THE COMBINED USE OF THE VIDEOCAPSULE AND BALLOON-ASSISTED ENTEROSCOPY IN PATIENTS WITH SUSPECTED SMALL BOWEL DISEASES

E. Ivanova[1,*], E. Fedorov[1], E. Polukhina[1], D. Seleznev[1]. [1]*Endoscopy, MOSCOW UNIVERSITY HOSPITAL №31, Moscow, Russian Federation*

INTRODUCTION: Both videocapsule endoscopy (VCE) and balloon-assisted enteroscopy (BAE) have their own specific limitations.
AIMS&METHODS: The aim: to estimate the benefits of combined use of CE and BAE. From 14.02.2007 to 30.04.2013 VCE followed by BAE were performed in 73 pts. (m-33, f-40, mean age 54,3±13,7 yrs., range 17-89) with suspected small bowel diseases. Obscure GI bleeding was an indication for VCE in 40 (54,8%) cases. The insertion route for BAE was determined according to the site of the suspected lesions detected by VCE.
RESULTS: In 8 (10,9%) pts. without a definite lesion on VCE there were no any abnormalities found by the BAE as well. In 1 (1,4%) case VCE revealed a cavernous haemangioma in the caecum missed by 2 prior colonoscopies. Small bowel lesions were suspected on VCE in 64 (87,7%) pts.: tumors in 32 (43,8%) pts.; enteritis in 20 (27,4%); vascular lesions in 12(16,4%).

Defined small bowel lesions	CE findings (pts.)	Insertion route for BAE (pts.)	BAE findings (pts.)	Biopsy taken (pts.)	Final diagnosis (pts.)	Treatment modality (pts.)
Tumors	32	Per os 22 Per rect. 4 Both 6	18	8	20	Endo 7 Surgery 11
Enteritis (incl. erosions and ulcers)	20	Per os 6 Per rect. 6 Both 8	20	16	20	Endo 2 Surgery 4
Vascular lesions	12	Per os 8 Per rect. 2 Both 2	11	1	7	Endo 9 Surgery 1
Total	**64**	**Per os 36 Per rect. 12 Both 16**	**49**	**25**	**48**	**Endo 18 Surgery 16**

The diagnosis was confirmed by BAE in 49 (75,4%) from 64 pts. Tumors were confirmed in 56,3% (18/32) pts. plus in 2 pts. with negative BAE we've performed laparoscopy and revealed tumors with extraorganic growth; inflammation and ulcerations - in 100,0% (20/20), however 1 case detected as an ulcer turned to be Meckel's diverticulum; vascular lesions - in 91,7% (12/11). Conservative treatment has been applied in 31 (48,5%) cases. Endoscopic treatment was performed in 18 (28,1%) pts.: APC and clipping in 9 cases, polyps removal in 7; bougienage strictures in Crohn's disease in 2. There were 16 (25,0%) pts. who underwent surgery: for tumors (11), Crohn's disease with a stricture (1), angioectasia and ulcers with recurrent GI bleeding (3), Meckel's diverticulum (1). The sensitivity, specificity, positive predictive value and negative predictive value, diagnostic accuracy of combined VCE and BAE for small bowel lesions were 100%, 93,7%, 98,4%, 100% and 80, 3%, respectively.
CONCLUSION: VCE can provide useful information on the indications and selection of the route for BAE. BAE can provide conservative management in 76,6% pts. (incl. 28,1% endoscopic treatment). Combined use of VCE and BAE has a high effectiveness (80,6%) in the diagnosis and management of patients with small bowel diseases.

P772 DOUBLE-BALLOON ENTEROSOCOPY HAS HIGHER DIAGNOSTIC YIELD AND BETTER CLINICAL OUTCOMES IN PATIENTS WITH ACUTE OVERT-OGIB WITH SHORT-TERM FOLLOW-UP: COMPARED WITH CAPSULE ENDOSCOPY

Q. He[1], Y. on behalf of yes, Bai[1], F. C. on behalf of yes, Zhi[1,*], W. on behalf of yes, H. X. Gong[1], Z. M. Gu[1], J. Q. Xu[1], B. Cai[1], Jiang[1]. [1]*Department of Gastroenterology, Nanfang Hospital, Southern Medical University,, Guangzhou , China*

INTRODUCTION: Capsule endoscopy (CE) and double-balloon enteroscopy (DBE) have been reported to provide comparable diagnostic yields in patients with obscure gastrointestinal bleeding (OGIB). In addition, CE has been recommended as a first-line tool for investigation of patients with OGIB. However, few studies have directly compared the two modalities in patients with acute overt-OGIB. The current study was to compare the diagnostic yield of direct CE and DBE in patients with acute overt-OGIB and evaluate the outcomes of short-term follow-up.
AIMS&METHODS: Prospective study was conducted between June 2012 and December 2012. EGD and colonoscopy were tandem performed in patients with melena or hematochezia within 24hrs after registration. Tandem CE and DBE were performed within 2 weeks after non-diagnostic EGD and colonoscopy given CE retention. Initially, retrograde DBE route was selected based on consideration of difficulty in griping the intestine if antegrade DBE was firstly performed. The primary outcomes assessed were the diagnostic yields of the both tests. All patients received short-term follow-up, including assessment of rebleeding, readmission, further transfusion or interventions, and mortality.
RESULTS: A total of 39 patients were included (26 males; mean age: 38.87 years, range13-84years). DBE detected more lesions of bleeding than (35, 89.7%) than that of CE (28, 71.8%) (P=0.039), both CE and DBE detected bleeding in 27 patients. CE retention occurred in 4 patients and intestinal perforation occurred in 1 patient with MD diagnosed by DBE. Patients with positive findings received drug therapy or were submitted to surgical procedure (24 cases). Definite diagnosis was confirmed in 36 patients, including MD (11cases), Crohn's diseases(8 cases), Gastrointestinal mesenchymal tumors (4 cases), erosions (3 cases), multiple xanthoma (2 cases), multiple diverticulum (2 cases), ganglioneuroma (1case), single ulcer(1case), adenocarcinoma (1case), vascular abnormality(1case), intestinal duplication(1case), metastatic renal clear cell carcinoma(1 case). All the patients received a mean of 5.8 months follow-up (range 2.4-9.0 months) except one lost. 3 patients complained of slight rebleeding, respectively, and received medicine for hemostasis. Further transfusion or interventions and mortality were not reported.
CONCLUSION: For patients with acute overt-OGIB, DBE provides higher diagnostic yield than that of CE and better outcomes due to timely intervention. (**Chinese Clinical Trial Register** ChiCTR-DDT-12002465)

P773 DIAGNOSTIC CONCORDANCE BETWEEN BALLOON-ASSISTED ENTEROSCOPY, VIDEOCAPSULE ENDOSCOPY AND CROSS-SECTIONAL IMAGING MODALITIES IN THE EVALUATION OF SMALL BOWEL DISEASE

F. Vilas-Boas[1,*], M. Marques[1], H. Cardoso[1], A. Ribeiro[1], M. Velosa[1], A. Albuquerque[1], S. Rodrigues[1], G. Macedo[1]. [1]*Gastroenterology, HOSPITAL DE SÃO JOÃO - PORTO, Porto, Portugal*

INTRODUCTION: Capsule endoscopy (CE), ballon-assisted enteroscopy (BE) and cross-sectional imaging modalities (computed tomography (CT) and magnetic resonance (MR)) are used for the detection of small bowel disease. Many studies evaluate the diagnostic yield of these procedures, however there are few reports establishing the concordance between the different methods.
AIMS&METHODS: We performed a retrospective single-center study describing the diagnostic agreement between CE, BE and CT or RM imaging in the evaluation of small bowel disease. The level of diagnostic concordance was quantified with the Cohen's kappa coefficient.
RESULTS: Ninety-nine patients (49 female, mean age 52±18 years) were submitted to 111 BE (59% antegrade procedures), performed between January 2011 and January 2013. Biopsy specimens were obtained in 44% of the procedures and endoscopic therapy was held in 20 exams. Complication rate was 0.9%, without serious adverse events. Sixty patients had been recently (<3 months) evaluated with capsule endoscopy and 29 had had cross-sectional imaging modalities (24 CT; 5 MR). The entire small bowel was examined in CE and BE, in 82 and 5 percent of the cases, respectively. Globally, in patients submitted to CE and BE, there was diagnostic agreement in 61% of cases (Kappa=0.44 – moderate). Diagnostic concordance between BE and imaging modalities was fair (Kappa=0.39).
CONCLUSION: BE is a safe diagnostic and treatment modality in small-bowel disease. BE and CE had a moderate concordance in our series. The agreement with CT and MR, in a smaller sample, was fair.

P774 CO2-INSUFFLATION DURING SINGLE BALLOON-ENTEROSCOPY IMPROVES ORAL INTUBATION DEPTH IN PATIENTS WITH HISTORY OF ABDOMINAL SURGERY

L. Philipp[1,*], T. Meister[2], M. Manno[3], M. Pennazio[4], R. Conigliaro[3], S. Lebkücher[1], H. Ullerich[1], A. Schmedt[1], M. Floer[2], T. Beyna[1], F. Lenze[1], D. Domagk[1]. [1]*Department of Medicine B, University of Muenster, Muenster,* [2]*Department of Medicine II, Helios Albert-Schweitzer University Teaching Hospital Northeim , Northeim, Germany,* [3]*Gastroenterology and Digestive Endoscopy Unit, New S.Agostino-Estense Civil Hospital, Baggiovara di Modena (Mo),* [4]*Division of Gastroenterology 2, San Giovanni Battista University Teaching Hospital, Turin, Italy*

INTRODUCTION: The use of CO_2 as insufflation gas during endoscopic procedure has already shown advantages regarding procedure-related pain and discomfort compared to standard air-insufflation. Additionally, CO_2-insufflation leads to greater oral insertion depth during double-balloon enteroscopy. The aim of the present study was to examine whether CO_2-insufflation also leads to a reduction of abdominal pain in patients having undergone single-balloon enteroscopy (SBE) and facilitates a deeper insertion of the small bowel.
AIMS&METHODS: This study is a randomized, international multicenter trial comparing CO_2- vs. air-insufflation during SBE (ClinicalTrials.gov Identifier: NCT01524055). Patients were blinded with regard to the type of insufflation gas used. Patients' discomfort during and after the procedure were scored using a visual analogue scale.
RESULTS: 107 patients were enrolled in this study (52 in the CO_2 group and 55 in the air group). Sixty-two patients were examined via both routes, 36 only orally and 9 patients by anal approach only. In both groups, patients' characteristics were comparable (age, diagnosis, previous intestinal surgery, indication for endoscopy). The oral intubation depth was not significantly higher in the CO_2 vs. air group (254 ± 80 vs. 238 ± 55 cm, $P = 0.726$, mean ± SD). In patients with previous abdominal surgery, oral intubation depth was significantly higher in the CO_2-group compared with air (258 ± 84 vs. 192 ± 42 cm, $P < 0.05$). Via anal route, CO_2 showed no significant difference regarding intubation depth compared to standard air insufflation (86 ± 67 vs. 110 ± 68 cm, $P = 0.155$, mean ± SD). The diagnostic yield of balloon-assisted enteroscopy procedures was comparable and high for both groups (CO_2: 67 %, Air: 73 %). The procedure times and dosage of sedation did not differ between CO_2 versus air in both approaches.
Patients' pain and discomfort were significantly better in the CO_2 group at almost every questioned time point but reached only statistic significance at 1 hour after the anal examination ($P = 0.020$). No severe adverse events were observed in both groups.
CONCLUSION: This study underlines the advantage of CO_2 in balloon-assisted enteroscopy techniques, especially in patients with a history of previous abdominal surgery. The reduction of patient discomfort, especially in the anal approach, implies a general indication for the usage of CO_2 in balloon-assisted enteroscopy.

P775 SMALL BOWEL STRICTURE TREATMENT BY DOUBLE BALLOON ENTEROSCOPY AND REVIEW OF PUBLISHED STUDIES FOR STRICTURE DILATION WITH MODERN ENTEROSCOPY

M. Raithel[1,*], A. F. Hagel[1], A. Nägel[1], S. Raithel[1], M. F. Neurath[1], P. Konturek[2], J. Maiss[1]. [1]*Medicine 1, University Erlangen, Erlangen,* [2]*Medizinische Klinik, Thüringen Kliniken, Saalfeld, Germany*

INTRODUCTION: Small bowel strictures may be well reached by modern enteroscopy using DBE, single balloon- or spiral enteroscopy (SBE, SpE). This study reports our experience with enteroscopic stricture treatment in comparison to 9 published studies using modern enteroscopy techniques.
AIMS&METHODS: Stricture treatment was achieved after DBE identification of one or more strictures by balloon dilation, either through the scope or through the overtube, and by steroid injection into the stricture. These results from our center were compared to published results available from nine studies (n=169 pts).
RESULTS: From 30 pts with endoscopically identified small bowel strictures, DBE balloon dilation could achieve short term remission in 22/30 pts (73%), long term remission (>12 mo) in 17/30 pts (56%), while 7pts (23%) got re-dilatations and/or steroid injection, and 6pts (20%) were referred to surgery. 2/30 pts (6%) with malignant strictures experienced perforations.
In the 9 published studies similar results (median, 25-75%) were found with a short or long term remission rate of 80% (72-95) or 71.5% (64-74) and necessity for surgery in 27% (20-38%). However, major complication rate varied up to 9% for perforation, 5% for bleeding, 4% pancreatitis and 3% for sedation related adverse events.
CONCLUSION: Small bowel stricture dilation with modern enteroscopy was currently performed in approximately 200 pts, primarily with the DBE technique. With some caution because 5-yr follow up data are scarce, it appears to be an effective treatment modality for 70% of pts, while 20-38% have still to undergo surgery because of recurrence, complex strictures or inaccessibility of the stricture for the enteroscope.

P776 EFFICACY OF NARROW BAND IMAGING IN SINGLE BALLOON ENTEROSCOPY

N. Ogata[1,*], K. Ohtsuka[1], S. Hayashi[1], K. Kodama[1], H. Inoue[1], S.-E. Kudo[1]. [1]*Digestive Disease Center, SHOWA UNIVERSITY NORTHERN YOKOHAMA HOSPITAL, Yokohama, Japan*

INTRODUCTION: The current technique and technology of image-enhanced endoscopy (IEE) is available to augment the detection, diagnosis and treatment of gastrointestinal lesions. The IEE techniques are applied to enhance microvascular contour and improve resolution of surface patterns and color differences. The advent of balloon-assisted enteroscopy has enabled assessment and treatment of small intestinal lesions. One of the most common diseases indicated for balloon-assisted enteroscopy is obscure gastrointestinal bleeding (OGIB). However, sometimes it is difficult to differentiate small lesions, angioectasia or clot or abrasion mark made by contact. Narrow band imaging (NBI) shows surface vessels in the mucosa as brown and deeper as green. We reported that angioectasia shows dark green colored area -which is called 'dark green sign'- contrary to abrasion mark or clot showing brown by NBI.
AIMS&METHODS: In this study, we evaluated the usefulness of NBI in single-balloon enterscopy (SBE) for angioectasia in the small intestine.Between March 2008 and October 2012, endoscopic treatment of angioectasias in small intestine was performed in 23 cases by SBE. We divided the suspected lesions into two groups, lesions with dark green sign (DG) and brown colored lesions (B) and assessed the result and efficacy of differentiation for two groups.
RESULTS: In 23 cases, 119 small lesions were detected each lesion was observed with NBI. Of 119 lesions, 61 lesions (51.3%) were DG group, while 58 lesions (48.7%) were B group. We recognized the DG group lesions as angioectasia and treated by argonplasma coagulation or clipping. We left the lesions in B group. One case had recurrent bleeding from the same lesion. Two cases had 2nd SBE for another angioectasia. We followed patients for an average of 18.3 months, and the rest of the cases didn't need further treatment.
CONCLUSION: NBI in SBE was effective for the diagnosis of angioectasia in the small intestine. IEE such as NBI could be useful for diagnosis of small intestinal diseases.

P777 USEFULNESS OF SINGLE-BALLOON ENTEROSCOPY FOR TREATMENT OF THE STENOSIS IN SMALL INTESTINE

N. Ogata[1,*], K. Ohtsuka[1], S. Hayashi[1], K. Kodama[1], H. Inoue[1], S.-E. Kudo[1]. [1]*Digestive Disease Center, SHOWA UNIVERSITY NORTHERN YOKOHAMA HOSPITAL, Yokohama, Japan*

INTRODUCTION: Before the progress of balloon-assisted enteroscopy (BAE) and wireless capsule endoscopy, the stenoses of the small intestine were detected by CT or radiological enteroclysis. They were often difficult to diagnose, and surgery was selected for diagnostic therapy. BAE has enabled to make diagnosis and treat small intestinal lesions. We evaluated the efficacy of single-balloon enteroscopy (SBE) for treatment of small intestinal stenosis.
AIMS&METHODS: A total of 543 cases of SBE were performed between September 2005 and October 2012 at our center, and 60 stenotic cases of the small intestine detected by SBE were enrolled in the study. Stenosis was defined as difficulty in penetrating the enteroscope or sliding tube. Endoscopic balloon dilation (EBD) was performed to the suitable cases of benign stenosis. The indications of EBD were as follows: ①benign stenoses with the length being less than or equal to 5cm, ②strictures without deep ulcers, fistulas, or abscesses, and ③stenoses without sharp angle. Adopted cases were divided into two groups: 'CD' group with stenoses caused by Crohn's disesase, and 'non CD' group with benign stenoses caused by other factors. We assessed the first EBD success rate, restenotic rate, duration until restenosis, cumulative surgical free rate and occurrence of complications.
RESULTS: The causes of the stenosis cases included 21 Crohn's disease (CD, 47.7%), 4 postoperative stenosis (9.1%), 4 ischemic enteritis (9.1%), 6 adenocarcinoma (37.5%), 4 cases of invasion of small intestine from other carcinoma (25%), 6 malignant lymphoma (37.5%), 5 other cases (11.4%), and 10 cases of unknown etiology. Of the 60 cases, 19 were suitable for EBD therapy, and 10 cases were included in the 'CD' group while 9 cases (2 ischemic enteritis, 2 postsurgical stenoses, and 5 others) were in the 'non CD' group. The first EBD successful rate was 100% for each. Six of the 10 CD cases had restenosis, while restenosis occurred in one of nine non CD cases. The two groups had a significantly different restenotic rate ($P<0.05$). Duration until occurrence of restenosis was 11.5±4.5 months on average. The cumulative surgical free rate after EBD was 94.7% (18/19), and the observation period was almost 3 years. One case had a post-EBD bleeding, but perforation or other complications did not occur.
CONCLUSION: EBD was performed safely in most cases. The result suggests it is necessary to consider periodical SBE for stenotic lesions in the small intestine, especially in CD cases. There is a possibility that surgery can be avoided by doing EBD in cases of small intestinal stenoses.

P778 SEDATION TECHNIQUES AND SAFETY IN DOUBLE BALLOON ENDOSCOPY – EXPERIENCE FROM A DISTRICT GENERAL HOSPITAL

R. Bevan[1,*], C. Parker[1], S. Panter[1]. [1]*Gastroenterology, SOUTH TYNESIDE DISTRICT HOSPITAL, South Shields, United Kingdom*

INTRODUCTION: Double balloon enteroscopy (DBE) is now used widely to examine the small bowel, using an antegrade or retrograde approach. To maximise the comfort and acceptability levels of this procedure, deep sedation using propofol is increasingly being used (as opposed to conscious sedation with benzodiazepines). Despite guidelines existing in favour of the safe use of propofol[1] in endoscopic procedures, there are still concerns about safety. As a result, propofol sedation is not in common use.
We review the data from our site with regards to safety and indicators of quality of DBE procedure.
AIMS&METHODS: Retrospective review of all DBEs performed at South Tyneside District Hospital between January 2010 and March 2013. Information reviewed; route of procedure, depth of insertion, duration of procedure, sedation used, complications. In our centre, propofol sedation is performed in the endoscopy unit, with administration of propofol and monitoring of the patient by an anaesthetist.
RESULTS: 56 DBEs have been performed on 46 patients (26 male, 20 female, median age 49.5 years (range 16-83). 29 procedures were antegrade, 24 retrograde. 13 were performed under propofol sedation, 43 under midazolam conscious sedation. No serious complications have been recorded. Depth of insertion, and duration of procedure are shown in table 1. Results shown are in the format: median (range).
Table 1.

Route	Measurement	Propofol*	Midazolam†
Antegrade	Time (mins)	50 (40-80)	48 (30-110)
	Depth (cm)	200 (75-250)	200 (75-350)
Retrograde	Time (mins)	65 (48-80)	59 (10-90)
	Depth (cm)	145 (140-150)	87.5 (10-200)

*n=13. 13 had depth recorded, 12 had time recorded. †n=43. 38 had depth recorded, 30 had time recorded
CONCLUSION: We conclude that in our centre, DBE performed under propofol sedation is safe, and non-inferior compared to midazolam sedation in terms of procedure duration and depth of insertion. It may in fact be superior with regards to depth of insertion during retrograde procedures, but numbers are too small to draw a confident conclusion.

P779 A RETROSPECTIVE ANALYSIS OF PUSH ENTEROSCOPY IN A TEACHING HOSPITAL OVER 6 YEARS

S. S. Ansari[1,*], J. S. Jennings[1]. [1]*Department of Gastroenterology, Leeds Teaching Hospitals Trust, Leeds, United Kingdom*

INTRODUCTION:
Push enteroscopy (PE) is used for the evaluation of the proximal small bowel. The diagnostic yield in gastrointestinal (GI) bleeding varies considerably from 38-75%[1]. A previous study showed that 64% of responsible lesions identified on PE were in reach of a standard gastroscope[2].
AIMS&METHODS:
The aim of our study was to analyse the PE data from Leeds and to establish the diagnostic yield, rates of endoscopic intervention and the proportion of cases where pathology was in reach of a standard gastroscope.
A retrospective analysis was conducted of all push enteroscopies performed between January 2006 and December 2011 at Leeds Teaching Hospitals Trust (LTHT). A list of all cases of PE was generated using the ADAM endoscopy software. For each case, we recorded patient demographics, indication, endoscopic findings, endoscopic management and distance from the pylorus.
RESULTS:
Over the 6 year period, a total of 135 Push enteroscopies were performed (58% female; mean age 59 years; range 19-91). The main indications were GI blood loss (61%), abnormal small bowel imaging (22%), suspected coeliac disease (5%) and assessment of crohn's disease (4%). Blood loss was either occult, in 52 patients with iron-deficiency anaemia (39%), or overt, in 30 patients with haematemesis and/or melaena (22%).
Overall an abnormality was identified in 101 cases out of 135 (75%). The diagnostic yield in the group referred with overt or occult GI blood loss was 55%. Angioectasia was by far the commonest abnormality which was seen in 69% of these cases. An ulcer (gastric, duodenal or jejunal) was found in 13%. Miscellaneous findings included small bowel tumour (4%), large hiatus hernia (4%), oesophageal varix (<1%) and haemobilia (<1%). The mean distance beyond the pylorus was 62cm (range 15 to 150cm). Lesions were within reach of standard gastroscope in 28 of the 45 (62%) with GI blood loss.
Endoscopic treatment was performed in 27% and biopsies in 41%. Argon plasma coagulation (APC) was performed in all 31 angioectasia, endoscopic clips placed in 6, adrenaline injected in 2 and polypectomy performed in 1 case of Peutz-Jeghers syndrome. There were no significant complications.
CONCLUSION:
REFERENCES:
1. Linder J, Cheruvattath R, Truss C, Wilcox C. Diagnostic yield and clinical implications of pushenteroscopy: results from a nonspecialized center. J Clin Gastroenterol.2002;35(5):383-6
2. Zaman A, Katon R. Push enteroscopy for obscure gastrointestinal bleeding yields a high incidence of proximal lesions within reach of a standard endoscope. Gastrointest Endosc.1998;47(5):372-6
Gastrointestinal blood loss was the commonest indication to perform PE (61%). Significant pathology to account for the blood loss was found in 55%. Angioectasia was the commonest pathology accounting for 69% of abnormal findings. Lesions were in reach of a standard gastroscope in 62% of cases, emphasising the importance of a second look gastroscopy prior to performing PE.

P780 ENDOSCOPIC MUCOSAL RESECTION FOR JEJUNAL POLYPS USING DOUBLE-BALLOON ENTEROSCOPY (DBE)

M. Klaus[1], S. Peter[1,*], L. C. Fry[1], C. M. Wilcox[1]. [1]*University of Alabama at Birmingham, Birmingham, United States*

INTRODUCTION: Endoscopic mucosal resection (EMR) is now a well-accepted and practiced method for treating esophageal, gastric and colon polyps and early carcinomas. Because the small bowel is less accesible and has a thinner wall as compared to other luminal parts of the GI tract, the experience using EMR here is very limited. Indeed, there is only one case report describing EMR of the jejunum in the literature.
AIMS&METHODS: To evaluate the feasibility and utility of double balloon enteroscopy assisted mucosal resection (EMR) in patients with familial and non-familial jejunal polyps.

Thirty-eight patients with jejunal polyp(s) (FAP, n= 14, PJS, n= 10, sporadic adenomas, n= 3, inflammatory pseudopolyps, n=3, lipomas, n= 4) undergoing DBE-assisted resection of their lesions at the University of Magdeburg Medical Center, Marienhospital Bottrop adn University of Alabama at Brimingham, USA between June 2007 and January 2013 were included and their data recorded in a prospectively collected database. For this case study we only selected patients undergoing EMR (n=9). Patients undergoing standard polypectomy were excluded.Mucosectomy technique: Before resecting the jejunal polyp the mucosal pit pattern analysis was performed using high definition white light and chromoendoscopy methods (standard and virtual chromoendoscopy). All lesions were resected using previous submcuosal injection.

RESULTS: : Nine (9) patients underwent DBE assisted jejunal EMR. Median age of patients was 42 years (range 24-62 years), male:female ratio 1.5:1. DBE was done through the antegrade (i.e. oral) route in all patients. Four patients had FAP; three had Peuth-Jeghers syndrome, one had a sporadic adenoma and one had a bleeding jejunal polyp, which on histological examination turned out to be lipoma. 4/9 underwent piece-meal EMR. Post EMR or DBE complications including perforation, bleeding or pancreatitis were not observed in any of these patients.

CONCLUSION: This is the first and largest study so far presenting the technique, feasibility and outocmes of EMR of the small bowel. EMR of the jejunum is feasible and safe during DBE.

P781 CLINICOPATHOLOGIC FEATURES OF SMALL BOWEL OBSTRUCTION: COMPARISON BETWEEN FINDINGS OF DOUBLE-BALLOON ENDOSCOPY AND ABDOMINAL CT SCAN

S. Y. Kim[1,*], B. J. Lee[1], Y. A. Jung[1], S. H. Kim[1], J. W. Choe[1], M. K. Joo[1], J.-J. Park[1], J. S. Kim[1], Y.-T. Bak[1]. [1]*Gastroenterology, internal medicine, Korea university kuro hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Small bowel obstruction (SBO) is a commonly encountered pathologic condition and is caused by a variety of etiologies. In case of strangulated bowel, emergent surgery is required for the lifesaving without preoperative diagnosis of etiology. However, differentiating the etiologies of SBO is critical to proper management of patients and to improve clinical outcomes. Abdominal CT scan with various protocols is a useful tool in the initial diagnosis and assessment of patients with SBO and widely performed especially in the emergent condition. The recently developed balloon-assisted enteroscopy system provides the capability of the exact diagnosis of small bowel diseases including malignancy. So, we evaluate the clinicopathologic features of SBO with the comparison between findings of double-balloon enteroscopy (DBE) and abdominal CT scan.

AIMS&METHODS: We retrospectively analyzed 22 consecutive cases between January 2009 and November 2012 for investigation of SBO without bowel strangulation. Both DBE and Abdominal CT scan were performed to all patients to confirm SBO. Pathologic, DBE and abdominal CT findings were collected and analyzed.

RESULTS: Total 23 DBE were performed in 22 patients (14 male, 8 female; mean age 49±25.3yrs). Antergrade approach was done in 12 patients while retrograde and both approaches were performed in 6 and 4 cases respectively. Abnormal findings were detected at DBE in 18 cases (81.8%). The most common pathologic findings were small bowel tumors (11 cases, 50 %) such as lymphoma (5), metastatic cancer (2), Peutz-jegher polyp(2), lipomatosis (1) and GIST (1). Strictures were found at seven cases; Crohn's disease (3), NSAID induced stricture (3) and idiopathic (1). We analyzed DBE findings according to abdominal CT findings. Small-bowel intussusceptions on CT were found at seven cases (31.8%). Four cases (57.2%) were small- bowel tumors; lymphoma (2), lipoma (1) and Peutz-jegher polyp (1) and no abnormal findings at DBE had shown in three cases (42.8%). Appearances of eccentric long-segment of small bowel on CT were found at three cases. All cases were small bowel tumors; two cases were lymphoma and metastatic cancer was found in one case. Normal findings on CT were found in two cases of stricture (Crohn's diseases, lymphoma).

CONCLUSION: DBE is a valuable diagnostic method for detecting the etiologies of SBO without bowel strangulation. Preoperative diagnosis of SBO with DBE might be essential for decision and change the treatment modalities of the patients with SBO.

P782 INDICATIONS, DIAGNOSTIC YIELD, THERAPEUTIC IMPACTS AND COMPLICATIONS OF BALLOON-ASSISTED ENTEROSCOPY OVER THE FIRST DECADE OF ITS USE IN KOREA: RETROSPECTIVE MULTICENTER STUDY

S. N. Hong[1,*], D. K. Chang[1], E. R. Kim[1], S. R. Jeon[2], S. J. Park[3], B. D. Ye[4], H. J. Jang[5], J. P. Im[6], C. H. Choi[7], H. Choi[8], Small Intestine Research Group of the Korean Association for the Study of Intestinal Diseases (KASID). [1]*Internal medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine,* [2]*Internal medicine, Soonchunhyang University College of Medicine,* [3]*Internal medicine, Yonsei University College of Medicine,* [4]*Internal medicine, University of Ulsan College of Medicine, Seoul,* [5]*Internal medicine, Hallym University College of Medicine, Dongtan,* [6]*Internal medicine, Seoul National University College of Medicine,* [7]*Internal medicine, Chung-Ang University College of Medicine, Seoul,* [8]*Internal medicine, Catholic University of Korea College of Medicine, Incheon, Korea, Republic Of*

INTRODUCTION: Since double-balloon enteroscopy was introduced in 2004 in Korea, balloon-assisted enteroscopy (BAE) can be used to explore a large part of the small bowel. Over the past decade, the BAE has been performed for the diagnosis and management of patients with suspected and established small-bowel diseases. However, technical difficulty and reimbursement policy by insurance system can affect the selectivity for BAE. We performed a retrospective study to assess indications, diagnostic yield, therapeutic impacts and complications of BAE during last 9 years and investigate the changes of them between different time periods in Korea.

AIMS&METHODS: The Small Intestine Research Group of the KASID constructed the multicenter retrospective BAE registry and 9 centers registered a consecutive of 1108 BAE cases from initial case to latest case performed their hospital. The registry includes the indications, the enteroscopic finding, and clinical outcomes of BAE. To evaluate the changes of the practice pattern of BAE over time, we compared in indication, diagnostic yield, and complications of BAE divided by the early stage (period of initial half: Jan. 2004–Jul. 2008, n=543 procedures) and late stage (period of later half: Aug. 2008–Dec. 2012, n=565 procedures).

RESULTS: The most common indication of BAE was obscure GI bleeding (50.9%, 556/1108). BAE to assess unexplained GI symptoms was more common in early stage (18.8% vs. 9.7%), whereas BAE to confirm the abnormal finding of imaging modality was more common in late stage (9.4% vs. 18.8%, $p<.001$). The diagnostic yields of BAE was 77.3% (838/1084), which did not showed a significant difference between early and late stage (72.0% vs. 76.6%, p=.085). Therapeutic intervention was performed during 213 BAE procedures (22.8%). The BAE-associated complications were occurred in 1.1% (12/1108), which was decreased significantly in late stage compared to early stage (1.8% vs. 0.4%, p=.020).

CONCLUSION: BAE is safe and useful tool for the diagnosis and treatment for small-bowel pathology. Over the first decade of its use in Korea, the usage of BAE for the exploration of symptoms appears to be replaced by other image modalities and the complications associated BAE are decreased.

P783 EMERGENT SINGLE-BALLOON ENTEROSCOPY IN OVERT OBSCURE GASTROINTESTINAL BLEEDING - EFFICACY AND SAFETY

T. Pinto-Pais[1,*], R. Pinho[1], A. Rodrigues[1], C. Fernandes[1], I. Ribeiro[1], J. Fraga[1]. [1]*Gastroenterology Department, CENTRO HOSPITALAR GAIA ESPINHO, Gaia, Portugal*

INTRODUCTION: Endoscopic examination of the small bowel has dramatically improved with the advent of balloon-assisted enteroscopy (BAE) allowing both diagnostic and therapeutic procedures. There are few data concerning emergent BAE for Overt Obscure Gastrointestinal Bleeding (OGIB).

AIMS&METHODS: AIM: Evaluate the use of emergent BAE in active-overt OGIB and assess its impact on diagnosis and treatment. Furthermore, compare their effectiveness in active vs. inactive overt OGIB.

MATERIAL&METHOD: Retrospective analysis of all BAE performed for active-overt OGIB in our department. Demographics, clinical and endoscopic data were collected, as well as therapeutic procedures and complications. Single-balloon-enteroscopy (SBE) was used in all examinations. Emergent SBE was defined when performed for active-overt OGIB within a 24-hour period after confirmation of GI bleeding.

RESULTS: A total of 126 SBE were performed in 3 years, 99 for evaluation of the small intestine, of which 60.6% (60/99) for OGIB. Of these, 88.3% (53/60) of the examinations were conducted by overt OGIB (42 patients, 30 men, mean age 65.3 years) who were the object of our study; the remaining by occult OGIB. In the context of overt OGIB, there were 15 emergent SBE for active-overt OGIB (15/53). In these, the origin of small bowel bleeding was diagnosed in 15: angiodysplasia (n=5), erosion/ulceration (n=3), tumors (GIST 3, neuroendocrine 1), eroded polyps (n=2) and bleeding diverticulum (n=1). Hemostatic therapy performed: argon plasma coagulation - 5, adrenaline and hemostatic clips - 3 and polypectomy - 2. There were no complications regarding the examination or endoscopic treatment. Bleeding recurrence occurred in one (angiodysplasia, additional coagulation session needed). In SBE for inactive overt OGIB (38/53), the etiology detection rate was 65.7% (25/37). In comparative analysis between active vs inactive overt OGIB, bleeding etiology identification rate was significantly higher in active-overt OGIB ($\chi 2$ $p<0.05$).

CONCLUSION: The study revealed the important role of emergent enteroscopy in the diagnosis and treatment of active-overt OGIB, being a safe and effective tool.

P784 LEWIS SCORE IN SMALL-BOWEL CAPSULE ENDOSCOPY AND FAECAL CALPROTECTIN; AS GOOD AS IT GETS?

A. Koulaouzidis[1,*], A. Nemeth[2], G. Wurm Johansson[2], E. Toth[2]. [1]*CLDD, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom,* [2]*Department of Gastroenterology, Skane University Hospital, Malmo, Sweden*

INTRODUCTION: Lewis Score (LS) is one of the 2 inflammatory scores in small-bowel capsule endoscopy (SBCE). In a previous paper [1], we showed that LS shows only a moderate correlation with faecal calprotectin (FC) levels. The amount of calprotectin in faeces is directly proportional to the granulocyte migration to the gut mucosa and cell shedding in the intestinal lumen.

Hence, FC is considered a reliable, almost a 'gold standard', marker of gastrointestinal inflammation. Interestingly, both LS and FC are not disease-specific. One of the major factors that could potentially influence the correlation between FC and LS is the time lag from stool collection and FC measurement to SBCE [2].

AIMS&METHODS: We aim to assess the correlation between the FC and LS from a cohort of patients who underwent SBCE within 7 days from a FC measurement. A two-centre retrospective study; [Edinburgh (RIE) & Malmo (MUH)].

Methods: SBCE and biochemistry database cross check; SBCE videos of patients who underwent SBCE no later than 7 days from a FC measurement were reviewed for LS calculation. By convention, FC $<20\mu$g/g was transform to 0. Categorical data are described as mean±SD or median(IQR). FC/LS correlation was calculated using Kendall's tau-b rank coefficient. Furthermore, correlations of FC with each of the parameters/descriptors of LS were calculated; those with the higher tau-b values were selected and a second correlation was attempted between a "simplified LS" and FC.

RESULTS: 74 patients (55 RIE[§]/19 MUH; 20M/54F; mean age: 42±18.19) had a FC measurement within 7 days of their SBCE (median: 1.5; IQR: 5). 26 SBCE were performed with MiroCam® and 48 with PillCam®. 69 (93.24%) SBCE were complete to caecum; 2 capsules were delivered endoscopically in the duodenum. Median FC level was 127.5 (IQR:280); median LS was 135 (IQR:450). Kendall's correlation between FC and LS was –as previously shown[1]– only moderate (taub: 0.34). In detailed correlation sub-analysis, the strongest coefficients were between FC and summative villous score i.e. tertile 1+2+3 , summative ulcer score (tertile 1+2+3, but only ulcer number & size) and regular stenosis score at 0.21, 0.34 and 0.3, respectively. When the rank coefficient between the new summative "simplified LS" and FC was calculated, their correlation was at similar levels; tau-b: 0.33.

[§]**part of this cohort of patients presented previously (ref 1)**.

CONCLUSION: LS shows only moderate correlation to FC. This seems to be an inherit limitation of LS and consideration should be given to the creation of new, composite inflammation score/index for SBCE.

P785 REVISITING THE "MASS OR BULGE" QUESTION IN CAPSULE ENDOSCOPY; PRELIMINARY RESULTS OF 3D SOFTWARE APPLICATION

E. Rondonotti[1], A. Koulaouzidis[2,*], A. Karargyris[3], L. Fini[4], M. Pennazio[5], C. M. Girelli[4]. [1]*Gastroenterology Unit,, Ospedale Valduce, Como, Italy,* [2]*CLDD, The Royal Infirmary of Edinburgh, Edinburgh, United Kingdom,* [3]*National Library of Medicine, National Institutes of Health, Bethesda, United States,* [4]*Service of Gastroenterology and Digestive Endoscopy, Hospital of Busto Arsizio, Busto Arsizio,* [5]*Division of Gastroenterology , San Giovanni Battista University Teaching Hospital, Torino, Italy*

INTRODUCTION: Submucosal masses (SM) and innocent mucosal bulges (MB) often look similar on small-bowel capsule endoscopy (SBCE) [1]. Differentiating them is often a challenging task, even for experienced SBCE readers. Recently, software algorithms that enable three-dimensional (3D) reconstruction in SBCE have become available [2].

AIMS&METHODS: The aim of this study was to explore whether the application of such 3D reconstruction software helps readers of difference experience level in distinguishing SM from MB. 24 de-identified, short SBCE video clips containing either SM (5) or MB (19) were selected. In all cases, diagnosis (SM or MB) was confirmed by a reference standard (RS) (CT-enterography and/or device-assisted enteroscopy and/or surgery). Each video clip was reconstructed in 3D by means of a software developed in Mathworks©Matlab. For the evaluation process, a Matlab®program with user interface was devised (**fig. 1**). Two SBCE readers groups were involved in the evaluation: a group of SBCE experts (n=3; all > 1,000 SBCE reviews), and a group of novice readers (n=3; all < 5 SBCE reviews). All readers reviewed, blind to others and in a random order, first the standard 2D video clips and then (5-7 days later) the combined 2D+3D video clips. For each case, the diagnosis (SM or MB) reached after 2D and 2D+3D review -by each group- was compared with that of the RS. Diagnostic accuracy and precision were calculated. Inter-observer agreement (using the Randolph's free-marginal multirater *kappa*; *K*) for each group and each reviewing session was also calculated [3].

RESULTS: In 2D review, the diagnostic accuracy/precision of experts and novices were 0.87/0.65 and 0.79/0.5, respectively. In combined 2D+3D review, the diagnostic accuracy/precision for experts and novices were 0.81/0.52 and 0.87/0.79, respectively. In 2D review, the inter-observer agreement (*K*) of experts and novices was 0.78 and 0.44, respectively. In 2D+3D review, the *K* value for experts and novices was 0.5 and 0.56, respectively.

When false negative/true positive rate (FN/TP) was examined in 2D review, results for experts and novices were 2/13 and 4/11, respectively. In 2D+3D review, relevant results for experts and novices were 0/15 and 6/11, respectively.

Limitations: low number of video clips; high number of MB, as compared with SM included.

CONCLUSION: The application of 3D reconstruction software improves, although not significantly, the capability of novice SBCE readers in distinguishes MsM from ImB. Its integration in training SBCE videos should be considered.

P787 THE ROLE OF TRANSNASAL CAPSULE ESOPHAGOSCOPE (E.G SCAN) FOR THE PREDICTION OF HIGH RISK ENDOSCOPIC LESIONS IN PATIENTS WITH UPPER GI BLEEDING: A PILOT TRIAL OF FEASIBILITY, SAFETY, AND UTILITY.

A. Rosztóczy[1,*], R. Róka[1], K. Vadászi[1], É. Benkő [1], P. Pák[2], T. Wittmann[1], L. Madácsy[3]. [1]*First Department of Medicine, UNIVERSITY OF SZEGED, Szeged,* [2]*Department of Internal Medicine, Vaszary Kolos Hospital, Esztergom,* [3]*2nd. Department of Internal Medicine, Semmelweis University, Budapest, Hungary*

INTRODUCTION: The optimal timing of urgent endoscopy (within 24 hours) for patients with upper GI bleeding (UGIB) remains controversial. Emergency endoscopy (EE) (within 4 hours) is indicated in patients with high risk laseions (Forrest I-IIA), but risk stratification (triage) based on only the clinical criteria can be insufficient to properly select these patients. A novel disposable transnasal capsule esophagoscope, the E.G.Scan (EGSC) allows direct visualization of the esophageal and gastric content.

AIMS&METHODS: The **aim** of the present study was to determine whether the application of EGSC in patients with acute UGIB could be useful to improve current pre-endoscopic risk stratification.

Patients and methods: We prospectively investigated 22 patients admitted with UGIB into our emergency department. UGIB was defined as a history of vomiting fresh or altered blood with or without melaena in the preceding 7 days. After hemodynamic stabilization, both nasogastric tube aspiration (NGA) and EGSC obtained before EE. The first generation EGSC system (Intromedic) was applied successfully without complications in all patients with a disposable ultrathin transnasal probe with camera capsule at the tip. Esophageal and gastric content was defined as clear, coffee ground material and bloody. Endoscopic findings were defined as high risk (HRL) (Forrest I, IIA-B) and low risk (LRL) (Forrest IIC, III) lesions. Finally results of NGA and EGSC were compared to the diagnosis EE.

RESULTS: In all but one patient there was an excellent correlation in the assessment of esophageal and gastric content between the EGSC and EE, in contrast in 8 out of 22 patients NGA and endoscopy demonstrated discordant results. Ongoing bleeding (bloody content) was demonstrated in 5 out of 6 patients with EGSC. More importantly, compared to EE Forrest HRL and LRL were differentiated with EGSC better than with NGA: PPV: 78% vs. 65%,; NPV: 87% vs. 100%, sensitivity: 78% vs. 100%, specificity: 85% vs. 46% and accuracy: 82% vs. 68%, respectively. 100% of patients with bleeding esophageal varices were also identified on EGSC.

CONCLUSION: EGSC is feasible, safe and valuable method to assess gastric and esophageal content in the emergency room setting. Our pilot study demonstrated that EGSC can be useful to predict high-risk endoscopic lesions in patients with UGIB. Further, randomized prospective study is needed to determine the diagnostic value of EGSC as to able to identify patients who would benefit from EE. The study was supported by Intromedic Co.

P788 REPEAT VIDEO CAPSULE ENDOSCOPY (VCE)- IS IT WORTH IT?

C. Parker[1,*], P. Rajasekhar[1], R. Bevan[1], C. Davison[1], S. Panter[1]. [1]*Gastroenterology, SOUTH TYNESIDE DISTRICT HOSPITAL, South Shields, United Kingdom*

INTRODUCTION: Few studies have reported on the yield of repeat capsule endoscopy (CE) in the same patient and data regarding this diagnostic strategy are limited.[1,2] The aims of this work were to assess the indications for repeat capsule and to determine the diagnostic yield of repeat capsule in our trust.

AIMS&METHODS: A retrospective review of all patients who underwent CE at South Tyneside District Hospital between August 2004 and October 2012 was conducted. Patients who underwent a repeat CE were identified and divided into one of four subgroups. Findings were classified as positive or negative; positive findings were taken as presence on report of ulcers, tumours, strictures, polyps, blood or angioectasia.

RESULTS: A total of 1083 studies were performed, 83 were repeat studies. 7 patients were noted to have greater than 2 repeats.

Indications:

- Group 1 Gastric retention or technical failure (N=16)
- Group 2 Surveillance (N=7)
- Group 3 Poor views (as commented on by reporting physician on report) or incomplete (not seen to enter the colon) on initial study (N=31)

- Group 4 Ongoing symptoms/ assessment of disease extent/ unclear findings on initial VCE (N=36) (7 cases are reported in both group 3 and 4)
Yield: Overall yield, excluding gastric retention was 38% for the first study and 46% for 2nd study, of those with an initial negative study (42 patients), 21% of these had a positive repeat. (those with poor views had been given bowel preparation, those with an incomplete capsule study had a capsule recording time of 8-9 hours on both studies).
Positive findings:

Group	Positive findings 1st study	Positive findings 2nd study
1	N/A	5/16 (31%)
2	4/7 (57%)	4/7 (57%)
3	3/31 (10%)	10/31 (32%)
4	16/36 (44%)	17/36 (47%)

Subgroup analysis group 4:
- Ongoing symptoms with consistent with ?Crohn's or known Crohn's the yield remains the same on 1st and 2nd capsule 4/9 (44%).
- Ongoing IDA/ GI bleeding show an increased yield with 8/17 (47%) having a positive 1st study and 10/17 (59%) a positive 2nd study.
21 had a repeat despite a positive 1st study (excluding surveillance), 71% had positive repeat with resulting change in management in 73%. 9/15 done for ongoing symptoms, 6/15 for incomplete/ poor views.
CONCLUSION: Limited data exist regarding the yield of repeat CE, it is suggested by the literature that yield of a repeat study is better in those with GI bleeding/ anaemia. Our results suggest that the group with the highest yield (3 fold increase) on repeat are those with poor views or an incomplete initial study. There is an improvement in yield with 2nd study for those with ongoing symptoms of IDA or GI bleeding in keeping with previous literature.

P789 SAFETY OF OMOM CAPSULE ENDOSCOPY IN PATIENTS WITH PACEMAKERS AND IMPLANTABLE CARDIAC DEFIBRILLATORS: AN "IN VIVO" ELECTROPHYSIOLOGICAL STUDY.

D. Moneghini[1,*], A. Lipari[2], G. Missale[1], R. Bozzi[3], L. Minelli[1], G. Cengia[1], L. Bontempi[2], A. Curnis[2], R. Cestari[1]. [1]*Digestive Endoscopy Unit,* [2]*Electrostimulation Lab, SPEDALI CIVILI - UNIVERSITY OF BRESCIA, Brescia,* [3]*Surgery and Digestive Endoscopy, A.O. dei Colli, Napoli, Italy*

INTRODUCTION: The role of capsule endoscopy (CE) in small bowel investigation is well established. Once swallowed by the patient, capsule transmits images from the gut to an external recorder over a digital radiofrequency communication channel. Potential electromagnetic interferences with electronic cardiac devices (CD) have been postulated, so the manufacturers consider their presence as a contraindication for CE. Whereas safety data on the use of Given SB capsule in patients with pacemakers (PM) and automatic implantable cardiac defibrillators (AICD) are available, there are no studies on the OMOM capsule in this field.
AIMS&METHODS: We report the results of the first electrophysiological "in vivo" study about the use of OMOM capsule system (Wuhan Zhongxin Medical Instrument Co.) in 8 consecutive patients with CD prospectively evaluated over a 9-months period. Capsule ingestion was performed in the morning after a overnight fast and bowel preparation (2L of polyethylene glycol solution the day before). A full technical check of CD was performed before and after CE. During CE patients were continuously monitored with cardiac telemetry, performed in a hospital setting.
Table: P789

Patient CD		1 AICD Medtronic Protecta	2 PM Medtronic Advisa	3 PM Boston Sc. Altrua	4 PM Medtronic Advisa	5 AICD St. Jude Med. Atlas HF	6 PM St. Jude Med. Accent	7 AICD Boston Sc. Cognis	8 PM Medtronic Advisa
Results during CE exam	Changes in device parameters	NO	NO	NO	NO	NO	NO	NO	NO
	Inappropriate Shocks	NO	NO	NO	NO	NO	NO	NO	NO
	Inappropriate anti-tachycardia therapy	NO	NO	NO	NO	NO	NO	NO	NO
	Inappropriate Sensing	NO	NO	NO	NO	NO	NO	NO	NO
	Inappropriate Pacing	NO	NO	NO	NO	NO	NO	NO	NO
	Noise Detected	NO	NO	NO	NO	NO	NO	NO	NO
	Device Reset	NO	NO	NO	NO	NO	NO	NO	NO
	Programmation Changes	NO	NO	NO	NO	NO	NO	NO	NO
	Permanent Electrical Damages	NO	NO	NO	NO	NO	NO	NO	NO

RESULTS: In 7 cases the indication for CE was obscure gastrointestinal bleeding (OGIB) and intestinal polyposis (IP) in one. Mean age was 73 years (range 56-83); all the patients were males. CD parameters and results of recordings are reported in the table.
Capsule reached ileo-cecal valve in 6 cases. No complications related to capsule transit were observed. No technical problems related to imagine transmission were recorded. Causes of OGIB were found in 57,1% of cases. CE in IP patient was normal. No CD malfunction nor interference in sensing or pacing were recorded; no malfunction of CE caused by CD was registered.
CONCLUSION: Our results suggest that OMOM capsule can be safely performed in patients with different types of CD.

P790 KINETICS OF COLON CAPSULE ENDOSCOPY: PILOT STUDY WITH PRUCALOPRIDE.

I. D. Gutiérrez[1,*], C. G. Gutiérrez[2], I. G. Moreno[3], A. D. Gutierrez[2]. [1]*Digestive Diseases, H.U.V.ROCIO, Sevilla,* [2]*Digestive Diseases, Institute of gastrointestinal pathology,* [3]*Internal Medicine, H.U.V.Macarena, Seville, Spain*

INTRODUCTION: Up until now, the use of colon capsule endoscopy (CCE) has been limited by the inabilities to achieve a complete examination. A pilot study was conducted to determine the efficacy of a new preparation based on associating Prucalopride (Resolor) and polyethylene glycol plus ascorbic acid (Moviprep). Prucalopride is a highly selective serotonin 5HT4 receptor agonist which stimulate the release of acetylcholine necessary for smooth bowel muscle contraction and therefore peristalsis. After observing its benefits on the treatment for constipation, we believe that Prucalopride could be useful in the preparation of colon capsule endoscopy, speeding up intestinal transit and therefore making the examination shorter, increasing the excretion rate. This article presents the results obtained in terms of transit times, total examination time and expulsion rates.
AIMS&METHODS: Pilot study with 40 patients (cases) with the new preparation compared with 40 control patients with the standard preparation (PEG/ Fosfosoda/). Each video is read by two researchers.
Preparation protocol: - Two days of residue-free diet - Day before the test, liquid diet - Resolor 2 mg, 1 on each day of the diet and 2 on the examination day - Moviprep, 1 liter in the evening prior to the examination and 1 liter in the morning of the examination – Then 2 boosters of half a liter each in alarms 1 and 2.
RESULTS: A cohort with 32 men and 48 women, mean age of 53.3 years old (10-90). Expulsion rate over time of 87.5% in the cases with respect to 67.5% in the controls (p=0.188). The mean gastric transit time (75 vs. 49.5 minutes; p=0.12), intestinal transit time (81.4 vs. 42.4 minutes; p=0.001) and colon transit time (262 vs. 271.3 minutes; p=0.89) were shorten.
CONCLUSION: The higher excretion rate as well as the shortened gastric and intestinal transits, without modifying the colon transit, with the new preparation (Prucalopride+Polyethylene glycol plus ascorbic acid), allow conducting a higher quality study of the colon over time and with less adverse effects and better tolerance as a result of excluding sodium phosphate.

P791 PATIENTS PERCEPTION OF COLONOSCOPY: ASTONISHING REASONS FOR COLON CAPSULE ENDOSCOPY PREFERENCE

M. Benes[1,*], J. Spicak[1], P. Drastich[1], T. Hucl[1]. [1]*Hepatology and Gastroenterology, Institute of Clinical and Experimental Medicine, Prague, Czech Republic*

INTRODUCTION: Colonoscopy is considered to be the gold standard for colon evaluation and screening for colorectal cancer (CRCA). Classical colonoscopy (CC) is an invasive method with an unfavourable reputation amongst patients which may be a reason for noncompliance with CRCA screening programs. Colon capsule endoscopy (CCE) is an innovative non-invasive technique which has gained patients interest in CRCA screening despite the fact of being very costly.

AIMS&METHODS: The aim of this prospective, multicentric study was to assess reasons for preference for CCE over CC. The data from all consecutive patients scheduled to undergo CCE were obtained using a questionnaire.

RESULTS: From December 2010 to October 2012 one hundred patients (68 men, 32 women, average age 52 years) were included in the study. Seventy eight (78%) patients had university education and 20 patients (20%) were high school graduates. Seventy nine (79%) were senior managers with at least 10 or more employees. Sixty five (65%) had their salary at least four times the nation's avarage income. The main reasons of CCE preference were concerns about a patient's privacy and embarrassment (38 patients, 30 males, 8 females), concerns of pain (35 patients, 18 males, 17 females) , fear of a loss of discernment (20 patients, 15 males, 5 females). Forty six (46%) patients had undergone CC in the past. In this subgroup, privacy issue was main reason for 33 (71%) patients and pain for 13 (28%) patients. Forty two patients (42%) would never undergo a screening CC even though 19 (45%) of them had a positive family history.

CONCLUSION: The main reason for CCE preference over CC was mental discomfort and fear of embarrassment during CC, rather than concerns of pain. The results imply a need of improvement of our CC management.

P792 URGENT CAPSULE ENDOSCOPY FOR BLEEDING SITE LOCALIZATION & LESION DIAGNOSIS OF PATIENTS WITH SEVERE HEMATOCHEZIA

M. Camus[1,*], D. M. Jensen[2], G. V. Ohning[2], T. O. Kovacs[2], R. Jutabha[2], K. A. Ghassemi[2], the CURE Hemostasis Research Group. [1]*Department of Digestive Disease, LARIBOISIERE UNIVERSITY HOSPITAL APHP, Paris, France,* [2]*CURE Hemostasis Research Group, CURE Digestive Diseases Research Center, Division of Digestive Diseases, UCLA Ronald Reagan Medical Center, David Geffen School of Medicine , UCLA, Los Angeles, United States*

INTRODUCTION: There is no agreement about the best strategy for diagnosis of patients presenting with severe hematochezia.

AIMS&METHODS: For patients with severe hematochezia, our aims were: 1) to determine diagnostic yield of urgent capsule endoscopy (UCE) for bleeding site localization in the gut & for etiologic or lesion diagnosis & 2) to compare results with red blood cell (RBC) scan &/or angiogram (eg. standard angiography, CT, or MR angiogram) & with endoscopy (colonoscopy, upper endoscopy). We retrospectively reviewed charts of consecutive patients presenting with severe hematochezia, & without a recent history of hematemesis, melena,& a negative NG aspirate who underwent a UCE within 12 hours of GI consultation at our center. Demographics, clinical & laboratory data, results of RBC scanning, angiogram, UCE, endoscopies, & GI surgery were recorded. With the combination of endoscopic & surgical results as gold standard for lesion location & etiologic diagnosis, the diagnostic yield, sensitivity (Se) and specificity (Sp) of UCE were computed.

RESULTS: 15 patients (12M/3F, mean age [±SD] 57.9 years [±24.0]) had UCE for severe hematochezia. 13 (87%) patients had a final etiologic diagnosis: 2 colon angiodysplasia, 3 definitive diverticulosis, 3 presumptive diverticulosis, 3 Meckel's diverticulum, 1 jejunal Dieulafoy's lesion and 1 ileal tumor. CE was delayed in the stomach in 2 patients & failed to pass the pylorus in 1. All other patients had visualization of the entire small bowel & 47% had some colon visualization. All patients had endoscopies. 6 patients underwent RBC scan &/or angiogram. UCE had a higher diagnostic yield than RBC scan or angiography for bleeding site localization: 67% vs. 33%. But these techniques often failed to determine an etiologic or lesion diagnosis. Overall diagnostic yield of UCE for bleeding site localization in the gut was 67%. But for etiologic diagnosis, the yield of UCE was only 20% vs. 53% for endoscopy. The Se and Sp of CE were 80% and 60% respectively for bleeding site localization. The Se and Sp of CE were 15% and 50% respectively for lesion diagnosis.

CONCLUSION: In patients hospitalized for severe hematochezia and no sign of upper GI bleeding, the diagnostic yield of CE for localization of the bleeding site (67%) was higher than for RBC and/or angiogram, but the ability to make an etiologic diagnosis was low with all these procedures. The overall rate of bleeding site localization with UCE was 67%. These results suggest a potential important role for UCE as the initial approach for lesion localization in patients with severe hematochezia.

INTRODUCTION: Between 5-10% of colonoscopies are incomplete for a variety of reasons. With this in mind, it was proposed to complete the visualization of unexplored segments of the colon with Pillcam® Colon2® n capsule endoscopy (CCE) and to assess the number and type of lesions identified, improvement of diagnostic yield and modification of therapeutic interventions.

AIMS&METHODS: After ethics committee approval of all 10 participant hospitals, patients were accrued to the study from November 2010 to April 2013. Patients with incomplete colonoscopy due to technical reasons which were not contraindicated to the capsule procedure were included in the study.

RESULTS: 96 patients were enrolled, 68 women and 28 men, median age of 50 (22-86). The most common cause for incomplete colonoscopy was a repeated loop that could not be overcome with standard manoeuvres. Complete CCE visualization was obtained in 69 patients (72%). Of the 27 patients in which the capsule did not reach the hemorrhoidal plexus, CCE visualised the colonic segments not explored with previous colonoscopy in 20, so the combined approach (CCE plus colonoscopy) permited a completed visualization of colonic mucosa in 93% of the patients.

CCE was incomplete because of capsule delay in the stomach and small bowel in 4 cases, unsatisfactory bowel preparation in 3 and technical failure in 2 cases.

CEC revealed new lesions in 58 patients (60%). Polyps were the most frequent finding (41 patients), followed by diverticulae (8 patients); neoplasia (2 patients), and solitary colonic ulcers (2 patients) In 43 of these patients (45%) the new findings modified the therapeutic approach, which included a new trial of colonoscopy for polyp resection or surgery in case of colon neoplasia. Minor changes in therapeutics were made when colonic diverticulae were found.

CONCLUSION: CCE is potentially a useful diagnostic tool in the setting of incomplete colonoscopy, revealing a significant number of lesions in unexplored colonic mucosa. Results may produce favorable changes in the therapeutic approach for these patients.

P794 CAPSULE ENTEROSCOPY IN OBSCURE GASTROINTESTINAL BLEEDING: THE PARAMOUNT IMPORTANCE OF ANTITHROMBOTICS

P. B. Carvalho[1,*], M. J. Moreira[1], J. Cotter[1]. [1]*Gastrenterology, Centro Hospitalar do Alto Ave, Guimarães, Portugal*

INTRODUCTION: Capsule enteroscopy (CE) plays a decisive role in the obscure gastrointestinal bleeding (OGIB) diagnosis. Antiplatelet and anticoagulant drugs may result in an increased digestive bleeding risk, both in patients with pre-existent lesions as well as through mucosal aggression.
AIMS&METHODS: Our aim was to analyze and correlate these drugs with potential bleeding lesions found in CE.
Unicentric retrospective study including 219 consecutive and complete CE performed in 5 years for OGIB diagnosis. The lesions observed during the CE were classified as P0 (no potential for bleeding), P1 (uncertain potential for bleeding) and P2 (high potential for bleeding). We also assessed antiplatelet and anticoagulant drug usage during the 30 days previous to the CE. Statistical analysis was performed with SPSS 17.0.
RESULTS: OGIB had a visible presentation in 17,4% of the patients. Approximately one quarter of the patients was taking antithrombotics (21,5% were on antiplatelet and 6,4% on anticoagulant drugs). Angiectasias (18%), erosions (15%) and ulcers (5%) were the most frequently observed lesions in the CE. Patients presenting with occult OGIB used antithrombotics significantly more often than the ones with visible OGIB (p=0,049).
We found no significant correlation between antithrombotics and P1 or P2 lesion findings in CE. However, when a sub-analysis was performed, there was a significant correlation between anticoagulant drugs and a higher incidence for P1-P2 lesions in the small bowel (p=0,045).
CONCLUSION: Antithrombotic drugs, whose usage was very frequent in patients presenting with OGIB, were significantly associated with an occult bleeding presentation.
Both uncertain bleeding potential (P1) and high bleeding potential (P2) small bowel lesions were more frequently found in the capsule enteroscopy when the patient was on anticoagulant drugs.

P795 COMPARISON OF DIFFERENT COLONIC PREPARATION PROTOCOLS DURING COLONIC CAPSULE ENDOSCOPY BASED ON QUANTITATIVE COMPUTER ANALYSIS OF MUCOSAL VISIBILTY – A RANDOMIZED PROSPECTIVE STUDY

P. Pak[1,*], G. Balogh[2], L. Madacsy[3]. [1]*Department of Gastroenterology, Department of Internal Medicine, Vaszary Kolos Hospital, Esztergom,* [2]*Department of Surgery, Kaposi Mór Teaching Hospital, Kaposvár,* [3]*2nd Department of Internal Medicine, Semmelweis University, Budapest, Hungary*

INTRODUCTION: Development of new colonic preparation protocol (CPP) is needed to improve the overall accuracy of colon capsule endoscopy (CCE) and to diminish side effects. Recently we developed and validated a quantitative score of colonic cleanliness that was derived from the spectral color analysis of the CCE images.
AIMS&METHODS: The aim of the present prospective, randomized study was to quantitatively compare different CPPs during CCE. A quantitative assessment of colonic cleanliness and mucosal visibility was developed based on computer spectral analysis of red color intensities in the color bar (CB) of Rapid Reader with the software Colors ®™. The feasibility of this score was retrospectively tested in 28 CCE studies with the original CPP as we published earlier and these results were served now as controls. A prospective, randomized study was now conducted in 30 consecutive patients undergone CCE. The first-generation PillCam GIVEN CCE was applied. 16 patients were prepared with Fleet phospho-soda (FPS group) and a split dose of 3L of PEG, and the remaining 14 patients were prepared with Picoprep (sodium picosulfate) (SPS group) and a split dose of 3L of PEG. The red color intensity (RCI=R*R/G*B) of the total spectral color from the CB representing the whole colonic section was measured and then compared.
RESULTS: Anal capsule expulsion and complete CCE study was successfully accomplished 13 out of 14 (93%) in the SPS group and 13 out of 16 (81%) in the FPS group versus 19 out of 28 (68%) in the controls ($p < 0.05$). More importantly RCI was significantly higher in the SPS group than in the controls (5.1+1.1 vs. 4.4+0.6; p=0.015), whereas FPS group did not differ significantly from the controls (4.5+0.8 vs. 4.4+0.6; p=0.14). SPS group had significantly faster colonic capsule transit than the FPS group and the controls (157 min vs. 245 min vs. 259 min; p=0.047).
CONCLUSION: Quantitative assessment of colonic mucosal visibility with RCI is a useful method to compare different CPPs during CCE. Preparation and booster during CCE with SPS combined with split dose of PEG is superior to FPS based colonic preparation in respect of mucosal visibility, colonic transit time and anal capsule expulsion. Routine application of SPS (Picoprep) in the bowel preparation before CCE may further improve the diagnostic yield and patient acceptance with no or only minimal side effects.

P796 OPEN VERSUS LAPAROSCOPIC RIGHT HEMICOLECTOMY IN THE ELDERLY POPULATION

A. Quyn[1,*], O. Moussa[2], D. Smith[2], R. Steele[1]. [1]*Surgery and Oncology, University of Dundee,* [2]*General Surgery, Ninewells Hospital and Medical School, Dundee, United Kingdom*

INTRODUCTION: Laparoscopic colorectal surgery is associated with superior perioperative outcomes when compared to open surgery. However, in the elderly population these benefits are often overshadowed by co-morbidities and difficulties in achieving rapid discharge. Right hemicolectomies (RH) represent a distinct group of colorectal resections where the benefits of the laparoscopic approach may be reduced.
AIMS&METHODS: The aim of this study was to compare short term outcomes of elective laparoscopic and open RH in an elderly population.
All patients over the age of 70 undergoing elective RH at Ninewells Hospital, Dundee and Perth Royal Infirmary were included in our analysis. Intra-operative details and hospital length of stay was obtained from a prospective database. The primary endpoints for analysis were morbidity and mortality. Our secondary endpoints were operative duration, length of hospital stay and discharge destination.
RESULTS: 206 patients were included in our analysis. 125 patients underwent an open resection and 81 patients had a laparoscopic resection. The mean operating time was 139+/-36 minutes in the open group versus 197+/-53 minutes in laparoscopic (p=0.001). The mean length of hospital stay was 11.2 days in open and 9.6 days in laparoscopic. The incidence of post-operative morbidities was 27% in the open group and 38% in the laparoscopic group. Overall mortality was 0.8% in open procedures versus 1% in laparoscopic.
CONCLUSION: Laparoscopic RH was associated with a significantly longer operative time compared to open RH. In our study, laparoscopic RH was not associated with reduced post-operative morbidity or significantly shorter length of hospital stay.

P797 INCOMPLETE HISTOLOGICAL EVALUATION AS A RISK FACTOR FOR SURGERY OF MALIGNANT COLORECTAL POLYPS

B. M. Gonçalves[1,*], V. Fontaínhas[1], A. Caetano[1,2], C. Rolanda[1,2], P. Bastos[1], A. Ferreira[2,3], J. B. Soares[1], R. Gonçalves[3]. [1]*Gastroenterology, Hospital de Braga,* [2]*Life and Health Sciences Research Institute, School of Health Sciences, University of Minho,* [3]*Hospital de Braga, Braga, Portugal*

INTRODUCTION: Malignant colorectal polyp is the earliest form of clinically relevant colorectal cancer. It corresponds to 0,5-8% of the resected adenomas. After endoscopic resection additional surgery may be necessary, although decision criteria remain debatable.
AIMS&METHODS: Assess oncologic outcomes in terms of locoregional disease and study risk predictors and areas of work improvement that may facilitate patients' management.
Retrospective study of forty patients with T1 colorectal cancer endoscopically resected during the last 5 years. Clinicopathological features were assessed and correlated with locoregional disease.
From the associated risk factors (margins, depth submucosal and lymphovascular invasion, differentiation, budding) we could not evaluate depth invasion and budding.
RESULTS: Thirty-one patients underwent subsequent surgery while 9 were followed-up. After segmentectomy, residual disease was confirmed in 15 (48.4%) patients. No recurrence was detected in the follow-up group. Polyp configuration (p=0.03), differentiation (p=0.02) and margins status (p=0.02) were factors for residual wall disease. The presence of only one risk factor is determinant of poor outcome (p=0.08) while the presence of no risk factor is strongly associated with lower incidence of residual disease (p=0.13). We verified that 22 patients were operated because of inadequate evaluation, mainly consequence of piecemeal

resection, and half of them were disease free. Postoperative anastomotic leakage was highly associated with rectum anterior resection (p=0.03). Study main limitations were the sample size and retrospective design.
CONCLUSION: The need for surgery in case of any risk factor versus cautious follow-up if no risk factors was corroborate. Was also demonstrated a clear need for technical improvement in endoscopic resection and pathologic evaluation in order to prevent unnecessary surgeries, especially for rectal lesions.

P798 KINETICS OF SERUM PROCALCITONIN IN THE SMALL BOWEL OBSTRUCTION'S MANAGEMENT

C. Cosse[1,2,*], L. rebibo[1], C. sabbagh[1], G. grelpois[1], D. lignier[1], J. M. regimbeau[1]. [1]*digestive, metabolic and oncologic surgery department, amiens university hospital,* [2]*INSERM U1088, amiens university, amiens, France*

INTRODUCTION: Small bowel obstruction (SBO) is a frequent intestinal disease that requires either conservative management (with a nasogastric tube) or surgical management in case of failure of the nasogastric tube. For the digestive surgeon, the timing before the necessity of the surgery is difficult because of the absence of preoperative markers. Procalcitonin (PCT) has been recently proposed as a marker for helping in this discrimination. The aim of this study is to determine the kinetics of PCT in patients with SBO and the best predictive timepoints to propose conservative management and surgical management.
AIMS&METHODS: Between January and April 2013, 23 patients were hospitalized in the Amiens Digestive Surgery Department for SBO. In all of these patients, serum PCT were taken every four hours for three days or until the transit was restored and measured with Kryptor TRACE analyzer. Patients were divided into subgroups considering the success (CM) or the failure (FM) of conservative management.
RESULTS: At admission, serum PCT is significantly lower in CM group (n= 18; 0.13 vs 0.35; $p < 0.01$) compared with the FM group (n=5). At 12 hours after the admission, a PCT > 0.21 ng/mL has a positive predictive value (VPP) of 89.6% and a negative predictive value (NPV) of 73.2% and at 24 hours, a PCT > 0.16ng/mL has a VPP of 83.2% and a NPV of 78.3% to predict conservative management failure. The Area under the Curve was 0.85 for conservative management failure.
CONCLUSION: serum Procalcitonin could help to discriminate patients with SBO in whose the surgical management has to be proposed. A larger effective is required to confirm this trend.

P799 PRESENTATION OF FEMORAL HERNIA AND ITS CONSEQUENCES: A POPULATION BASED STUDY USING LINKED PRIMARY AND SECONDARY CARE DATA

D. J. Humes[1,*], R. Radcliffe[1], C. Camm[1], J. West[2]. [1]*Surgery, UNIVERSITY OF NOTTINGHAM,* [2]*Division of Epidemiology and Public Health, University of Nottingham, Nottingham, United Kingdom*

INTRODUCTION: Emergency admission with femoral hernia is high compared to other hernias and the reasons for this are unclear.
AIMS&METHODS: Our aim was to determine the outcomes of patients admitted as an emergency with a femoral hernia and describe the mode of presentation to primary care. Computerized health care records of patients from the Clinical Practice Research Datalink (CPRD) linked to Hospital Episode Statistics (HES) data from the UK from 1997 to 2007 with a first hospital admission for a femoral hernia repair. The demographics of the emergency and elective patients were described with respect to age, gender, comorbidity and first presenting complaint to primary care either hernia or other presentation (groin pain, obstructive symptoms). Length of stay, bowel resection rates and 30 day mortality were calculated.
RESULTS: We identified 885 patients (78% female) who underwent a femoral hernia repair with 406 (45.9%) as an emergency. The median age of those presenting as an emergency was 77.5 years (IQR 68-84 years) which was significantly greater than those presenting electively 61.0 years (IQR 46-75 years) (Kruskal-Wallis $p < 0.0001$). The majority of emergency admissions (81.5%, 331/406) presented to their GP for the first time with symptoms of a hernia in the 7 days prior to admission compared with just 2% of elective admissions (Chi squared 585, $p < 0.0001$). Patients presenting for elective repair were 7 times more likely to present with a history of a hernia compared to those presenting as an emergency (Odds Ratio 6.7, 95% CI 4.95-9.12). In those presenting as an emergency 72.2 % (293/406) presented with evidence of small bowel obstruction or strangulation with 22.9% (93/406) having a bowel resection. The median length of stay in those undergoing elective surgery was 1 day (IQR 0-2) and for those undergoing emergency repair it was 5 days (IQR 3-9) (Kruskal-Wallis $p < 0.0001$). There were no deaths within 30 days in the elective group with a 1.7% 30 day mortality in the emergency group.
CONCLUSION: A substantial number of patients present as an emergency with a femoral hernia. These patients are older and present to primary care in a different manner in terms of timing and presenting complaint compared to those having an elective repair. Morbidity associated with these admissions is high and therefore preventing emergency admission is likely to improve outcomes.

P800 TREATMENT OF LOW RECTAL CANCER BY ELRR OR TETMR BY TEM

G. D'Ambrosio[1,*], A. M. Paganini[1], S. Quaresima[1], A. Balla[1], A. Picchetto[1], G. Intini[1], E. Lezoche[1]. [1]*Sapienza University of Rome, Azienda Policlinico Umberto I, Roma, Italy*

INTRODUCTION: Surgical sphincter saving procedure in patients with low rectal cancer are hugely successful,but today there is still no universally adopted standardized technique.From the beginning of the 90's, the authors have introduced an original technique of loco-regional resection by Transanal Endocopic Microsurgery (TEM) named ''Endoluminal Loco-Regional Resection'' (ELRR).This technique is a valid alternative to traditional surgery for early rectal cancer (Tis-T1) and for T2N0 after neoadjuvant radio-chemotherapy (n-RCT). From 2008 authors have developed a new combined technique: Transanal Endoluminal Total Mesorectal Resection (TETMR) by TEM in patients not eligible for ELRR (T2-T3N0/N+).Transanal TME is achieved with a modified TEM rectoscope.Abdominal laparoscopic time is performed as usual, followed by colo-anal anastomosis and ileostomy**.**
AIMS&METHODS: From 2001 to 2013,115 patients (67 male,48 female,median age 65 years) affected by rectal cancer were selected. All patients were studied preoperatively with tumor markers assay (CEA,Ca19.9,Ca125),digital rectal examination,colonoscopy with macrobiopsies,vital staining and marking of the lesion,total body CT scan,pelvic MRI and endorectal ultrasound.One hundred and six patients with T1-T2N0 rectal cancer underwent to ELRR and nine patients with T2-T3N0/N+ underwent TETMR.All T2-T3 patients underwent to n-RCT.
RESULTS: Mean operative time for ELRR and TETMR was 138 min (range 40-300) and 450 (range 360-600) respectively.No intraoperative complication occurred for both procedure.Final staging was pT0N0(2), pTis(49), pT1(41), pT2(20), pT3N0(2), pT3N1(1).Ileostomy was performed in 5 patients underwent TETMR.Mean hospital stay was 4 days for ELRR and 16 days for TETMR.No late complications were observed in ELRR group.In TETMR group were observed 2 anastomotic leakage,2 anastomotic stenosis,1 rectovaginal fistula. Mortality was nil.
CONCLUSION: In patients with low rectal cancer quality of life should be considered as primary objective as well as oncological results.Nowadays TME is considered the gold standard surgical procedure,but high postoperative functional sequelae are observed.Many surgical alternative procedures are described in literature,but no universally standardized technique is still adopted.Modified TEM procedure (ELRR) is a valid alternative to traditional surgery in selected patients T1 or T2 after n-RCT.Authors described a new technique named TETMR to treat patients with T2-T3 rectal cancer.Main advantage is the preliminary identification of tumor distal margin,dissection of distal part of perineal muscle and fascia in order to detect perirectal tumoral invasion and verify the possibility to perform a sphincter saving procedure.

P801 SECONDARY PROCTECTOMY AFTER COLECTOMY AND ILEORECTAL ANASTOMOSIS IN FAMILIAL ADENOMATOUS POLYPOSIS

L. Koskenvuo[1,*], L. Renkonen-Sinisalo[1], H. J. Järvinen[1], A. Lepistö[1]. [1]*Department of Gastrointestinal surgery, Helsinki University Central Hospital, Helsinki, Finland*

INTRODUCTION: Familial adenomatous polyposis (FAP) is a hereditary disease characterized by hundreds or thousands of polyps in the colon and rectum. The aim of surgery is to prevent otherwise almost inevitable colorectal cancer. Surgical treatment options include proctocolectomy and conventional ileostomy (IS), colectomy and ileorectal anastomosis (IRA), and proctocolectomy with ileal pouch-anal anastomosis (IPAA) [1]. The choice of surgery for each patient is made case by case, taking into account the patient's age, location and number of polyps, comorbidities, and patient's wish [2]. Also genotype has been suggested to guide the decision between IPAA and IRA [3]. Colectomy with IRA is considered to be safer than proctocolectomy with IPAA, but it is associated with an elevated risk of rectal cancer.
AIMS&METHODS: The aim of our retrospective study was to review the outcome of patients undergoing colectomy with ileorectal anastomosis (IRA) due to familial adenomatous polyposis (FAP) in Finland during the last 50 years.
The cumulative risk of rectal cancer and the rate of anus preservation were analyzed. Total of 140 FAP patients with previous colectomy combined with ileorectal anastomosis were included. Kaplan-Meier analysis was performed to evaluate cumulative risks.
RESULTS: Secondary proctectomy was performed for 39 (28%) of 140 patients. The median follow-up time after colectomy and IRA was 15 years (range 0-44 years, mean 16 years). The cumulative risk of secondary proctectomy was 53% at 30 years after colectomy with IRA. A total of 17 (44%) secondary proctectomies were performed due to cancer or suspicion of cancer, and another 17 (44%) secondary proctectomies were performed due to uncontrollable rectal polyposis. During our study, the anus preservation rate in secondary proctectomies was 49%. Estimated cumulative risk of

rectal cancer was 24% at 30 years after colectomy with IRA. The cumulative rectal cancer mortality 30 years after colectomy with IRA was 9%. Patients with attenuated FAP had no rectal cancer in our study.
CONCLUSION: Proctocolectomy and ileal pouch-anal anastomosis (IPAA) should be favored as a primary operation for patients not having technical or medical contraindications for it, because almost one-third of patients with colectomy and IRA will experience rectal failure and secondary proctectomy during 20 years after the operation and over half after 30 years. Approximately 10% will develop rectal cancer in 20 years and 20% in 30 year's follow-up, resulting in a cumulative mortality of 8% in 20 years. Patients with attenuated FAP form a group where IRA should still be the first choice as an exception.

P802 MODULATION OF VISCERAL SENSITIVITY BY ACUTE SACRAL NERVE STIMULATION IN RAT.

L. Langlois[1,*], E. Lelong[2], W. Ouelaa[1], P. Ducrotté[2], P. Déchelotte[2], A.-M. Leroi[2], M. Méleine[1], G. Gourcerol[2]. [1]*University of Rouen,* [2]*CHU rouen, Rouen, France*

INTRODUCTION: Fecal incontinence remains a therapeutic problem in patients when conservative measures fail and sphincter repair is unsuccessful or inappropriate. Sacral nerve stimulation (SNS) is an alternative surgical approach proposed initially to treat urinary incontinence, and has been used for the past decade as a successful treatment of fecal incontinence. Despite its overall efficacy that is reported to be between 70 and 80%, the mechanisms involved in this symptomatic effect remain unclear, and may involve modification of visceral sensitivity.
AIMS&METHODS: We assessed whether SNS could modify colorectal sensitivity to colorectal distension (CRD). These experiments were carried out in healthy rats and in a cross-organ hypersensitive rat model using acetic acid bladder instillation. We monitored the variation of arterial blood pressure (BP) as a marker of visceral sensitivity in anesthetized rats in response to graded CRD from 20 to 80 mmHg during either SNS or sham stimulation. In addition, c-fos protein (neuronal activation marker) expression was quantified by immunohistochemistry within the S1 sacral dorsal horn of the spinal cord, the solitary tract nucleus (NTS) and parabrachial nucleus (PBN) in response to 80 mmHg CRD during either NS or sham NS.
RESULTS: Graded CRD led to an increase of BP that was decreased by SNS in both models, with an effect that was more prominent in the hypersensitive model. The effect of SNS on visceral pain was prevented in both models by administration of intravenous (iv) or intrathecal naloxone, while L-Name administered iv had no effect. In addition, SNS prevented the increase of the number of c-fos immunoreactive cells in response to CRD in the lamina I of dorsal horn of the sacral spinal cord, in the NTS and in the PBN in both models.
CONCLUSION: Our study shows that SNS modifies visceral sensitivity in healthy and hypersensitive rat by acting on the central nervous system through an opioid (but not nitrergic) -dependent pathway. Further investigations are necessary to determine mediators involved both at the peripheral and central levels.

P803 TRIPLE TEST FOR EXCLUDING ACUTE APPENDICITIS IN ADULTS

M. Sakr[1,*]. [1]*Department of Surgery, Faculty of Medicine, University of Alexandria, Egypt, Alexandria, Egypt*

INTRODUCTION: Appendectomy is by far the commonest major emergency general surgical operation.
AIMS&METHODS: The present prospective clinical study was conducted to investigate whether a negative triple test (NTT) (total leukocyte count [TLC], neutrophil percentage [NP], and C-reactive protein [CRP] level) can rule out acute appendicitis in adults. It included 452 consecutive patients with suspected acute appendicitis. Children (<16 years) (n=91) and pregnant women (n=7) were excluded. The remaining 354 patients were enrolled but only those with a NTT (n=130) were analyzed. The NTT meant TLC <11,000/μL, NP <75%, and CRP <5 mg/L. Data collected included demographics, clinical presentation, laboratory tests, histopathology, and outcome. Negative predictive value (NPP) was calculated.
RESULTS: Eighty-seven patients (66.9%) were female and 43 (33.1%) were male. Their ages ranged between 16 and 52 years (mean 27.8 years). Most patients (87.7%) had their symptoms for 12-36 hours before hospital admission. The mean values for TLC, NP, and CRP were 7,693/μL, 55.61%, and 0.65 mg/L, respectively. Of the 130 patients with NTT, only one proved to have appendiceal inflammation (NPV=99.2%). Only 49 patients were operated upon, of whom 48 (98%) had a normal appendix, and the remaining patients were either discharged (n=56) or referred to other specialties (n=25). There were significantly more women (77.1%, 37/48) with negative appendectomy than men (22.9%, 9/38) (X^2= 21.1, p=0.0001).
CONCLUSION: Triple test (TLC, NP and CRP levels) should be measured upon hospital admission of adult patients with clinically suspected acute appendicitis. If used judiciously, they may spare the group of patients with a NTT an unnecessary surgical operation with its cost and potential risks.

P804 MOLECULAR CHARACTERIZATION OF SERRATED POLYPS CAN DIFFERENTIATE MORE ADVANCED LESIONS

M. Juarez[1,*], C. Egoavil[2], M. Rodriguez-Soler[3], C. Guarinos[1], L. Andreu[1], E. Rojas[2], F. Ruiz-Gomez[3], J. A. Casellas[3], J. Martinez-Sempere[3], R. Jover[3]. [1]*unidad de investigacion,* [2]*Departamento de patología,* [3]*Departamento de Gastroenterología, hospital of Alicante, Alicante, Spain*

INTRODUCTION: Serrated polyps could be premalignant acting through the serrated pathway of carcinogenesis.
AIMS&METHODS: The objective of our study was to compare a group of polyps with mutations in KRAS, BRAF and not mutated in order to determine molecular and histological differences between them.
We performed a retrospective study including 163 patients and determining the clinical and molecular feature of a total of 613 polyps belonging to these patients. We analyze KRAS and BRAF mutations in the DNA of polyps. Mutation analysis for KRAS (codons 12 and 13) was performed by DNA sequencing while BRAF mutation (V600E) was studied using allelic discrimination.
RESULTS: A total of 378 polyps were classified as adenomas. BRAF mutation was present in 0.6% of adenomas and KRAS mutation in a 6.8%. A total of 204 polyps were classified as serrated polyps, 188 (92,1%) were hyperplastic polyps (HPs), 10 (4,9%) as sessile serrated polyps (SSP) and 6 (2,9%) as traditional serrated adenomas (TSA). We observed that polyps harbouring BRAF mutation are more frequently larger than 10 mm than non-mutated polyps (70,4% vs 29,6%; p=0,03). When we compare mutations in BRAF and KRAS we can observe that BRAF mutated polyps appeared more frequently in the right colon (75% vs 25%; p=0,015). KRAS mutated polyps are located mainly in the left colon with an upward progression of the number of polyps to rectum (p<0,001). There were no differences in the morphology of serrated polyps depending on the BRAF or KRAS mutational status. On the other hand when we only considered the HPs polyps we observed that KRAS mutated polyps are smaller than 10mm (75%vs25%) and are located with statistical significance in rectosigmoid colon (p=0.002).
CONCLUSION: BRAF mutation is almost exclusive of serrated polyps. Serrated polyps showing BRAF mutation have more frequently features of advanced polyps, being higher in size and right-sided.

P805 EARLY CLOSURE OF TEMPORARY ILEOSTOMY, A LARGE PROSPECTIVE STUDY

O. Wijers[1,*], A. M. Coester[1], R. Bakx[2], H. Bruine de[3], P. Verbeek[1]. [1]*Surgery, Flevoziekenhuis, Almere,* [2]*Surgery, AMC, Amsterdam,* [3]*Radiology, Flevoziekenhuis, Almere, Netherlands*

INTRODUCTION: A temporary ileostomy is a frequently used method to protect a distal colorectal anastomosis and to reduce the morbidity and mortality in case of an anastomotic leakage (AL). Usually, closure is performed 8 – 12 weeks after the primary operation although currently there is no evidence that this period is required for complete healing of the colonic anastomosis. During this prolonged period, stoma-related complications can occur and medical expenditures may rise.
AIMS&METHODS: The aim of this large prospective, single-center cohort study was to analyze the complications and stoma-related morbidity after early (7 – 14 days) and postponed closure of loop ileostomy in patients who received a colonic anastomosis between 2002 and 2011. All included patients underwent a bowel enema study, ten days postoperatively, to judge the presence of AL. When no clinical and/or radiological signs of anastomic leakage were present, early closure of ileostomy was attempted. Reasons to postpone ileostomy closure were analyzed. Patients were monitored from the primary construction of the loop ileostomy until one year after closure of the ileostomy.
RESULTS: Seventy-five patients were included in this study. Early closure of the loop ileostomy was performed in 42 patients. Late closure was necessary in 30 patients. In three patients the stoma was not closed. Reasons for postponing closure were clinical and/or radiological signs of AL (6), delayed recovery (20), gastroparesis (3), and logistic reasons (1). In the postponed closure group were more major surgery related complications (p<0.01): haemorrhages (n=3) and abcesses (n=2) for which a relaparatomy was performed. Intra-abdominal abcesses occurred in n=2 in the early group. Minor surgery related complications were not different in the early group vs the postponed group, p=0.06, although wound infection was more frequent in the early group. Total average in-hospital stay, from the initial operation until the day of discharge , was 18 days (11 – 107) in the early closure group and 27 days (16 – 63) in the late closure group.

CONCLUSION: This large prospective study shows that early closure of the temporary ileostomy is safe in patients without clinical and radiological signs of AL. The most important criterion for early closure of the ileostomy is the presence of a radiologically proven sufficient healed anastomosis in a clinically stable patient.

P806 EXTERNAL VALIDATION OF A PROGNOSTIC MODEL OF PREOPERATIVE RISK FACTORS FOR POUCH FAILURE

S. Sahami[1,*], S. A. Bartels[1], L. Bos[1], R. Lindeboom[2], C. J. Buskens[1], W. A. Bemelman[1]. [1]*Surgery,* [2]*Clinical Methods and Public Health, AMC, Amsterdam, Netherlands*

INTRODUCTION: A prognostic model of preoperative risk factors for ileoanal pouch failure has been proposed by the Cleveland Clinic. The model incorporates four predictive variables: completion proctectomy, diabetes mellitus, handsewn anastomosis and Crohn's disease.[1]
AIMS&METHODS: Aim of the present study is to perform an external validation of this model in a new cohort of patients having had an ileal pouch-anal anastomosis (IPAA).
Validation was performed in a cohort of 371 consecutive patients who had an IPAA between 1999 and 2012 in a single tertiary referral center in the Netherlands. The proposed prognostic model was validated in this cohort using a Kaplan-Meier survival analysis and Cox regression analysis and the performance of the model was expressed using the Harrell's concordance error rate.
RESULTS: Kaplan Meier analysis showed a worse pouch survival for completion proctectomy (P=0.021) and no significant difference for diabetes (P=0.368). A trend was seen for handsewn anastomosis (P=0.072) and Crohn's disease (P=0.065). Although the observed hazard ratios for pouch failure were similar to those reported for the Cleveland Clinic sample, multivariable analysis showed no significant independent predictors in this cohort. Harrell's concordance error rate was 0.42, indicating poor performance.
CONCLUSION: Although no independent significant predictive differences were observed, the variables completion proctectomy, handsewn anastomosis and Crohn's disease were also associated with pouch failure in our cohort with relatively few events. However, the poor performance of this proposed prognostic model does not make it suitable for application in daily practice.

P807 MUCINOUS AND SIGNET-RING CELL CARCINOMAS DIFFER FROM CLASSICAL ADENOCARCINOMAS IN TUMOR BIOLOGY AND PROGNOSIS

U. Nitsche[1,*], A. Zimmermann[1], C. Späth[1], T. Müller[1], M. Maak[1], J. Slotta-Huspenina[2], K.-P. Janssen[1], H. Friess[1], R. Rosenberg[3], F. G. Bader[1]. [1]*Department of Surgery, Klinikum rechts der Isar der TU Muenchen,* [2]*Institute of Pathology, TU Muenchen, München, Germany,* [3]*Department of Surgery, Kantonsspital Baden, Baden, Switzerland*

INTRODUCTION: Most colorectal cancers are classical adenocarcinomas (AC). Less frequent subtypes include mucinous adenocarcinomas (MAC) and signet-ring cell carcinomas (SC). The histological subtype has no therapeutical consequences so far, although it may reflect different biological behavior.
AIMS&METHODS: To define the prognostic value of different histological subtypes of colorectal cancer. Between 1982 and 2012, a total of 3479 consecutive patients underwent surgery for primary colorectal cancer (AC, MAC, or SC). Clinical, histopathological, and survival data were analyzed.
RESULTS: ***MAC and SC were rare histological subtypes.*** Of all 3479 patients, 3074 cases were AC (88%), 375 cases were MAC (11%), and 30 cases were SC (0.9%). Although potentially induced by radiation, the prevalence of MAC and SC was not significantly altered after neoadjuvant treatment (p=0.200).
MAC and SC had distinct clinicopathological characteristics. MAC (51%, $p<0.001$) and SC (50%, $p=0.029$) occurred more frequently in right-sided tumors than AC (28%), and had poorer histological grading ($p<0.001$ for both). Subgroup analysis revealed higher rates of microsatellite instability for MAC and SC compared to AC (p=0.006). Rates of angioinvasion were lower in MAC than in AC (5% vs. 9%, $p=0.011$). Rates of lymphatic invasion were higher in SC than in AC (67% vs. 25%, $p<0.001$).
Only SC were an independent prognostic factor. Five-year cause-specific survival was 67±1% for AC, 61±3% for MAC, and 21±8% for SC ($p<0.001$ for difference between the groups). Compared to AC, tumor stages were higher in MAC and SC ($p<0.001$). After stage correction, survival of AC and MAC did not differ significantly (p=0.991), whereas SC remained an independent prognostic factor associated with worse survival compared to AC (HR=2.5, 95% CI 1.6–3.8, $p<0.001$).
CONCLUSION: MAC and SC are uncommon histological subtypes of colorectal cancer with different characteristics than classical AC. Both are diagnosed in more advanced tumor stages, but the dismal prognosis of SC appears to be caused by its intrinsic tumor biology. The consideration of the histological stubtyp in future classification systems could increase prognostic accuracy.

P808 THE SACCHAROMYCES BOULARDI'S ROLE IN THE COMPLEX OF MEDICAMENTAL CORRECTION OF INTRAINTESTINE HOMEOSTASIS (IIH) IN EARLY POSTOPERATIONAL PERIOD (EPP) IN PATIENTS WITH ACUTE APPENDICITIS (AA) A CONTROLLED, RANDOMISED STUDY

A. Kvit[1,*], V. Kunovsky[1]. [1]*Endosurgery, Lviv National Medical University, Lviv, Ukraine*

INTRODUCTION: Optimization of the diagnostic-medicative program which includes integrated surgical treatment of patients with AA is still an urgent problem.
AIMS&METHODS: The aim of the research is to optimize the medicamental therapy in epp of patients with AA considering results of the bacteriological examination of the peritoneal exudation. The patient's with AA medicamental and operational treatment in the Lviv Emergency Hospital in 2010-2011 was analyzed. The observation group consisted of 77 patients, by who simultaneously with antibacterial treatment (amenably to the schemes and standards to renew the adequate peristalsis) the probiotic Saccharomyces boulardi was also applied (in dosage 1 dose three times a day) to effect the correction of IIH starting from the 2-nd day of the treatment.
RESULTS: By extension of the illness period the patients per cent in which the signs of the peritoneal exudation infection are confirmed is increasing in geometrical progression, which has a huge negative influence on the movement of intestinal contents though the digestive tract and has an effect on the development of intestine wall microcirculatory malfunctions and can also provide to IIH malfunction.
The bacteriological examination data gave us information, that in peritoneal exudation prevailed pathogenic E.coli (75; 97,4%), in monoculture (27; 35%), and in association with other cultures (48; 62,4%): Enterococcus faecalis (14; 18,2%), Pseudomonas aerogenosa (13;16,9%), Enterobacter aerogenes (5; 6,5%), Hl. Pneumoniae (1; 1,3%), Pr. vulgaris (5; 6,5%), Streptococcus aureus (4; 5,2%), Streptococcus haemolyticus (6; 7,8%), there was no growth only in 2 cases (2,6%). The bacteriological research of defecation, made on the 3-rd and 7-th day of treatment confirmed the renewal of the large intestine microbiocenosis, we recorded reliable ($p<0,005$) quantitative growth of lactobacteria (з 6,88±0,19 до 7,91±0,15 lg CFU/ml) and bifidobacteria (з 7,71±0,23 до 8,62±0,21 lg CFU/ml) in 89,6% of patients.
CONCLUSION: The bacteriological examination of abdominal cavity exudation in patients with acute appendicitis confirmed, that the main microflora gained as a result of the examination is E.coli in monoculture - 35%, and in association with other cultures (62,4%), mainly with Enterococcus faecalis, Pseudomonas aerogenosa та Streptococcus haemolyticus. The antibacterial therapy in association with probiotic Saccharomyces boulardi promotes the elimination of the pathogenic microflora and helps to renew the IIH in 69 patients (89,6%).

P809 HOW WELL DO WE UNDERSTAND SEPSIS? A CROSS SECTIONAL SURVEY

D. Longbotham[1,*], L. Stevens[1], R. Singh[1], J. Sarveswaran[1], G. Kaur[1]. [1]*Surgery, SCUNTHORPE GENERAL HOSPITAL, Scunthorpe, United Kingdom*

INTRODUCTION: Sepsis is a major cause of morbidity and mortality, with an incidence of 1 per 1000 population per year and mortality ranging from 20-50%. Sepsis, Severe sepsis, septic shock and SIRS are very clearly defined by the Surviving Sepsis Campaign, according to which, one of the most important influences on outcome is prompt recognition and subsequent equally prompt treatment to reduce morbidity and mortality.
AIMS&METHODS: The purpose of this study is to assess knowledge of medical students and junior doctors within the local hospital and within the Deanery. Medical students and junior doctors – house officers (F1) and Senior house officers (F2 and core surgical trainees) were questioned to see if there is any improvement of knowledge over time
Over a one month period in January 2013, 40 participants were provided questionnaires, 36 people completed this; 7 final year medical students, 11 F1, 8 F2 and 11 Core Surgical Trainees.
RESULTS: Medical students – 14% defined SIRS correctly,14% defined sepsis. 71% believed empirical antibiotics should be given in less than an hour for a patient identified with sepsis. None of the medical students had heard of local trust sepsis protocols, antibiotic policies and critical care outreach. F1 – 18% defined SIRS correctly, 72% defined sepsis. 9% could identify severe sepsis, and septic shock. 91% would give antibiotics in less than an hour after diagnosis. 54% didn't know their trust had a sepsis management protocol. F2 – 0% defined SIRS correctly, 75% defined sepsis as SIRS with evidence of infection, and 12.5% defined severe sepsis. 37.5% weren't aware their hospital had a sepsis protocol. 75% had used their trust antibiotic policy. Core surgical trainees – 9% defined SIRS correctly, 90% defined sepsis as SIRS plus evidence of infection, 9% defined severe sepsis. 90% would give antibiotics within an hour. 81% were aware of their trust's sepsis guidelines, and all used their hospital antibiotic policy and critical care outreach.
CONCLUSION: The awareness of what SIRS was found to be inadequate in all groups tested, but what was more worrying was that the more senior surgical trainees were less aware than juniors. However senior trainees seemed more aware of the management of sepsis.

REFERENCES:
1. Angus DC, Linde-Zwirble et al, Epidemiology of severe sepsis in the United States: analysis of incidence, outcome, and associated costs of care. Crit Care Med. 2001;29:1303-1310
2. Definitions for sepsis and organ failure and guidelines for the use of innovative therapies in sepsis. The ACCP/SCCM Consensus Conference Committee. American College of Chest Physicians/Society of Critical Care Medicine. FREE TO VIEW
3. R C Bone; R A Balk; F B Cerra; R P Dellinger; A M Fein; W A Knaus; R M Schein; W J Sibbald. Chest. 1992; 101(6):1644-1655. doi:10.1378/chest.101.6.1644

Correct identification of SIRS and sepsis is the first and most important step, as without identification, appropriate treatment cannot be implemented. This highlights the need for improved education to be introduced at all levels of junior medical training, from medical school, foundation level and core training in regards prompt recognition of this common but live threatening problem. The next step would be a repeat survey after steps are put in place to improve sepsis knowledge.

P810 COMPARISON OF PREOPERATIVE CT-BASED AND INTRAOPERATIVE PANCREATIC RISK ASSESSMENT IN PREDICTING PANCREATIC FISTULA AFTER PANCREATODUODENECTOMY

F. Frozanpor[1,*], L. Loizou[2], C. Ansorge[3], N. Albiin[2], L. Lundell[3], R. Segersvärd[3]. [1]*Surgical department Danderyd Hospital Stockholm, Karolinska,* [2]*Radiology, Karolinska Univ. Hospital,* [3]*Gastrocentrum, Karolinska Univ. Hospital, CLINTEC, Stockholm, Sweden*

INTRODUCTION: Postoperative pancreatic fistula (POPF) remains the predominant cause of morbidity after pancreatoduodenectomy (PD). As previously shown, intraoperative evaluation of pancreatic texture and main pancreatic duct (MPD) size provides a reliable measure of risk for clinically relevant POPF (ISPFG grade-B/C (Ansorge Br. J.Surg 2012). Likewise, the preoperative CT-based determination of the remaining gland volume and MPD diameter can reliably predict the risk of POPF (Frozanpor WJS 2012).
AIMS&METHODS: To evaluate the predictive value of preoperative radiological features compared to intraoperative risk estimation for the development of clinically relevant POPF. In all 296 consecutive PDs at Karolinska University Hospital that had undergone preoperative CT determination of residual gland volume and MPD diameter were included. In 216 of these patients, a standardized intraoperative assessment of gland texture and MPD size were done. Both the preoperative and intraoperative risk assessments were conducted in three POPF-risk groups: low, intermediate and high risk. The risk estimates were calculated as OR and 95% confidence interval (CI).
RESULTS: Results of the radiological arm exhibits: low risk 4.3 % (OR 7.5; CI 3.1-18, $p<0.001$), intermediate risk 22 % (OR 2.4; CI 1.2- 4.5, $p<0.01$), high risk 41% (OR 5.0; CI 2.2-11, $p<0.001$). Results of the intraoperative risk assessment arm exhibits: low risk: 4.8 % (OR 8.6; CI 3.4-22, $p<0.001$), intermediate risk 26 % (OR 2.7; CI 1.3-5.7, $p<0.01$). high risk 39% (OR 4.7; CI 2.0-11, $p<0.001$).
CONCLUSION: The preoperative CT-based risk assessment and the intraoperative assessment done by experienced pancreatic surgeons had comparable POPF-predictive impacts.

P811 COMPLICATIONS AFTER ADJUSTABLE GASTRIC BANDING FOR OBESITY; THE ENDOSCOPIST'S POINT OF VIEW

F. Dimoulios[1,*], J.-C. Bertrand[2], J.-F. Rey[1]. [1]*Gastroenterology Department,* [2]*Surgery Department, Institute Arnault Tzanck, St Laurent du Var, France*

INTRODUCTION: Bariatric surgery is currently the most effective measure for treating morbidly obese patients. Laparoscopic adjustable gastric banding (AGB) is a restrictive, widely applied technique, with good results. The gastroenterologist who is called to evaluate the postoperative bariatric patient is obliged to face a completely new anatomy and must be able to recognize and, if possible, to manage the potential complications.
AIMS&METHODS: The files of 298 patients (36 men) submitted to laparoscopic AGB during an 8-year period by a single surgeon, were retrospectively reviewed. Postoperatively, all patients (mean age 41.5±11.4, range 16-70) were submitted at least once to upper endoscopy due to inadequate weight loss or symptoms that implicated complications or as part of a routine control, usually at 24 months after the operation. Mean follow-up time was 37.4±21.8 months (range 2-96). The postoperative complications, as diagnosed by endoscopy, were analyzed.
RESULTS: 91 patients had at least one kind of abnormal findings. A total of 106 abnormal endoscopic findings were recorded. Mean time of diagnosis was 35.2±17.9 months after operation. Sixty-nine of the patients had to be reoperated due to complications or inadequate weight loss.The endoscopic complications recognized were: esophagitis 12%, Barrett's esophagus 1.5%, pouch dilatation/gastric prolapse 5.5%, transgastric migration of ring 4%, inflammation of the mucosa covering the ring 1.2%, gastric bezoar 0.3%, proximal slippage of the ring 7.3%, stomal stenosis 1.8%, hemorrhage 0.6%, adenocarcinoma 0.3%. Patients with gastric bezoar and stomal stenosis were able to be treated endoscopically.
CONCLUSION: Endoscopic complications after laparoscopic AGB are frequent. The endoscopist must be aware of the surgically altered anatomy and the appearance of the potential complications.

P812 POST-CHOLECYSTECTOMY ACUTE BILE DUCT INJURIES: PRESENTATIONS AND OUTCOME

J. Abraham[1,*], V. K. Kapoor[1], A. Prakash[1], A. Behari[1], A. Gupta[1], R. Singh[1], R. Saxena[1]. [1]*SURGICAL GASTROENTEROLOGY, SANJAY GANDHI POST-GRADUATE INSTITUTE OF MEDICAL SCIENCES, Lucknow, India*

INTRODUCTION: Management of post-cholecystectomy acute bile duct injuries (BDI) has been addressed in the literature less frequently than the management of established benign biliary strictures (BBS). We have reviewed our experience with management of acute BDI and reported the short term and long term outcome of the patients with acute BDI.
AIMS&METHODS: Retrospective analysis of prospectively kept data of 239 patients with post-cholecystectomy acute BDI that were managed in a single institution from January 1989 to Dec 2010 and in whom follow up information was available.
RESULTS: Of the 239 patients**, t**here were 77 males & 162 females patients with a median age of 40.0 (12-74) years. The index surgery was open cholecystectomy in 147, open cholecystectomy with common bile duct (CBD) exploration in 12 and laparoscopic cholecystectomy in 80 patients. Patients were referred to us at a median duration of 22 days (1-270) days after cholecystectomy.106/239(44%) had jaundice on presentation. 100/239(42%) patients had single or multiple pre-referral interventions.
Based on their clinical presentation, the patients with BDI were classified into external biliary fistula EBF(n=107), Bilioma(n-100), Bile ascites(n=10), Bile peritonitis(n=20) and 2 pts presented with only jaundice of which 1 underwent early repair, 1 refused surgery.
70 patients were managed conservatively, 112 had percutaneous intervention, 40 had endoscopic intervention, 37 were operated and 36 had combination of these procedures including surgery. 9/309(3%) patients died due to the complications of BDI and were excluded from the study. Post- intervention, on the basis of scintigraphy (HIDA), cholangiography (MRCP, ERCP, Tubogram), 138/239 (58%) had complete injury and 101/239 (42%) had partial injury
Early outcome (at 4 weeks of intervention): In pts. with complete injury, 79/158(57%) had controlled external biliary fistula whereas 85/101(84%) with partial injury had closure of fistula.
Late outcome (6 weeks to 3 months): 129/138(93%) of pts. with complete injury went on to have biliary stricture requiring surgical intervention compared to only 29/101(29%) in the group with partial injury.
CONCLUSION: Post-cholecystectomy BDI presents as EBF, Biloma, bile peritonitis, bile ascites, only jaundice and management differs in each of these presentations.

1. Chapman WC, Halevy A, Blumgart LH, Benjamin IS. Postcholecystectomy bile duct strictures. Management and outcome in 130 patients. Arch Surg. 1995 Jun; 130(6): 597-602.
Majority of patients with post-cholecystectomy BDI referred to surgical units have 'complete' injury.
The short term and long term outcome of the acute BDI could be predicted based on the clinical and radiological presentation of the patients.

P813 REGENERATIVE OF THE BLADDER WALL FOR THE TREATMENT OF A BIOABSORBABLE POLYMER SHEET

K. Okada[1,*], M. Miyazawa[1], M. Aikawa[1], I. Koyama[1]. [1]*Saitama Medical Univercity, Saitama-ken HIdaka-shi , Japan*

INTRODUCTION: If the segmental resection of the bladder wall where the rectal cancer invased is required, absorption thread is often used for the direct sutures. With a decrease in bladder capacity, it might be micturition and the long-term urethra catheter custody. The surgery to extend of the bladder with intestinal canal of caulescent may be stressful for the patients. Nowadays, there is no reinforcing materials which can substitute a defective part. Our group successes the renovation of various organs, such as an extrahepatic bile duct, and a gastric parietal using the bio absorbable polymer sheet ;BAPS In this study, we investigated the renovation of the bladder wall using BAPS.

AIMS&METHODS: The body weights with 20kg Mongrel (hybrid) pigs were laparotomized under general anesthesia. A 5×2-cm or 9×7-cm oval-shaped portion of the bladder wall was excised, and a BAPS was implanted with consecutive sutures at the excision site. BAPS is a porous fiber material composed of a 50:50 copolymer of polylactic acid and polycaprolactone and reinforced with polyglycolic acid fibers. The hydrolysis in the living body is absorbed in about 8 weeks. The pigs were relaparotomized at 4 weeks (5×4-cm, 9×7-cm, each n=3), and 20 weeks(5×4-cm, n=1) after implantation. The histological findings of the repaired diagrams were evaluated. We compared the bladder capacity with the BAPS non-transplant group (9×7-cm consecutive sutures at the excision site, n=2), BAPS transplant group

RESULTS: Four weeks later, neither group accepted the failure or the urinary leakage of the transplant part. Significant shrinkage was recognized at 30% in both 5×4-cm and 9×7-cm patches, and the regeneration of bladder wall was not found. The bladder capacity with the BAPS transplant group (9×7cm) was 400 cc , compared with 300cc of non-transplant group. It showed a slight increase at the bladder capacity. BAPS could not keep the dome-shape after the 9×7-cm excision and suturing, and this might be the reason of the shrinkage. Therefore, the plastic spherical prop/stent was inserted into the bladder to maintain the shape of the sheet site. In the results, there was no shrinkage at the implantation site after 4 weeks later.

CONCLUSION: BSAP repaired the defective bladder wall after partially bladder wall excision site. However, there was a problem for the remarkable shrinkage of BAPS in thebladder capacity by a more extensive loss. To avoid this shrinkage, we placed a stent to maintain the shape of the bladder after implantation, and this method was successfully to repair the bladder. It is suggested that this model which use BAPB for the defective tissue should approach the goal of clinical surgical use in future.

P814 SIGNIFICANT ERRORS IN CODING OF GENERAL SURGICAL READMISSIONS IN A UK DISTRICT GENERAL HOSPITAL

M. D. Gill[1,*], D. Silman[2]. [1]*North West Deanery, Manchester,* [2]*Tameside General Hospital, Ashton-under-Lyme, United Kingdom*

INTRODUCTION: The UK Department of Health have proposed ceasing payment for emergency hospital readmissions. This would affect 430,000 patient spells with an estimated loss in revenue of £790 million.

AIMS&METHODS: Aims were to establish the accuracy of recorded readmissions in a district general hospital in the UK over a six month period. The computerised hospital records of all general surgical readmissions between March and September 2012 were reviewed.

RESULTS: Of 1,320 admissions, 197 (14.2%) were readmissions in 169 patients. 194 readmissions in 166 patients were suitable for analysis. 72 (43.4%) were male, 94 (56.6%) female with a median age of 52.4 years (range 6.3 – 99.4). No difference was found in age group (p=0.1), or mean age (p=0.2), between gender. 174 primary admissions had one readmission, 17 had two readmissions, and one had five readmissions. 85/174 (48.9%) 1st readmissions were invalid, of which 58 (68.2%) were due to differing specialities at each admission, 14 (16.5%) readmissions were planned admissions, 9 (10.6%) were due to a flare of a chronic condition, 3 (3.5%) were readmitted with an unrelated pathology, and 1 (1.2%) patient self discharged at initial admission. Total hospital length of stay (LOS) for invalid readmissions was 542 days. For valid readmissions, no correlation was found between initial LOS and time to readmission (R^2 linear = 0.012) or LOS for readmission (R^2 linear = 0.006).

CONCLUSION: Robust systems need to be instituted to ensure that readmissions are coded correctly, to ensure hospital trusts are appropriately reimbursed.

P815 CHOLECYSTECTOMY DOES NOT INFLUENCE GASTROINTESTINAL TRANSIT: RESULTS OF A PROSPECTIVE STUDY USING RADIO-OPAQUE MARKERS

N. Mottacki[1,*], A. Bajor[1], M. Simren[2], K.-A. Ung[3]. [1]*Department of Gastroenterology, Sahlgrenska University Hospital,* [2]*Sahlgrenska Academy, University of Gothenburg, Gothenburg,* [3]*Department of Internal Medicine, Kärnsjukhuset i Skövde, Skövde, Sweden*

INTRODUCTION: Cholecystectomy has been shown to lead to changes in gastrointestinal (GI) transit by reducing transit time through the colon, though this remains disputed. However, studies in this area are sparse, and have often used lactulose, which in itself influences transit times.

AIMS&METHODS: We aimed to assess prospectively whether cholecystectomy affects GI transit using a radiological procedure developed at our unit.

Twenty-four patients (21 female, 3 male), prior to elective cholecystectomy, ingested 10 radio-opaque rings daily for 6 days, dividing the dose in two on the final day to improve measurement of fast colonic transit. On day 7, 20 radio-opaque spherical markers were added, and the positions of markers were observed every 30 minutes using fluoroscopy for a maximum of 8 hours. Gastric emptying time, small intestinal transit time (SITT), oro-anal transit time (OATT) and segmental colonic transit times were determined. The procedure was repeated 3 months post-operatively and pre- and post-operative transit times were compared.

RESULTS: No difference was shown between pre-operative median gastric emptying time (2.65 hours, range 0.4-8.6) and post-operative times (2.80 hours, range 0.3-5.3; Z=-1.759, p=0.079, Wilcoxon signed rank test), nor between pre-op SITT median (5.30 h, range 1.2-73.3), and post-op SITT (6.00, 2.0-21.7; Z=-0.556, p=0.578). Colonic segmental transit times were also unchanged: pre-operative median right colon segmental transit time was 0.5 days (range 0-1.0), compared to 0.5 days post-operatively (0-1.9; Z=-0.825, p=0.410); pre-op transverse colonic transit 0.15 days (0-0.9), post-op 0.3 days (0-0.9; Z=-0.141, p=0.888) and pre-op left colonic transit 0.6 days (0-3.1), post-op 0.55 (0-1.3; Z=-0.786, p=0.432). Median total oro-anal transit time pre-operatively was 1.6 days (0.4-4.9) and post-operatively 1.7 days (0.4-3.1; Z=-0.540, p=0.589), again showing no measurable effect after cholecystectomy.

CONCLUSION: Cholecystectomy does not appear to affect a change in gastric emptying, small bowel transit time, segmental colonic transit times, or oro-anal transit times in a 3-month prospective follow up. Longer follow-up periods may be of value to establish whether changes are induced in the longer term.

P816 DERANGEMENT OF THE RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM AND GLYCAEMIC CONTROL AFTER COLECTOMY

S. Mallappa[1,*], M. Samarasinghe[2], S. M. Gabe[3], R. K. Phillips[2], M. D. Robertson[4], S. K. Clark[2]. [1]*The Polyposis Registry, St Mark's Hospital,* [2]*The Polyposis Registry, St Mark's Hospital,* [3]*Department of Gastroenterology & Intestinal Failure , St Mark's Hospital, Harrow,* [4]*Faculty of Medicine, University of Surrey, Guildford, United Kingdom*

INTRODUCTION: There is increasing evidence that colon is an active metabolic organ, removal of which leads to sodium and water depletion, chronic activation of renin-angiotensin-aldosterone system (RAAS), hyperaldosteronism and abnormal glucose tolerance[1]. Previous work has studied patients who have undergone colectomy for inflammatory bowel disease[2]. This is the first such study in patients with familial adenomatous polyposis (FAP). Patients with FAP undergo prophylactic colectomy to prevent development of colorectal cancer and so long term metabolic abnormalities resulting from the surgery would be of immense clinical interest.

AIMS&METHODS: We aimed to determine the prevalence of metabolic disturbance in patients with FAP following colectomy.

30 FAP patients who had undergone either colectomy and ileo-rectal anastomosis or restorative proctocolectomy at our institution were recruited. After fasting, urine and blood samples were collected to measure sodium loss, hydration status and RAAS activation. An oral glucose tolerance test was performed as per the World Health Organisation recommendation. Health related quality of life was assessed using Short Form 36 (SF-36) Health Survey (Version 2) and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) (Version4) questionnaires.

RESULTS: Median time since prophylactic colectomy was 11.5 years. Fourteen patients (47 per cent) demonstrated fasting hyperaldosteronism (>250pmol/L) leading to higher urinary losses of potassium (p=0.01) and creatinine (p=0.002). Thirteen patients (43 per cent) also demonstrated abnormal glucose tolerance in the form of hypoglycaemia. Patients with hypoglycaemia had a significantly higher early insulin secretion (p=0.04, insulinogenic index) without the expected reduction in tissue insulin sensitivity, resulting in inappropriately low blood glucose levels. Patients exhibiting hypoglycaemia had significantly lower body mass index (p=0.005), lower energy levels with increased fatigue. However, there were no significant differences between the two groups with regard to age (p=0.29) or time elapsed since colectomy (p=0.09).

CONCLUSION: Our work suggests that prophylactic colectomy in FAP patients results in metabolic disturbances leading to a negative impact on the quality of life.

P817 COMPLIANCE WITH THE ERAS (ENAHANCED RECOVERY AFTER SURGERY) PROTOCOL IN AN OPEN INTESTINAL SURGERY.

Z. Serclova[1,*], O. Ryska[1], J. Fulik[2]. [1]*Surgical Department, Military University Hospital,* [2]*Surgical Department, Bulovka Hospital, Prague, Czech Republic*

INTRODUCTION: Modern perioperative care (ERAS, Fast Track) after elective intestinal surgery decreases postoperative complications and shortens hospital stay (1) and is more comfortable for patients than traditional care. These programs arising from EBM are difficult to implement and to follow (2). Randomized study was carried in between 2005-2007 at the authors' work place (3). The intervention group was managed strictly according to the ERAS protocol. The ERAS protocol became standard perioperative care in the department after that.

AIMS&METHODS: The aim of this study was to audit compliance with the ERAS protocol after a prospective study finishing.

Data of the 91 patients (54% women, mean age 36,9 years) who underwent planned open abdominal surgery during the period 9/2010-3/2011 was processed retrospectively. All patients underwent resection of the small or large intestine, proctectomy was performed in 17 patients.

RESULTS: Preoperative oral intake (D-1) was an average of 2418 ml (SD ± 1014), all patients drank PreOp (Nutricia) evening and morning before surgery (average 5,7 units, SD ± 1,4). Nasogastric tube (NGT) was not introduced during surgery in any patient, in 4 patients (4%) it was necessary to introduce it in the postoperative period. Urinary catheter was not inserted in 63 (69%) patients primarily, of which 51 patients (81%) urinated spontaneously and in 12 (19%) was necessary to introduce the catheter for urinary retention. Mean postoperative oral intake was at the day of surgery 738 ml (SD ± 522), postoperative days (POD) 1-4: 1176 ml (SD ± 606 ml), 1477 ml (SD ± 687 ml), 1761 (SD ± 750 ml), 1998 ml (SD ± 611 ml). An epidural catheter for postoperative analgesia was introduced in 82 patients (90%), in 13 (16%) patients was dysfunctional. Analgesia as measured by VAS (visual analgesic scale) was superior in patients with epidural catheter, within the 2nd POD significantly (mean VAS 0,96; SD ± 0,92 vs. 1,7, SD ± 0,99, p = 0,0039). The average length of hospital stay was 8,3 days (SD ± 5,0). Surgical site infection rate was 14,3% (13 patients). SSI I was noted in 7 (7,7%) patients, SSI II and III in 3 (3,3%).

CONCLUSION: All patients (100%) preoperatively drank maltodextrin cocktail, 96% underwent postoperative period without NGT and 56% without urinary catheter. Epidural catheter was established in 90% of the patients and reduced postoperative pain significantly. Length of hospital stay was comparable to that as in a prospective randomized study conducted in the workplace. Compliance with the ERAS protocol for its extensive introduction into practice remained high.

P818 IMMUNOSUPPRESSANT EFFECT OF MESENCHYMAL STROMAL CELLS ON MUCOSAL T CELLS FROM CROHN'S DISEASE PATIENTS

R. Ciccocioppo[1], A. Gallia[1,*], V. Imbesi[1], G. C. Cangemi[1], E. Betti[1], G. Petazzi[1], L. Vanelli[2], C. Picone[2], P. Comoli[3], A. Gurrado[3], L. Pozzi[4], M. E. Bernardo[5], F. Locatelli[5], G. R. Corazza[1]. [1]*Clinica Medica I,* [2]*Laboratorio di Citometria Clinica e Terapia,* [3]*Onco-Ematologia Pediatrica,* [4]*Endoscopia Digestiva, Fondazione IRCCS Policlinico San Matteo; Università di Pavia, Pavia,* [5]*Ospedale Pediatrico Bambino Gesù, Roma, Italy*

INTRODUCTION: Mesenchymal stromal cells (MSC) are multipotent non-hematopoietic stem cells able to promote tissue repair and to exert potent effects on all cells involved in immune response. Crohn's disease (CD) is caused by a dysregulated T cell response towards components of the intestinal microbiota, of which the muramyl dipeptide (MDP), a peptidoglycan constituent of the bacterial wall, plays a crucial role in triggering the inflammatory cascade leading to intestinal injury.

AIMS&METHODS: We investigated the *in vitro* effects of MSC on mucosal T cells in terms of mortality, proliferative response, immunophenotype and cytokine production upon specific antigen stimulation.

A pure population of bone marrow-derived MSC at passage 3 was obtained from 3 adult CD patients. T cells were isolated from inflamed and not-inflamed colonic mucosa of 6 CD patients (F/M 4/2, mean age: 32 years, range 18-56) and 4 healthy controls (F/M 1/3, mean age: 43 years, range 27-52), and expanded *in vitro* through weekly cycles of stimulation with interleukin (IL)-2 (40 U/ml). Parallel cultures were settled in the presence or absence of allogeneic MSC (MSC:T ratio 1:20, 1:200) and MDP (10 mg/ml). The T cell mortality rate and immunophenotype were assessed by flow cytometry, the proliferation rate by incorporation of [^{3}H]-thymidine (0,5μCi/well) upon MDP stimulation. The following cytokines were detected by ELISA assay (SearchLight): transforming growth factor (TGF)-β1, interferon (IFN)-g, IL-6, IL-8, IL-10, IL-21. Student *t* test was applied for statistical analysis.

RESULTS: T cells from inflamed CD mucosa showed a lower mortality rate upon MDP stimulation in comparison with those unstimulated (18% vs 43%, $p<0.05$). MSC at both ratios were able to revert this finding ($p<0.01$), whilst they did not affect the mortality of T cells from not-inflamed CD and healthy control mucosa. A reduction of the activation marker CD25 and an increase of the CD69 in T cells cultured with MSC at both ratios ($p<0.01$), together with a reduction of the inflammatory cytokines IL-21 and IFN-g and an increase of TGF-β1 ($p<0.01$), were found. Finally, MSC inhibited T cell proliferative response upon MDP ($p<0.005$ and <0.05 for inflamed and not-inflamed mucosa, respectively) at both MSC:T cell ratios.

CONCLUSION: MSC display a robust immunosuppressant effect *in vitro* on antigen-reactive pathogenic T cells, thus paving the way to a possible therapeutic use in CD.

P819 VITAMIN D POTENTIATES THE IMMUNOSUPPRESSIVE EFFECT OF ANTI-TNF INDUCED REGULATORY MACROPHAGES

A. Levin[1,*], M. Wildenberg[1], C. Vos[1], F. Bloemendaal[1], G. D'Haens[1], G. Van den Brink[1]. [1]*Department of gastroenterology and Hepatology and Tytgat institute for Liver and Intestinal Research, AMC, Amsterdam, Netherlands*

INTRODUCTION: We have previously shown that anti-TNF-α antibodies induce a distinct population of macrophages with immune regulatory and wound healing properties. An environmental factor that has been shown to induce tolerogenicity in dendritic cells is Vitamin D. Interestingly, epidemiological studies have shown that Crohn's disease patients have a high prevalence of vitamin D deficiency. These results incited us to investigate the role of Vitamin D in anti-TNF induced macrophages.

AIMS&METHODS: The aim of this study was to see if the Vitamin D receptor pathway is involved in the induction of anti-TNF induced macrophages and if Vitamin D can potentiate immunosuppressive effect of these macrophages.

PBMC's were isolated from peripheral blood of healthy donors. Mixed lymphocyte reactions were established by co-culturing PBMC's of two healthy individual donors in a 1:1 ratio. Cultures were treated with anti-TNF to induce anti-TNF induced macrophages. Inflammatory M1 type macrophages were generated by culturing of monocytes in the presence of IFN-gamma. Gene expression of anti-TNF compared to M1 macrophages was determined by microarray followed by pathway analysis.To determine the effect of Vitamin D on the immunosuppressive effect of anti-TNF induced regulatory macrophages, cell culture experiments were performed in the presence or absence of 1,25-dihydroxyvitamin D. Macrophages were isolated with CD14 microbeads and co-cultured with activated T-cells from a third donor. Proliferation was measured by 3H thymidine incorporation.

RESULTS: Anti-TNF induced macrophages displayed an increased expression of a number of components of the vitamin D receptor pathway, including the vitamin D receptor (VDR) and osteopontin (OPN). Addition of 1,25-dihydroxyvitamin D to the cultures did not result in enhanced numbers of regulatory macrophages. However, macrophages generated in the presence of 1,25-dihydroxyvitamin D did show an increased inhibition of T-cell proliferation, indicating increased immunosuppressive function.

CONCLUSION: Anti-TNF induced macrophages show an increased activation of the vitamin D receptor pathway. Furthermore the immunosuppressive properties of wound healing macrophages induced by anti-TNF-α can be potentiated by 1,25-dihydroxyvitamin D.

P820 QUORUM SENSING DRIVEN BY N-ACYL-HOMOSERINE LACTONE IN INFLAMMATORY BOWEL DISEASES ASSOCIATED DYSBIOSIS

C. Landman[1,*], A. Besse[1], M.-A. Maubert[1], L. Brot[1], L. Humbert[1], J. Cosnes[2], L. Beaugerie[2], G. Trugnan[1], H. Sokol[1,2], D. Rainteau[1], E. Quévrain[1], P. Seksik[1,2]. [1]*ERL U1057,* [2]*Gastroenterology, Saint Antoine Hospital, Paris, France*

INTRODUCTION: Dysbiosis is a key factor in inflammatory bowel diseases (IBD) physiopathology. Quorum sensing (QS) driven by N-acyl-homoserine lactone (acyl-HSL), a bacterial communication network, has not been studied in the human gut microbiota yet and could be involved in dysbiosis.

AIMS&METHODS: The aims of this study were to look for acyl-HSLs in human gut microbiota and to investigate their features in IBD associated dysbiosis.

Fecal samples from 19 IBD patients in remission (n=10) and during flare (n= 9) and from 11 healthy subjects (HS) were analyzed. After extraction, an acyl-HSL profile was determined for each sample using HPLC coupled with tandem mass spectrometry. Concentrations were estimated by AUC of each peak (arbitrary units +/- SEM). Acyl-HSL biologic activity was validated on a bacterial biosensor system (*Agrobacterium tumefasciens* NTL4). In parallel, fecal microbiota composition was assessed by real-time quantitative PCR. For statistical analysis, a non parametric test was used.

RESULTS: Nine acyl-HSLs were identified in fecal samples while 2 were prominent: acyl-HSL at *m/z* 216.1 (3-OH-C6-HSL) and acyl-HSL at *m/z* 294.2 (3-oxo-C12:2-HSL or C13:2-HSL) recognized by NTL4 biosensor. Their concentrations

differed between IBD patients and HS: acyl-HSL at *m/z* 216.1 was significantly increased in inactive IBD compared to HS (AUC=2897+/-572 vs 1242 +/-353, P=0.04) and acyl-HSL at *m/z* 294.2 was significantly decreased in active IBD (AUC=2726+/-2726) compared to HS (AUC=30532+/-12230, P=0.007) and to inactive IBD (AUC=26409+/-12291, P=0.02). In parallel, dysbiosis was observed in active IBD: low counts in Firmicutes (*C. coccoïdes* P=0.01 and *C. leptum* P=0.003 including *F. prausnitzii* P=0.04), significant increase in Lactobacilli (P=0.002) and non significant increase in *E. coli* (P=0.6). In samples with high acyl-HSL at *m/z* 294.2 (concentration above median), *C. leptum* was significantly more represented (10.22+/-0.07 vs 9.72+/-0.19 log/g of feces, P=0.046). In these samples, there was also a trend towards higher counts in *C. coccoïdes* (P=0.06) and lower counts in *E. coli* (P=0.09).

CONCLUSION: Our study showed for the first time that QS driven by acyl-HSLs occurs in human gut microbiota. Moreover, in IBD, acyl-HSLs profile characterized by prominent acyl-HSL at *m/z* 216.1 and a decrease in acyl-HSL at *m/z* 294.2 during flare differs from HS. The lack of this acyl-HSL was associated with low counts in Firmicutes. These results invite us to investigate acyl-HSL functional role in dysbiosis onset and in host physiology.

P821 MAGNETIC RESONANCE COLONOGRAPHY IN RATS WITH TNBS-INDUCED CHRONIC COLITIS. A FEASIBILITY AND VALIDATION STUDY

C. Melchior[1,2,*], E. Loeuillard[1], R. Marion-Letellier[1], L. Nicol[3], P. Mulder[3], C. Guerin[1], C. Bôle-Feysot[1], M. Aziz[4], P. Déchelotte[1,5], G. Savoye[1,2], C. Savoye-Collet[6,7]. *[1]INSERM U1073, Rouen University, [2]Gastroenterology, Rouen University Hospital, [3]INSERM U644, Rouen University, [4]Pathology, [5]Nutrition, [6]Radiology, Rouen University Hospital, [7]QUANTIF-LITIS EA 108 , Rouen University, ROUEN, France*

INTRODUCTION: Magnetic resonance colonography (MRC) has been recently developed to assess bowel inflammation in IBD patients.

AIMS&METHODS: We aimed to assess the feasibility of MRC in rats with TNBS-induced chronic colitis and to confront results to model features.

Chronic colitis was induced in rats by weekly intrarectal injection of increasing doses of TNBS (n=9) for 6 wks while controls received vehicle (n=7). Fibrosis was assessed histologically. Fibrosis mediators were measured at wk7. Bowel wall thickness, wall signal intensity on T1 and T2w images, thickening diameter, presence of stenosis and mucosal detachment were recorded.

RESULTS: Chronic colitis was associated with significant body weight loss, higher colon weight/length as compared to control (p=0.0002). Inflammatory parameters were significantly higher in TNBS than in control: IL1β (4531 vs 1067pg/ml, p=0.011) and COX2 (0.8 vs 0.2, p=0.001). Fibrosis mediators were increased: IL13 (68.1 vs 3.6pg/ml, P=0.015), αSMA production (0.9 vs 0.6pg/ml, p=0.03). Fibrosis score was higher in TNBS than in control (p=0.03).

Colon wall thickness was higher in the TNBS than in control: maximal thickness (2.4 vs 0.7mm, p=0.0002) and minimal thickness (1.3 vs 0.5mm, p=0.0002). The wall signal intensity on T2w images was significantly higher in TNBS than in control (9040 vs 6192, p=0.002). Thickening diameter was significantly more important in TNBS than in control (50 vs 10%, p=0.0002). Stenosis was observed in 7/9 TNBS and in 0/7 control (p=0.002). Mucosal detachment was found in 4/9 TNBS and 0/7 control (p=0.04).

MRI data were associated with inflammation and fibrosis parameters:

	Colon weight/ length	Fibrosis score	TNFα	IL1β	COX2	IL13	αSMA
Maximal thickness	**<0.0001**	**0.0013**	0.2556	**0.0184**	**0.0005**	0.0634	**0.0425**
Minimal thickness	**<0.0001**	**0.0141**	0.0555	0.1798	**0.0007**	0.0538	**0.0113**
T2w signal	**0.0010**	**0.0047**	0.2454	0.0677	**0.0005**	0.0594	0.2545
Thickening diameter	**0.0076**	0.0769	**0.0131**	0.3121	**0.0014**	0.0579	**0.0187**

CONCLUSION: MRC is feasible and easily distinguished control from colitic rats. MRC signs are strongly associated with fibrosis parameters. MRC evaluation may be part of new anti-fibrotic drug assessment in experimental models of chronic colitis.

P822 DIFFERENT INFLAMMASOME TYPES COLLABORATE IN HUMAN INFLAMMATORY BOWEL DISEASES

D. Staelens[1,*], P. Peeters[2], J. Van der Goten[1], E. F. Wouters[2], G. Van Assche[1], M. Ferrante[1], S. Vermeire[1], P. Rutgeerts[1], K. Nys[1], I. Arijs[1]. *[1]Translational Research Center for Gastrointestinal Disorders, KU Leuven, Leuven, Belgium, [2]Department of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands*

INTRODUCTION: Recently, intracellular danger – and pathogen receptor activation has been described in the gut. Inflammasome activation in the cytosol of myeloid and epithelial cells leads to potent caspase-1 mediated pyrogene and alarmin secretion (such as IL-1β and HMGB1) that might be involved in the pathogenesis of IBD[1]. Moreover, inflammasome activation has been shown to be pivotal in a murine model of IBD colitis[2]. However, the functional importance of the combined inflammasome subtype activation during IBD pathogenesis remains unknown.

AIMS&METHODS: This study investigated whether there are different inflammasomes activated in colonic mucosa of active IBD patients before and after anti-TNF-α therapy. Therefore, gene expression of genes involved in inflammasome activation was investigated in colonic mucosa from 43 active IBD patients [24 ulcerative colitis (UC) and 19 Crohn's disease (CD)] before and 4-6 weeks after their first infliximab (IFX) infusion and from 6 normal controls. Total RNA was used to analyze gene expression via Affymetrix Human Genome U133 Plus 2.0 Arrays and qRT-PCR. Data was analyzed using Bioconductor software. Protein localisation of AIM2, IFI16, cleaved IL-1-β, CASP1 and HMGB1 was determined by immunohistochemistry (IHC) on formalin-fixed, paraffin-embedded mucosal biopsies of IBD patients and controls. dsDNA-induced intracellular IL-1β cleavage was determined by western blot in protein lysates from intestinal FHC cells.

RESULTS: Gene expression analysis showed a significant (false discovery rate $<5\%$) increase in colonic expression of *AIM2, IFI16* and a borderline significant increase of *NLRP3* in active IBD vs. controls. Moreover, after IFX therapy, a significant decrease in expression of *AIM2* and *IFI16* was observed in IBD responders showing complete mucosal healing when compared to their baseline samples. Interestingly, IHC demonstrated an epithelial expression pattern for AIM2 with minor expression in inflammatory cells. In contrast, we observed positive staining for IFI16 in lymphocytes and epithelial cells. Finally, we confirmed the presence of active IL1-β, CASP1 and HMGB1 in tissue sections of inflamed mucosa and we endorsed the epithelial presence/activation of an AIM2/IFI16-mediated inflammasome since dsDNA (AIM2/IFI16 specific stimulus) could induce IL-1β cleavage in intestinal FHC cells.

CONCLUSION: For the first time we have shown combined transcriptional and functional activation of the different inflammasome subtypes NLRP3, AIM2 and IFI16 in the inflamed colon of active IBD patients, accompanied with expression levels of activated CASP1, IL-1β and HMGB1.

P823 DETERMINATION OF IMMUNE SURVEILLANCE IN CEREBROSPINAL FLUID (CSF) IN PATIENTS WITH CROHN'S DISEASE: INITIAL RESULTS OF THE TOSCA STUDY

G. D'Haens[1,*], A. Van Gossum[2], R. Ransohoff[3], O. Stuve[4], J. Cheng[5], Y. Zhang[5], S. Rivers[5], G. Comer[5], B. Jin[5], K. Gorelick[5], M. Hassan-Zahraee[5], F. Cataldi[5], W. Reinisch[6], Tosca study. *[1]Gastroenterology, Academic Medical Center, Amsterdam, Netherlands, [2]Gastroenterology, Erasmus University, Brussels, Belgium, [3]Neurology, Cleveland Clinic, Cleveland, [4]Neurology, University of Texas, Dallas , [5]Gastroenterology, PFIZER INC, Cambridge, United States, [6]Gastroenterology, University of Vienna, Vienna, Austria*

INTRODUCTION: Natalizumab (N), a therapeutic monoclonal antibody (MAb) for Multiple Sclerosis and Crohn's Disease (CD), increases progressive multifocal leukoencephalopathy (PML) risk. It blocks $\alpha_4\beta_1$ and $\alpha_4\beta_7$ integrins, and inhibits both CNS and gut lymphocyte trafficking. This results in marked reduction in CSF total and CD4+ lymphocytes, and inverted CD4:CD8 ratio, signs of deficient immune surveillance, and the putative mechanism contributing to PML due to JC virus infection/reactivation.[1]PF-00547659 (PF) is an investigational, fully human, anti-MAdCAM MAb designed to reduce gut lymphocyte homing, to treat inflammatory bowel disease. Because of the low incidence of N associated PML, comparing risk between these drugs in clinical trials is not feasible. However, 6 weeks after 1 injection of N, a dramatic drop in CSF lymphocytes and CD4 cells occurs.[2] An alternative approach to assess drug-induced PML risk may be to assess the effect of a new agent on CNS T lymphocytes. The purpose of this study is to see if PF alters trafficking of the lymphocyte population to the CNS reflecting immune surveillance in CD patients (pts).

AIMS&METHODS: TOSCA is a 2 cohort open-label study of PF. Cohort 1 explored baseline CSF values at 2 different lumbar puncture (LP) visits before PF administration, while cohort 2 will investigate CSF composition before and after induction with PF. We present here the data from Cohort 1, along with concurrent data from 5 healthy subjects. CSF from adults with moderately-to-severely active CD, who failed prior immunosuppressants (IS) and anti-TNF treatment was analyzed by FACS

RESULTS: Of 10 CD pts, 8 were men, age (mean±sd) was 40.8±16.0y, CD duration was 13.5±6.1y and HBI was 8.6±2.8 for 7 pts (3 had stomas). Data from 2 pts were discarded because of inaccurate cell counting. 3 pts did not have a 2nd LP because of headache. FACS data, in cells/mL, are shown below

Population	Total Lymphs	CD3+	CD4+	CD8+	CD4:CD8
LP1 (n=8)	678 (64.4)	571 (72.2)	408 (74.3)	178 (142.0)	2.3 (140.2)
LP2 (n=5)	832 (65.9)	796 (63.2)	551 (73.8)	206 (55.9)	2.7 (67.7)
Healthy Subjects (HS) (n=5)	672 (66.4)	654 (66.4)	498 (65.6)	199 (60.1)	2.5 (23.3)
Geometric mean values (CV%)					

CONCLUSION: CSF lymphocyte counts are similar in HS and pts with moderate-to-severe CD. Repeat testing showed stable CSF lymphocyte populations, showing lack of inflammatory changes after LP. This is a promising approach to assess risk of anti-integrin therapy

P824 ROLE OF TOPICAL CALCIUM BUTYRATE IN INFLAMMATORY AND PROLIFERATIVE COLON DISEASES

G. Celasco[1,*], L. Moro[2]. [1]*Cosmo Research & Development SpA, Lainate, Italy,* [2]*Cosmo Technologies Ltd, Dublin, Ireland*

INTRODUCTION: Butyric acid (BA) is a physiological component of colonic environment endowed with anti-inflammatory properties. Moreover BA is a pivotal regulator of cell-cycle since it inhibits histone deacetylase, and activates acid sphingomyelinase leading to production of antiproliferative molecules such as ceramide and sphingosine.

AIMS&METHODS: To investigate the topical anti-inflammatory activity of BA calcium salt (calcium butyrate, CB) in chemically-induced colitis in rat, and to evaluate "in vivo" and "in vitro" its anti-proliferative properties.

i) The anti-inflammatory activity of CB (10-30 mg) was evaluated in rat in the dinitrobenzene (DNB)-induced colitis test, after intracolonic instillation for 6 consecutive days starting 3 days before colitis induction. ii) The "in vivo" anti-proliferative activity of CB (3.5 mg) was evaluated in F344 rat in the azoxymethane (AOM)-induced aberrant crypt foci (ACF) test, after intracolonic instillation six days a week for four weeks. iii) The "in vitro" anti-proliferative activity of CB (2.5-5-10 mM) was assessed by incubation for 48h with HT29, SW620 and HCT116 tumour cell lines evaluating the rate of [^{3}H]thymidine incorporation.

RESULTS: i) In DNB-induced colitis, the intracolonic instillation of CB 30 mg completely prevented the decrease of body weight of the animals, and counteracted the local noxious effects of the irritant by reducing both the colon swelling (-23%) and the mucosal damaged area (-48%) respectively. ii) In AOM-induced aberrant crypt foci test, the intracolonic instillation of CB significantly reduced the number of ACF in the whole colon (-22.7%). iii) CB, incubated with HT29, SW620 and HCT116 tumour cell lines, induced in all strains a significant anti-proliferative dose-dependent effect measured by reduction of [^{3}H]thymidine incorporation.

CONCLUSION: CB, when directly applied to the mucosa of the colon of the rat, is able to ameliorate the colonic inflammation, suggesting a possible beneficial role in the treatment of inflammatory colon diseases. Moreover, CB showed "in vivo" and "in vitro" interesting anti-proliferative activities, whose clinical relevance needs to be confirmed in additional clinical investigations.

P825 CROHN'S DISEASE-ASSOCIATED ADHERENT-INVASIVE ESCHERICHIA COLI MANIPULATE HOST AUTOPHAGY BY IMPAIRING SUMOYLATION

G. Dalmasso[1,*], H. T. T. Nguyen[1], L. Goulème[1], A. Cougnoux[1], L. Gibold[1,2], J. Delmas[1,2], A. Darfeuille-Michaud[1,2], R. Bonnet[1,2]. [1]*M2iSH, Inserm UMR 1071, INRA Usc 2018, University of Auvergne,* [2]*Centre Hospitalier Universitaire, Clermont-Ferrand, France*

INTRODUCTION: Crohn's disease (CD) is an inflammatory intestinal disorder involving genetic and environmental factors, as well as microbiota. It has been established that intestinal mucosa of CD patients is abnormally colonized by pathogenic adherent-invasive *Escherichia coli* (AIEC) able to adhere to and to invade intestinal epithelial cells (IECs). SUMOylation is a reversible modification in which SUMO, a ubiquitin-like polypeptide of about 10 kDa, is covalently linked to target proteins. SUMOylation has been emerged to regulate numerous cellular processes, such as transcription and protein stability.

AIMS&METHODS: Here, we investigated the role of SUMOylation in host defense against AIEC infection. SUMO-conjugated protein levels in human intestinal epithelial cells T84 and in mouse intestinal epithelia were analyzed by Western blot. The number of intracellular AIEC in cells over-expressing SUMOs was determined by bacterial invasion assay and confocal microscopy. SUMOylation status of ATG5 and ATG16L1 was assessed by immunoprecipitation analysis. Autophagic activity was characterized by Western blot and immunofluorescent analyses of LC3 and p62 levels.

RESULTS: AIEC infection markedly decreased the levels of SUMO1-, 2- and 3-conjugated proteins in IECs. This was also observed in IECs from AIEC-infected mice. Over-expression of SUMO1, 2 or 3 significantly decreased the number of intracellular AIEC in IECs. As we previously showed that the intracellular replication of AIEC is tightly controlled by autophagy, the involvement of SUMOylation in such process was investigated. We observed that autophagic activity was increased in T84 cells transfected with SUMOs as shown by increased LC3-II and p62 protein levels. Bioinformatics prediction revealed ATG5 and ATG16L1, two key elements of autophagy induction, as potential targets of SUMOs. Immunoprecipitation and Western blot analyses confirmed the SUMOylation of these proteins in IECs, which was decreased upon AIEC infection. Plasmids encoding ATG5 or ATG16L1 wild-type or mutated for the SUMO-binding site were respectively transfected in ATG5 or ATG16L1-deficient MEFs. Absence of SUMOylation of ATG5 and ATG16L1 in MEFs resulted in a less efficient autophagy response to AIEC infection.

CONCLUSION: Our results suggest that AIEC infection inhibits host autophagy response to replicate intracellularly via a SUMOylation-mediated mechanism.

P826 AUTONOMIC NERVOUS SYSTEM FUNCTION PREDICTS THE INFLAMMATORY RESPONSE OVER A THREE-YEAR FOLLOW-UP

V. Gunterberg[1], L. van Oudenhove[2], L. Öhman[1], M. Simrén[1], H. Strid[1,*]. [1]*Department of Internal Medicine, Sahlgrenska University Hospital, Institute of Medicine,Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden,* [2]*Department of Clinical and Experimental Medicine , Translational Research Center for Gastrointestinal Disorders, University of Leuven, Leuven, Belgium*

INTRODUCTION: The autonomic nervous system (ANS) modulate disease activity in several animal models of intestinal inflammation. The parasympathetic nervous system (PNS) acts anti-inflammatory via the vagus nerve, while the sympathetic branch (SNS) is considered pro-inflammatory. However, clinical evidence confirming such an influence of the ANS on gut or systemic inflammation in patients with inflammatory bowel disease (IBD) is sparse.

AIMS&METHODS: We aimed to investigate whether ANS function is associated with severity of inflammation at onset of ulcerative colitis (UC), and whether ANS function at onset predicts the evolution of inflammatory parameters longitudinally.We followed 49 patients from onset of UC for 3 years. Three months after inclusion, ANS activity was assessed by HRV analysis of 24-hour Holterrecordings. RMSSD was used as an indicator for PNS activity and LF/HF for SNS activity. Blood and stool samples were obtained at the visits to assess inflammatory parameters. Rectal biopsies were obtained for analysis of mucosal cytokine mRNA levels. Linear regression analysis was used to test associations between ANS activity and inflammation at onset; linear mixed models were used to test if ANS function at onset predicts the evolution of inflammation over the next 3 years.

RESULTS: SNS was significantly associated with higher levels of several systemic inflammatory parameters at onset (Table 1A). Moreover, SNS activity was also positively associated with mucosal IL-8 mRNA (β=0.52±0.24, p=0.035). PNS activity predicted the evolution of systemic inflammation, assessed by sedimentation and WBC count, over the 3 year period (Table 1B). Moreover, trends were found for both SNS (β=13.4±8.0, p=0.099) and PNS (β=-2.3±1.3, p=0.075) activity to predict the course of mucosal inflammation (fecal calprotectin) during follow-up. Over all analyses, signs are consistently positive for SNS activity and negative for PNS activity, confirming their pro- and anti-inflammatory properties, respectively, as found in animal studies.

Table1. Beta coefficients from linear regression analysis[1], Beta coefficients from linear mixed models[2]

A.Onset[1]	Symp,LH/HF	p	Parasymp,RMSSD	p
Sedimentation Rate	**1.44±0.51**	**0.007**	-0.10±0.061	0.12
CRP	**5.67±1.79**	**0.0029**	-0.27±0.22	0.22
IL17	*0.44±0.24*	*0.080*	-0.04±0.025	0.11
TNF	**0.63±0.28**	**0.028**	-0.06±0.034	0.11
B.Followup[2]				
Sedimentation Rate	0.20±0.46	0.66	**-0.13±0.06**	**0.027**
WBC count	0.006±0.10	0.95	**-0.03±0.01**	**0.007**

CONCLUSION: In patients with UC there is a close interplay between ANS activity and the inflammatory response, which might be an important contribution to understand the pathogenesis of UC, to predict the inflammatory activity and improve treatment.

P827 RELATIONSHIP OF VASCULAR DAMAGE TO DISRUPTION OF MUCOSAL EPITHELIUM IN DEXTRAN SULPHATE SODIUM-INDUCED COLITIS IN MICE

H. Saijo[1,*], A. Hoshino[1], S. Arihiro[2], T. Kato[2], M. Matuoka[2], M. Saruta[2], M. Mitunaga[2], M. Okabe[1], H. Tajiri[2], H. Hashimoto[1]. [1]*Anatomy,* [2]*Gastroenterology and Hepatology, Jikei univrsity school of medicine, Tokyo, Japan*

INTRODUCTION: Ulcerative colitis (UC) is a multifactorial disorder of unknown cause. Dextran sulphate sodium (DSS)-induced colitis in mice is often used as a model of UC, but the pathogenesis of the colitis is also poorly understood. We focused on the mucosal blood vessels in this model in order to define their relationship to epithelial damage.
AIMS&METHODS: Eight-week-old C57BL/6J mice (n = 48) were administered 3% DSS in their drinking water, which was freely accessible, for 7 days. Six mice were euthanized each day from the start of the administration. The large intestine of three of the mice was extirpated after the vessels had been perfused with rhodamine B isothiocyanate (RITC)-labeled gelatin. Thick sections of the excised tissue were stained with anti-CD31 and anti-α-SMA antibodies. The distribution and morphology of the vessels were observed with a confocal laser scanning microscope, and three-dimensional reconstruct images were obtained. From the other three mice, we prepared paraffin sections of the colon, stained them with hematoxylin-eosin and immunohistochemically with anti-Ki67 antibodies, and assessed the mucosal damage microscopically.
RESULTS: The animals had begun to lose weight from the fourth day and passed bloody stools from the fifth day. On day 3, we observed leakage of RITC-labeled gelatin from blood vessels in the lamina propria just above the muscularis mucosa, and detachment of vascular endothelial cells from pericytes. Immunostaining with anti-Ki67 antibodies during the same period revealed signal reduction in the crypt proliferative zone, indicating a decrease in epithelial-cell proliferation. Damage to the mucosal epithelium became evident histopathologically on day 5. The vascular damage progressed through day 7.
CONCLUSION: In the early stage of DSS-induced colitis, the cell cycle of crypt cells in the proliferative zone is arrested. Concurrently, and before inflammation develops in the mucosa, bleeding from blood vessels running in the lamina propria occurs. Our results suggest that in DSS induced-colitis, mucosal epithelial-cell damage is preceded by damage to mucosal blood vessels, resulting in decreased blood flow in the lamina propria. After mucosal epithelial damage has occurred, the mucosal barrier may be disrupted, leading to exacerbation of the colitis. Study of the colonic vasculature in UC may help in clarifying the pathogenesis of the disease.

P828 VITAMIN D SUPPLEMENTATION DOES NOT IMPROVE ACUTE DSS COLITIS

E. Seidman[1], I. Elimrani[1,*], J. Koenekoop[1], M. Paquet[2], S. Dionne[1], E. Delvin[3]. [1]*Gastroenterology, MCGILL UNIVERSITY HEALTH CENTRE,* [2]*Comparitive PAthology and Diagnostic Laboratory, McGill Univeristy,* [3]*McGill University Health Centre, Montreal , Canada*

INTRODUCTION: Vitamin D (vD) plays an important role in the regulation of the immune system and its deficiency is associated with an increased risk of developing IBD. Studies have shown that patients with IBD often have low serum 25(OH)D3 levels compared to healthy controls and suggest that vD supplementation may serve as a novel treatment strategy for this prevalent health problem. The purpose of this study is to investigate the possible benefical role of vD on the severity of dextran sulfate sodium (DSS)-induced acute colitis model.
AIMS&METHODS: The purpose of this study is to investigate the possible benefical role of vD on the severity of dextran sulfate sodium (DSS)-induced acute colitis model. We utilized the murine DSS colitis model. BALB/c mice were divided into 4 specific treatment groups: Group 1 was provided a normal diet; Group 2 was given a vD deficient diet; Groups 3 and 4 were given a diet supplemented with *1 IU/g and 5 IU/g vD, respectively. Groups 2-4 were supplemented four weeks prior to and then during* 2% DSS administration in drinking water. Clinical assessment was monitored daily using a validated DSS Colitis Disease Activity Index (DAI). The mice were sacrificed 5 d after DSS administration. Colon length to weight ratio and histological damage were also scored.
RESULTS: In preliminary experiments, mice receiving 3% DSS had 50% mortality by day 5. We thus proceeded with 2% DSS, found to induce significant acute colitis, without mortality. vD failed to abrogate the weight loss associated with DSS induced colitis. Overall DAI scores and colonic weight/length ratios were lower in vD supplemented mice that received 2% DSS, although the differences did not achieve statistical significance. DAI and other measures as above were not statistically different in the mice on a vD deficient diet. Histopathology analyses also revealed non-significant differences between dietary groups. vD serum levels are pending.
CONCLUSION: Taken together, our data do not provide evidence that dietary supplementation with vD improves acute colitis in the DSS model. Limitations include the very short duration of the study, limited number of animals per group and the acute nature of the inflammatory colitis.

P829 MUCOSAL MICRORNA EXPRESSION IN PATIENTS WITH ULCERATIVE COLITIS BEFORE AND AFTER INFLIXIMAB TREATMENT

J. Van Der Goten[1,*], I. Arijs[1], L. Van Lommel[2], M. Ferrante[1], P. Rutgeerts[1], F. Schuit[2], S. Vermeire[1]. [1]*Translational Research Center for Gastrointestinal Disorders (TARGID),* [2]*Gene Expression Unit, KU Leuven, Leuven, Belgium*

INTRODUCTION: MicroRNAs (miRNAs) are increasingly recognized as major regulators of gene expression in many processes, including inflammation and tissue remodeling. Recently, altered expression of miRNAs has demonstrated association with ulcerative colitis (UC).
AIMS&METHODS: In this study, we investigated the effect of infliximab therapy on the miRNA expression in UC colonic mucosa. Therefore, colonic mucosal biopsies were obtained during endoscopy from 7 UC patients before and after infliximab induction therapy (infusions at weeks 0, 2 and 6) and from 10 normal controls. Endoscopic response was assessed at 14 weeks after start of infliximab and was defined as a Mayo endoscopic subscore of 0 or 1 (inactive UC). Endoscopic non-response was defined as a Mayo endoscopic subscore of 2 or 3 (active UC). Total RNA, including small RNA, was extracted from the biopsies and used to analyze the miRNA expression via Affymetrix GeneChip® miRNA 2.0 arrays. Data were analyzed with Bioconductor software. A false discovery rate $<5\%$ and >2-fold change was considered as significant.
RESULTS: Compared to normal controls, we identified 58 significantly differentially expressed miRNAs in active UC at baseline before therapy (18 up- and 40 downregulated). Between inactive UC after therapy and controls, still 33 significantly dysregulated miRNAs were seen (15 up- and 18 downregulated), with 17 out of 33 miRNAs common to the significant miRNAs between active UC and controls.
Four out of 7 patients showed endoscopic response. In these 4 endoscopic responders, 4 mature miRNAs were significantly upregulated (hsa-miR-10b-5p, hsa-miR-375, hsa-miR-378a-3p and hsa-miR-422a) and 6 were downregulated (hsa-miR-21-5p, hsa-miR-31-5p, hsa-miR-146b-5p, hsa-miR-155-5p, hsa-miR-330-3p and hsa-miR-3187-3p) after infliximab therapy when compared to their baseline samples. These miRNAs were predominantly immune-cell derived and have been implicated in inflammation and autoimmunity. By contrast, infliximab did not significantly affect miRNA expression in the 3 non-responders.
For prediction of response to infliximab therapy, we compared endoscopic responders and non-responders before treatment. No significant differences in miRNA expression were observed.
CONCLUSION: Infliximab therapy has a profound effect on the mucosal expression of miRNAs. This suggests the involvement of miRNAs in pathways affected by infliximab therapy and implies a role for mucosal miRNAs as potential biomarkers for response to infliximab therapy.

P830 INFLAMMATION DRIVEN FIBROSIS IN ULCERATIVE COLITIS – INVESTIGATION OF A NEGLECTED PROBLEM

J. De Bruyn[1,2,*], S. Meijer[3], M. Wildenberg[1], G. van den Brink[1,2], G. D'Haens[2]. [1]*Tytgat Institute for Liver and Intestinal Research,* [2]*Gastroenterology,* [3]*Pathology, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Intestinal fibrosis in Crohn's disease is a chronic inflammation driven process leading to an increase of myofibroblasts in all layers of the intestinal wall. However strictures and stenosis in Ulcerative Colitis (UC), which classically affects the mucosa and submucosa but occasionally leads to transmural disease, are very rare. It is suggested that a thickening of the muscularis propria predominates this process. There is however no systemic evaluation of fibrostenosing UC available.
AIMS&METHODS: We aimed at investigating whether there is a different fibrotic load in acute vs longstanding UC and whether the degree of fibrosis in UC correlates with the severity and extent of inflammation.
Colectomy specimens from all UC patients operated at the AMC between 2009-2012 were reviewed. Specimens from patients with recent onset ($<$ 2 years) and longstanding UC ($>$ 10 years) were selected. On H&E stainings the cumulative

Geboes histological inflammatory activity score (0-22 points) was determined. Sirius Red stainings were done for collagen, and α-smooth muscle (α-SMA) was stained immunohistochemically for detection of myofibroblasts and smooth muscle cells. From every patient the surgical resection margin and the microscopically most inflamed region were selected, so that every patient served as its own control. Staining signals were investigated by image analysis software (Image J, NIH).

RESULTS: We compared 8 resection specimens from patients with recent onset refractory UC, and 10 from patients with longstanding UC operated for dysplasia.

Patients with short disease duration had a higher cumulative Geboes score gradient (maximal inflamed area–resection margin) compared to patients with longer disease duration (6 vs 14 points, p=0.02).

There was no difference in increase of collagen deposition in early vs longstanding UC (4.2% vs 2.0%) or α-SMA positivity (=number of α-SMA positive vs total number of cells; 3.6% vs 1.6%).

In both early and long UC duration, we did not find a correlation between collagen deposition and α-SMA expression.

In early vs long UC the muscularis mucosa (MM) was not significantly thicker (0.9 vs 1.8 mm). There was no correlation between MM thickness and collagen or α-SMA expression.

CONCLUSION: In our series of colectomy specimens, no association between disease duration and increased collagen deposition or myofibroblast activation could be found. In addition, no correlation between the severity of inflammation and deposition of collagen or expression of α-SMA could be detected. Fibrosis in UC does not appear to increase significantly over time.

P832 A WATER-SOLUBLE EXTRACT FROM GANODERMA LUCIDUM FUNGUS MYCELIA (DESIGNATED AS MAK) PREVENTS INDOMETHACIN-INDUCED SMALL INTESTINAL INFLAMMATION.

K. Nagai[1,*], S. Tanaka[2], S. Sagami[1], Y. Ueno[2], K. Shinagawa[2], S. Oka[2], S. Yoshida[1], T. Hiyama[3], M. Ito[1], Y. Kitadai[1], M. Yoshihara[3], K. Chayama[1]. *[1]Department of Gastroenterology and Metabolism, [2]Department of Endoscopy, Hiroshima University Hospital, [3]Health Service Center, Hiroshima University, Hiroshima, Japan*

INTRODUCTION: "*Ganoderma lucidum*" Karst also known as "Reishi", is a traditional food in China and Japan, and we have previously reported that MAK has anti-inflammatory effects in murine colitis induced by trinitrobenzene sulphonic acid. However, its effects on small intestinal inflammation is unknown. The present study was designed to investigate the preventing effects of MAK on indomethacin-induced ileitis in mice.

AIMS&METHODS: To assess the preventive role of dietary MAK, the C57BL/6 mice were sacrificed after 24 hours of indomethacin treatment and the intestinal inflammation was evaluated. Mucosal lymphocytes taken from the small intestine of treated mice were stimulated in vitro for 48 hours, and mucosal lymphocytes taken from small intestine of non-treated mice were stimulated in vitro with MAK for 48 hours, then the concentration of interferon-gamma (IFN-gamma) was determined by ELISA. In addition peritoneal macrophages (PMs) were stimulated in vitro with MAK and adoptively transferred intra-peritoneally to C57BL/6 mice, which were then given indomethacin. After 24 hours, the intestinal inflammation was evaluated. PMs stimulated with MAK and labeled with fluorescent dye were adaptively transferred intra-peritoneally to treated mice, we determined the localization by confocal microscopy.

RESULTS: The shortness of the small intestine was prevented in MAK administered mice. Indomethacin-induced small intestinal injury was inhibited by feeding with MAK in a dose-dependent manner. The IFN-gamma production from intraepithelial lymphocytes of indomethacin treated mice was increased compared to control group. In vitro stimulation of intraepithelial lymphocytes, but not lamina propria lymphocytes, the IFN-gamma production from intraepithelial lymphocytes was inhibited by MAK. The development of macroscopic lesions, the number of ulcers, and vascular permeability by indomethacin were significantly prevented in the transfer of PMs that had been stimulated in vitro with MAK compared to PMs from the control group. The transferred PMs were detected in mesenteric lymph node, the submucosa and lamina propria of a small intestine.

CONCLUSION: MAK is effective in the prevention of acute intestinal inflammation by indomethacin. PMs stimulated by MAK were detected in small intestine, and appear to contribute to the anti-inflammatory response.

P833 CD80 SIGNALING MANIPULATION AFFECTS TUMOR IMMUNOSURVEILLANCE IN EXPERIMENTAL COLITIS-ASSOCIATED CANCER

M. Scarpa[1,*], P. Brun[2], I. Castagliuolo[2], S. Morgan[3], M. Scarpa[1], A. Porzionato[2], A. Kotsafti[1], R. D'Incà[2], A. Buda[2], G. C. Sturniolo[2], R. Bardini[2], C. Castoro[1], I. Angriman[2]. *[1]Veneto Institute of Oncology (IOV-IRCCS), [2]University of Padova, Padova, Italy, [3]Sheffield Teaching Hospitals, Sheffield, United Kingdom*

INTRODUCTION: In patients with ulcerative colitis (UC), the inconsistency between cumulative risk of colon cancer and cumulative rate of dysplasia suggests the presence of an immunosurveillance mechanism. In a previous study, we observed a significant overexpression of the costimulatory molecule CD80 in the colonic mucosa of UC patients with dysplasia and its down-regulation at more advanced stages of carcinogenesis.

AIMS&METHODS: The aim of this study was to explore the role of CD80 in an experimental model of colitis-associated cancer. To this end, the AOM/DSS murine model of inflammation-related colon carcinogenesis was used. Neutralizing antibodies against CD80 or its inhibitory receptor CTLA4 were administered after the last DSS cycle in order to inhibit or enhance CD80 signalling, respectively. Animals were randomized to receive specific abs or isotype control and sacrificed after 0, 7, 28 or 56 days. Colons were processed for microscopic examination of histopathologic and inflammatory changes.

RESULTS: Invasive carcinoma frequency was increased in mice treated with antiCD80 compared to isotype control mice. Notably, no evidence of invasive carcinoma was observed in mice treated with antiCTLA4, instead (p=0.02). High grade dysplasia (HGD) foci number and extension were significantly augmented in mice treated with antiCD80 and minimal in those treated with antiCTLA4 (p=0.005). The extension of LGD was not different among the three groups. Inflammatory score was significantly lower in mice who received antiCD80 but it was similar in isotype control and antiCTLA4 treated mice.

CONCLUSION: After the oncological damage is arrested at a relatively early stage half of the mice spontaneously clear off HGD demonstrating the presence of an active immunosurveillance mechanism at the level of the colonic mucosa. This mechanism is significantly impaired if CD80 signaling is altered. Indeed, CD80 signaling blockade leaded to carcinogenesis progression, while its enhancement triggered a reduction of HGD frequency and extension. The inhibition did not affected LGD, suggesting that CD80 signaling is the checkpoint of LGD to HGD progression.

P834 HYPOXIS HEMEROCALLIDEA CORM AMELIORATES ACUTE EXPERIMENTAL COLITIS

I. Villegas[1], D. Todorova-Aleksieva[2], S. Sanchez-Fidalgo[1], M. Aparicio-Soto[1,*], A. Cardeno[1], M. Uceda-Martin[1], C. Alarcon de la Lastra[1]. *[1]Pharmacology, University of Seville, Seville, Spain, [2]Pharmacology, Medical University of Sofia, Sofia, Bulgaria*

INTRODUCTION: The preventive effect of *Hypoxis hemerocallidea* corm (African potato, AP), a plant widely used in South Africa as a natural remedy for its anti-inflammatory and hypoglycaemic properties, was evaluated. Anti-inflammatory activity has been ascribed to hypoxoside, one of the major constituents of the plant, which is transformed to rooperol in the gut. Rooperol is a biologically active compound that balances the immune system.

AIMS&METHODS: The aims of the present study was to evaluate an AP dietary extract (APE) supplementation on acute ulcerative colitis (UC) and deep insight into possible mechanisms of action involved.Seven week old female C57BL/6J mice were randomized into three groups (n=14): two of them received a standard diet during 35 days, while the third group was fed with the standard diet supplemented with APE powder 0.67 % for the same interval. The supplied APE powder for the experiment contained 58.0 % of hypoxoside. UC was induced by the addition of 3 % dextran sulfate sodium (DSS) in the drinking water on day 26 and for 5 days, followed by a regime of 5 days of tap water. Control healthy mice were allowed to drink only water. Disease activity index (DAI) was evaluated and colonic inflammation was determined by both histological and biochemical assays.

RESULTS: DSS administration caused severe colon damage, as indicated by body weight loss and colon shortening, increased DAI and myeloperoxidase (MPO) levels. Furthermore, an acute inflammation with neutrophil infiltration as well as haemorrhagic foci developed on colons from DSS-control animals. On the contrary, treatment with APE-supplemented diet significantly attenuated macroscopic colonic damage as well as MPO activity, compared to non-treated colitic animals. DSS exposure also caused significant expression of cyclooxygenase (COX)-2 and inducible nitric oxide synthase (iNOS), which were reverted to the control levels in the APE-supplemented diet group. P38 and c-Jun N-terminal kinase (JNK) mitogen-activated protein kinases (MAPKs) phosphorylation and the nuclear factor kappa B (NFkB) expression were also significantly increased by DSS. By contrast, these changes were prevented in animals fed with the APE-supplemented diet.

CONCLUSION: Dietary enrichment with APE reduces the damage in acute colitis model, alleviating the oxidative events and returning pro-inflammatory proteins expression to basal levels probably through JNK MAPK and NF-kB signalling pathways. *H. hemerocallidea* corm diet might provide a basis for developing a new strategy in dietary supplementation for the prevention of UC.

P835 DISTINCT CELL SIGNALLING MECHANISMS DRIVE THE TUMOUR NECROSIS FACTOR ALPHA AND INTERFERON GAMMA-INDUCED TRANSCRIPTIONAL DOWNREGULATION OF AQUAPORIN 3 RNA EXPRESSION

M. A. Peplowski[1,*], A. J. Vegso[1], W. K. MacNaughton[1]. [1]*Physiology and Pharmacology, University of Calgary, Calgary, Canada*

INTRODUCTION: Altered absorption and secretion of water, resulting in diarrhea, is a key characteristic of inflammatory bowel diseases (IBD). Although aquaporins (AQP) are known to be involved in water movement, the role of AQP3 in the barrier dysfunction that characterizes IBD remains unknown. *We hypothesized that AQP3 transcription was inhibited in intestinal inflammation by the cytokines tumour necrosis factor (TNF) α and interferon (IFN) γ.*

AIMS&METHODS: 1. C57Bl/6 mice were administered 2.5% dextran sodium sulfate (DSS) in drinking water for up to 7 days to induce colonic inflammation. AQP3 protein expression was assessed using western blot of mucosal scrapings and immunofluorescence of fixed tissue. **2.** The human adenocarcinoma cell line HT29 was used for treatments with either human recombinant TNFα (25 ng/mL) or human recombinant IFNγ (500 U/mL). AQP3 pre-mRNA and mRNA expression were assessed by real-time RT-PCR. Inhibitor studies to reverse the cytokine-induced downregulation of AQP3 were performed using a 1 hr inhibitor pre-treatment prior to the addition of cytokine.

RESULTS: 1. AQP3 protein expression was downregulated early in colonic inflammation at 3 days post-commencement of DSS with diminished basolateral membrane staining in epithelial cells lining colonic crypts. These changes were no longer evident at 7 days, where surviving epithelial cells expressed similar levels of AQP3 compared to controls. However, there was an increase in AQP3 positive, E-cadherin negative cells in regions lacking normal crypt architecture. **2.** Similarly, HT29 cells treated with TNFα or IFNγ resulted in an early decrease in AQP3 pre-mRNA expression at 2 hr, which was followed by decreased mRNA expression at 6-12 hr, suggesting transcriptional repression of AQP3 expression. Commercially available AQP3 antibodies are unable to detect human AQP3 protein. The IFNγ-induced decrease in AQP3 mRNA expression at 12 hr was reversed using a broad-spectrum JAK inhibitor (JAK Inhibitor I, 10 μM), but not a JAK2 specific inhibitor (JAK2 Inhibitor II, 10 μM). In contrast, the TNFα-induced decrease in AQP3 mRNA expression at 12 hr was not reversed by inhibitors of the PI3K, AKT, NF-κB, ERK/MAPK and p38 MAPK pathways (LY294002, 10 μM; Triciribine, 1 μM; BAY11-7082, 30 μM; U0126, 10 μM and SB203580, 10 μM respectively), even though all of the above pathways were activated by TNFα and significantly inhibited by their respective inhibitors.

CONCLUSION: The data suggest that alterations in AQP3 expression represent early events that occur in colonic inflammation. *In vitro*, both TNFα and IFNγ are independently capable of decreasing AQP3 mRNA transcription through distinct mechanisms.

P836 TISSUE-SPECIFIC OVEREXPRESSION OF UPR-RELATED C/EBP HOMOLOGOUS PROTEIN IMPAIRS MUCOSAL TISSUE REPAIR

N. Waldschmitt[1,*], E. Berger[1], E. Heupel[2], E. Rath[1], M. V. Boekschoten[3], C. U. Riedel[2], B. Weigmann[4], J.-H. Niess[5], M. Müller[3], K.-P. Janssen[6], D. Haller[1]. [1]*Chair of Nutrition and Immunology, Technische Universität München, Freising,* [2]*Institute of Microbiology and Biotechnology, University of Ulm, Ulm, Germany,* [3]*Nutrition, Metabolism and Genomics Group, Division of Human Nutrition, Wageningen University, Wageningen, Netherlands,* [4]*1st Medical Clinic, University of Erlangen, Erlangen, Germany,* [5]*Department of Gastroenterology, Inselspital, University of Bern, Bern, Switzerland,* [6]*Department of Surgery, Klinikum rechts der Isar, Technische Universität München, München, Germany*

INTRODUCTION: Loss of epithelial cell homeostasis and apoptosis highly contribute to intestinal inflammation. While endoplasmic reticulum and mitochondrial unfolded protein responses (UPR) have been implicated in chronic intestinal inflammation, functional correlation between UPR-related C/EBP homologous protein (CHOP) expression and CHOP-mediated programming towards inflammation-related disease susceptibility remains to be elucidated. In this study, we generated and characterized a novel transgenic mouse model expressing high levels of HA-tagged CHOP in intestinal epithelial cells ($Chop^{IEC\ Tg/Tg}$).

AIMS&METHODS: We characterized mice by gene expression profiling of colonic epithelial cells and analyzed the consequence of CHOP overexpression on intestinal homeostasis in response to infection-driven and Dextran Sodium Sulphate (DSS)-induced colitis, as well as mechanical injury.

RESULTS: Transcriptional profiling of disease-free transgenic mice identified a set of CHOP-dependent target genes related to inflammatory and microbial defense program in the intestinal epithelium. Under conditions of acute colonic inflammation, transgenic mice are not affected by *Citrobacter rodentium* infection, but reveal more severe inflammation and tissue injury in response to acute DSS-induced colitis, resulting from transcriptional activation of CHOP-HA protein. Delayed recovery from DSS-induced colitis and impaired closure of mechanically-induced mucosal wounds clearly indicate a role of CHOP in epithelial cell homeostasis in response to injury.

CONCLUSION: In conclusion, transgenic epithelial cell-specific overexpression of CHOP aggravates intestinal inflammation associated with the loss of epithelial cell restitution as well as impaired tissue healing and repair, supporting a disease-conditioning role of UPR-related CHOP expression in the epithelium.

P837 OLIGOSACCHARIDE ALTERATIONS OF IGA IN CROHN'S DISEASE INDUCE INFLAMMATORY-TYPE IMMUNE RESPONSES

T. Inoue[1,*], H. Iijima[1], H. Fujii[2], M. Araki[1], S. Kawai[1], E. Shiraishi[1], S. Hiyama[1], S. Shinzaki[1], T. Nishida[1], M. Tsujii[1], E. Miyoshi[2], T. Takehara[1]. [1]*Department of Gastroenterology and Hepatology,* [2]*Department of Molecular Biochemistry and Clinical Investigation, Osaka University Graduate School of Medicine, Suita, Japan*

INTRODUCTION: Immunoglobulin (Ig) A serves as the first line of defense against pathogenic antigens in intestinal mucosa and plays a crucial role in the maintenance of intestinal homeostasis. Recent reports have revealed that monomeric IgA (mIgA) induces inflammatory immune response by neutrophils, whereas, secretary IgA (sIgA) reduces pathogen-mediated proinflammatory cytokines, such as TNF-α, IL-6 and IFN-γ. We have recently reported that *N*-acetylgalactosamine (GalNAc) in *O*-linked oligosaccharides of IgA was significantly decreased in IBD patients and the alteration was a novel biologic marker for Crohn's disease[1]. However, biological functions of altered IgA on mucosal immune system are unknown.

AIMS&METHODS: We aimed to investigate the influence of alteration in IgA glycan composition on inflammatory response and immune tolerance. GalNAc-deficient mIgA and control mIgA were purified from sera of Crohn's disease patients and healthy volunteers, respectively. Altered sIgA was obtained by the removal of oligosaccharides using *O*-glycanase and sialidase from purified human colostral IgA. Neutrophil migration toward mIgA was evaluated with common migration assay. Leukotriene B4 (LTB4) production was determined by ELISA. Differentiation of a human monocytic cell line THP-1 into macrophage-like cells (THP-1 macrophage) was induced by PMA and IL-4. Binding and uptake of sIgA by THP-1 macrophage were analyzed by flow cytometry. Cytokine production of sIgA-stimulated cells was evaluated by qRT-PCR.

RESULTS: To investigate whether oligosaccharide alteration of mIgA in Crohn's disease modifies neutrophil function, we first performed neutrophil migration assay. Neutrophil migration toward GalNAc-deficient mIgA was significantly enhanced compared to control mIgA. Moreover, LTB4 production from activated neutrophils was significantly elevated in GalNAc-deficient mIgA compared to control mIgA. We next studied the influence of oligosaccharide alteration on homeostatic-type of immune responses of sIgA. Ligand-lectin interaction and endocytosis of sIgA in THP-1 cells were not different between altered sIgA and control sIgA. However, both IL-6 and TNF-α levels were significantly elevated when the THP-1 macrophages were incubated with altered IgA compared to those with control IgA.

CONCLUSION: These results suggest characteristic functions of altered mIgA and sIgA on the induction of neutrophil migration and inflammatory cytokine production, respectively. Thus, oligosaccharide alteration of IgA may enhance the intestinal inflammation in pathological conditions of IBD.

P838 PROTEIN CARBONYLATION PROFILE IN PATIENTS WITH ULCERATIVE COLITIS: A COMPARATIVE PROTEOMIC STUDY

T. Gamberi[1,*], A. Modesti[1], F. Magherini[1], T. Fiaschi[1], M. Coppola[2], V. Annese[2], A. G. Bonanomi[2], M. Stio[1]. [1]*Experimental and Clinical Biomedical Sciences, University of Florence,* [2]*Gastroenterology Unit, Careggi Hospital, Florence, Italy*

INTRODUCTION: The IBDs (Crohn's disease, ulcerative colitis) are chronic idiopathic inflammatory disorders of the intestine and/or colon, characterized by the presence of large numbers of leukocytes such as neutrophils, monocytes, and lymphocytes in the intestinal and/or colonic interstitium. Although the primary etiology of IBD is multifactorial, gut leakiness and diffusion of intraluminal pro-inflammatory molecules are considered to be reasonable initial steps for subsequent intestinal inflammation. The mechanisms of inflammatory intestinal injury, leading to mucosal barrier dysfunction, are not completely clear. However, it is known that chronic gut inflammation is associated with enhanced production of ROS/reactive nitrogen species (RNS) and protein oxidation, which may be responsible for mucosal barrier dysfunction [1]. The presence of ROS is generally measured indirectly by the levels of oxidatively damaged molecules (lipid, DNA and protein). The most frequently used biomarkers of protein damage are carbonyl groups [2]. Increased levels of ROS and protein carbonyls were found in the inflamed mucosal lesions of Crohn's disease and ulcerative colitis biopsies [3] but the proteomic analysis of the protein oxidation profile have not yet been performed.

AIMS&METHODS: The aim of this study was to identified the proteins of the intestinal mucosa that undergo carbonylation in ulcerative colitis (UC). We compared the oxidized proteome of inflamed to that of non-inflamed colonic biopsies from 6 UC patients in order to establish a baseline of markers, which are associated to the inflammatory state related to active UC. The oxidative proteome of whole colonic biopsies were characterized using two-dimensional gel electrophoresis followed by Western blot analysis with antibodies against carbonylated proteins [4].

RESULTS: A total of 50 protein spots displayed a statistically different degree of carbonylation level between inflamed and non-inflamed tissue in the patient group.

CONCLUSION: The proteomic results show a clear sign of oxidative stress in inflamed colonic biopsies. Since oxidation does not appear to affect all proteins at the same extent, we are currently analyzing these carbonylated proteins and identifying them by means of MALDI-TOF analysis.

P839 INHIBITION OF EOTAXIN-1 (CCL-11) AMELIORATES DSS-INDUCED COLITIS – A NOVEL POTENTIAL THERAPEUTIC APPROACH FOR INFLAMMATORY BOWEL DISEASE

T. Adar[1,*], S. Shteingart[1], D. M. Livovsky[1], A. Bar Gil Shitrit[1], M. Mahamid[1], B. Koslowsky[1], E. Goldin[1]. [1]*Digestive Diseases Institute, Shaare Zedek Medical Center, Jerusalem, Israel*

INTRODUCTION: Eotaxin-1 (CCL-11) plays an important role in the regulation of eosinophil recruitment in colonic inflammation. Elevated eotaxin-1 is a feature in biopsy specimens from patients with IBD, which was shown to be positively correlated with disease severity. Targeting eotaxin-1 (CCL-11) may modulate the trafficking of eosinophils into inflammatory sites.
AIMS&METHODS: AIM - To evaluate the effect of anti-eotaxin-1 antibodies on the severity of dextran sodium sulfate (DSS)-induced colitis in mice.
METHODS - Experimental colitis was induced in BALB/c mice (N=10), by supplementation of DSS (3.5%, w/v) in drinking water for 7 days. Mice were divided into 2 groups. Group A was treated on days 0 and 4 with i.p injections of anti eotaxin-1 (100 mcg/animal) and group B was treated on the same days with isotype control antibody. Mice were monitored for body weight loss. On day 8 mice were sacrificed, 10 cm colon weight was measured. A Disease activity index (DAI) was calculated for each mouse using bleeding and diarrhea's severity.
RESULTS: I.p administration of anti eotaxin-1 resulted in significant smaller weight loss compared to the control group (15.7 and 23.2%, for group A vs. group B, respectively, $p<0.05$). DAI was decreased for anti-eotaxin-treated mice (4.8 and. 8, for group A vs. group B, respectively, $p<0.05$) and increased 10cm colon weight was recorded in the control mice (294.1 and 195 mg, for group B vs. group A, respectively, $p<0.001$).
CONCLUSION: Inhibition of eotaxin-1 (CCL-11) resulted in significant amelioration of DSS colitis in BALB/c mice. These results indicate the importance of eotaxin-1 in regulating intestinal mucosal inflammation, and its potential as a future therapeutic target in inflammatory bowel disease.

P840 IRSOGLADINE MALEATE, AN ANTI-ULCER DRUG, HAS PROPHYLACTIC EFFECT ON THE DEVELOPMENT OF SPONTANEOUS COLITIS IN INTERLEUKIN-10 GENE-DEFICIENT MICE THROUGH SUPPRESSING TH 1 AND TH 17 RESPONSES

T. Nakagawa[1,*], T. Katsuno[1], K. Okimoto[1], A. Oyamada[1], K. Saito[1], S. Minemura[1], S. Sazuka[1], D. Maruoka[1], T. Matsumura[1], M. Arai[1], O. Yokosuka[1]. [1]*Department of Gastroenterology and Nephrology, CHIBA UNIVERSITY HOSPITAL, Chiba, Japan*

INTRODUCTION: Irsogladine maleate [2,4-diamino-6-(2,5-dichlorophenyl)-s-triazine maleate] (IM) has been approved for peptic ulcer and acute gastritis in Japan since 1989. Recently we demonstrated that IM prevented the development of spontaneous colitis in interleukin (IL) -10 gene-deficient (IL-10 KO) mice, prompting us to investigate whether IM can regulate Th1 and Th17 responses in the colonic tissue.
AIMS&METHODS: The aim of this study is to elucidate the mechanisms by which IM prevents the spontaneous colitis of IL-10 KO mice in terms of Th1 and Th17 responses. IL-10 KO mice aged over 20 weeks were chosen and fed with normal chow diet or the diet mixed with 100 ppm of IM for 10 consecutive weeks ("aged mice group"). Five-week-old IL-10 KO mice were also grown with normal diet or the diet mixed with IM as well ("young mice group"). After the mice were euthanized, colons were removed and evaluated morphologically. Expression levels of mRNAs, such as tumor necrosis factor α (TNFα), IL-1β, interferon γ (IFNγ), IL-12p35, IL-12p40, IL-17A, and IL-23p19 in the colon tissues were measured by quantitative PCR (qPCR) using comparative CT method.
RESULTS: The differences of the body weight, colon weight, and colon length in the aged mice were not significant between control and IM group (29.5 ± 2.72 vs 22.9 ± 0.87 g and 1.60 ± 0.22 vs 1.16 ± 0.22 g and 10.5 ± 0.41 vs 9.82 ± 0.28 cm, respectively). In contrast, the differences of the colon weight and length in the young mice were significantly different between control and IM group (0.64 ± 0.03 vs 1.02 ± 0.07 g and 8.6 ± 0.2 vs 8.1 ± 0.1 cm respectively), suggesting that efficacy of IM in preventing colitis was remarkable in younger mice. The results of qPCR of the aged mice showed that IM tended to decrease the mRNA expression of IFNγ, IL-12p40, and IL-17A compared to control mice (26.0 ± 8.8 vs 12.6 ± 1.3, 22.6 ± 2.2 vs 17.4 ± 1.8, and 30.1 ± 7.9 vs 15.2 ± 7.9, respectively) but they were not significant. However, the results of qPCR in the young mice showed that IM markedly and significantly reduced the mRNA expression of TNFα, IL-1β, IFNγ, IL-12p35, IL-12p40, IL-17A, and IL-23p19 compared to control mice (2.5-, 5.4-, 4.5-, 21.0-, 3.4-, 113.0-, and 4.2-folds, respectively).
CONCLUSION: IM has prophylactic effect on the development of spontaneous colitis in IL-10 KO mice by down-regulating Th1 and Th17 responses, especially when administrating IM in their younger age.

P841 ASTHMA PREVALENCE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. Barreiro-de Acosta[1,2,*], G. Sánchez-Sindin[3], R. Ferreiro-Iglesias[1,2], N. García-Couceiro[4], A. Lorenzo-González[1], L. Valdés[4], F. J. González-Barcala[4], J. E. Dominguez-Muñoz[1,2]. [1]*Gastroenterology, University Hospital of Santiago de Compostela,* [2]*Foundation for Research in Digestive Diseases, Santiago de Compostela,* [3]*Emergency, Hospital do Salnés, Vilagarcía,* [4]*Respiratory, University Hospital of Santiago de Compostela, Santiago de Compostela, Spain*

INTRODUCTION: The relation between Inflammatory bowel diseases (IBD) and asthma is not clear and whether it is an extraintestinal manifestation it is unknown. In non-IBD population asthma is present in around 5% of people.
AIMS&METHODS: The aim of the study was to assess the prevalence of asthma in IBD patients. **Methods:** A prospective study was designed. The case-studies consisted of consecutive patients with IBD (Crohńs disease (CD) and ulcerative colitis (UC)) over 18 years of age who attended the monographic IBD unit for 6 months and who agreed to participate in the study. All patients completed the European Community Respiratory Health Survey (ECRHS) questionnaire. A spirometry with bronchodilator, a fractional exhaled nitric oxide (FeNO) test and a skin allergy test using the skin prick test method (SPT) were also performed. Probable asthma was considered as affirmative answer to one of the questions of the ECRHS questionnaire: 1) Have you been woken by an attack of shortness of breath at any time in the last 12 months?; 2) Have you been woken by an attack of coughing at any time in the last 12 months?; 3) Have you woken up with a feeling of tightness in your chest at any time in the last 12 months?; 4) Have you had an attack of asthma in the last 12 months?; 5) Are you currently taking any medicines including inhalers, aerosols or tablets for asthma?. Confirmed asthma was diagnosed in cases with Probable asthma if values in the FeNO test were over 30 ppb or a change in the FEV1 was over 12% and 200 ml. Results are shown in percentages.
RESULTS: 132 patients were consecutively included, 53 (40.1%) CD; 79 (59.9%) UC, having a mean age of 45 years, ranging from 18 to 77, 65 (49.2%) being female. Regarding asthma determination, 31 patients (23.5%) presented asthma symptoms according to the ECRHS questionnaire. The prick test was positive in 31.3% of patients, the FeNO test was over 30 ppm in 24.1% of patients and a positive bronchodilator test was observed in 30.5% of patients. Overall a probable asthma was observed in 23.5% of all IBD patients and confirmed asthma in 16.9% of our sample. These figures are clearly higher than that observed in a general population.
CONCLUSION: Asthma prevalence seems to be high among IBD patients, being superior to that of the average population

P842 INFLUENCE OF EXTRAINTESTINAL MANIFESTATIONS IN HEALTH-RELATED QUALITY OF LIFE IN INFLAMMATORY BOWEL DISEASE PATIENTS

M. Barreiro-De Acosta[1,2,*], M. iglesias-rey[2], A. Lorenzo[1], J. E. Dominguez-Muñoz[1,2]. [1]*Gastroenterology, University Hospital of Santiago de Compostela,* [2]*Foundation for Research in Digestive Diseases, Santiago de Compostela, Spain*

INTRODUCTION: Inflammatory bowel disease (IBD) patients are frequently associated with extraintestinal manifestations (EIM).
AIMS&METHODS: The aim of this study was to assess if the presence of EIM was associated with a worse health-related quality of life (HRQOL) in IBD patients regardless of the activity of the disease. **Methods:** A cross-sectional, prospective study with consecutive patient recruitment was designed. All patients with IBD who attended our IBD Unit were consecutively included. Patients were examined for the main reactive and non-reactive EIM of IBD. Reactive conditions were defined as those related to acute gut inflammation, i.e. dermatologic lesions, eye complications and peripheral osteoarthritis. Non-reactive conditions were those unrelated to gut inflammation, such as ankylosing spondylitis, sacroileitis and sclerosing cholangitis. Remission was defined as a Harvey-Bradshaw score $<=4$ for Crohńs disease (CD) and as a Mayo score $<=2$ in ulcerative colitis (UC). To assess quality of life we used the IBDQ, which included five dimensions. Total scores range from 36 to 252. We also used the SF-36 questionnaire, which included 8 scales. Total scores range from 0 to 100. In both cases, higher scores indicate better HRQOL. Results are shown as mean and standard deviation; the t-student test was used for comparing means.
RESULTS: 799 patients were consecutively included, 323(40.7%) CD; 470 (59.3%) UC, mean age of 44.63 years, range 18-81, 422 (52.8%) were female and 319 patients (39.8%) had a relapse. 159 patients (19,9%) presented any EIM. In Table 1 the means and p values of IBDQ and SF-36 dimensions are shown.
CONCLUSION: Patients with EIM have worse quality of life than those without EIM irrespective of the activity of the disease. The worse quality of life affects both physical and psychological aspects of the patients.

P843 PREVALENCE AND ETIOLOGIES OF CHOLESTASIS IN INFLAMMATORY BOWEL DISEASES PATIENTS IN THE SWISS IBD COHORT.

M. Girardin[1,*], A. Hadengue[1], J.-L. Frossard[1], the Swiss IBD Cohort Study Group. [1]*Gastroenterology & Hepatology, GENEVA UNIVERSITY HOSPITAL, Geneva, Switzerland*

INTRODUCTION: Patients with inflammatory bowel diseases (IBD) may present with cholestasis during the course of their disease. Causes are multiple including drug-induced liver toxicity (e.g. Azathioprine), specific liver diseases complicating IBD (e.g. primary sclerosing cholangitis (PSC)) or para-inflammatory (TNF-α induced). Prevalence of cholestasis in IBD is unknown. Cholestasis, plays a significant role in the absorption of vitamins and drugs; bile acids are thought to play a role in dysplasia, intra-cellular signalling as well as interaction with the intestinal flora. The aim of this study is to establish the prevalence of clinical and biological cholestasis in IBD patients using the clinical data and biosamples of the Swiss IBD Cohort (SIBDC).
AIMS&METHODS: All patients of the SIBDC with serum samples available were included. Total bile acid (TBA) assay was performed (ELISA). Cholestasis was defined as a TBA > 8 μmol/l. In a second time bile acid profile, using HPLC, was performed in serum samples from patients with high TBA as well as in a cohort of patients with low TBA. Clinical data were collected from the SIBDC.
RESULTS: 1342 patients were included; 96 patients had TBA > 8 μmol/l with a mean level of 21.8 μmol/l (8-483). This represents a prevalence of 7.15% cholestasis in the SIBDC. In univariate analysis, cholestasis (TBA>8) was associated with male sex (63% vs 51%, p=0.034), less smoking (17% vs 27%, p=0.023), a higher alcalin phosphatase (108 vs 70, p=10E-12), a lower albumin (38 vs 40, p=0.016), more PSC (5% vs 1%, p=0.00007), supplementation with calcium or vitamin E (p=0.047) and treatment with tacrolimus (3% vs 1%, p=0.038) or ursodesoxycholic acid (10% vs 1%, p=10E-8). Age, IBD subtypes and mean activity index were comparable. In multivariate analysis, PSC (OR=4.64, p=0.012) and treatment with tacrolimus (OR=5.5, p=0.017) were significant factor associated with cholestasis.
CONCLUSION: Prevalence of cholestasis in the SIBDC was high (7%). PSC, IBD inflammatory flare or adverse effect of treatments could be an explanation. In some cases, the exact cause of the cholestasis remains unclear. Further analysis on the subtypes of biliary acids is underway and should help understanding the causes of cholestasis.

P844 QUALITY OF LIFE IN A EUROPEAN INCEPTION COHORT OF INFLAMMATORY BOWEL DISEASE PATIENTS IN 2010 - AN ECCO-EPICOM STUDY

P. Weimers[1,*], J. Burisch[1], P. Manninen[2], S. Čuković-Čavka[3], J. F. Dahlerup[4], P. Munkholm[1], ECCO-EpiCom. [1]*Herlev University Hospital, Copenhagen, Denmark,* [2]*Tampere University Hospital, Tampere, Finland,* [3]*University of Zagreb School of Medicine, Zagreb, Croatia,* [4]*Aarhus University Hospital, Aarhus , Denmark*

INTRODUCTION: Inflammatory Bowel Disease (IBD) is a chronic condition impairing patients' quality of life (QoL). The EpiCom population-based inception cohort of unselected IBD patients was initiated in 2010 in 31 centres from 14 Western and 8 Eastern European countries, covering 10 million in background population[1].
AIMS&METHODS: The Short Form 12 (SF-12) and the Short Inflammatory Bowel Disease Questionnaire (S-IBDQ) were used to investigate the differences in Health-Related Quality of Life (HRQoL) in IBD patients across Europe. Patients completed the questionnaires at time of diagnosis (0-3 months) and at 1 year follow up (±3months).
RESULTS: Out of 1515 IBD patients, 842 completed S-IBDQ at time of diagnosis, 199 (24%) from Eastern Europe (Crohn's Disease (CD): 78 (39%), Ulcerative Colitis (UC): 118 (59%), IBD Unclassified (IBDU): 3 (2%)) and 643 (76%) from Western Europe (CD: 220 (34%), UC: 344 (54%) IBDU: 79 (12%)). Higher mean S-IBDQ scores were observed in Western European UC patients (49 (Range: 11-70)) compared to Eastern European patients (45 (Range: 18-67)), p<0.05. 369 (44%) patients completed the S-IBDQ questionnaire at follow up, the mean scores increased over time in both regions and reached levels equal to or above a good quality of life (S-IBDQ score ≥50). 7 of 30 centres (23 %) had mean S-IBDQ scores >50 at time of diagnosis and 24 (80 %) centres at follow up. 841 patients completed the SF-12 questionnaire at time of diagnosis, 202 (24%) from Eastern Europe (CD: 80 (40%), UC: 119 (59%), IBDU: 3 (1%)) and 639 (76%) from Western Europe (CD: 217 (34%), UC: 342 (54%), IBDU: 80 (12%)). 362 (43%) patients completed the SF-12 survey at follow up. Summary scores of Mental and Physical health are shown in Table 1.

Table 1. SF-12 summary measures

		Eastern Europe			Western Europe		
		CD	UC	IBDU	CD	UC	IBDU
At diagnosis:							
	Physical Summary measure	44,5	44,2	56,3	42,3	47,0 *	46,3
	Mental Summary measure	42,5	43,3	43,3	43,1	43,8	43,9
At follow up:							
	Physical Summary measure	49,8**	50,9**	60,9	49,1**	49,3	49,6
	Mental Summary measure	49,9**	51,0**	52,7	47,4**	48,6**	50,8**

*= difference in mean score between regions p<0.05.
** = difference in mean score between time of diagnosis and follow up p<0.05.
CONCLUSION: Generic and disease specific QoL increased within a year from diagnosis in both regions of Europe. However, the differences in HRQoL between the two areas were not statistical significant. The association of QoL and disease course and outcome are currently being investigated.

INTRODUCTION: Early disease progression and complications of inflammatory bowel disease (IBD) have not been assessed in population-based settings across Asia-Pacific.

AIMS&METHODS: We evaluated early disease outcome in incident IBD cases in Asia-Pacific. IBD patients diagnosed between 2011 and 2012 were prospectively followed-up for up to 18 months from seven countries in Asia and Australia. Data on disease phenotype, mortality medical and surgical treatment over one year were entered into a web-based database. We determined risk of disease behavior change and probability of surgery.
RESULTS: 164 IBD cases (Australia 41; Asia 123) were included [79 ulcerative colitis (UC), 74 Crohn's disease (CD), and 11 indeterminate colitis (IC)]. Median age at diagnosis was 37 (IQR: 27-51) and 59% were male. After 18 months, probability of CD behavior change from B1 to B2/B3 was 7.7% and 12.5% in Australia and Asia, respectively. In UC, proximal disease extension was observed in 17% with proctitis or left sided colitis in Asia. Probability of surgical resection for CD was 11.5% in Australia and 4.2% in Asia ($p = 0.337$). Probability of surgical resection for UC was 11.1 % in Australia and 0% in Asia (p=0.114), after 18 months of disease duration. Five CD patients in Australia had surgery for perianal disease. There was no mortality in Australia and one CD patient in Asia died of sepsis. Total steroid exposure was higher in Australia than Asia (51.2% vs. 16.3%; $p<0.001$) but immunosuppressant (36.6% versus 35.8%; p=0.93) and anti-TNF antibody exposure (7.3% vs. 4.1%; p=0.414) was not significantly different between Australia and Asia.
CONCLUSION: Early disease course for IBD, immunosuppressant use and surgical rates in Asia are comparable to that of Australia.

P846 ANORECTAL COMPLICATIONS AND FUNCTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: 14 YEARS FOLLOW-UP

T. J. Lam[1,*], A. Van Bodegraven[1], C. Mulder[1], R. Felt-Bersma[1]. [1]*Department of Gastroenterology and Hepatology, VU UNIVERSITY MEDICAL CENTER, Amsterdam, Netherlands*

INTRODUCTION: Little is known about the long-term sequelae of perianal disease in IBD with regard to function. The long term follow–up with anorectal function tests may clarify the course of the perianal lesions.
AIMS&METHODS: The aim of the study was to prospectively evaluate the course of anorectal complains and anorectal function in inflammatory bowel disease (IBD) patients with perianal lesions.
Between 1993-2000, 56 patients with IBD (43 Crohn's disease, 13 ulcerative colitis) with perianal complaints underwent anorectal function tests. For follow-up, the patients were approached in 2010-2012 by sending questionnaires including Inflammatory Bowel Disease Questionnaire (IBDQ), Perianal Disease Activity Index (PDAI), fecal incontinences scale (Vaizey) and an invitation for anorectal function tests.
RESULTS: At follow-up, 46 (82%) were available, 9 patients (16%) were lost and 1 patient (2%) had died. Seventeen patients were interviewed by phone and 30 patients returned the questionnaires of whom 17 also underwent anorectal function tests. Median follow-up was 14 years (IQR 25-75: 13-15 years). In 25 of the 46 patients (54%) perianal complaints persisted: fecal incontinence (n=5); soiling (n=17); fecal incontinence and soiling (n=2); fistula pain (n=1). Eighteen (39%) and 5 (11%) patients had an active fistula at baseline and follow-up respectively. Two of the five fistulas at follow-up were new (rectovaginal fistula and complex fistula). Mean IBDQ, Vaizey and PDAI were 178 (SD 29), 7 (SD 5) and 4.2 (SD 3.0) respectively. Anal endosonography showed healing in 9 of the 10 fistulas. Anal rest and squeeze pressures as well as rectal compliance remained unaltered.
CONCLUSION: After 14 years, 54% of the IBD patients with perianal lesions, still have mild complaints. Quality of life of patients with IBD and perianal lesions remained moderate over a long period, which is concerning.
Disclosure of Interest: None Declared
Keywords: anal disease, anal endosonography, anorectal manometry, Inflammatory bowel disease (IBD)

P847 ANEMIA IN CROHN'S DISEASE

C. Ji[1], X. Gao[1,*], M. Zhi[1], M. Zhang[1], H. W. Chen[1], P. J. Hu[1]. [1]*The Six affiliated hospital of Sun Yat-sun University, Guangzhou, China*

INTRODUCTION: Anemia is a common complication of patients with Crohn's disease (CD). The aim of this study is to estimate the characteristics of anemia in CD.
AIMS&METHODS: We performed a retrospective study in patients with CD followed-up between 2011 and 2013 in the Sixth Affiliated Hospital of Sun Yat-sen University. 175 proved CD patients underwent the analysis according to age, signs, clinical course and activity of the disease. Complications and treatment options were recorded. The routine blood test, erythrocyte sedimentation rate (ESR), high sensitive C-reactive protein (hs-CRP) were tested for each patient at first visit and subsequent visits at 3 months interval.
RESULTS: 175 CD patients were included. 56.5% (n=99) were diagnosed as anemia at first visit. Microcytic anemia accounted for 54.8% of anemia in CD, 45.2% were normocytic anemia and no macrocytic anemia occurred.The mean age was 29.77±12.87. 56.6% (n=56) had bachelor degree at least, 34.3% were high school. The incidence rate of manifestations including diarrhea (n=56 57.1%), abdominal pain (n=75 76.5%), hematochezia (n=25 25.8%), abdominal distension (n=16 7.9%), fever (n=29 29.6%), oral ulcers (n=25 25.5%), arthralgia (n=11 11.2%),abdominal mass (n=1 1%) were diverse. At first visit, 72.5% (n=72) were mild anemia, 22.2% (n=22) were moderate and only 2% (n=2) were severe. 17.2% (n=17) of patients were less than 18 years old, 70% were aged from 18-45, 11% and 1% were aged as mid-age and old-age respectively. 45% (n=45) still had anemia at 3-month visit, a key point when glucocorticoid therapy sufficiently taking effect, and 87% was mild anemia and 13% was moderate anemia. The incidence rates of anemia at 6, 9 and 12 month were 44%, 21% and 50% respectively (Fig 1).At first visit, the average hs-CRP was 9 mg/L, 55.1% (n=86) of them had hs-CRP≥10 mg/L. It was 36.2% , 43.2%, 36.8% , 50% at 3,6,9 and 12 month respectively. For CD with anemia at first visit, 62.8% (n=54) had hs-CRP more than 10 mg/L, and 41.3%, 48.1%,44.1%,54.5% at 3,6, 9 and 12 month, respectively. But Logistic regression analysis showed that hs-CRP seemed not to be correlated with anemia (p=0.052, OR 1.898, 95%CI, 0.995-3.624), while weight ($p<0.05$, OR 0.886 95%CI 0.819-0.958) and ESR ($p<0.05$, OR 1.057 95%CI 1.020-1.095) seemed to be the independent risk factors for anemia in CD.
CONCLUSION: Patient with CD has high morbidity of anemia, and microcytic anemia is the most common type. Though there was no significant relationship between anemia and hs-CRP in our cohort, CD patients with anemia seem to have higher hs-CRP than those without. The incidence and severity of anemia seem to parallel to the change of hs-CRP. Weight and ESR seem to be the independent factors to anemia.

P848 IS THERE A DIFFERENCE IN HEALTH QUALITY OF CARE IN A EUROPEAN INFLAMMATORY BOWEL DISEASE INCEPTION COHORT? – AN ECCO-EPICOM STUDY

Z. Vegh[1,*], J. Burisch[2], N. Pedersen[2], E. Björnsson[3], P. Lakatos[1], P. Munkholm[2], the EpiCom group. [1]*Semmelweis University, Budapest, Hungary,* [2]*Herlev University Hospital, Copenhagen, Denmark,* [3]*The National University Hospital, Reykjavik, Iceland*

INTRODUCTION: The ECCO-EpiCom study and inception cohort[1] was initiated in 2010 in 31 centres from 14 Western and 8 Eastern European countries, covering 10 millions in background population.
AIMS&METHODS: To investigate whether there is a difference between Eastern and Western Europe in Health Quality of Care (HQoC) of patients with inflammatory bowel disease (IBD), a HQoC questionnaire was developed in the EpiCom group consisting of 16 questions covering 5 items: time interval between the onset of symptoms and diagnosis-2 questions (q), information-6q, education-3q, empathy-4q and access to health care providers-1q.

Table: P848

Question	East	West	Question	East	West	Question	East	West
Q1. How long did you have IBD symptoms prior to IBD diagnosis?			**Q4. Did you get sufficient answers to your questions?**			**Q8. Are you satisfied with your current status of information?**		
0-12 months*	86%	74%	Yes	33%	38%	Yes	80%	83%
>1 year*	13%	24%	**Q5. Have you sought out information regarding your disease by yourself?**			**Q9. Do you have a specific nurse addressed to you regarding IBD questions?**		
Q2. If you received information, who gave it to you?			Yes*	76%	68%	Yes*	4%	21%
Specialist*	100%	94%	**Q6. If yes, what sources did you use?**			**Q10. Does your doctor indicate interest in how your IBD impacts your Quality of Life?**		
IBD nurse*	0%	8%	Internet*	72%	61%	Yes*	94%	72%
Patient organization	1%	3%	Booklets*	17%	24%	**Q11. Do you have easy access to the IBD staff?**		
Q3. Was the time the nurse spent with you relevant?			**Q7. Have you received IBD related education?**			Gastroenterologists*	80%	68%
Yes*	13%	37%	Yes*	76%	41%	Nurses*	47%	57%

RESULTS: Out of 1515 patients 947(n=217 East/730 West) answered the HQoC questionnaire: 84% of patients from Eastern and 57% of patients from Western Europe; m/f=519/428; median age at diagnosis: 38 years (Range: 15,2-89); 38% of patients had Crohn's disease, 51% had ulcerative colitis, 11% had indeterminate colitis. Excerpts from the HQoC questionnaire are shown in Table 1.

Table 1. Excerpts from the EpiCom HQoC questionnaire

* $p < 0,05$

CONCLUSION: HQoC differs significantly between Eastern and Western Europe in all items. As IBD is a more common disease in Western Europe, IBD nurses play a very important role in decreasing the burden of disease. Use of IBD nurses should be introduced in Eastern Europe, since in many countries the incidence of IBD is increasing.

P849 EPIGENETIC ALTERATIONS IN INFLAMMATORY BOWEL DISEASE: NEW INSIGHTS INTO DISEASE PATHOGENESIS

A. H. C. Bai[1,*], A. S. L. Cheng[1], W. Tang[1], M. Catarinella[1], M. Harbord[2], J. Yu[1,3], S. C. Ng[1,3]. [1]*Institute of Digestive Disease, The Chinese University of Hong Kong, Shatin, Hong Kong,* [2]*Chelsea and Westminster Hospital, Imperial College London, London, United Kingdom,* [3]*Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong*

INTRODUCTION: The rising incidence of inflammatory bowel disease (IBD) in Asia relates to changes in environmental factors. The exact mechanisms by which these factors predispose to IBD are not clear. Epigenetics may mediate effects of environment, genetic predisposition and intestinal microbiota on IBD pathogenesis[1,2]. Genome-wide association studies have shown that IBD-associated genetic variants differ between Caucasians and Asians,[3] but little is known of IBD epigenetic profiles.

AIMS&METHODS: In a screening cohort of 9 Crohn's disease (CD) and healthy control tissues, we evaluated the expression of 128 genes specifically related to epigenetic chromatin remodeling factors and chromatin modification enzymes using customized Real-time PCR (RT-PCR) based array. SAM and ANOVA were used to identify the most deviated candidate genes between healthy tissues and inflamed CD tissues as confirmed by histology. The expression levels of candidate genes were further validated by RT-PCR using independent set of primers in a larger cohort consisting of 56 tissue samples from CD, ulcerative colitis (UC) and healthy controls.

RESULTS: PCR array in the screening cohort showed that nine genes encoding bromodomain proteins, polycomb group proteins, inhibitor of growth family members, histone methyltransferase, acetyltransferase and demethylase were significantly down regulated in inflamed CD samples compared with control samples ($p < 0.01$). RT-PCR in the validation cohort confirmed that expression of ash1 (absent, small, or homeotic)-like (Drosophila) (ASH1L), bromodomain and WD repeat domain containing 3 (BRWD3), lysine(K)-specific demethylase 5C (KDM5C), and lysine(K) acetyltransferase 2B (KAT2B) were significantly downregulated in inflamed CD compared with control tissues ($p < 0.05$). In contrast, these genes did not show statistical significant changes in inflamed UC samples compared with controls.

CONCLUSION: This study identified novel chromatin-modifying genes associated with IBD. Concordant down-regulation of these genes may disrupt the transcriptome of the colon and small intestine leading to pathogenesis of IBD. The development of UC and CD appeared to be associated with different epigenetic alterations. Functional characterization of the downstream epigenetic changes will provide unique insights into the biological pathways of CD and UC that may translate into new therapeutic approaches.

P850 ULCERATIVE COLITIS PATIENTS UNDERGOING POUCH SURGERY HAVE ALTERATIONS IN GENE EXPRESSION BEYOND THE POUCH

H. Yanai[1,2,*], S. Ben Shachar[2,3], L. Baram[1,2], H. Elad[1,2], A. Ofer[1], E. Brazowski[2,4], H. Tulchinsky[2,5], M. Pasmanik-Chor[6], I. Dotan[1,2]. [1]*IBD center, Tel Aviv Medical Center,* [2]*Sackler faculty of Medicine, Tel Aviv University,* [3]*Genetic Institute,* [4]*Department of Pathology,* [5]*Department of Surgery, Tel Aviv Medical Center,* [6]*Bioinformatics unit, G.S.W. Faculty of Life Sciences, Tel Aviv University, Tel Aviv, Israel*

INTRODUCTION: Pouchitis is an inflammation developing in an a priori normal small bowel (SB) reservoir created in ulcerative colitis (UC) patients undergoing pouch surgery.

AIMS&METHODS: UC pouch patients were stratified to normal pouch (NP), chronic pouchitis (CP), and Crohn's-like disease of the pouch (CLDP). Biopsies were obtained from the pouch, the corresponding proximal SB, and SB of healthy volunteers (normal control (NC)). Gene expression was analyzed by microarrays. Significant alteration was defined a fold change ≥ 2, and corrected $p \leq 0.05$. We conducted an additional direct comparison between pouches and the corresponding proximal SB in each group.

RESULTS: Thirty-six subjects were included: NP (n=7), CP (n=10), CLDP (n=5), NC (n=14). All NP and CP patients had a normal appearing proximal SB, 3 CLDP patients had inflammation in the proximal SB. We detected 162 significant alterations in pouches of NP, 482 in CP, and 1132 in CLDP groups. The proximal SB of NP patients demonstrated only 9 alterations. In contrast, proximal SB of CP and CLDP patients demonstrated 80 and 230 alterations respectively. Overall, 76% and 97% of alterations detected in proximal SB of CP and CLDP overlapped with alterations detected in the pouches of each group. Two thirds of the changes in proximal SB of NP and CP overlapped with alteration detected in proximal SB of CLDP. Gene ontology analysis for the proximal SB alterations revealed many associated biological processes including inflammatory response, NOD-like receptor signaling pathway, response to nutrients and vitamins. Direct comparison of alterations in the proximal SB to those within the pouch revealed only few significant differences: none in the NP group, two in the CP group and 12 in the CLDP group.

CONCLUSION: Significant alterations were detected not only within pouches but in SB proximal to the pouch as well. Pouch and proximal SB mucosal alterations were comparable. The findings may suggest that the inflammatory process is not limited to the surgically manipulated region of the pouch but rather extends proximally, potentially exposing it to further inflammation.

P851 ATG16L1 GENOTYPE IS ASSOCIATED WITH RESPONSE TO ANTI-TNF

M. Wildenberg[1,*], A. D. Levin[1], A. C. W. Vos[2], J. F. Brandse[1], J. R. de Bruyn[1], G. D'haens[1], G. R. van den Brink[1]. [1]*Gastroenterology and Hepatology, ACADEMIC MEDICAL CENTER, Amsterdam,* [2]*Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands*

INTRODUCTION: We have previously shown that infliximab (IFX) treatment of mixed lymphocyte reactions results in the induction of macrophages with immunosuppressive and wound healing properties. In patients who respond to IFX treatment, the number of these macrophages increases significantly in the intestine. In contrast, no increase is seen in non-responders, indicating the clinical importance of this cell population. Genetic studies have shown an association between various autophagy related genes and the development of Crohn's disease. The aim of this study was to determine whether autophagy is involved in the induction of regulatory macrophages by IFX and whether autophagy related polymorphisms influence the response to IFX.

AIMS&METHODS: Peripheral blood was isolated from 28 healthy volunteers and rs_2241880 genotype was determined by pcr. After isolation of PBMC mixed lymphocyte reactions containing cells from 2 donors per reaction were established for 150 separate donor combinations. Cultures were treated with IFX or control IgG and incubated for 6-7 days. Cells were analyzed by gene array, immunofluorescence, flow cytometry and thymidine incorporation.

RESULTS: Anti-TNF induced regulatory macrophages displayed increased numbers of autophagosomes as well as an increased expression of autophagy related transcripts including *atg5*, *atg7*, *atg9* and *atg16l2*, suggesting induction of autophagy by IFX treatment.

Of all donors, 7 were homozygously carrying the CD associated risk allele, 14 were heterozygous and 7 were homozygous for the WT allele.

The number of CD14+ regulatory macrophages correlated significantly with the number of WT alleles present in each individual culture, with the largest number of macrophages found in cultures containing 3 or 4 WT alleles (2 WT donors or 1 WT and 1 heterozygous). Similarly, expression of CD206, which is associated with the immunosuppressive function of macrophages, positively correlated with the number of WT alleles present. To confirm the functional consequences of these findings, IFX mediated suppression of T cell proliferation was determined. Again, the level of suppression correlated significantly with the number of WT alleles present in the respective donor combinations.

CONCLUSION: Induction of regulatory macrophages by IFX is associated with induction of autophagy. In vitro, the number and function of IFX induced macrophages correlate with the number of WT alleles for ATG16L1. Given the association between induction of regulatory macrophages and clinical response, this suggests that an intact autophagy pathway is important for effectiveness of anti-TNF therapy.

P852 IDENTIFICATION OF DISEASE-ASSOCIATED DNA METHYLATION IN BLOOD FROM PATIENTS WITH INFLAMMATORY BOWEL DISEASE

P. Karatzas[1,*], M. Gazouli[2], M. Safioleas[3], G. Mantzaris[1]. [1]*A Gastroenterology Department, Evangelismos General Hospital,* [2]*Laboratory of Biology, School of Medicine, University of Athens,* [3]*4th Department of General Surgery, Attikon University Hospital, ATHENS, Greece*

INTRODUCTION: It is well known that inflammatory bowel disease (IBD) is caused by a complex interplay between genetic predispositions of multiple genes, combined with an abnormal interaction with environmental factors. Germline variation in the IBD implicated by genome-wide association studies (GWAS)

only accounts for approximately 25% of estimated heritability. The contribution of epigenetic alterations to disease pathogenesis is emerging as a research priority. In this study, we extended this approach to identify IBD-associated changes in DNA methylation in blood from 12 IBD patients [6 Crohn's disease, CD and 6 Ulcerative colitis, UC].

AIMS&METHODS: The promoter methylation status of 22 genes (ATF2, CCL25, CXCL14, CXCL3, CXCL5, CXCL6, FADD, GATA3, IL10RA, IL12A, IL12B, IL13, IL13RA1, IL15, IL17C, IL17RA, IL4R, IL6R, IL6ST, IL7, INHA, TYK2) whose involvement in inflammation and autoimmunity were profiled using the Human Inflammatory Response and Autoimmunity EpiTect Methyl II Signature PCR Array profiles.

RESULTS: Using this approach with strict statistical analysis, we identified concerning the CD that the CCL25, CXCL14, CXCL3, CXCL6, GATA3, IL15, IL17RA, IL4R, IL6R, IL6ST, IL7, INHA, TYK2 were hypomethylated compared to healthy individuals. Regarding the UC cases the CCL25, CXCL3, IL10R, IL12A, IL13, IL15, IL17RA, IL7, INHA and TYK2 were found to be hypomethylated, whereas the CXCL14, CXCL5, GATA3, IL12B, IL17C, IL4R and IL6R were found to be hypermethylated compared to the controls.

CONCLUSION: IBD- and subtype-specific changes in DNA methylation were identified in blood from IBD patients. Many of these genes have important inflammatory and autoimmunity response functions. These data provide an important insight into the impact of epigenetic mechanisms in the pathogenesis of IBD.

P853 CONTRIBUTION OF MDR1 GENE POLYMORPHISMS ON IBD PREDISPOSITION AND RESPONSE TO GLUCOCORTICOIDS IN IBD IN CHINESE POPULATION

Q. Yang[1,*], B. Chen[1], Q. Zhang[1], Y. He[1], M. Chen[1], Z. Zeng[1], IBD team worker. [1]*The first affiliated hospital of Sun-Yat Sen University, Guangzhou, China*

INTRODUCTION: Glucocorticoids (GCs) play a pivotal role in inducing remission of inflammatory bowel disease (IBD), however, the sensitivity to GCs vary from person to person. Genes such as Multidrug resistance 1 (MDR1), NACHT leucine-rich-repeat protein 1 (NALP1), Glucocorticoid receptor (GR/NR3C1) and its co-chaperone FK506-binding protein FKBP5 participate in modulating the metabolism of GCs. Variations of these genes were reported influencing on GCs response and MDR1 polymorphisms also associated with the susceptibility to IBD. This article aims to evaluate whether the polymorphisms of these genes influence the response to GCs in Chinese IBD patients as well as investigate the relationships between MDR1 and IBD susceptibility.

AIMS&METHODS: 8 single nucleotide polymorphisms (SNPs) were selected from genes mentioned above. These SNPs were genotyped in 156 IBD patients (including 117 Crohn's disease and 39 Ulcerative colitis cases) and 223 healthy controls by MALDI-TOF MS assay. Patients included were all treated with GCs and defined as GCs responders, dependants and resisters after one year follow up. The influences of these variations on GCs response or MDR1 effect on IBD susceptibility and clinical phenotypes were analyzed.

RESULTS: Among the 8 SNPs, the CC genotypes of rs1128503 (C1236T) (P=0.019, OR: 6.583 1.760-24.628, 95%CI 1.760-24.628) and rs1045642 (C3435T) (P=0.009, OR: 3.873, 95%CI 1.578-9.506) in MDR1 gene were more frequent in GC dependants compared with the respond patients of CD, while the other SNPs have no association with GCs response. In addition, the G allele of MDR1 rs2032582 (G2677A/T) was less frequent among CD cases in comparison to controls (P=0.014, OR: 0.668, 95%CI 0.484-0.921); Patients who carried G allele of MDR1 rs2032582 decreased risk for developing non-stricturing and non-penetrating CD (P=0.023, OR: 0.661, 95%CI 0.462-0. 946) and ileocolonic CD (P= 0.024, OR: 0.669, 95% CI 0.472-0.948). There was no significance finding in UC.

CONCLUSION: Our results revealed polymorphisms of MDR1 have an effect on GCs response and the predisposition to IBD in Chinese population. More studies are needed to further confirm our results and elucidate the role of these SNPs as genetic markers for GCs response.

P854 HLA-DRB1 AND THE DEVELOPMENT OF ANTIBODIES TO INFLIXIMAB IN INFLAMMATORY BOWEL DISEASE

T. Billiet[1,*], N. Vande Casteele[2], I. Cleynen[1], V. Ballet[1], A. Gils[2], M. Ferrante[1], P. Rutgeerts[1], S. Vermeire[1]. [1]*TARGID,* [2]*Dept. of Pharmaceutical and Pharmacological Sciences, KU Leuven, Leuven, Belgium*

INTRODUCTION: Infliximab (IFX) has proven to be a successful treatment in patients with inflammatory bowel disease. Unfortunately 15-20% of patients are primary non-responders and 40% of IFX treated patients will lose response over time. This can be partially explained by the formation of antibodies to IFX (ATI). This immunogenic response is seen in approximately 6-17% of patients treated with scheduled IFX. Little is known about host factors that determine immune responses to IFX but genetic factors may play a crucial role.

AIMS&METHODS: We hypothesized that the formation of ATIs is associated with specific HLA class II molecules. We retrospectively identified 78 ATI-positive patients and matched them with 58 controls. Controls required at least 2 years of therapy with 6 IFX trough level (TLI) measurements and no detectable ATI. ATI and TLI were measured with an in-house-developed ELISA. HLA class II alleles were imputed using immunochip data and HLA*IMP software. Imputation call thresholds were applied according to Dilthey's et al.[i] The number of allele carriers for the different class II HLA types were compared between cases and controls using the two tailed Fisher Exact test.

RESULTS: There was no difference between the number of allele carriers for HLA-DPB, HLA-DQA and HLA-DQB in the case and control group. For HLA-DRB1 however, we found that 23% of the cases carried the DRB1*0301 allele compared to 9% of controls (P=0.036; OR=3.18 [1.10-9.16]). When considering the total number of alleles, we found that 13% of the alleles in cases were DRB1*0301 positive compared to 6% in the control group (P=0.12; OR=2.28 [0.87-5.97]). As a drug holiday may influence ATI formation, we re-analyzed patients who had maintenance treatment only (61 cases and 40 controls) and found similar results (23% of the cases carried the DRB1*0301 allele compared to 8% of controls), although not significant (OR=3.67 [0.98-13.74], P=0.057) probably due to the small sample size.

CONCLUSION: The formation of ATI is influenced by specific HLA class II molecules as has also been shown for the formation of antibodies to interferon-β in multiple sclerosis. Although this retrospective study is impaired due to its small sample size and imputation of HLA alleles instead of direct typing, we did see a clear trend towards an association between HLA-DRB1*0301 and positive ATI. We therefore strongly feel that these findings warrant thorough examination in larger cohorts of patients.

INTRODUCTION: Our group previously reported singular molecular phenotypes in the inflamed areas of ileo-cecal resection specimens of patients with Crohn's disease (CD) [Zabana Y. JCC-sup 2012; 6 (1):S186]. However, their accuracy in predicting further post-surgical recurrence (PSR) was limited, possibly due to the predominance of inflammatory features in the studied samples.

AIMS&METHODS: To describe the functional genetic characteristics of non-inflamed intestinal areas of surgical resection specimens from CD patients and their relationship with the development of early PSR.**Methods:** Non-inflamed and inflamed samples were harvested from 15 CD patients undergoing ileo-cecal resection. Follow-up colonoscopies were performed at six, twelve, and eighteen months after surgery. Patients were grouped according to the development (n=5) or not (n=10) of endoscopic recurrence. Human whole genome microarray (Codelink) was performed. Transcriptomic profile of surgical samples was compared between recurrent versus non-recurrent patients. LIMA-R package was carried out for normalisation and comparisons. Changes in gene expression were considered significant when they occurred with a Fold Change (FC) of ± 1.5 and $p < 0.005$. Clustering of genes according to phenotype was done using *Qlucore* software, and biologic function prediction and genetic update were obtained using GeneCodis, gene set enrichment analysis (GSEA) and informatics database consultation (PubMed)

RESULTS: Macroscopically healthy intestinal tissue of patients with early PSR showed 16 up-regulated (DNAH3, GOLGA1, etc.) and 6 down-regulated genes (MAML2, CABYR, etc.) as compared to patients without PSR. These differently expressed genes are related to ciliar motility, extracellular matrix activity and, particularly, to the Notch pathway. This biological activity was also found in the profile obtained from inflamed ileal tissue (like SAMD4 and NFIC), but was not outstanding probably because the high inflammatory background.

CONCLUSION: Transcriptomic exploration of macroscopically healthy ileal tissue identified the ciliar motility/Notch pathway axis as a mechanism possibly related to early PSR in CD. Alterations of this biological activity have been

recently shown in the development of spontaneous colitis of murine models [Obata, et al, J Immunol, 2012].

INTRODUCTION: The incidence of endoscopic recurrence (ER) in Crohn's disease (CD), following curative resection, is up to 80% at 1 year. Endoscopy has proved to be the most sensitive method to detect the earliest mucosal changes and the severe ER at 1 year (Rutgeerts' score≥i2) seems to be predictive of clinical relapse
AIMS&METHODS: The aim of this prospective study was to evaluate the incidence of early ER 6 months after curative resection for ileal/ileo-colonic CD. 170 patients [pts](99 males [58%]; mean age at diagnosis 32.7±12.7) were included, in 11 Italian referral centers for IBD (April '05-June '10), in a trial designed to assess the role of AZA vs 5-ASA as early treatment of severe ER. All the pts started oral 5-ASA 2.4 gr/die 15 days after surgery. We evaluated as predictors of severe ER: sex, age at diagnosis, smoking habit, site/duration of disease, type of anastomosis, previous surgery, previous immunosuppressive treatment. Multivariable analysis was performed if at least two variables were significant (p-value <0.05) at univariable analysis
RESULTS: ER was observed within 6 months in 62% of pts (105/170). Of these 82/105 (78%) had severe ER. At univariable analysis only ileo-colonic disease was associated to a lower risk of severe ER (p=0.04; OR 0.52, 95% CI 0,277-0.974). The overall ER rate (≥ i1) was 61.7% (105/170) despite the treatment with 5-ASA
CONCLUSION: In this series ER at 6 months, in pts operated-on for ileo-colonic CD, was high with a significant rate of severe ER (78% of all ER vs 83% [at 1 year] in Rutgeerts' study). This suggest that post-surgical endoscopic evaluation should be performed at 6 months instead of 1 year. Ileo-colonic disease was associated to a lower risk of severe ER at 6 months. The percentage of early ER was similar to that reported in the placebo arm of other studies, suggesting a weak role of 5-ASA in the prevention of early ER

P857 DIFFUSION WEIGHTED MAGNETIC RESONANCE IMAGING IN CROHN'S DISEASE: VALIDATION OF QUANTITATIVE INDEX OF ACTIVITY

A. Buisson[1,2,*], C. Hordonneau[3], J. Scanzi[1], F. Goutorbe[1], B. Pereira[4], C. Borderon[5], G. Bommelaer[1,2], V. Petitcolin[3]. *[1]Gastroenterology department, CHU Estaing Clermont-ferrand, [2]Microbes, inflammation, intestine and susceptibility of the host, UMR 1071 INSERM/Auvergne University USC-INRA 2018, [3]Radiology department, [4]Biostatistics unit, DRCI, [5]Pediatry department, CHU Estaing Clermont-ferrand, Clermont-ferrand, France*

INTRODUCTION: Diffusion-weighted imaging (DWI)-MRI is useful for assessing inflammation in ileal Crohn's disease (CD)[1].
AIMS&METHODS: We aimed to compare the performances of the Apparent Diffusion Coefficient (ADC), the quantitative parameter of the DWI sequences, compared to the MaRIA (Magnetic Resonance Index of Activity) score calculated from injected sequences (reference standard)[2] in defining active CD; to define the best ADC threshold in discriminating active versus non-active CD; and to perform an external validation of the DWI-MaRIA score (Clermont Score)[1] in assessing ileal inflammation in CD. 130 patients from the Clermont-Ferrand IBD unit, France, underwent consecutively and prospectively MR Enterography (MRE) with gadolinium injection and DWI sequences between July 2011 and December 2012. 7 segments (jejunum, proximal and distal ileum, right, transverse and left/sigmoid colon, and rectum) were defined except for operated-patients, thus 848 digestive segments were evaluated. Each examination was interpreted independently by 2 radiologists.
RESULTS: 175 segments (20.6%) were active (small bowel=111, colon/rectum=64) defined as MaRIA score ≥ 7. Using a ROC curve, we determined an ADC threshold of $1.9x10^3 mm^2/s$ which yielded a sensitivity and a specificity in discriminating active from non active CD, of 96.9% and 98.1%, respectively, for the colon/rectum, and 85.9% and 81.6%, respectively, for the ileum. ADC was better correlated to MaRIA score ≥ 7 than related contrast enhancement obtained with injected sequences ($p<0.001$). Clermont score (=1.646 x bowel thickness – 1.321 x ADC + 5.613 x oedema + 8.306 x ulceration + 5.039) was highly correlated with the MaRIA score (rho=0.98) in CD involving distal ileum but not in colonic CD (rho < 0.80). Inter-observer agreement was high for ADC measurement (correlation and concordance > 0.9, p< 0001).
CONCLUSION: ADC is accurate to differentiate active from non active colonic CD. The Clermont score is a validated tool in assessing inflammation in ileal CD. In this context, DWI-MRE should be wider spread in CD and could avoid gadolinium injection in daily practice.

P858 PERIPHERAL BLOOD BIOMARKERS FOR THERAPY RESPONSE IN CROHN'S DISEASE

C. P. Peters[1,2,*], F. H. van Dooren[1], N. W. Duijvis[1,2], P. C. Stokkers[3], C. I. Ponsioen[2], A. A. te Velde[1]. *[1]Tytgat institute for Liver and Intestinal research, [2]Gastroenterology and Hepatology, ACADEMIC MEDICAL CENTRE, AMSTERDAM, [3]Gastroenterology and Hepatology, St Lucas Andreas Hospital, Amsterdam, Netherlands*

INTRODUCTION: Monitoring of remission induction therapy for active Crohn's disease is hampered by the lack of objective markers for therapy response. This also impedes development of new drugs since only subjective markers for therapeutic response can be used in clinical trials. CRP levels are rarely increased and thereby often inappropriate to monitor therapy response. As an alternative, consecutive colonoscopies to assess mucosal healing may be too burdensome. Therefore, measurements of objective biomarkers in peripheral blood are best applicable in daily clinical practice to assess therapy response and monitor individual patients during the remission induction phase.
AIMS&METHODS: This study aimed to identify biomarkers in peripheral blood to distinguish responders from non-responders at an early stage of remission induction therapy. Whole blood RNA was obtained by PAXgene blood RNA tubes before therapy and after 3, 7, 14 and 56 days of remission induction from 10 responders and 10 non-responders. To identify a biomarker for therapy response in general and not for a specific treatment, both anti-TNF and prednisone remission induction strategies were included. Response was defined by improvement in CDEIS at colonoscopy before and 8 weeks after start of therapy, improvement according to the global physician's assessment, as well as improvement in subjective questionnaires (CDAI, IBDQ), next to normalization of inflammation markers. Gene expression profiles were obtained by R2 software analysis of differential gene expression between responders and non-responders at consecutive timepoints, and confirmed by qPCR.
RESULTS: Our first analyses showed several genes to be differentially expressed between responders and non-responders. Within the first 2 weeks of remission induction therapy, responders could be differentiated from non-responders by more expression of ARAP3 ($p<0.01$), and triggering receptor expressed on myeloid cells-1 (TREM1) ($p<0.01$). ARAP3 was recently described as an inhibitor of neutrophil activation. Furthermore, EIF2S1 appeared to be more abundant in responders ($p<0.01$), and is known to regulate autophagy.
CONCLUSION: Here we describe several genes that are differentially expressed in peripheral blood making a distinction between responders and non-responders to Crohn's disease remission induction therapy. These genes might serve as candidate biomarkers for therapy response in peripheral blood.

P859 BODY COMPOSITION IN CROHN'S DISEASE PATIENTS BUT NOT IN ULCERATIVE COLITIS PATIENTS IS DIFFERENT COMPARED TO HEALTHY CONTROLS

C. Dölger[1,*], H. Schulze[1], J. Thieringer[1], J. Stein[2], A. Dignaß[1]. *[1]Department of Medicine I, Markus Hospital, [2]Interdisziplinäres Crohn Colitis Centrum, Frankfurt/Main, Germany*

INTRODUCTION: Chronic illness, various intestinal and extraintestinal disease manifestations, and malnutrition affect the health status of inflammatory bowel disease patients. An impaired health status can be accompanied by changes of the body composition. The bioelectrical impedance analysis (BIA) is a widely used method to examine body composition in patients suffering from chronic diseases. In this study we compared the body composition/phase angle of Crohn's disease (CD) and ulcerative colitis (UC) patients with pair-matched controls.
AIMS&METHODS: We evaluated the body composition of 38 CD patients (19 male and 19 female) and 34 UC patients (16 male and 18 female). The four groups were compared to 72 pair-matched healthy individuals. Matching criteria were body mass index (± 2 kg/m^2), age (± 5 years), and gender. Body composition was assessed by BIA. Additionally, we measured biochemical markers of inflammation and nutrition as well as clinical activity indices.
RESULTS: The phase angle in female CD patients was 5.5° and significantly lower than in healthy controls (6.0°, p=0.037). Comparing male CD patients with healthy controls we also found a significant difference (6.3° versus 6.8°, p=0.015). Interestingly, no significant difference of body composition/phase angle was observed when comparing UC patients with matched healthy controls.

We observed no general correlation of any of the disease activity markers with the phase angle as a parameter of body composition.
CONCLUSION: Our observations demonstrate a significant difference of the phase angle as a global parameter of body composition between CD patients and healthy controls. No significant differences were found when comparing UC patients and healthy controls. These observations may reflect the different nature of both diseases (course of disease, affected parts of the gastrointestinal tract, medications, etc.). Generally, BIA seems to be an appropriate method to assess the health status in IBD patients.

P860 LOWER PREVALENCE OF COLONIC DIVERTICULOSIS IN PATIENTS AFFECTED BY ULCERATIVE COLITIS THAN IN ADULT PATIENTS IN A SINGLE CENTRE

E. V. Avallone[1,*], C. Cassieri[1], R. Pica[1], M. Zippi[1], P. Paoluzi[1]. [1]*INTERNAL MEDICINE AND MEDICAL SPECIALTIES, SAPIENZA UNIVERSITY OF ROME, ROME, Italy*

INTRODUCTION: Diverticulosis of the colon is an acquired condition that results from herniation of the mucosa and submucosa through defects in the muscular layer. The true prevalence of colonic diverticulosis is difficult to measure because most individuals are asymptomatic. In particularly, in literature, there are few study about the prevalence of colonic diverticulosis in patients affected by ulcerative colitis (UC).
AIMS&METHODS: Aim of this study has been to investigate the prevalence of colonic diverticulosis in UC and in adult patients referred in a single centre. Computerized data of consecutive patients, referred to our Institution to undergo a colonoscopy for colorectal cancer screening and/or for UC control, between January 1, 2009 and December 31, 2009, were retrospectively studied. From this study were excluded patients who had previous history of colonic surgery, affected by proctitis and without a complete colonoscopy.
RESULTS: Six hundred and five consecutive patients were retrospectively studied. Of these patients, 438 (72.4%) underwent colonoscopy for colorectal cancer screening (Group A) and 167 (27.6%) for UC assessment (Group B). In group A 224 patients (51.1%) were male (average age of 62.7 ± 14.2 SD years, range 35-86 years), in group B 102 (61.1%) were male (average age of 57.6 ± 12.1 SD years, range 25-84 years). Prevalence of colonic diverticulosis was higher in group A (122 patients, 27.8%) than group B (18 patients, 10.8%) a difference statistically significant ($p < 0.0001$, Fisher's exact test). Female gender in patients with colonic diverticulosis was higher in group A than group B (68 patients, 55.7% and 4 patients, 22.2%, respectively) with a difference statistically significant ($p = 0.0106$, Fisher's exact test). In group A sigma and left colon was involved in 119 (97.6%) patients versus 12 (66.7%) of Group B, with a difference statistically significant, ($p=0.0001$, Fisher's exact test), in Group B the right colon was involved in 4 (22.2%) patients versus 1 (0.8%) of Group A, a difference statistically significant, ($p=0.0009$, Fisher's exact test). No difference was found between the presence of colonic diverticulosis and extension of UC.
CONCLUSION: Results of our study demonstrated that prevalence of colonic diverticulosis was significantly lower in patients with UC than in adult population, underlining, nevertheless, the relevance of the coexistence of UC and colonic diverticulosis that could make be difficult the clinical management of these patients.

P861 REAL TIME EVALUATION USING CONTRAST ENHANCED ULTRASOUND IN COMPLICATED CROHN'S DISEASE PATIENTS

E. Calabrese[1,*], F. Zorzi[1], E. Stasi[1], E. Lolli[1], S. Onali[1], P. Scarozza[1], L. Biancone[1], F. Pallone[1]. [1]*Gastroenterology Unit, University of Rome Tor Vergata, Rome, Italy*

INTRODUCTION: Crohn's disease (CD) is associated with penetrating complications such as phlegmons and intra-abdominal abscesses. As the management of the patients is influenced by the presence and characterization of such complications, a readily available tool for the diagnosis of extramural complications in CD is needed. Ultrasonography has a good diagnostic accuracy and can be used as the first-line imaging technique in complicated CD patients. Preliminary findings suggest that the assessment of vascularity within intra-abdominal masses may distinguish between phlegmons and abscesses.
AIMS&METHODS: Aim of our study was to evaluate the use of contrast enhanced ultrasound (CEUS) to distinguish between phlegmons and intra-abdominal abscesses in CD patients. From November 2011, consecutive patients with complicated CD were enrolled. Indications of patient evaluations by CEUS were symptoms, signs and biochemical exams indicating penetrating behavior (abdominal pain, mass, fever, elevated CRP and leukocytosis). A total of 17 CD pts (10 M; median age 27 yrs, range 21-54; disease duration: median 48 mos, range 6-360; CD site: ileal in 9 pts, ileo-colonic in 8 pts; CD behavior: penetrating in 16 pts, stricturing in 1 pt; previous ileocolonic resection in 6 pts) were included. Clinical evaluations by an IBD expert and other cross sectional imaging techniques (MR and CT) were considered as gold standard.
RESULTS: CEUS detected abscesses in 7 pts and phlegmons in 10 pts. Five out of 7 abscesses were confirmed by CT-Enteroclysis and these pts underwent surgery during the follow up. The remaining 2 pts with abscesses were treated with antibiotic therapy and are still in follow up (10 mos). In the group of patients with phlegmons, 4 out of 10 patients were evaluated by CT or MRI that confirmed phlegmons in 3 cases but in one patient a deep abscess was identified and surgery was scheduled. Six out of 10 pts were clinically followed up (median: 6 mos). Two patients developed an abscess after one week from CEUS despite medical treatment. Overall CEUS correctly identified 14 out of 17 lesions on the basis of cross sectional imaging modalities and clinical follow up used as final diagnosis.
CONCLUSION: Our preliminary results indicate that CEUS is a non-invasive, radiation free and real time imaging modality able to differentiate phlegmons from abscesses driving a prompt clinical management in complicated CD patients.

P862 CORRELATION BETWEEN THE CROHN'S DISEASE ACTIVITY INDEX AND A WEB-BASED SELF-REPORTING SYMPTOMS DIARY OF CROHN'S DISEASE

E. S. Kim[1,*], K. B. Cho[1], K. S. Park[1], B. I. Jang[2], K. O. Kim[2], S. W. Jeon[3], M. K. Jung[3], E. Y. Kim[4], C. H. Yang[5], Daegugyeongbuk Gastrointestinal Study Group (DGSG). [1]*Internal Medicine, KEIMYUNG UNIVERSITY SCHOOL OF MEDICINE,* [2]*Internal Medicine, Yeungnam University College of Medicine,* [3]*Internal Medicine, Kyungpook National University School of Medicine,* [4]*Internal Medicine, Catholic University of Daegu School of Medicine,* [5]*Internal Medicine, Dongguk University School of Medicine, Daegu, Korea, Republic Of*

INTRODUCTION: Crohn's Disease Acitivity Index (CDAI) is known to be complex, time-consuming, and impractical.
AIMS&METHODS: The aim of this study was to investigate whether a newly-developed, simple web-based self-reporting symptoms diary of CD (CDSD) was equally effective in assessing disease severity. CDSD consisted of 5 clinical items (general well being, abdominal pain, number of liquid stools, abdominal mass, and complications) which could be easily recorded through online web site (www.CDSD.or.kr). Images were inserted to help patients better understand the complications. All patients were asked to visit and record their symptoms on weekly bases. CDAI and CDSD were recorded on patients visit to the hospitals. Data were analyzed to determine if scores from the CDAI correlated with those from the CDSD for defining disease remission.
RESULTS: Analysis of 288 data pairs showed a positive correlation between scores. The correlation between the systems was 0.673 (Spearman correlation coefficient). Through ROC curve, the score ≤ 5 points of CDSD was identified to correspond to a CDAI score ≤ 150 points (clinical remission). Using cutoff value 5 points of CDSD, the positive and negative predictive value for the clinical remission were 92.4% and 86.8%, respectively.
CONCLUSION: This study demonstrates that results from the CDAI correlated well with those from CDSD. Use of CDSD might permit simpler and patient-friendly CD activity assessment which can provide useful early-phase information of patients with CD in the long term clinical study.

P863 SUSTAINED HIGH PERFUSION IN THE GASTROINTESTINAL WALL IN PATIENTS WITH CROHN'S DISEASE DURING MEDICAL TREATMENT INDICATES LACK OF RESPONSE

F. Saevik[1,2,*], K. Nylund[1,2], T. Hausken[1,2], O. H. Gilja[1,2]. [1]*Institute of Clinical Medicine, University of Bergen, Bergen,* [2]*National Centre of Ultrasound in Gastroenterology, Haukeland University Hospital, Bergen, Bergen, Norway*

INTRODUCTION: Crohn's disease is characterized by periods of remission and relapse. To improve patient management objective measurements of the degree of local inflammation in the gastrointestinal wall should be made. Increased microvessel density and perfusion are typical features of acute inflammation. Indirect measurements of these parameters could be measured using contrast-enhanced ultrasound (CEUS).
AIMS&METHODS: The study aim was to investigate whether CEUS can provide prognostic information about patients treated medically for an acute exacerbation of Crohn's disease. 13 patients with Crohn's disease were prospectively recruited in a pilot study at Haukeland University Hospital. All patients received medical treatment for an acute exacerbation with systemic steroids, adalimumab or infliximab. Patients who had to change treatment regime during the follow-up were categorized as having insufficient treatment effect. The patients were examined at time 0, 1, 3 and 12 months after initiation of the treatment with clinical scoring, blood tests and CEUS. Ultrasound was performed with a Logiq E9 ultrasound scanner (GE Healthcare, Milwaukee, USA) and contrast agents (Sonovue, Bracco, Milan Italy). The perfusion analysis was performed with commercially available software (Vuebox, Bracco Suisse SA, Geneva Switzerland). The program analyzes the contrast intensity in a selected area, fits the data to a standardized curve and derives variables such as peak contrast intensity, area under the curve and slope of the curve.
RESULTS: In six of the 13 patients, the treatment regime was changed during the study period. There were no significant differences in perfusion between the two groups at the start of the treatment or examinations after 3 and 12 months. There was, however, a significant difference between the two groups for peak contrast intensity ($p=0.022$), wash in area under the curve ($p=0.014$) and slope (wash in rate: $p=0.035$, wash out rate: $p=0.014$, respectively) at the examination one month after the initiation of the treatment.

CONCLUSION: Perfusion analysis of the intestinal wall with CEUS one month after starting treatment in patients with Crohn's disease can provide prognostic information regarding treatment efficacy.

P864 ELEVATED MATRIX METALLOPROTEINASE-3 LEVELS IN SERUM CORRELATED WITH CROHN'S DISEASE SEVERITY: EFFICACY AS CLINICAL BIOMARKER

K. Kawashima[1,*], S. Ishihara[1], H. Sonoyama[1], Y. Tada[1], A. Oka[1], R. Kusunoki[1], N. Fukuba[1], N. Oshima[1], I. Moriyama[1], T. Yuki[2], Y. Kinoshita[1]. [1]*Second Department of Internal Medicine, Shimane University School of Medicine,* [2]*Division of Gastrointestinal Endoscopy, Shimane University Hospital, Izumo, Japan*

INTRODUCTION: Matrix metalloproteinase-3 (MMP-3), a 59-kDa protein and 1 of 4 known stromelysins among MMPs, has been reported to be up-regulated in inflamed areas in Crohn's disease (CD) and is considered to play an important role in tissue destruction. However, MMP-3 levels in serum and its clinical effects in CD patients remain unknown.
AIMS&METHODS: We investigated whether serum MMP-3 levels are correlated with clinical and endoscopic evidence of CD. This study was prospectively conducted from November 2011 to September 2012 at 2 hospitals in Japan. Patients with an artificial anus and coexisting collagen disease were excluded. Serum samples were measured at the first visit and serum MMP-3 levels were assessed in regard to CD activity index (CDAI). MMP-3 in serum was also measured within 1 week before undergoing a complete ileocolonoscopy, with those patients scored according to a simple endoscopic score for CD (SES-CD), defined as follows: 0-3, inactive; 4-10, mildly active; and >11, moderately to severely active. We then assessed the correlation of serum MMP-3 levels with SES-CD results.
RESULTS: Sixty-two patients with CD (mean age 36.7±8.8 years; 44 males, 18 females) were enrolled in this study. The mean serum MMP-3 level was significantly higher in the active (n=20, 97.1±51.4 ng/ml) as compared to the inactive (n=42, 61.9±23.0) phase ($p<0.001$). In addition, that level was significantly correlated with CDAI (Spearman's rank correlation coefficient r=0.28, p=0.03). A complete ileocolonoscopy was performed 56 times in 44 patients during the study period. In those cases, the mean serum MMP-3 level was 62.5±28.3 ng/ml for inactive (n=16), 69.7±38.5 ng/ml for mildly active (n=20), and 101.8±48.0 ng/ml for moderately to severely active (n=20) SES-CD cases. Serum MMP-3 levels in cases with moderately to severely active SES-CD were significantly elevated as compared to both inactive (p=0.004) and mildly active cases (p=0.03), and showed a significant correlation with SES-CD (r=0.42, p=0.002).
CONCLUSION: Our results showed that serum MMP-3 levels were elevated during active phases of CD and had a significant correlation with ileocolonoscopy findings. Thus, MMP-3 may be useful as a clinical biomarker measurement in CD patients.

P865 INFLUENCE OF STRESS IN THE CLINICAL COURSE OF INFLAMMATORY BOWEL DISEASE PATIENTS

M. Barreiro-De Acosta[1,2,*], M. Iglesias-Rey[2], R. Ferreiro-Iglesias[1,2], A. Lorenzo-Gonzalez[1], J. E. Dominguez-Muñoz[1,2]. [1]*Gastroenterology, University Hospital of Santiago de Compostela,* [2]*Foundation for Research in Digestive Diseases, Santiago de Compostela, Spain*

INTRODUCTION: Psychological stress has been defined as a process in which environmental equal or exceeds the adaptative capacity of an organism. There is a long but inconsistent history of studies about the relationship between stress and Inflammatory Bowel Disease (IBD).
AIMS&METHODS: The aim of this study was to assess the influence of stress on the clinical course of IBD patients. **Methods:** A prospective observational, cohort study was designed. Crohńs Disease (CD) and Ulcerative Colitis (UC) patients older than 18 years of age were included. Stress was assessed with the Spanish version of the Perceived Stress scale (PSS). This scale is a self-reported instrument that assesses the level of perceived stress during the previous month, PSS consists of 14 items with a response format of a five-point scale (0 = never, 1 = hardly ever, 2 = once in a while, 3 = often, 4 = very often). The sum score obtained indicates that a higher score corresponds with a higher level of perceived stress (range 0-56). In order to assess the clinical course of IBD, during a follow-up period of 18 months all emergency visits and hospitalizations related with IBD were recorded. The influence of stress on clinical course was analyzed by Multiple Regression analysis.
RESULTS: 716 patients were included; 343 (47.9%) male, mean age 44.5 years, range from 18 to 86 years, 297 (41.8%) patients with CD and 413 (58.2%) with UC. The mean in the PSS was 23.67, with an SD of 9.59. The mean of emergency visits was 1.05 (SD: 1.68, range 0-14) and for hospitalizations it was 0.35 (SD: 0.94, range 0-9). At month 18 higher stress at baseline was related with more emergency visits in the follow up (B=0.11; CI95%: 0.01-0.03; p=0.005) but not with more hospitalizations (B=-0.02; CI95%: -0.01-0.01; p=0.685). Only the type of disease (CD) (B=-0.13; CI95%: -0.39-0.11; $p<0.0001$) and presence of relapse at baseline (B=0.22; CI95%: 0.29-0.57; $p<0.0001$) were related with more hospitalizations after 18 months.
CONCLUSION: A higher perception of stress in IBD patients is related with an increased number of emergency visits related with the disease in the following months. These patients could probably benefit from a psychological intervention that would improve their psychological status.

P866 USE OF FAECAL CALPROTECTIN AS PREDICTOR OF RELAPSE IN INFLAMMATORY BOWEL DISEASE (IBD) PATIENTS UNDER MAINTENANCE TREATMENT WITH INFLIXIMAB

M. Barreiro-de Acosta[1,2,*], R. Ferreiro-Iglesias[2,3], M. F. Otero-Santiago[4], A. Lorenzo-González[1], C. Alonso-de la Peña[4], J. E. Dominguez-Muñoz[1,2]. [1]*Gastroenterology, University Hospital of Santiago de Compostela,* [2]*Foundation for Research in Digestive Diseases,* [3]*University Hospital of Santiago de Compostela, Santiago de Compostela, Spain,* [4]*Laboratoty Medicine, University Hospital of Santiago de Compostela, Santiago de Compostela, Spain*

INTRODUCTION: In inflammatory bowel disease (IBD) predicting relapse by measuring non-invasive biomarkers could allow early changes to treatment. Data is scarce regarding the usefulness of close monitoring with calprotectin to predict relapse.
AIMS&METHODS: The aim was to evaluate the predictive value of a faecal calprotectine test checking for flares in patients with IBD under maintenance treatment with Infliximab. **Methods**: A prospective and observational study was designed. Inclusion criteria were Crohn's disease [CD] and ulcerative colitis [UC] patients in clinical remission under maintenance 5 mg/kg Infliximab therapy. Fresh faecal calprotectin was measured using a rapid test in the stool sample collected just before the drug infusion. Clinical examination was performed the day of the infusion and after two months. Relapse was defined as a Harvey–Bradshaw score >4 in CD and as a Mayo score >2 in UC. The U-Mann–Whitney test and the ROC analysis were performed in SPSS.
RESULTS: 53 patients were included; mean age 46±12 years; 28 (52.8%) female, 62.3% with CD and 37.7% UC. After two months, 41 (77.4%) patients remained in remission and 12 (22.6%) presented a relapse. For patients in remission mean calprotectin levels were 110±170 µg/g (95% CI 225-439). Calprotectin levels in patients relapsing during the follow up had a mean of 332±168 µg/g (95% CI 57-164). Patients who flared had significantly higher calprotectin levels than those who maintained remission ($p < 0.005$). These differences were found in both CD and in UC. A further ROC analysis (flare vs remission) suggested that a calprotectin level > 110 µg/g was the best cut-off point showing high sensitivity (100%) to predict the flare. The area under the curve was (95% [CI]) = 0.888 (0.801 - 0.975) with good accuracy ($p < 0.005$).
CONCLUSION: In IBD patients under infliximab maintenance therapy calprotectin levels highly correlate with a predictor of relapse. Remission is associated with low calprotectine levels. More studies and an increased number of patients should confirm the usefulness of calprotectin to modulate therapy during medical checks.

P867 EFFECTS OF PHYSICAL EXERCISE ON BONE MINERAL DENSITY IN PATIENTS WITH ULCERATIVE COLITIS

M. Sanges[1,*], D. Trio[1], M. Miniero[1], O. Donatore[1], R. Sollazzo[1], D. Mattera[1], A. D'Arienzo[1]. [1]*Departmento of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy*

INTRODUCTION: A higher incidence of osteoporosis and fractures is a recognized complication of ulcerative colitis (UC). The cause of metabolic bone disease in this population is believed to be multifactorial and may include the disease itself and associated inflammation, high-dose corticosteroid use, weight loss and nutritional deficiencies, a lack of exercise and physical activity, and an underlying genetic predisposition to bone loss. Measures to prevent and treat osteoporosis in this high-risk group have not yet been well established and despite the benefits of specific exercises being well documented in healthy populations, the role of physical activity and exercise in the prevention and treatment of UC-related bone loss has received little attention.
AIMS&METHODS: The aim of this study was to evaluate the effects of a 1-year exercise training program on bone mineral density (BMD) in patients with UC. Sixty patients (M/F=32/28, median age 46 years) with quiescent UC and low BMD (T-score $\leq$ 1.1) were enrolled in the study. Patients were randomly assigned into control group (n=30) and exercise group (n=30). In exercise group, a mQuiz Ref IDoderate-intensity physical activity progressed to 60 minutes, 3 days per week was prescribed. Both groups received supplementation with 1 g calcium carbonate and 800 IU vitamin D per day. BMD (g/cm^2) was measured at baseline and at 12 months at femoral neck (FN) and lumbar spine (LS) by dual-energy X-ray absorptiometry.
RESULTS: Fifty-two patients completed the study. Significant increases compared with baseline in BMD were observed for both groups at 1 year, with significantly higher increases for exercise group compared with control group. Exercise group showed a BMD increase (± SD) at the LS of +5.7% (±2.1) compared with +3.6% (±2.0) observed in control group ($p<0.05$). Similarly, exercise group showed better performance compared with control group for BMD increase at the FN, with an observed increase +5.5% (±1.9), compared with a change of +3.2% (±1.8) observed in control group ($p<0.05$).
CONCLUSION: Our study has demonstrated that the association of physical exercise and supplementation with calcium and vitamin D is better than

supplementation alone to increase BMD in patient with UC. Physical exercise is a potentially effective method of increasing BMD and reducing the risk of osteoporotic fracture in UC patients.

P868 DEVELOPMENT OF THE ULCERATIVE COLITIS PATIENT-REPORTED OUTCOMES (UC-PRO) QUESTIONNAIRE

P. D. Higgins[1,*], G. Harding[2], D. L. Patrick[3], D. Revicki[2], S. Trease[4], G. Globe[5], H. N. Viswanathan[5], K. Fitzgerald[4], D. Borie[5], B. G. Ortmeier[5], N. K. Leidy[2]. [1]*University of Michigan Health System School of Public Health, Ann Arbor,* [2]*United BioSource Corporation, Bethesda,* [3]*University of Washington, Seattle,* [4]*Genentech Inc., South San Francisco,* [5]*Amgen Inc., Thousand Oaks, United States*

INTRODUCTION: Well-defined and reliable patient-reported outcome (PRO) measures are needed to provide direct evidence of treatment benefit in clinical trials evaluating new therapeutic agents for the treatment of ulcerative colitis (UC).
AIMS&METHODS: To develop a new instrument covering the signs, symptoms and impacts of UC important to patients with this condition. To determine instrument content and structure, concept elicitation from six focus groups (n=38) and ten 1:1 interviews were conducted in moderate to severe UC patients. Content analysis was performed by independent coders, with data organized using qualitative data analysis software (NVivo or ATLAS.ti). Based on the analytic findings and input from clinical experts, a draft instrument was developed. Two subsequent rounds of 1:1 cognitive interviews were conducted in UC subjects (n=16) to examine readability, interpretability, and comprehensiveness. Saturation was evaluated throughout the data collection process.
RESULTS: Of the 64 participants, 24 (38%) were male; mean age was 44 years (SD=14.3). The most important and relevant UC signs and symptoms were: frequency of bowel movement (BM), consistency of BM, blood in BM, pain in stomach area, joint pain/general body pain, tiredness, urge/need to have a BM right away, mucus in BM, gas, bloating, weakness, loss of appetite, and feeling dehydrated. Important impacts included the use of daily coping strategies and effects on emotional well-being and daily life. No new concepts were identified toward the end of data collection, indicating saturation had been achieved. Based on findings, the UC-PRO was developed to measure the UC signs, symptoms and impacts elicited from and important to the patients themselves. Given the day-to-day variability described by subjects, daily recall is used for recording signs and symptoms (14 items) and coping strategies (8 items), with a one-week recall used for assessing UC impact on activities of daily life (9 items) and emotions (8 items). During cognitive interviews, patients found items in the instrument clear, easy to understand, and relevant.
CONCLUSION: The UC-PRO was developed based on patient input and addresses signs and symptoms of UC, coping strategies, daily life impact, and emotional impact. Research examining the quantitative performance properties including reliability, validity, and ability to detect change, is currently underway.

INTRODUCTION: Ulcerative colitis (UC) is associated with an increased risk of colorectal cancer. Chromoendoscopy with intravital staining techniques showed better results than random biopsies (RB) in surveillance studies aiming high-risk patients, particularly those with history of primary sclerosing cholangitis (PSC) and/or intraepithelial neoplasia (IEN).
AIMS&METHODS: Aims: Compare chromoendoscopy-guided endomicroscopy (CGE) with RB for IEN detection in patients with long-standing UC and no history of PSC and/or IEN. Determine confocal laser endomicroscopy (CLE) performance in IEN detection.
Patients and methods: 113 patients with distal/extensive UC with $\geq$ 8 years of disease and no history of PSC and/or IEN, were prospectively randomized at a 1:1 ratio to undergo RB or CGE. In the RB group (n = 55) 4 random biopsies every 10 cm and targeted biopsy/polypectomy of the detected lesions were performed. In the CGE group (n = 58) the circumscribed lesions identified by chromoendoscopy were evaluated by CLE and then targeted biopsy/polypectomy was performed.
RESULTS: 9 IEN, all low-grade, were detected. These included 4 IEN in the RB group and 5 IEN in the CGE group ($p > 0.05$), distributed by 2 patients in the RB group and 4 in the CGE group ($p > 0.05$). Regarding the number of biopsies performed, it was 36.0 ± 6.4 in the RB group and 5.0 ± 5.2 in the CGE group ($p < 0.001$). The proportion of biopsies with IEN was 1/496 in the RB group and 1/58 in the CGE group ($p < 0.01$). Colon screening takes on average 42.0 ± 8.5 min in the RB group and 61.5 ± 16.6 min in the CGE group ($p < 0.001$). Of the 88 circumscribed lesions identified in the CGE group, IEN was found in 5. IEN detection by CLE revealed: sensitivity = 80.0%, specificity = 97.6%, positive predictive value = 66.7% and negative predictive value = 98.8%.
CONCLUSION: In patients with long-standing UC and without history of PSC and/or IEN, CGE doesn't perform significantly better than RB in detecting IEN. CGE takes longer than the RB, but it decreases the number of biopsies performed and significantly increases the proportion of biopsies with IEN. CLE has a good performance in IEN detection, with a particularly high negative predictive value.

P870 PATIENT'S DEFINITION OF A FLARE COMPARED TO HBI / SCCAI

S. Mumtaz[1,*], C. J. Williams[1], J. Hamlin[1], A. C. Ford[1,2]. [1]*Leeds Gastroenterology Institute, Leed General Infirmary.,* [2]*Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, United Kingdom*

INTRODUCTION: Inflammatory bowel disease (IBD) is a chronic relapsing remitting disease, with flares of disease activity, often requiring escalation in treatment. Harvey-Bradshaw index (HBI) and simple clinical colitis activity index (SCCAI) are two validated clinical scores to assess activity of Crohn's disease (CD) and ulcerative colitis (UC) respectively. Although these two scores are widely used in clinical research and practice, there are no studies comparing patient's perception of a flare with them.
AIMS&METHODS: This was a prospective cross-sectional survey conducted among consecutive patients with CD or UC attending an IBD clinic in a single teaching hospital. All patients completed HBI and SCCAI questionnaires, and demographic data were collected. Participants were also asked if they were attending the clinic due to a flare of disease activity. We cross-tabulated the results using a 2x2 table, assuming HBI and SCCAI to be the gold-standard for defining a flare of disease activity (a score >4 for both), in order to calculate sensitivity, specificity, and positive and negative predictive values (PPV and NPV) for patient's perception of a flare of disease activity. We also calculated a kappa value (K) in order to measure the agreement between the two factors.
RESULTS: 281 patients with IBD were recruited (143 (51.1%) female, 156 (55.7%) CD, 47 (16.8%) smokers, 115 (41.1%) non-drinkers, mean age 46.3 years (range 17 to 89)). In CD 32 (20.5%) patients attending clinic self-reported a flare of disease activity, whereas 69 (44.2%) met criteria for a flare according to HBI. Sensitivity of a patient's self-report of a flare was 36.2%, specificity was 91.9%, PPV was 78.1%, and NPV was 64.2% (K value = 0.30). In UC 50 (39.7%) self-reported a flare, while 51 (40.5%) met criteria for a flare on SCCAI. Sensitivity was 62.7%, specificity 76.0%, PPV 64.0%, and NPV 75.0% (K value = 0.39)
CONCLUSION: Agreement between a patient's report of a flare of disease activity and available validated scores is modest, at best. This may have implications when therapies are altered based on patient's opinion of disease activity alone.

P871 DIFFUSION WEIGHTED MRI OF INFLAMMATORY BOWEL DISEASE

S. Aurakzai[1,*], S. Gourtsoyianni[2], J. Sanderson[3], S. Anderson[3], P. Irving[3], V. Goh[2], N. Griffin[2]. [1]*Imaging Sciences, King's College London,* [2]*Radiology,* [3]*Gastroenterology, Guys and St Thomas, London, United Kingdom*

INTRODUCTION: The management of Crohn's disease (CD) is largely dictated by the degree of inflammatory activity within the bowel. Current methods of assessing this include endoscopy and clinicopathological markers of disease activity but these have limitations. Diffusion weighted - MR enterography (DW-MRE) is a recently introduced noninvasive, non-ionising imaging technique that provides comprehensive evaluation of small and large bowel disease. Preliminary studies have suggested that restricted diffusion is seen in segments of inflamed bowel in CD, thought to be due to the presence of an inflammatory cell infiltrate reducing the extravascular extracellular space, and thus restricting the movement of water molecules (1, 2).
AIMS&METHODS: The aim of this study was to compare apparent diffusion coefficient (ADC) measurements on DW-MRE in the inflamed terminal ileum in patients with histologically proven CD compared to the control population. A retrospective study was performed on 59 consecutive patients (median age 35 years, range 16-72 years, 30 female, 29 male) with terminal ileal CD who underwent DW-MRE between January and December 2011. During this same time period, 54 patients (median age 34 years, range 14-73 years, 23 female and 31 male). underwent DW-MRE for investigation of small bowel symptoms with no

endoscopic or histopathological evidence of CD who then served as the controls. One radiologist reviewed the DW images and ADC maps for both patients and controls, with ADC measurements obtained by drawing a standardised region of interest over the wall of the terminal ileum. Analysis was performed using diffusion analysis software on an open source Mac-based Dicom Viewer (Osirix 3.9).
RESULTS: There was a significant difference in ADC measurements between patients with terminal ileal disease and controls, with the median (range) ADC value of inflamed and normal terminal ileum measured as 1.249 (0.900-1.629) $x10^{-3}$ mm^2/s and 2.276 (1.279-3.325) $x10^{-3}$ mm^2/s respectively ($p < 0.0001$, Mann Whitney).
CONCLUSION: Restricted diffusion is present in Crohn's patients with terminal ileal disease, with mural ADC measurements significantly lower than in control subjects. This study supports the hypothesis that diffusion may well have a role as an imaging biomarker in assessing disease activity.

P872 OBSERVATION OF PEYER'S PATCH USING NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY IS USEFUL IN PREDICTING THE RECURRENCE IN ULCERATIVE COLITIS PATIENTS

S. Hiyama[1,*], H. Iijima[1], S. Shinzaki[1], T. Inoue[1], E. Shiraishi[1], S. Kawai[1], M. Araki[1], T. Nishida[1], M. Tsujii[1], T. Takehara[1]. [1]*Department of Gastroenterology and Hepatology, Osaka University, Graduate School of Medicine, Suita, Japan*

INTRODUCTION: Peyer's patches (PPs) are aggregates of lymphoid follicles mainly located in distal ileum, which play a major role in mucosal immunity. Using narrow-band imaging with magnifying endoscopy (NBI-ME), we recently reported that patients with ulcerative colitis (UC) have alternate PPs, but its clinical significance is unapparent.
AIMS&METHODS: The aim of this study was to evaluate the relationship between images of PPs using NBI-ME and clinical findings in UC patients. Sixty-three UC patients under 65 years who underwent total colonoscopy from April 2009 to March 2013 were prospectively enrolled, and images of PPs from NBI-ME were collected. Alteration in the villi of PPs were evaluated by ''villi index'' as previously reported (Hiyama S. et al, *Digestion* in press); the sum of three categories; irregular formation, hyperemia, and altered vascular network pattern. Patients were divided into two groups based on ''villi index'', low (L) type = 0 or 1, and high (H) type = 2 or 3. Clinical background data, including age, gender, clinical activity, endoscopic score, extent of involvement, and clinical course were obtained, and factors which contribute to the alteration in PPs were analyzed. Twenty-three patients with mucosal healing (Mayo endoscopic subscore = 0) were followed and were evaluated for the clinical recurrence rate within six months after colonoscopy.
RESULTS: UC patients included 36 men and 27 women, and mean age was 39.9 (17-64) years. Fifty-one percent (32/63) of the patients had L type PPs, while 49% (31/63) had H type. Gender, age, clinical activity, endoscopic score and extent of involvement did not affect the alteration in PPs. All the patients with chronically active course (8/8) had H type PPs, which was significantly higher proportion than in patients with relapsing-remitting or first attack type [42% (23/55); $p < 0.01$]. Additionally, among 23 patients who showed mucosal healing (L type, 12; H type, 11) at the time of endoscopic examination, patients with H type PPs had significantly higher recurrence rate within six months compared to those with L type PPs [64% (7/11) vs 17% (2/12), $p < 0.05$].
CONCLUSION: Alteration in PPs was associated with chronically active disease course and clinical recurrence in UC patients. Observation of PPs using NBI-ME may be a useful method to differentiate treatment-resistant patients in UC.

P873 DEVELOPMENT OF A NOVEL INDEX OF CT ENTEROGRAPHY FOR EVALUATING SEVERITY OF CROHN'S DISEASE

S. Sazuka[1,*], T. Katsuno[1], K. Saito[1], M. Saito[1], T. Nakagawa[1], S. Minemura[1], A. Oyamada[1], K. Okimoto[1], T. Taida[1], D. Maruoka[1], T. Matsumura[1], M. Arai[1], O. Yokosuka[1]. [1]*Department of Gastroenterology, CHIBA UNIVERSITY HOSPITAL, Chiba, Japan*

INTRODUCTION: The use of computed tomography enterography (CTE) for assessment of patients with Crohn's disease (CD) is expanding. For evaluating severity of the small and large bowel lesions in patients with CD, we developed a novel ''CTE index'' as a parameter of disease activity.
AIMS&METHODS: Patients underwent CTE and double balloon endoscopy (DBE) after oral administration of polyethylene glycol solution on the same day. CTE parameters evaluated in this study included bowel wall thickening (WT), mucosal hyperenhancement (MH), submucosal fat deposition (SF), mural stratification (target sign), stenosis/sacculation (S/S), mesenteric hypervascularity (comb sign), increased fat density (FD), fibrofatty proliferation (FP) and enlarged lymph nodes (LN). Each CTE parameter was graded in a scale of 0 (no), 1 (mild) or 2 (severe). Endoscopic findings were evaluated by the parameters in the Simple Endoscopic Score for Crohn's Disease (SES-CD). The small and large intestine was divided into 3 and 4 distinct anatomic segments, respectively. The segments observed by both CTE and DBE were subjected to evaluation in this study. We sought to determine CTE parameters that were best correlated with endoscopic findings using Spearman's rank correlation and multiple regression analysis to develop "CTE index".
RESULTS: Seventy four segments from 14 patients with CD were observed by both CTE and DBE and subjected to analysis. Spearman's rank correlation showed that most CTE parameters highly correlated with a subtotal score of SES-CD in each segment. Next, regression formulae for each endoscopic parameter were obtained by the multiple regression analysis; Presence and size of ulcers=0.3+0.8*FD+0.4*LN. Extent of ulcerated surface=0.4+1.2*FD. Extent of affected surface=0.7+0.9*FD+0.6*S/S. Presence and type of narrowings=0.7*WT-0.5*MH+S/S. Finally, subtotal score for each segment was found to correlate with the following regression formula; [CTE index (segment)=1.4+2.5*FD +1.2*LN+S/S] ($r=0.66$, $p < 0.0001$). Interestingly, endoscopic findings were more strongly correlated with extraenteric CTE parameters such as increased fat density and enlarged lymph nodes rather than enteric CTE parameters such as wall thickening, mucosal hyperenhancement.
CONCLUSION: This study demonstrated that CTE parameters highly correlated with endoscopic parameters in the small and large bowel lesions of CD. A novel "CTE index" validated by the endoscopic parameters should be useful in non-invasive assessment of disease activity in CD.

P874 PREDICTING MUCOSAL HEALING IN CROHN'S DISEASE USING PRACTICAL CLINICAL INDICES WITH REGARD TO THE LOCATION OF ACTIVE DISEASE

S. Bamba[1,*], T. Tsujikawa[2], H. Ban[1], H. Imaeda[1], Y. Mochizuki[3], O. Inatomi[1], M. Sasaki[4], Y. Saitoh[3], A. Andoh[5], Y. Fujiyama[1]. [1]*Division of Gastroenterology,* [2]*Department of Comprehensive Internal Medicine,* [3]*Division of Endoscopy,* [4]*Division of Clinical Nutrition,* [5]*Division of Mucosal Immunology, SHIGA UNIVERSITY OF MEDICAL SCIENCE, Otsu, Japan*

INTRODUCTION: Only a few reports have examined the relationship between balloon-assisted enteroscopy (BAE)-based mucosal lesion severity in Crohn's disease (CD) with clinical variables such as serum levels of disease activity markers and Crohn's Disease Activity Index. We analyzed whether clinical variables are useful to predict mucosal healing (MH) in various CD types.
AIMS&METHODS: A total of 173 CD patients who underwent BAE were enrolled. Endoscopic findings were assessed by Modified Rutgeerts Score (MRS). MRS was scored by the following five point scale: 0, no lesions or scar; 1, ≤ 5 aphtous lesions; 2, ≥ 5 aphtous lesions with normal mucosa between the lesions; 3, diffuse aphtous mucosal lesions including smaller ulcers (0.5-2cm); 4, diffuse inflammation with already larger ulcers (>2cm). MH was defined as MRS 0-1. MRS was scored in the most affected area. In this study, all observed intestine, small bowel and large bowel were individually scored. The ''predominantly ileum group'' included patients with MRS ileum score greater than or equal to the MRS colon score (n = 139), whereas the ''predominantly colon group'' included patients who had the ileum score greater than or equal to the MRS colon score (n = 56).
RESULTS: Spearman's rank correlation between MRS and practical clinical parameters were stronger in the predominantly colon group than in the predominantly ileum group. C-reactive protein (CRP) was the most accurate marker for predicting MH in all groups. ROC analysis revealed that the predominantly colon group had better correlativity for the prediction of MH than the predominantly ileum group. The MH index using CRP and serum albumin obtained from logistic regression analysis improved the accuracy in the prediction of MH. A decision-tree model using CRP and serum albumin levels was built; 83.6% (133/159) of all patients and 76.1% (54/71) of patients who underwent second BAE attempts were correctly classified.
CONCLUSION: In the dominant ileal CD, clinical practical parameters such as CRP and serum albumin were less affected by active mucosal lesions. Therefore we need to pay attention to the slight changes of CRP and serum albumin not to overlook active mucosal disease especially for dominant ileal CD. In this context, combination of these parameters or decision-tree model can be used as a guide to predict MH probability in the clinical settings.

P875 SERUM CHEMERIN LEVELS ARE INCREASED IN IBD PATIENTS AND ASSOCIATED WITH THE DEVELOPMENT OF OSTEOPOROSIS

S. P. Terzoudis[1,*], N. Malliaraki[2], I. Damilakis[3], I. Neratzoulakis[4], C. Georgousaki[1], V. Tzimourtos[1], E. Kouroumalis[1], I. Koutroubakis[1]. [1]*Gastrenterology, University Hospital of Heraklion,* [2]*Biochemistry, University Hospital of Heraklion Crete,* [3]*Medical Physics,* [4]*Radiology, University Hospital of Heraklion, Heraklion, Greece*

INTRODUCTION: Chemerin has been found to play an important role in inflammation by signaling autocrine/paracrine actions. Inflammatory bowel disease (IBD) is characterized by a chronic inflammatory process and a high prevalence of bone loss. Our aim was to examine the serum levels of chemerin in a Greek IBD population in comparison with healthy controls (HC) and to investigate for possible correlation between chemerin and the bone mineral density.

AIMS&METHODS: One hundred and twenty five consecutive IBD patients were included in the study [64 Crohn's disease (CD) and 61 ulcerative colitis (UC)]. All patients underwent bone densitometry by dual energy x-ray absorptiometry at the femoral neck and lumbar spine, and body mass composition with GE-Lunar Prodigy along with host software Encore. Chemerin serum levels were measured in IBD patients and in 98 matched healthy controls (HC) using commercially available enzyme-linked immunosorbent assays. The results of body mass composition include measurements of soft tissue, fat tissue, lean body mass, free fat mass, % total body mass, BMI and total body weight.
RESULTS: Mean (±standard deviation) serum chemerin levels were 14.1±6.6 ng/ml in CD patients, 13.5±3.3 ng/ml in UC patients and 7.8±2.7 ng/ml in healthy controls ($P<0.0001$). No difference between CD and UC was found. No association with disease activity and no difference between males and females were demonstrated.Subgroup analysis of correlation of chemerin levels with clinical characteristics showed significant association only with indices of osteoporosis. Chemerin serum levels were found significantly correlated with T score both at the femoral neck and lumbar spine (r= 0.25 P=0.007 and r =0.19, P=0.03 respectively). No association between chemerin levels and all examined parameters of body mass composition was found.
CONCLUSION: Serum chemerin levels are significantly elevated in IBD patients compared with HC and positive correlated with the development of osteoporosis.

INTRODUCTION: INTRODUCTION: The diagnosis of collagenous colitis (CC) relies on the histological evaluation of colonic biopsies. There is uncertainty about where and how many colonic biopsies should be obtained to make a reliable diagnosis.
AIMS&METHODS: AIMS: To determine the topographical distribution of diagnostic histopathological criteria of CC.
METHODS*:* We analyzed patients with active CC from 2 prospective multicenter trials (BUC60/COC, BUC63/COC) in whom biopsies from multiple colonic segments have been obtained during baseline colonoscopy. Collagen band thickness and chronic lamina propria inflammation were assessed for each colonic segment based on H&E and van Gieson staining.
RESULTS: RESULTS*:* 187 patients were available for analysis including 79 patients with biopsies from all 5 segments. While chronic lymphoplasmocytic (LP) inflammation was evenly distributed throughout the colon, the mean collagenous band thickness in the rectum (15,8 mm) and sigmoid (18,9 mm) was significantly lower compared to descending (21 mm), $p<0.0001$, $p=0.018$) and ascending colon (20,9 mm, $p<0.0001$, $p=0.043$). Thus, the diagnostic criteria of a collagenous band >10 mm was significantly more common in the ascending (89,9%) compared to the sigmoid (75.9%, $p=0.043$) and the rectum (55.7%, $p<0.0001$). Biopsies taken from the ascending, transverse and descending colon resulted in a diagnostic yield for a collagenous band >10 mm of 96.2%.
CONCLUSION: CONCLUSION: To establish the diagnosis CC it is advisable to perform a complete colonoscopy as the thickened collagenous layer is mainly found in the right colon. In this disease a chronic inflammation in the lamina propria seems to be present in the whole colon which should prompt the pathologist to look for the characteristic findings of CC

P877 IS FECAL CALPROTECTIN USEFUL IN THE FOLLOW-UP OF CROHN'S DISEASE PATIENTS WITH ANTI-TNF THERAPY ?

O. Fratila[1], C. Banciu[2], T. I. Ilias[1,*]. [1]*1st Medical Clinic, University of Oradea, Oradea,* [2]*"Victor Babes" University, Timisoara, Romania*

INTRODUCTION: The assessment of Crohn's disease (CD) activity is amenable to endoscopic examination and subsequent histological analysis, but these methods are time-consuming, expensive and invasive. So, if quantifying low calprotectin levels after treatment indicates response of disease activity, this non-invasive marker can become routinely used in optimizing treatment and compliance.
AIMS&METHODS: Aim: to evaluate the role of fecal calprotectin in monitoring the anti TNF-alpha treatment in patients with CD. **Methods:** We prospectively included 25 patients (44±3 years) with moderate to severe ileocolonic CD (CDAI 250-450), who were about to receive either Infliximab i.v. (13 patients) or Adalimumab s.c. (12 patients). Stool samples were collected and calprotectin was measured before starting the treatment and after the induction period (lateral flux immunchromatography technique). In addition, clinical activity was measured using CDAI index before and after induction treatment. For mucosal healing assessment, colonoscopy was performed before and after 6 months of anti-TNF treatment and CDEIS (Crohn's Disease Severity Index) index was assessed. Statistics was done using the U-Mann-Witney test from SPSS.
RESULTS: Clinical response (expressed by CDAI drop) at 6 months was obtained in 19 out of 25 patients (76%) - 8 with Infliximab and 11 with Adalimumab. Calprotectin value was $>300\mu g/g$ before starting the treatment in all patients and after the induction period between 50-200μg/g in 19 patients. Of the 25 patients, 18 (72%) showed an endoscopic response to treatment and 9 of these achieved endoscopic remission (CDEIS<3) and calprotectin concentration below 50μg/g. Patients with clinical and endoscopic response had significantly lower calprotectin levels than the others ($p< 0.05$).
CONCLUSION: Fecal calprotectin has great potential to become widely use as a simple, non-invasive, cheap marker of response to treatment in patients with clearly established diagnosis of Crohn's disease. Further studies with increased number of patients should confirm its role in monitoring the response and the mucosal healing during anti-TNF therapy.

P878 SUPERFICIAL SMALL BOWEL CROHN'S DISEASE - AN EMERGING NEW NOSOLOGIC ENTITY?

U. I. Aujla[1,*], F. Fasci Spurio[1], B. Hayee[1], I. Bjarnason[1]. [1]*Gastroenterology, Kings College Hospital, London, United Kingdom*

INTRODUCTION: The diagnosis of small bowel Crohn's disease has been facilitated by imaging modalities, particularly CT and MRI enterocolysis. However, capsule endoscopy (CE) may be more sensitive for detecting superficial erosions not obvious on CT or MRI enterocolysis. We use faecal calprotectin as a gatekeeper for invasive investigations for patients referred to the outpatient department, with elevated values suggesting intestinal inflammation and leading to further investigations. We describe patients with a long established diagnosis of IBS that have consequentially been diagnosed with a superficial small bowel Crohn's disease by CE.
AIMS&METHODS: We retrospectively analysed all patients who had undergone CE over between 2007 and 2011 (1903 studies). Patients with abnormal studies were then looked up on the integrated hospital electronic database for clinical details, faecal calprotectin, radiology, endoscopy and pathology results.
RESULTS: Most patients reviewed had a clear precipitant or pre-existing diagnosis (e.g. normal, IBD, NSAID-use, radiation enteropathy, etc.). However, there were 15 patients, 8 (53%) male and 7 (47%) female, median ages 47 years and 40 years, respectively) with a firm clinical diagnosis of (mostly) diarrhoea -predominant IBS for an average of 4 years, range 6 months to 10 years, who (apart from one) had raised faecal calprotectin (median 247 g/L, range 10-1384 (normal range < 50). In all cases, superficial aphthous ulceration was detected at CE, predominantly in the terminal ileum. All had normal colonoscopic and large-bowel histological findings. CT or MRI enterocolysis showed no evidence of mural wall thickness, fistulae or stricturing disease. None had an alternative explanation for the aphthous ulceration. All were treated by conventional means as Crohn's disease (variably steroids, 5-aminosalicylic acid, Azathioprine) with improvement in inflammatory activity (reduction or normalization of calprotectin). Four patients required biologics (anti-TNF agents). No patients have developed small bowel strictures to date.
CONCLUSION: The combined use of faecal calprotectin and capsule endoscopy has identified a superficial form of small bowel disease characterized by aphthae and inflammation that responds to conventional Crohn's disease treatment. The disease severity is not trivial, as 4 (25%) required biologics for symptomatic control. These findings represent either 'early' small bowel Crohn's disease or a hitherto unrecognized form of the disease that does not progress to stricturing disease.

P879 INFLIXIMAB (IFX) DOES NOT INCREASE THE RISK OF CYTOMEGALOVIRUS (CMV) INFECTION AND CMV IS NOT ASSOCIATED TO RESISTANCE TO IFX THERAPY

S. Pillet[1], E. Del Tedesco[1], M. courault[1], E. presles[1], A. moreau[1], B. Pozzetto[1], X. Roblin[1,*]. [1]*UNIVERSITY, Saint etienne, France*

INTRODUCTION: Cytomegalovirus (CMV) infection has also been implicated in resistance to successive lines of immunosuppressive therapies in ulcerative colitis (UC) (1). In contrast to corticoid and anti-calcineurin therapies, the use of anti-TNF antibodies (infliximab, IFX) seems to have a limited impact on CMV infection but limited data are currently available (2).

AIMS&METHODS: The aims of our work were to evaluate (i) if the use of IFX was associated to an increased risk of CMV infection, (ii) if CMV infection is associated to failure of IFX, and (iii) if the intestinal CMV DNA load is increased when using IFX for treatment of UC acute flare. A first prospective cohort included 53 patients exhibiting UC with a Mayo endoscopic score of at least 2. When an acute flare was diagnosed, 2 biopsies of the inflamed mucosa were analysed for CMV DNA load by real-time PCR. A second retrospective cohort included 20 patients exhibiting a positive DNA load in inflamed mucosa and receiving IFX; after 8 to 12 weeks of IFX, the CMV DNA load was measured.
RESULTS: The 53 patients (mean of age: 49.4 years; sex ratio M/F: 0.7; 28 cases of E3) included prospectively exhibited a total of 82 acute flares. A total of 26 CMV infection of the inflamed mucosa was observed: it was observed in 12 cases (26.7%) when flare occurred under IFX therapy whereas in 14 cases (37.8%) of flare without IFX (not statistically significant). The median of CMV DNA load was higher in flares without IFX compared to those under IFX (P=0.06). Among the 12 flares that occurred under IFX, all patients xere optimised with the same dose (10mg/kg). After optimisation at 8W, 6(30%) recovered with IFX and 6 (23.1%) failed to IFX treatment (not statistically significant). Of note, the median of CMV DNA load tends to be higher in case of failure to IFX (P=0.13). For the 20 patients (10 patients naïve for IFX therapy), the follow-up of the intestinal CMV infection after 8 to 12 weeks of IFX showed that the CMV DNA load was undetectable in 4 cases, still positive but decreased in 2, stable for 12 patients, and increased only in 3 patients. No relation was observed between the CMV DNA load and the dose of IFX.
CONCLUSION: The use of IFX was not associated to an increased risk of CMV infection and CMV infection did not increase the risk of IFX failure after optimisation. The mean of CMV DNA load did not increase when using IFX for treatment of the UC acute flare; moreover, the viral DNA load is lower when using IFX. IFX therapy should be recommended for the treatment of UC acute flare when associated to a CMV infection.

P880 THE PLATELET-CRIT IS A VALUABLE BIOMARKERS FOR ACTIVE CROHN'S DISEASE

J. Tang[1], X. Gao[1,*], M. Zhi[1], M. Zhang[1], H. Chen[1], C. Ji[1], P. Hu[1]. [1]*Department of gastroenterology, The sixth affiliated hospital of Sun yat-sen university, Guangzhou, China*

INTRODUCTION: Platelet indices is a set of parameters of the standard full blood count tests, measuring the size variability of thrombocytes. We investigated whether platelet indices are biomarkers of active disease in patients with CD.
AIMS&METHODS: We performed a retrospective study, in order to examine if platelet indices variation could be biomarkers of active CD. In total, 89 patients with Crohn's disease (CD) were enrolled in the study group, and 20 age- and-sex-matched healthy volunteers were included as the control group. A CD activity index >150 in patients with CD indicated active disease. In addition to platelet indices including platelet counts(PLT), mean platelet volume (MPV), platelet distribution width (PDW), platelet large cell ratio (P-LCR) and platelet-crit (PCT), high sensitive serum C-reactive protein levels(hsCRP), erythrocyte sedimentation rates(ESR) and red cell distribution width (RDW) were measured.
RESULTS: The PLT, PCT and PDW level were significantly higher in patients with active CD than in normal controls and in remission patients. ($p<0.001$). PLT(r: 0.261 $p<0.001$),PDW (r: -0.232 p: 0.002) and PCT (r: 0.268 $p<0.001$) had a significant correlation with CD disease activity. A ROC curve analysis indicated that for a PCT cut-off of 0.285, the sensitivity for detecting active CD was 67%, and the specicity was 63% (area under curve [AUC], 0.672; $p<0.001$). PCT was the third sensitive and specific marker for active CD only weaker than hsCRP and ESR. In those patients which hsCRP were lower than 10mg/l, PCT turned to be the most sensitive and specific marker for active CD. In those patients, a ROC curve analysis indicated that for a PCT cut-off of 0.285, the sensitivity for detecting active CD was 71%, and the specicity was 85% (area under curve [AUC], 0.763; $p<0.001$).
CONCLUSION: PLT, PDW and PCT were elevated in active CD in comparison with healthy controls and remission patients. Our pilot study demonstrated that PCT may be a sensitive and specific biomarker for determining active CD, especially in those patients which hsCRP are lower than 10mg/l.

P881 TNF- ALPHA EXPRESSION PREDICTS RESPONE TO INFLIXIMAB

A. Ben Yehuda[1,*], L. Baram[2], Y. Ron[2], L. Werner[2], I. Dotan[2]. [1]*surgery division ,* [2]*IBD Center, Department of Gastroenterology and Liver Diseases and the Research Center for Digestive Diseases, TASMC, tel aviv, Israel*

INTRODUCTION: Crohn's disease (CD) is characterized by aberrant mucosal immune response and over expression of T-helper 1 cytokines such as tumor necrosis factor-alpha (TNF-alpha). Antibodies targeting TNF-alpha are the most efficient therapy. However, primary non response, and loss of response are common.
AIMS&METHODS: We hypothesized that pretreatment TNF- alpha expression may predict response to anti- TNF-alpha therapy in CD patients.
CD patients treated with infliximab were prospectively recruited. Response was defined either by post-treatment Crohn's Disease Activity Index (CDAI) lower than150 or 70 points reduction, or a senior gastroenterologist evaluation in the face of pretreatment CDAI < 150. Serum TNF-alpha was assessed using ELISA. TNF-alpha expression was analyzed using immunohistochemistry and the area of lamina propria positive for TNF-alpha was semi-quantified by computerized software.
RESULTS: Out of 69 recruited CD patients with serum or tissue samples, 41patients were responders (59.5%). No difference in age, gender, infliximab level or pretreatment CRP level was documented between groups .Twenty seven patients had pretreatment biopsies and 51-serum samples. Nineteen out of twenty seven (70.5%) infliximab loading patients were primary responders. Lamina propria TNF-alpha expression among responders was significantly higher compared to non responders: 15.4% vs.5.7%, P=0.012. TNF-alpha positive area>12% had a PPV of 100% and NPV of 58%. A correlation (R sq linear=0.74) between lamina propria TNF-alpha expression and treatment efficacy as evaluated by CDAI score reduction was found. Non significant higher serum TNF-alpha levels were detected among nonresponders: 65.2vs. 41.5 pg/ml, p=0.47.
CONCLUSION: High TNF-alpha expression in the lamina propria of CD patients predicts response to treatment with Infliximab. This may be used to improved stratification of CD patients into infliximab responders.

P882 USE OF ANTI-TNF TROUGH LEVELS IN CLINICAL PRACTICE

R. K. Roopram[1], J. P. Maljaars[1], N. Ipenburg[1], M. H. Verwey[1], J. C. Hardwick[1], R. A. Veenendaal[1], A. E. van der Meulen - de Jong[1,*]. [1]*Gastroenterology, Leiden University Medical Center, Leiden, Netherlands*

INTRODUCTION: Anti-TNF trough levels are frequently assessed in clinical trials. Although the value of drug levels are limited in clinical practice because a lot of questions are still unresolved (e.g. optimal trough level, consequences), in general gastroenterologist determine these values to evaluate clinical situations (e.g. control of adherence, side effects, loss of response).
AIMS&METHODS: To limit costs and work load, we wanted to construct a local protocol in order to decrease the current variability in indications for ordering drug levels and to clarify the clinical consequences of the test results to local IBD doctors and nurses. All IBD patients at our hospital (tertiary referral center) who received either adalimumab or infliximab in the year 2011 and / or 2012 (n=353) were retrospectively evaluated with respect to trough levels during the period 2010 – March 2013. We identified 4 reasons for ordering trough levels: (1) complaints / loss of response; (2) to titrate the dosis actively; (3) for clinical interest; and (4) to control trough level after a medication change. Medication change is defined as change in dosis of immunomodulator and / or anti-TNF. Our trough levels are performed by sanguine (Amsterdam) in mg/L.
RESULTS: A total of 342 trough levels were ordered in 228 patients. In Table 1 the indication of the trough level and the results are shown. In the control group, in 27 cases the first trough level was < 3 and after medication change the trough level was > 3 in 12 cases. In just 2 cases with undetectable trough levels (n=7) at the first measurement, these were still undetectable after medication switch. Changes to medication were made in 72 cases (41.4%) of the complaints group, in 20 cases (51.3%) of the titration group, and in 34 (37.8%) cases of the clinical interest group. Overall, in 49 cases the dose of anti-TNF was increased, in 46 cases the dosis was decreased and in 25 cases the current anti-TNFdrug was stopped.
Table 1

	Reason of ordering trough level				
Trough level (mg/L)	Complaints	Titration	Clinical interest	Control	Total
< 0.002	10	4	4	2	20
0.002 – 3	34	3	12	13	62
3-7	45	13	27	13	98
>7	85	19	47	11	162
Total	174	39	90	39	342

CONCLUSION: Each individual doctor and nurse practitioner at our center has gained clinical experience with anti-TNF trough levels. When the exact clinical implications of trough levels are known, the values can help to give optimal individual treatment and will reduce costs. Till then we suggest to assess trough levels at least (1) when stopping an anti-TNFdrug, for any reason, to evaluate the possibility of future re-introduction, (2) before stopping an anti-TNF drug in case of loss of response to exclude low drug levels as the reason for failure.

P883 MUCOSAL TNF-ALPHA PROTEIN LEVELS AND OTHER PRO-INFLAMMATORY CYTOKINES ARE SUPPRESSED AFTER CLINICALLY EFFECTIVE ADALIMUMAB TREATMENT IN CHRONIC, ACTIVE COLLAGENOUS COLITIS

A. Münch[1,*], A. K. Kumawat[2], H. Strid[2], E. Hultgren Hörnquist[2], M. Ström[1]. [1]*Gastroenterology, University hospital, Linköping,* [2]*School of Health and Medical Sciences, Örebro, Sweden*

INTRODUCTION: Collagenous colitis is a common diarrhoeal disorder of inflammatory origin that in rare cases can present with a chronic, active course despite prior treatment with high dose budesonide and methotrexate. We describe 3 consecutive patients who were given adalimumab (ADA) as a third line therapy and where colonic biopsies were investigated for mucosal cytokine protein levels before and after ADA treatment.
AIMS&METHODS: Three patients (2 women, mean age 45 years and 1 man, 74 years old) were included. ADA was given in doses 160 mg s.c. (baseline), 80 mg (week 2) and 40mg (week 4). The patients were followed clinically and histopathologically and biopsies were taken at baseline and after 6 weeks. Protein levels of IFN-γ, IL-1b, -2, -4, -5, -6, -10, -12p70, -13, -17A, -21, -23 and TNF-α in colonic biopsies were analysed with Luminex. Results are given in pg/mg tissue.
RESULTS: The two women tolerated the treatment well and achieved clinical remission at week 6 with a decrease of mean stool frequency/day from 11 to 2. The mean stool weight/24 hours changed from 600g to185g and the QoL improved drastically. There were no changes in histology. The man developed, despite clinical response, side effects (vomiting, abdominal pain) after 80 mg adalimumab and the treatment was stopped as side effects reoccurred after rechallange. In the two female patients the mucosal TNF-α protein levels were suppressed from mean 1.3 pg/mg to undetectable levels after treatment. Furthermore, the pro-inflammatory cytokines IFN-γ, IL-1b, IL-6, IL-12p70 and IL-17A were suppressed from 1.4, 0.9, 1.4, 1.5, 0.6 pg/mg to undetectable levels whereas IL-23 decreased from 16.4 to 8.8 pg/mg. The levels of the anti-inflammatory cytokines were more or less unchanged in IL-13 (3.6 vs 3.4); and decreased in IL-4 (2.7 vs 2.3); IL-10 (0.6 vs undetectable).
IL-2 declined from 7.3 pg/mg to undetectable levels after treatment in one patient, whereas IL-21 levels were slightly increased, from 4.1 to 4.9 pg/mg.
IL-5 was not found in any of the biopsies.
CONCLUSION: Adalimumab seems to be effective and improves Quality of Life in patients with chronic, active collagenous colitis. ADA treatment leads to suppression of TNF-α and other pro-inflammatory cytokines to undetectable protein levels in colonic biopsies.

P884 EFFICACY AND SAFETY OF ADALIMUMAB IN MODERATE TO SEVERE PAEDIATRIC CROHN'S DISEASE: SINGLE TERTIARY CENTRE OUTCOME

A. Angelakopoulou[1,*], D. Curwen[1], K. Lindley[1], N. Shah[1], M. Elawad[1], F. Kiparissi[1]. [1]*GREAT ORMOND STREET HOSPITAL NHS FOUNDATION TRUST, LONDON, United Kingdom*

INTRODUCTION: The role of Adalimumab in the treatment of paediatric Crohn's disease (CD) is increasingly recognised. The aim of our study was to evaluate the efficacy and safety of Adalimumab in children with Crohn's disease who failed conventional treatment.
AIMS&METHODS: All patients with CD receiving Adalimumab between September 2006 and January 2013 were identified retrospectively. All patients had either failed to respond to Infliximab, lost response or had allergic reaction before commencing Adalimumab. Clinical response and long term outcomes were assessed.
RESULTS: Twenty-one patients (10 females) with median age 12.7 years (8.8y-16.6y) at the time of first Adalimumab injection were included. Seventeen patients (17/21, 81%) showed sustained clinical response to Adalimumab with symptomatic improvement and increased time between relapse (if at all) over a mean period of 2 years 6 months. Ten patients (10/12, 83%) responded to combined therapy of Adalimumab and Methotrexate, compared to four patients (4/4, 100%) responding to Adalimumab and Azathioprine. For the remaining four patients where treatment failed to work over a mean of 11 months, medical treatment was escalated with other immunosuppressive agents, but disease progression remained. Links were also found indicating that those with a higher atopic activity (IgE) and lower inflammatory status (ESR) tended to respond better to the drug. Lastly, there was no major difference in age between groups, with 12.4 years for the responders compared to a mean of 11.7 years for the non-responders. Methotrexate and Azathioprine were the most successful adjuvants, when combined with Adalimumab. No adverse reactions were recorded with the use of Adalimumab during the study period.
CONCLUSION: Adalimumab was efficacious in 81% of children and adolescents with moderate to severe CD unresponsive to Infliximab and should therefore be considered as a treatment option. Adalimumab was additionally found to be safe as no adverse reactions recorded. Results linked to IgE and ESR warrant further studies.

P885 PREDICTOR OF EFFECT OF ORAL TACROLIMUS ON REFRACTORY ULCERATIVE COLITIS

A. Ito[1,*], T. ohmori[1], B. iizuka[1], K. shiratori[1]. [1]*Departoment of Medicine, Institute of Gastroenterology, Tokyo Women's Medical Unvercity, Tokyo, Japan*

INTRODUCTION: Patients who received tacrolimus (TAC) administration for refractory ulcerative colitis (UC) at our hospital were divided into those who did and did not achieve clinical remission (clinical remission and non-remission groups, respectively), and a predictor of the effect of TAC was investigated.
AIMS&METHODS: Twenty-nine patients treated with TAC between February 2010 and March 2013 were divided into the clinical remission group consisting of 24 patients (12 males and females) and non-remission group consisting of 5 patients (5 males). TAC was administered in a fasting state or before meals at a single dose of 0.025-0.075 mg/kg, twice daily, as a rule. The target blood level was set at a trough level of 10-15 ng/ml after 2 weeks of administration, and the trough level after 2 weeks was adjusted to 5-10 ng/ml. The clinical activity was evaluated using the Lichtiger score (CAI) before the initiation of TAC administration and at the time when the blood TAC level reached the target level. The CAI score before TAC administration was 10 or higher in all patients. Clinical remission was defined as a condition with a CAI score of 4 or lower after 4 weeks of TAC administration.
RESULTS: The endoscopic findings before the introduction of TAC were evaluated using the UCAI and EAI, and the clinical background was investigated with regard to the gender, age, affected area, duration of illness, total dose of PSL administered 4 and 2 weeks before introduction of TAC, CRP and Hb on admission, CAI before TAC administration, and time required for the blood TAC level to reach the target level, but no significant difference was noted in any item. However, a significant difference was noted in the CAI score at the time when the blood TAC level reached the target level between the clinical remission (7.0 ± 2.5) and non-remission (12.6 ± 2.3) groups ($p<0.005$). When the interval estimation of the mean CAI score was compared between those on admission and at the time of reaching the target TAC level, the reduction rate was 40.1-54.5% in the clinical remission group and 72.1-103.5% in the non-remission group.
CONCLUSION: The rate of reduction of the CAI score from that before TAC administration to that at the time of reaching the target blood TAC level may be an important predictor of the effect.

P886 SMALL BOWEL ILEITIS AS DETECTED BY CAPSULE ENDOSCOPY AS A PREDICTOR OF RESPONSE TO IMMUNOMODULATOR THERAPY - A 3 MONTH MUCOSAL HEALING ASSESSMENT

B. Hall[1,*], G. Holleran[1], R. Leen[1], T. Raftery[1], D. McNamara[1]. [1]*Department of Clinical Medicine and Gastroenterology, Adelaide and Meath Hospital, Dublin, Ireland*

INTRODUCTION: Mucosal healing and deep remission confer improved long-term outcomes in Crohn's disease(CD) as opposed to clinical indices alone. While immunomodulator therapies have demonstrated improved symptomatic response in CD and their early use and mucosal healing may allow for modification of the natural history of CD, little is currently known of this with regard to Ileitis, which is increasingly diagnosed using Wireless Capsule Endoscopy(WCE).
AIMS&METHODS: To assess clinical, biochemical and ileal mucosal response to therapy in a cohort with established CD at baseline and 12 weeks using WCE. Following informed consent and successful patency exam, symptomatic patients commencing on immunomodulator therapy for CD were invited to participate. Baseline demographics, Harvey Brashaw Index (HBI), Work Productivity and Activity Index(WPAI) and EuroQol(EQ-5D) questionnaires, along with C-reactive protein(CRP) and calprotectin samples were collected at WCE (Given SB2). Calprotectin levels were assessed with a commercially available ELISA kit (MedLab Pathology). A Lewis score (LS) was used to assess severity of ileitis. At week 12 of treatment all parameters were reassessed. Mucosal healing was defined as absence of visible small bowel ulceration. Results at baseline & week 12 were compared using two-tailed Wilcoxon analysis, a p value of <0.05 was considered significant.
RESULTS: To date, 30 patients have been enrolled, 17(56%) female, mean age 38 (range 19-63). Overall, 16(53%) have undergone 12 week assessment, 12 were commenced on adalimumab, 3 on azathioprine and 1 remains on steroids only. Baseline and 12 week values are expressed as a mean in Table 1. Overall there was a statistically significant reduction in all clinical and biochemical parameters at week 12. In all, 13 (81%) had a decrease in LS with 2 $<$135. No patient achieved mucosal healing or deep remission by week 12.
Table 1 Baseline values and 12 week response to treatment values (n=30)

Parameter (normal values) p value	Baseline Values [mean (range)]	12 Week Values [mean (range)]
HBI (<5) $p<0.05$	7 (0-15)	4 (0-14)
WPAI (0-10) $p<0.05$	3 (0-8)	2 (0-7)
EQ-5D (0-100) $p<0.05$	60 (40-100)	70 (40-100)
Calprotectin($<50\mu g/g$) $p<0.03$	195 (30-1600)	65 (0-700)
Lewis score (<135)	552 (225-5050)	318 (0-3000)
CRP (<5mg/dl) $p<0.03$	5 (1-160)	2 (1-17)

CONCLUSION: Symptomatic and biochemical response in our CD ileitis cohort has not been mirrored by mucosal healing at this early stage. This may be due to a lag in mucosal healing that will eventually "catch up" with symptomatic response. Repeat mucosal healing assessment at one year from treatment baseline is warranted to further assess for deep remission rates.

INTRODUCTION: Long-term corticosteroid use in ulcerative colitis (UC) and Crohn's disease (CD) leads to adverse effects/dependence. Vedolizumab (VDZ), an anti–$\alpha_4\beta_7$ integrin antibody, has been studied in UC and CD patients (pts) on corticosteroids.

AIMS&METHODS: Two phase 3 UC/CD studies involved induction (wks 0-6) and maintenance (wks 6-52), during which pts received placebo (PB) or VDZ 300 mg intravenously every 8 or 4 wks (Q8W/Q4W). Pts on corticosteroids at wk 0 with a clinical response began corticosteroid tapering at wk 6. Wk 52 corticosteroid-free remission rates (prespecified) and wk 6 associations with wk 52 corticosteroid-free remission (post hoc) were assessed.

RESULTS: In UC, VDZ led to greater wk 52 corticosteroid-free remission rates and decreased corticosteroid use for up to 180 d than did PB. Of pts in wk 6 remission, more in the VDZ Q4W group than the PB group had corticosteroid-free wk 52 remission. In pts with wk 6 mucosal healing, wk 52 corticosteroid-free remission rates were higher with VDZ than PB. In CD, VDZ also led to greater wk 52 corticosteroid-free remission rates (Q8W, Q4W) and decreased corticosteroid use for up to 180 d (Q8W) than did PB. In pts in wk 6 clinical remission, no significant differences from PB in VDZ wk 52 corticosteroid-free remission rates were seen.

	UC			CD		
	VDZ			VDZ

INTRODUCTION: The success of medical treatment for entero-urinary fistulas (EUFs) in CD has so far been modest and surgery is the standard treatment. The advent of anti-TNF therapy has provided a powerful new potential treatment option. The aim of this study was to evaluate the effectiveness and predictors of response of anti-TNF therapy for inducing remission of EUF in CD patients and avoiding the need for surgery.

AIMS&METHODS: In this multicentre observational study a retrospective search was performed for CD patients with EUF treated with any anti-TNF. We defined remission as the absence of clinical symptoms with a radiological confirmation of EUF closure. Multivariate Cox regression analysis was performed to determine factors predictive of achieving remission without need for surgery.

RESULTS: Thirty-three patients received anti-TNF therapy (21 infliximab, 9 adalimumab and 3 both) and were included in the study. Twenty-five (75%) patients were male. Mean (SD) age at diagnosis of EUF was 33 (13) years and median disease duration was 31 months (IQR 12-97). Seventeen patients (51%) were treated concomitantly with an immunomodulator (IMM). Fifteen patients (45%) achieved sustained remission (median follow-up from remission 34 months, IQR 18-44) without needing surgery (10 with infliximab and 4 with adalimumab) and 14 of these continued on anti-TNF therapy. A further 15 (45%) patients achieved sustained remission after surgery (median follow-up 59 months; IQR 26-74). Three patients were in partial response at the last follow-up visit and continued on anti-TNF therapy. In the Cox analysis (adjusted for age, gender, fecaluria and/or pneumaturia, concomitant IMM or antibiotics and type of anti-TNF), only patients with concomitant IMM showed a tendency towards an increased rate of remission without need for surgery (HR 0.42, 95% CI 0.16-1.12; $p<0.08$).

CONCLUSION: Anti-TNF therapy was effective for EUFs in CD, with 45% of patients achieving sustained remission without need for surgery. There was a trend in favour of the concomitant use of IMM.

P889 NEED FOR INFLIXIMAB DOSE INTENSIFICATION IN PATIENTS WITH CROHN'S DISEASE AND ULCERATIVE COLITIS AND ASSOCIATED COSTS

C. Taxonera[1,2,*], D. Olivares[1,2], J. L. Mendoza[1,2], M. Cañas[1,2], M. Diaz-Rubio[1,2], E. Rey[1,2]. [1]*H Clinico San Carlos,* [2]*IdISSC, Madrid, Spain*

INTRODUCTION: In Crohn's disease (CD) patients the annual risk for loss of infliximab (IFX) response and needing for IFX dose intensification is around 15% per patient/year. The requirement for IFX dose intensification in ulcerative colitis (UC) is not well known. The need for dose intensification is one of the main drivers of the increased direct drug costs.
AIMS&METHODS: The aim of the study was to compare the costs of IFX in two cohorts of patients (CD or UC). We also estimated the impact of the requirements for dose intensification on costs. All consecutive CD and UC patients who received IFX were enrolled in the study. We compared the differences in the rates of patients requiring dose intensification per month with IFX treatment in both cohorts. We also compared the interval between first IFX induction dose and the first escalated IFX dose. The primary endpoint was the pharmacological costs derived from the IFX administration (patient per kg/year) (IFX, pre-medication, and day hospital costs) in patients of each cohort who were in treatment for at least 1 year.
RESULTS: Seventy-nine patients were in treatment for at least 1 year (51 CD and 28 UC). The rate per month of patients who needed intensification was 1.5% vs 3.6% (p=0.008) respectively. In patients who underwent IFX optimization, median time between the first IFX induction dose and the first escalated IFX dose was 10 months vs 6 months (p=0.021) for CD patients and UC patients, respectively. In the survival analysis, the cumulative probability of avoiding IFX dose intensification was significantly higher in CD patients (p=0.006). In the multivariate analysis, disease (UC vs CD) was the only factor significantly associated with dose intensification. The costs per patient per kg were significantly higher in UC patients than in EC ($p < 0.001$). In the multivariate analysis, only the need for IFX dose intensification was associated with increased cost (p=0.008).
CONCLUSION: Direct (one-year) cost of IFX is significantly higher in patients with UC compared with CD patients. The increased costs of IFX in the UC cohort was driven by the higher rate per month of UC patients who needed IFX dose intensification. Our data provide a rational basis for economic planning in patients with UC selected for IFX therapy.

P890 OPTIMISING OF ANTI TUMOR NECROSIS FACTOR ALPHA STRATEGY IN IBD PATIENTS: WHO NEED AND WHO BENEFIT?

C. Melchior[1,2,*], L. Armengol-Debeir[1], C. charpentier[1], L. Thomassin[1], E. Lerebours[1,2], G. Savoye[1,2]. [1]*Gastroenterology, Rouen University Hospital,* [2]*INSERM U1073, Rouen University , ROUEN, France*

INTRODUCTION: From 25 to 40% of IBD patients who initially benefit from anti-TNFα will develop intolerance, adverse events or lose of response while on maintenance treatment. Optimisation of anti-TNFα based therapies may help to overcome theses loses of response. Strategies available to optimise an anti-TNFα before switch to another agent include shortening the dosing interval, increasing dose, re-induction or introduction of an immunosuppressive drug. The aim of our study was to identify patients who need optimisation and those who will benefit from it.
AIMS&METHODS: This retrospective study was performed in a single tertiary care centre. All IBD patients who received anti-TNFα treatment from September 2009 to September 2011 were analysed. Demographics, IBD type and characteristics according to Montreal classification as well as treatments received, modalities of treatment optimisation and theirs results were collected. Optimisation failure was defined as a need for surgery, switch to other anti-TNFα, ciclosporin or experimental drugs. Characteristics of patients requiring and benefiting from optimisation were compared to patients succeeding on standard anti-TNFα dosage using univariate analysis.
RESULTS: 300 patients of mean age 37± 11 years with 56% of female were included. IBD type was Crohn's disease (CD) in 70.7%, ulcerative colitis (UC) in 26%. CD was of ileo-colic location in 62%, of non-inflammatory phenotype in 13% and with perianal disease in 44%. In UC patients 54% had pancolitis. Extra digestive manifestations were present in one third. In 74% of the cases the first anti-TNFα treatment was infliximab and combination therapy was used in 70% mainly with azathioprin.
Optimisation was required in 104 patients (40%). Strategies used were shortening dosing interval (n=59, 57 %), increasing dose (n= 13, 12 %), combination of both (n= 19, 18%), introduction of an immunosuppressive drug (n=3, 3 %). Optimisation's requirement was more frequent in female (p=0.02) and in CD (p=0.04). Among patients who were optimised, 76 (73.1%) of them had benefit. Optimisation's success was associated with female ($p < 0.0001$), absence of perianal disease (p=0.047) and tended to be more frequently achieved with infliximab (p=0.055).
CONCLUSION: Optimisation of anti-TNF treatment is required in 40% of IBD patients while on maintenance therapy. These strategies avoided unfavourable outcome and anti-TNF failure in 74% of cases. Female and CD patients were more likely to require optimisation while female and absence of perianal disease were associated with optimisation success.

P891 EFFICACY OF INFLIXIMAB IN PAEDIATRIC ULCERATIVE COLITIS: SINGLE TERTIARY CENTRE EXPERIENCE

E. Volonaki[1,*], K. Lindley[1], N. Shah[1], F. Kiparissi[1], M. Elawad[1]. [1]*GREAT ORMOND STREET HOSPITAL NHS FOUNDATION TRUST, LONDON, United Kingdom*

INTRODUCTION: The role of Infliximab in the treatment of paediatric ulcerative colitis (UC) is increasingly recognised. The aim of our study was to evaluate the efficacy of Infliximab in children with ulcerative colitis who failed conventional treatment.
AIMS&METHODS: All children with UC who received Infliximab between April 2006 and October 2012 in our centre were identified. Clinical response and long term outcomes were assessed.
RESULTS: Twenty eight (28) patients with moderate/ severe UC were included in the study (17 males). Median age at histological diagnosis was 11.6 years (range 2.6y-15.2y), with median duration of disease prior to first Infliximab infusion 1.6y (5 weeks-5.5y) and median follow up post Infliximab regardless of outcome 1.6y (0.5y- 5.4y). Fifteen patients (15/28, 53.5%) responded initially to the treatment. Nine patients (9/15, 60%) had sustained clinical response at 5mg/kg 8 weekly with histological evidence of mucosal healing, with median duration of treatment 1.6y (0.7y-5.4y). In six patients (6/15) Infliximab had to be discontinued due to either loss of initial response or allergic reaction. Out of 13 patients with partial or no response to Infliximab (13/28, 46.4%), 6 failed escalation of medical treatment with other immunosuppressive agents , including Adalimumab and Sirolimus, and underwent colectomy 1 month-11 months later (median 0.6y), at median age 13.7y (8.9y-15y).
CONCLUSION: Infliximab was efficacious in 53.5% of children with ulcerative colitis who failed conventional treatment, with response maintained in 60% of those patients. Therefore, Infliximab should be considered not only as rescue treatment, but also as maintenance treatment in children with refractory disease.

P892 EFFICACY OF ADALIMUMAB IN CHILDREN AND ADOLESCENTS WITH MODERATE TO SEVERE ULCERATIVE COLITIS

E. Volonaki[1,*], N. Shah[1], K. Lindley[1], F. Kiparissi[1], M. Elawad[1]. [1]*GREAT ORMOND STREET HOSPITAL NHS FOUNDATION TRUST, LONDON, United Kingdom*

INTRODUCTION: Adalimumab is licensed for treating moderately to severely active ulcerative colitis (UC) in adults whose condition has responded inadequately to conventional therapy, but data on its role in paediatric UC are lacking. The aim of our study was to evaluate the efficacy of Adalimumab used as indicated above in children and adolescents treated in a single tertiary UK centre.
AIMS&METHODS: All patients with UC who received Adalimumab between April 2008 and October 2012 in our hospital were identified. Clinical response and long term outcomes were assessed.
RESULTS: Ten patients (7 females) with median age 14 years (6.8y-16.6y) at the time of first Adalimumab injection were included in our study, with median follow up 1.9 years (1y-3y). All patients had failed Infliximab after 6.5 months median duration of treatment (2–24 months). Three patients (3/10, 30%) showed sustained clinical response to Adalimumab with histological evidence of mucosal healing (follow up 16, 22 and 24months respectively). All three received concurrent treatment with Azathioprine or Methotrexate and one of them was successfully weaned off Adalimumab after 21 months, without relapse to date. For the remaining 7 patients, medical treatment was escalated with other immunosuppressive agents, with 4 of them ending up with colectomy (4/10, 40%).
CONCLUSION: Adalimumab was efficacious in 30% of children and adolescents with moderate/ severe ulcerative colitis who failed Infliximab and should therefore be considered as treatment option in refractory disease in this age group.

P893 ORAL BECLOMETHASONE DIPROPIONATE VERSUS 5-AMINOSALYCILIC ACID ENEMA IN ACTIVE ULCERATIVE COLITIS PATIENTS: LOWER EFFICACY BUT BETTER COMPLIANCE

R. Pica[1], H. Unim[1], E. V. Avallone[1,*], C. Cassieri[1], M. Zippi[1], P. Paoluzi[1]. [1]*INTERNAL MEDICINE AND MEDICAL SPECIALTIES, SAPIENZA UNIVERSITY OF ROME, ROME, Italy*

INTRODUCTION: Treatment of patients with mild-moderate active ulcerative colitis (UC) is based on combination of oral and topical sulfasalazine or 5-aminosalycilic acid (5-ASA), or use of oral and topical glucocorticosteroids, but prolonged use of steroids is limitated by the risk of side effects. A new

glucocorticosteroids, beclomethasone dipropionate (BDP), with the same efficacy as traditional ones, but with more favourable safety profile was developed.
AIMS&METHODS: Aim of this study has been to define the efficacy and safety of oral BDP compared to 5-ASA enema in left-sided active UC. In eight-week, investigator blind comparative study, patients with left-sided mild-moderately active UC were randomized to receive oral 5-ASA (2.4 g/day) plus oral BDP (10 mg/day) or 5-ASA enema (4 g/day). Efficacy was evaluated by the Disease Activity Index (DAI). Safety was evaluated by monitoring adverse events, haematochemical parameters and adrenal function.
RESULTS: Sixty-two outpatients were enrolled and randomly treated with BDP (n= 30) or 5-ASA enema (n= 32). Twelve patients did not complete the study: 2 (6.7%) in the BDP group and 10 (31.3 %) in the 5-ASA group, with a difference statistically significant (p=0.0226). According to *intention-to-treat* (ITT) analysis complete remission was achieved in twelve out of thirty patients in BDP group (40%) and in fourteen out of thirty-two patients in 5-ASA group (43.8%) with a difference not statistically significant. According to *per protocol* (PP) analysis, complete remission was achieved in 42.9% of BDP patients vs 63.6% of 5-ASA, a difference not statistically significant. Mild signs of hypothalamic-pituitary-adrenal axis suppression were observed in 4 (14.3%) patients of BDP group.
CONCLUSION: Oral BDP gave an overall treatment result in patients with left-sided active UC with few signs of systemic side-effects, so it can be considered, a useful therapeutic regimen in patients not compliant to 5-ASA enema.

P894 EFFICACY AND SAFETY OF INFLIXIMAB SALVAGE THERAPY FOR PATIENTS WITH ULCERATIVE COLITIS WHO FAILED TO TACROLIMUS

H. Tsukamoto[1,*], S. Tanida[1], T. Mizoshita[1], K. Ozeki[1], T. Joh[1]. [1]*Department of Gastroenterology and Metabolism, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

INTRODUCTION: Tacrolimus and anti-TNFα therapy are effective for the treatment of patients with moderate or severe corticosteroid-dependent/refractory ulcerative colitis. However, regarding treatment for these patients, whether tacrolimus therapy should precede anti-TNFα therapy as a secondline therapy remains controversial. To address this issue, we retrospectively investigated the efficacy of infliximab salvage therapy for patients with severe or moderate ulcerative colitis who failed to respond to tacrolimus.
AIMS&METHODS: We assessed retrospectively clinical backgrounds and therapeutic outcomes at baseline, 8, and 30 weeks for 16 patients receiving infliximab between beginning of 2009 and the end of 2012 for severe or moderate ulcerative colitis who showed refractoriness or loss of response to tacrolimus, or no tolerance.
RESULTS: Mean partial Mayo score was significantly decreased ($P<0.05$) to 5.75, 3.38, and 2.38 at baseline, 8, and 30 weeks, respectively. Five of 16 patients (31.2%) showed clinical remission at 8 weeks and seven (43.8%) showed clinical remission at 30 weeks. Two patients who did not respond to infliximab finally underwent colectomy. Rates of clinical remission at 8 and 30 weeks were 28.6 and 42.9% in tacrolimus responders, and good remission rates of 33.3 and 44.4%, respectively, were also obtained in tacrolimus nonresponders. There was no factor which was useful in predicting response to infliximab. No serious adverse events were encountered.
CONCLUSION: Infliximab salvage therapy following tacrolimus appeared to be efficacious in both tacrolimus responders (loss of response or no tolerance) and in nonresponders (refractoriness), and 14 (87.5%) of 16 patients avoided colectomy. Sequential therapy may thus prove useful and well tolerated. Infliximab was thus considered to be a therapeutic option. In addition, we should avoid missing the proper timing of colectomy, and care is warranted regarding adverse events.

P895 DAIKENCHUTO (TU-100) RAISES PLASMA LEVELS OF ADRENOMEDULLIN IN PATIENTS WITH CROHN'S DISEASE: POSSIBLE MECHANISM OF CLINICAL ACTION

H. Yamasaki[1,*], K. Mitsuyama[1], T. Kobayashi[1], K. Kuwaki[1], S. Yoshioka[1], K. Nagayama[1], H. Takedatsu[1], O. Tsuruta[1], M. Sata[1]. [1]*KURUME UNIVERSITY SCHOOL OF MEDICINE, Kurume, Japan*

INTRODUCTION: Daikenchuto (TU-100), a traditional Japanese medicine, reportedly up-regulates the adrenomedullin (ADM)/calcitonin gene-related peptide (CGRP) system, which is involved in potent tissue repair and anti-inflammatory actions in the intestine. TU-100 exerted beneficial effects in a Crohn's disease (CD) mouse model through the induction of ADM release, and a clinical study involving the use of TU-100 in humans with CD is in the planning stage. However, nothing is known about the effect of TU-100 on ADM/CGRP release in the treatment of human CD. The primary objective of this study was to evaluate the efficacy of TU-100 treatment on circulating ADM/CGRP levels in patients with active CD. Additional objectives included the assessment of disease activity and a safety evaluation.
AIMS&METHODS: The plasma levels of total ADM (tADM) and mature form-ADM (mADM) and the serum levels of CGRP were measured in 17 patients with active CD and 24 healthy subjects using enzyme-linked immunosorbent assays (ELISAs), for the measurement of tADM [detection limit, 2 fmol/mL] and mADM [1 fmol/mL], for CGRP [7.8 pg/mL]). Then, 10 patients with active CD received 15 g of TU-100 (Tsumura & Co., Japan) daily for 8 consecutive weeks in an open-label treatment protocol while the baseline anti-inflammatory therapy was continued. The pre- and post-treatment plasma levels of tADM and mADM were measured. The response to treatment was evaluated clinically using the international organization for the study of inflammatory bowel diseases (IOIBD) score.
RESULTS: The plasma tADM and mADM levels were higher in the patients with active CD than in the healthy subjects (mean $\pm$ SEM**:** 16.4 ± 1.1 vs**.** 11.8 ± 0.4 fmol/mL, $P < 0.001$; 1.7 ± 0.1 vs**.** 1.4 ± 0.1 fmol/mL, $P = 0.008$, respectively). Simultaneous determinations of the serum CGRP level were not detectable in most of the subjects. After 8 weeks of treatment with TU-100, the patients showed elevated levels of plasma tADM (16.4 ± 1.1 vs. 20.2 ± 1.7 fmol/mL, $P = 0.0218$) and plasma mADM (1.7 ± 0.1 vs. 2.2 ± 0.1 fmol/mL, $P = 0.0284$). The patients' IOIBD scores also improved, with a significant decrease in the score from 3.9 ± 0.5 to 2.4 ± 0.4 ($P = 0.0284$). Of the 10 components of the IOIBD score, the scores for 2 components (''abdominal pain'' and ''abdominal tenderness'') decreased significantly ($P = 0.014$ and $P = 0.046$, respectively). No side effects were observed.
CONCLUSION: This pilot study showed that the pharmacologic action of TU-100 is related to changes in the ADM levels. Treatment with TU-100 may have a place in the management of CD.

P896 EFFICACY OF PROBIOTIC TREATMENT WITH BIFIDOBACTERIUM LONGUM 536 FOR INDUCTION OF REMISSION IN ACTIVE ULCERATIVE COLITIS: A RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED MULTICENTER TRIAL

H. Tamaki[1,*], H. Nakase[2], K. Namba[3], M. Shibatoge[1], T. Chiba[2]. [1]*Department of gastroenterology and hepatology, TAKAMATSU RED CROSS HOSPITAL, Takamatsu, Kagawa,* [2]*Department of gastroenterology and hepatology, Kyoto University, Kyoto,* [3]*Nutritional Science Institute, Morinaga Milk Industry, Tokyo, Japan*

INTRODUCTION: Probiotic treatment in patients with ulcerative colitis (UC) has been focused on improving the intestinal microbial balance and cytokine profile. We have previously reported that upregulation of T-bet and tight junction molecules by *Bifidobacterium longum 536* (BB536) improves colonic inflammation in patients with UC. Therefore, to investigate the efficacy of BB536 supplementation for induction of remission in patients with active UC, we conducted a randomized, double-blinded, placebo-controlled multicenter trial.
AIMS&METHODS: A total of 56 consecutive patients with mild-to-moderate UC (27 male, 29 female; mean age 44±14) were enrolled in the study. Eight patients of these (14%) were affected with pancolitis and 31 (56%) had left-sided colitis; 17 (30%) had proctitis. Patients were randomly treated with 2–3 $\times 10^{11}$ freeze-dried viable BB536 (28 patients) or placebo (28 patients) for 8 weeks.
RESULTS: Twenty-four patients in the BB536 group and 23 patients in the placebo group completed the study (86% and 82%, respectively). In 7 of the remaining 9 patients, other treatments were needed because of exacerbation. One patient from the BB536 group withdrew from the study because of a mild side effect, and 1 patient from the placebo group withdrew from the study on entry. In total, 63% of patients receiving BB536 showed clinical remission (UC disease activity index [UCDAI], ≤ 2) at week 8 compared to 52% of those receiving placebo ($p = 0.395$). There was a significant decrease in UCDAI scores from 3.5 ± 1.9 at baseline to 2.5 ± 1.7 at week 8 in the BB536 group ($p = 0.034$), whereas there was no significant decrease in these scores in the placebo group. The Rachmilewitz endoscopic index (EI) score also decreased significantly for the items of granulation scattering reflected light (from 1.8 ± 0.7 to 0.8 ± 1.0, $p < 0.001$) and vulnerability of mucosa (from 1.4 ± 1.2 to 0.6 ± 0.9, $p < 0.001$) in the BB536 group. One patient (1.8%) in the BB536 group reported a mild side effect (dry cough), but no other serious adverse reactions were observed.
CONCLUSION: Supplementation with BB536 was safe and efficacious in reducing UCDAI scores in patients affected by mild-to-moderate UC. Moreover, BB536 improved EI scores in patients with active UC after 8 weeks of treatment.

P897 EFFECT OF A PROBIOTIC PREPARATION(VSL#3) IN THE PATIENTS WITH ULCERATIVE COLITIS: ITS EFFECT ON CYTOKINES

J. H. Lee[1,*], H. J. Kwon[1], W. J. Jung[1], P. J. Seo[1]. [1]*Digestive Endoscopic Center, Seoul Song Do Colorectal Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Ulcerative colitis is chronic inflammatory disease. Probiotics could possibly induce remission in the treatment of active UC. Assess the efficacy of VSL#3 on induction and maintenance of remission and evaluate cytokine concentration change in patients withactive UC.
AIMS&METHODS: We evaluated the clinical efficacy of probiotic preparation VSL#3 and assessed cytokine concentration changes in the treatment of mild to moderate UC patients.Thirteen eligible patients with mild to moderate UC between the ages of 20 to 70 received VSL#3 4 sachets daily in 2 divided doses

for 8 weeks. The disease activity pre- and post-VSL#3 therapy was assessed by Mayo ulcerative colitis endoscopic score; colonic tissue cytokine profiling done at baseline and at week 8.
RESULTS: Thirteen patients (8 males and 5 females) were enrolled in the open-label VSL#3 study and completed 8 weeks of VSL#3 treatment. VSL#3 treatment outcome demonstrated remission (defined as UCDAI $\leq$2) in 61.5% of subjects (n=8); response (decrease in UCDAI $\geq$2) in 15.4 % (n=2); no response 15.4 % (n=2); worsened in 7.7 % (n=1).
CONCLUSION: Our study demonstrated that using VSL#3 in the treatment of mild to moderate UC is effective in induction of remission / response. Those who responded to VSL#3 treatment had a significant decrease in their UCDAI scores and colonic tissue pro-inflammatory cytokine levels.

P898 THE EFFICACY OF TACROLIMUS IN PATIENTS WITH ULCERATIVE COLITIS REFRACTORY TO CORTICOSTEROIDS AFTER FAILURE OF INFLIXIMAB REMISSION INDUCTION THERAPY

K. Hirayama[1,*], A. Yamada[1], K. Takeuchi[1], R. Furukawa[1], R. Iwasa[1], H. Iwashita[1], T. Sasaki[1], M. Katsumata[1], M. Miyuki[1], H. Kikuchi[1], K. Sono[1], A. Osamura[1], K. Nakamura[1], H. Aoki[1], Y. Yoshimatsu[1], Y. Tsuda[1], N. Takada[1], Y. Suzuki[1]. [1]*Internal Medicine , Sakura Medical Center,Toho University, Sakura,Chiba, Japan*

INTRODUCTION: The calcineurin inhibitor, tacrolimus (Tac) and the anti-tumour necrosis factor (TNF)-alpha antibodies like infliximab (IFX) are alternative medications for patients with severe corticosteroids-refractory ulcerative colitis (UC). However, currently, there is no guideline pertained to the order or the timing of these medications.
AIMS&METHODS: This study was to investigate the efficacy of Tac in patients with active UC refractory to corticosteroid who failed to respond to IFX remission induction therapy. In a single centre, open-label setting, 94 patients with corticosteroid-refractory UC, average age 38.3yr, range 15-79yr were given IFX (5mg/kg bodyweight) at weeks 0, 2 and 6 as remission induction therapy. At week 8, 26 patients had not achieved remission. Seventeen of these IFX refractory patients were given Tac, orally, aiming for an initial blood trough level of 10-15ng/ml as remission-induction therapy and then at 5-10ng/ml blood as maintenance therapy for longer than 3 months. The other 9 patients were given alternative medications (without Tac). Efficacy was assessed by applying the Mayo disease activity index (DAI). DAI equal or smaller than 2 meant remission, while at least a 30% decrease in the DAI score was defined as response to therapy.
RESULTS: In the Tac arm (n=17), before Tac remission induction therapy, the DAI score was 8.95+/-1.17 and C-reactive protein level was 2.37+/-2.45mg/dL, indicating active UC in spite of IFX administration. Eight weeks after Tac administration, the rates of remission induction, clinical response and no-response were 29.4% (5 of 17 patients), 58.8% (10 of 17 patients), and an 11.7% (2 of 17 patients), respectively. The maintenance rate and the surgery rate one year after Tac treatment were 20% (1of 5 patients) and 17.6% (3 of 17), respectively. The maintenance rate in the without Tac arm was 0% while the surgery rate was 44.4% (4 of 9 patients). Side effects were tremor, kidney disfunction and thrombosis 1 patient each.
CONCLUSION: The efficacy of Tac in patients with UC refractory to corticosteroids who failed to achieve remission within 8 weeks of initiating IFX remission induction therapy is potentially interesting. A randomized study in a large cohort of patients including a control arm is warranted to fully evaluate the efficacy and safety of Tac in patients with UC refractory to corticosteroids and anti-TNF biologics.

P899 TIMING OF SWITCHING FROM INFLIXIMAB TO ADALIMUMAB IN THE TREATMENT OF CROHN'S DISEASE

K. Takeuchi[1,*], A. Yamada[1], Y. Suzuki[1]. [1]*Division of Gastroenterology, Department of Internal Medicine, Sakura Medical Centre, Faculty of Medicine, Toho Unversity, Chiba, Japan*

INTRODUCTION: Patients who receive infliximab (IFX) for Crohn's disease (CD), at some time point may require dose escalation or shortening of infusion interval for maintaining an adequate efficacy level. This is often called loss of response to IFX. Switching from IFX to adalimumab (ADA) has been considered as an alternative strategy for minimizing adverse side effects and overcoming the loss of response.
AIMS&METHODS: In this investigation, we were interested to better understand the timing of switching from IFX to ADA in patients who had developed active CD in spite of IFX dose escalation or shortened infusion interval. In this endeavour, we retrospectively evaluated CD patients who were treated with anti-tumour necrosis factor (TNF)-α agents from November 2010 to September 2012 and assessed the efficacy of ADA among patients with anti-TNF-α naïve (naïve group), switching from 5mg/kg of IFX (5mg/kg group), and from10mg/kg of IFX or reducing the interval of IFX infusion (dose-escalation group).
RESULTS: A total of 60 patients with CD were included, 15 were anti-TNF-α naïve, and 45 had switched from IFX to ADA. Seven patients had switched to ADA because of IFX infusion reaction. 12 of 15 patients (80%) who were anti-TNF naïve together with 24 of 45 patients (53%) who had switched from IFX to ADA could continue the treatment with ADA up to week 52. 11 of 15 patients in the 5mg/kg group could continue the treatment with ADA up to week 52 compared with 11 of 28 patients in the dose-escalation group (73% vs 39%, P = 0.033). The CD activity index (CDAI) in the naïve group was significantly lower than in either the 5mg/kg group or the dose-escalation group at 52 weeks after the start of ADA administration (P = 0.02). Further, both CDAI and C-reactive protein levels in the 5mg/kg group were significantly lower than the dose-escalation group at 52 weeks (P = 0.02, and P = 0.006, respectively).
CONCLUSION: In CD patients with the loss of response to IFX, switching to ADA before IFX dose escalation appears to be a clinically relevant therapeutic decision.

P900 LONG-TERM OUTCOME AFTER DISCONTINUATION OF INFLIXIMAB IN PATIENTS WITH CROHN'S DISEASE ACHIEVING CLINICAL REMISSION

K. Papamichail[1,2,*], N. Vande Casteele[2], S. Tops[2], V. Ballet[1], A. Gils[2], M. Ferrante[1], P. Rutgeerts[1], S. Vermeire[1]. [1]*Translational Research in Gastro-Intestinal Disorders (TARGID-IBD),* [2]*Laboratory for Therapeutic and Diagnostics Antibodies, KU Leuven, Leuven, Belgium*

INTRODUCTION: The STORI trial showed that in CD patients who stop infliximab (IFX) for remission but continued immunomodulators (IMM), half will relapse within 1 year after discontinuation, while biologic or endoscopic features of persistent inflammation were predictors of relapse. We investigated the long-term outcome of CD patients who discontinued IFX, while in clinical remission (CR) and searched for predictors of sustained clinical remission (SCR) after IFX cessation including serum levels of IFX.
AIMS&METHODS: Observational, retrospective, single-centre study of 90 CD patients [36 males, median age at last follow up 43 (IQR 35-56)] years who discontinued IFX therapy due to CR after a median of 7.6 (IQR 1.4-17.6) months and a median of 4 (IQR 2-6) infusions. The majority had been treated with episodic IFX, n=70 (78%), 12 with maintenance from the start (13%) and 8 (9%) had switch from episodic to maintenance therapy. After stopping IFX, 76 (84%) patients continued on IMM (AZA, n=60), while 14 (16%) received 5-ASA or no therapy. Primary outcome was SCR after discontinuation of IFX and secondary objectives included the identification of predictors for SCR. SCR was defined as maintained disease remission without any biological or surgical treatment until the end of follow up. Serial IFX trough (TR) and intermediate (IM) levels in prospectively collected serum samples were analyzed by an in house ELISA.
RESULTS: With a median follow up of 9.4 (IQR 7.6-11.2) years, 49/90 (54.5%) had SCR [22/49 (45%) treated mainly for fistulising, 27/49 (55%) for luminal disease]. The median time between stop of IFX and relapse was 4.7 (IQR=3.5-7.0) years. In univariate analysis, potential factors associated with SCR included long-term partial or complete mucosal healing (MH) 2-48 months after stop of IFX [OR=4.427 (95% CI, 1.74-11.267), n=49, $p<0.001$], while there was a trend for albumin >35g/l at the time of last IFX [OR=1.156 (95% CI, 1.018-1.313), n=71, p=0.055]. Logistic regression analysis did not reveal any independent factor predicting SCR. Median TR and IM levels at different available time points of treatment (w2, w6 for those with an induction phase, n=27 and at the time of discontinuation of IFX, n=18) were not able to predict SCR.
CONCLUSION: In this single centre cohort, 54% of CD patients who discontinued IFX therapy while in CR remained in SCR and mainly with continued IMM treatment. This implies that within the variable responses to IFX some patients may achieve indefinite remission after IFX discontinuation. Unfortunately we were not able to identify any independent factor predicting SCR.

P901 AZATHIOPRINE ACHIEVES MUCOSAL HEALING IN PATIENTS WITH EARLY-ONSET CROHN'S DISEASE

K. Papamichael[1,*], E. Archavlis[1], N. Kyriakos[1], D. Tsironikos[1], P. Karatzas[1], X. Tzanetakou[1], I. Internos[1], S. Anastasiadis[1], G. J. Mantzaris[1]. [1]*A' Gastroenterology Clinic , Evangelismos Hospital, Athens, Greece*

INTRODUCTION: Although azathioprine (AZA) may prevent relapses of steroid-dependent Crohn's disease (CD) its healing effects range between 16.5 (SONIC trial) and 85%. This may be due to patient selection, disease activity, definition of mucosal healing (MH) and timing of colonoscopy after starting AZA. We aimed to assess MH in patients with early onset CD receiving AZA monotherapy.

AIMS&METHODS: Retrospective analysis of prospectively acquired data in patients followed in a single center from 2006 to 2013. Eligible patients had a recent onset of luminal CD (≤6 months of symptom onset and diagnosis), ileocolonoscopy and full laboratory assessment at disease diagnosis and were received AZA at or within 6 months of diagnosis. Patients received budesonide or classical steroids with AZA (2.5 mg/kg); steroids were tapered off within 8-12 weeks. Patients were followed by a strict protocol including regular clinical examination and laboratory tests. Patients maintained in clinical (CDAI < 150) and serological (CRP < 0.6 mg/dL) remission underwent ileocolonoscopy between 22-26 months after starting AZA. Exclusion criteria were AZA intolerance, relapse despite adequate AZA dose, or lost to follow up. At baseline ileocolonoscopy, the SES-CD was used to describe and localize lesions. At follow up colonoscopy, MH was graded in 4 categories compared to baseline endoscopy: complete MH (no lesions); near-complete MH (occasional aphthae, residual superficial erosions, or thickened folds); partial MH (length of inflamed areas shortened but still considerable numbers of persisting ulceration and/or cobblestone), and unchanged/worse (lesions same or more severe than baseline).

RESULTS: Of 65 patients who received AZA 20 were excluded [8 adverse events, 10 persisting activity, 3 lost to follow up); 45 patients fulfilling the study criteria were identified [20 males, mean age 28 (range 16-67)y, smokers 23, ileitis (9), ileocolitis (21), colitis (13), median CDAI 265 (range 170-320), 20 steroid-dependent]. Patients had achieved steroid-free clinical and serological remission (SFR) between months 5-7 after starting AZA and maintained remission until follow up colonoscopy. MH at 2 years was complete in 53% (23/43); near-complete in 16% (7/43); partial in 19% (8/43) and unchanged in 12% (5/43) patients. Ileal lesions were more resistant than colonic lesions; healing rate in ileocolitis was higher for colonic than ileal lesions.

CONCLUSION: AZA can effectively heal luminal CD if started early after the onset of CD but is more effective for colonic lesions. Maintenance of SFR does not imply MH. MH should be assessed after 12 months in deep-remission.

P902 EFFECTS OF ANTI-TNF THERAPY IN THE MONITORING OF HISTOLOGICAL ACTIVITY IN PATIENTS WITH CROHN'S DISEASE

L. L.-B. Pinzon[1,*], T. C. Espinosa[1], M. Salamanca[1]. [1]*Gastroenterología, ISSSTE, Distrito Federal, Mexico*

INTRODUCTION: Crohn's disease (CD) is a chronic inflammatory disorder characterized by periods of clinical remission alternating with periods of relapse. Historically, clinical response and remission have been the primary treatment goals. A working definition of sustained deep remission which includes long-term biological remission and symptom control with defined patient outcomes has been proposed. However, the optimal treatment goal should be the complete resolution of the inflammatory process, and this can only be confirmed by the corresponding histological assessment.

AIMS&METHODS: Our objective was to assess the clinical, biochemical, endoscopic and histological effects of anti-TNF therapy in patients with Crohn's disease. The inflammatory bowel disease clinic at the National Medical Center "20 de Noviembre" currently gives follow-up to 11 patients with moderate to severe Crohn disease. We conducted a retrospective review of 6 female patients and 5 male, whose ages were within a range of 17 to 62 years, of which 4 were smokers and 3 had history of appendectomy. The variables studied were: clinical features (Montreal's classification and the CDAI score), biochemical (erythrocyte sedimentation rate and C reactive protein), endoscopic (CES-CD scale) and histopathological findings (lymphoid aggregates, plasmocytosis, granulomas and cellular hyperplasia).

RESULTS: Below, the results are presented in frequencies and measures of central tendency. According to the Montreal's classification, the patients were classified as following: 6 in A3 and 5 A2, 6 in L3 and 5 L2, 7 in B1 and 4 B2. Prior to the anti-TNF therapy, the CDAI score was calculated, with a maximum value of 386 and a minimum of 240 with an average of 307.63. After therapy, the minimum value was 110 and maximum of 280 with an average of 183 points. Pretreatment average of ESR value was 43.54 and PCR 48.6; and post-treatment 25.36 and 8.55 respectively. A maximum value of 10 was obtained with the CES-CD scale and a minimum value of 4, with an average of 6.90 and at the end a maximum of 7 and a minimum of 3, with an average of 4.72.

Histopathological findings are expressed in table 1

Histopathological findings	Pre	Post
Lymphoid aggregates	11	8
Plasmocytosis	9 moderate 2 intense	7 mild 3 moderate
Granulomas	3	0
Celullar hyperplasia	7	5
Fibrosis	11	11

CONCLUSION: Histological healing would substantially improve the evaluation of the actual effectiveness of a given treatment. Histological assessment is widely available and has a low cost. In our population, anti-TNF therapy has shown that after 48 weeks of treatment, there are changes in most of the evaluated biopsies.

P903 PHARMACOLOGY OF ETROLIZUMAB IN A PHASE 2 STUDY IN MODERATE TO SEVERELY ACTIVE ULCERATIVE COLITIS

M. Williams[1,*], M. Keir[1], C. Looney[1], F. Fuh[1], W. Tew[1], K. Howell[1], S. Klabunde[1], C. Johnson[1], X. Wei[1], M. Tang[1], D. Luca[1], A. Salas[2], C. Lamb[3], S. Vermeire[4], C. Perrier[4], J. Panes[2], D. Baumgart[5], J. Mansfield[3], M. Paulsen[6], P. Rosenstiel[6], S. Schreiber[6], I. Dotan[7], P. Rutgeerts[4], S. O'Byrne[1], W. Mathews[1]. [1]*Genentech, Inc., South San Francisco, United States,* [2]*Hospital Clinic-IDIBAPS, Barcelona, Spain,* [3]*Newcastle University, Newcastle, United Kingdom,* [4]*Catholic University of Leuven, Leuven, Belgium,* [5]*Charité Medical School- Humboldt University of Berlin, Berlin,* [6]*University of Kiel, Kiel, Germany,* [7]*Tel Aviv Medical Center, Tel Aviv, Israel*

INTRODUCTION: Etrolizumab, a humanized antibody to the integrin b7, blocks a4b7 binding to MAdCAM-1 as well as aEb7 interactions with its ligand, E-cadherin. We examined pharmacodynamic (PD) effects of etrolizumab at two dose regimens in peripheral blood and colonic tissue in a Phase2 study of patients with ulcerative colitis (UC).[1]

AIMS&METHODS: Patients (n=124) were randomized in a 1:1:1 ratio to either 2 dose levels of etrolizumab (100mg SC on wks 0,4, and 8 or 300mg SC on wks 2,4, and 8 + 420mg wk 0) or placebo. Two types of biomarkers were assessed by flow cytometry in peripheral blood and colonic biopsy tissue:an Occupancy Biomarker to confirm etrolizumab binding to b7-expressing cells and an Expression Biomarker to track b7-expressing cells in the presence of drug.

RESULTS: Demographics and baseline characteristics were similar across patient groups. Etrolizumab administration resulted in maximal occupancy of b7 on mucosal-homing CD4+ and CD4- T and CD19+ B cell subsets in peripheral blood in both dose cohorts (0% vs >85% available b7 in active vs placebo). Receptor occupancy correlated with elevated numbers of circulating b7-expressing mucosal-homing lymphocyte subsets (~20-80% median increase), consistent with the proposed MOA of blocked homing. Maximal occupancy of b7 receptors (a4b7 and aEb7) on T cells in colonic tissues was also observed in both etrolizumab cohorts (<10% available b7) with no apparent occupancy in placebo patients (>90% available b7). Additionally, occupancy of b7 in colonic tissue coincided with occupancy in peripheral blood in all assessed patients.

Occupancy: Median % Available Beta7 Expressing Cells

	Treatment (n)	Day 43	Day 71
Blood Mucosal Homing CD4+ T cells	100mg (29)	0	0
	300mg (34)	0	0
	Placebo (39)	87	111
Tissue aEb7+ CD4- T cells	100mg (5)	4	8
	300mg (7)	2	7
	Placebo (9)	107	94

CONCLUSION: These studies confirmed etrolizumab target binding and demonstrated biological effects of target engagement in blood and at the site of disease pathogenesis. Examination of etrolizumab pharmacologic effects was central to the elucidation of MOA and provided proof of concept to support Phase3 studies in UC. Analysis of exposure-response relationships and modeling of these data would aid regimen refinement moving forward.

P904 INFLIXIMAB IS EFFECTIVE AT PREVENTING RESTENOSIS AFTER THE ENDOSCOPIC BALLOON DILATATION THERAPY IN PATIENT'S WITH CROHN'S DISEASE.

M. Saruta[1,*], S. Arihiro[1], M. Matsuoka[1], M. Mitsunaga[1], D. Ide[1], T. Iwasaki[1], N. Komoike[1], Y. Arai[1], T. Kato[1], H. Tajiri[1]. [1]*Department of Gastroenterology and Hepatology, THE JIKEI UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan*

INTRODUCTION: Crohn's disease (CD) has a characteristic of fibrotic stenoses caused by healing process from chronic ulceration. Endoscopic balloon dilation (EBD) is very useful to dilate stenotic lesions and can prevent the patients from receiving surgical operation, however patients sometimes have restenosis several months after EBD. Recently, Regueiro et al. reported that administration of infliximab (IFX) after intestinal resective surgery is effective at preventing endoscopic and histologic recurrence of CD. We therefore evaluated whether IFX can also prevent CD patients from having restenosis after EBD.

AIMS&METHODS: The aim of this study is to evaluate the efficacy and the safety of IFX at preventing restenosis after EBD.

We enrolled 13 CD patients with severe stenoses at our hospital from March 2009 to April 2013. We first measured the distance of stenosis by endoscope and did not perform EBD if the stenosis was over 3 cm in distance. We dilated the stenosis to 10-18 mm in diameter by EBD, and then started or continued IFX. Seven patients started IFX after EBD, and six patients have already treated with IFX before EBD. Every two months the patients were evaluated with their symptoms and blood examination. The definition of restenosis is to be needed EBD again or to have abdominal symptoms caused by gastrointestinal stenosis. All patients were followed up for 22.8 months (11 to 45 months) on average.

RESULTS: We performed EBD for 22 stenotic lesions of 13 CD patients. The average number of stenoses in the patient was 1.6 ± 0.9 (one to four stenoses). Seven patients had stenoses of ileocecal valve, four had stenoses of ileum, two had stenoses of surgical anastomosis, and three had stenoses of anal or rectum. We succeeded to dilate the stenoses to 14.6 mm (10 to 18 mm) in diameter on average. There were no any complications related to EBD. Ten patients had no resteoses by administration of IFX. Five of them received endoscopy and had no restenoses endoscopically. Two patients were required EBD again, and one patient was required a surgical operation. One of the patients had treated with IFX before EBD, and the others started IFX after EBD. One of the patients had continuous positive for CRP although the patient was relieved symptoms of obstruction after EBD. The patients who had no restenoses had been negative for CRP. The predict marker for restenosis after EBD was not determined in this study, however continuous positive for CRP may be the risk for restenosis.

CONCLUSION: IFX is very useful treatment to prevent CD patients from having restenosis after the EBD.

P905 IMPACT OF CYTOMEGALOVIRUS AND ITS TREATMENT ON INFLAMMATORY BOWEL DISEASE FLARE-UPS

M. Delvincourt[1,*], A. Lopez[2], S. Pillet[3], A. Bourrier[1], P. Seksik[1], J. Cosnes[1], F. Carrat[4], J. Gozlan[5], L. Beaugerie[1], X. Roblin[6], L. Peyrin-Biroulet[2], H. Sokol[1]. [1]*Gastroenterology, Hôpital Saint Antoine, Paris,* [2]*Gastroenterology, CHU Nancy, Nancy,* [3]*Virology, CHU Saint-Etienne, Saint-Etienne,* [4]*Epidemiology, INSERM,* [5]*Virology, Hôpital Saint Antoine, Paris,* [6]*Gastroenterology, CHU Saint-Etienne, Saint-Etienne, France*

INTRODUCTION: Impact of latent cytomegalovirus reactivation on inflammatory bowel disease (IBD) flare is debated. It is either considered as a worsening factor or as a simple bystander of severe flare.

AIMS&METHODS: The aim of our retrospective study was to evaluate the impact of antiviral treatment on IBD control in patients hospitalized for IBD flare with CMV reactivation.

One hundred and five patients (23 Crohn's disease [CD], 82 ulcerative colitis [UC]) hospitalized for IBD flare with systemic and/or colonic CMV reactivation (plasma PCR, n=80; PCR in colon biopsies, n=28) were indentified in the database of 3 tertiary centres. Viral load significance threshold was defined according to the techniques in use (500 to 2500 copies /mL for plasma PCR, semi-quantitative method for PCR in colon biopsies). Short-term (10 ± 4 days) and middle-term evolution from CMV reactivation diagnosis were compared between patients with antiviral treatment and those without. Results are shown as mean and standard deviation. On analysis, Mann Whitney test, paired Wilcoxon test, Chi2 test or logrank test were used when appropriate.

RESULTS: Among the 80 patients with systemic CMV reactivation, no difference was observed between treated (n=49) and untreated (n=31) patients at inclusion regarding age, gender, IBD type, immunosuppressant, CRP and haemoglobin level. No significant difference was observed between treated and untreated patients regarding decrease of CRP level at 10 days (11.0 ± 49.4 vs 17.7 ± 27.3 mg/L, p=0.6) and colectomy rate at 3 months (10.6% vs 13.3%, p=0.7). Antiviral treatment was associated with lower serum albumin level at inclusion (30.1 ± 5.9 vs 26.8 ± 4.6g/l, p= 0.03) and longer hospitalization (16.3 ± 10.6 vs 8.3 ± 5.8 days, $p < 0.0001$). In the severe colitis UC subpopulation (Lichtiger score ≥ 10), no significant difference was observed between treated and untreated patients regarding decrease of CRP level at 10 days (20.6 ± 46.1 vs 7.0 ± 15.2 mg/L, p=0.4), decrease of Lichtiger score (4.1 ± 4.7 vs 6.2 ± 3.4, p=0.35) or colectomy rate (logrank : p=0.8). In the treated group, hospitalization was longer than in the untreated group (15.3 ± 8.3 vs 8.8 ± 4.8 days, p= 0.04). Similar results were observed for colonic CMV reactivation.

CONCLUSION: Treatment of systemic or colonic CMV reactivation in IBD patients hospitalized for flare-up does not seem to impact on IBD evolution. These results should be confirmed prospectively.

P906 THE SAFETY OF BIOLOGICAL TREATMENT OF INFLAMMATORY BOWEL DISEASE

M. Konecny[1,*]. [1]*2nd internal clinic , FACULTY HOSPITAL OLOMOUC, CZECH REPUBLIC, Olomouc, Czech Republic*

INTRODUCTION: The present clinical practice of biological treatment (BT) of inflammatory bowel disease (IBD) in the Czech Republic includes using of two drugs (infliximab and adalimumab), where the active substance are antibodies against tumor necrosis factor alpha (TNF-α). The therapeutical effect is very good not only for induction of remission of the intestinal inflammation, but also for a long-term maintenance treatment. For some patients, however, BT is associated with the occurrence of sometimes serious side effects. Their pathogenesis is not known yet and in some cases these serious side effects are the cause of the termination of the treatment.

AIMS&METHODS: In the period 2007-2012, 126 patients with IBD TNF-α were treated at the Department of Internal Medicine II of the University Hospital in Olomouc. In this set of patients, the occurrence of serious side effects of TNF-α was observed within the dispensarization. The difference in the occurrence of side events was compared with the control set of 102 patients with IBD, who underwent only conventional therapy (aminosalicylates, corticosteroids, immunosuppressants). The observed side effects included skin, articulary, ocular, infectious, metabolic and hematopoietic disorders. The data were statistically processed using standard descriptive methods for continuous data.

RESULTS: The serious side effects were documented in 11 (8.7%) patients with TNF-α therapy; the most common complications were skin complications (54.3%). In the set of patients under the conventional therapy, the side effects of the treatment have been reported in 7 (6.9%) patients, mostly involving hematopoietic disorders (61.2%). The observed difference of occurrence of serious side effects was not statistically significant ($p = 0.11$).

CONCLUSION: In the last decade, the introduction of BT has caused a significant change in the routine clinical treatment of IBD. It turns out that this treatment is relatively safe, the incidence of serious side effects is not higher than when using conventional drug therapy. It is necessary to indicate the TNF-α treatment properly, the patient must be carefully examined before the initiation of the treatment and intensively monitored during the course of the treatment.

P907 LONG-TERM EFFICACY OF A PH-DEPENDENT RELEASE MESALAMINE FORMULATION, ASACOL IN PATIENTS WITH ULCERATIVE COLITIS WHO SHOWED INADEQUATE RESPONSE TO A TIME- DEPENDENT RELEASE MESALAMINE FORMULATION, PENTASA: A PROSPECTIVE STUDY

N. Yoshimura[1,*], T. Kawaguchi[1], M. Sako[1], A. Saniabadi[1], M. Takazoe[1]. [1]*Department of Internal Medicine, Social Insurance Central General Hospital, Tokyo, Japan*

INTRODUCTION: Mesalamine has been a first-line medication for inducing and maintaining remission in patients with mildly to moderately active ulcerative colitis (UC). However, there is no evidence for efficacy difference between the pH-dependent release mesalamine formulation, Asacol and the time-dependent release formulation, Pentasa.
AIMS&METHODS: We were interested to evaluate the efficacy of Asacol instead of low dose (≤2.25g/day), moderate dose (3.0g/day) or high dose (4.0g/day) Pentasa for inducing and maintaining clinical remission in UC patients who had active disease while on Pentasa for ≥4 weeks. In a single-centre prospective setting, 180 consecutive patients with mildly to moderately active UC willingly switched from Pentasa (mean dose 2.9±0.8g/day; range 1.5-4.0/day) to Asacol (3.6g/day). At entry and week 4, patients were assessed for clinical and endoscopic response. Clinical response was defined as Rachmilewitz's clinical activity index (CAI) ≤4, essentially CAI ≤ 1 meant remission. Mucosal remission was defined as Rachmilewitz's endoscopic index (EI) ≤1. Patients who switched to Asacol and achieved remission received maintenance Asacol at 2.4 or 3.6g/day, and were followed for 52 weeks. Long-term outcomes were evaluated by using the Kaplan-Meier survival analysis.
RESULTS: The CAI fell from 5.8±1.7 at entry to 3.0±2.6 at week 4 (n=180, $P<0.001$). Similarly, the EI fell from 6.8±1.7 to 2.2±2.4 (n=37, $P<0.001$). Sixty patients (33.3%) achieved clinical remission, 76 (42.2%) achieved response level. Further, the CAI in patients on low dose (≤2.25g/day) Pentasa subgroup fell from 5.6±1.3 to 2.4±2.6 (n=51, $P<0.001$), from 5.7±1.8 to 3.1±2.3 (n=95, $P<0.001$) in moderate dose (3.0g/day), and from 6.7±1.7 to 3.4±3.4 (n=34, $P<0.001$) in high dose (4.0g/day) Pentasa, showing significant efficacy for Asacol at 3.6g/day. After 52 weeks, 33 of 59 (55.9%) patients with CAI ≤1 at week 4 had maintained clinical remission, compared with 15 of 42 (35.7%) patients with CAI ≥2 at week 4 ($P<0.05$). Likewise, 15 of 19 (78.9%) patients with EI ≤1 vs 6 of 13 (46.2%) with EI ≥2 ($P<0.05$) had maintained complete remission. The Kaplan-Meier survival analysis showed higher remission rate in CAI ≤1 or EI ≤1 subgroup ($P<0.05$).
CONCLUSION: This study showed that patients who do not respond well to Pentasa might benefit from switching to Asacol at 3.6g, regardless of Pentasa dose. Further, a low CAI together with mucosal healing after induction of remission should be a good predictor of long-term maintenance of remission.

P908 INFLUENCE OF MELATONIN ON THE COURSE OF ULCERATIVE COLITIS

O. A. Rassokhina[1,*], A. Dorofeyev[1], I. Vasilenko[1]. [1]*National Medical University, Donetsk, Ukraine*

INTRODUCTION: Melatonin is one of the essential hormones, which regulates circadian rhythms, has anticancerogenic, antioxidant, immunomodulating effects, inhibits proliferation of the colon mucosa, influents on microbiota, modifies peristaltics and the gut transit. A significant amount of extrapineal melatonin is produced in the large intestine. Administration of melatonin can be one of the new therapeutic options in the treatment of ulcerative colitis (UC).
AIMS&METHODS: Aim: to investigate the efficacy of melatonin in comparison with standard treatment of UC.
Methods: double-blind, randomized clinical study in 62 patients with mild and moderate UC in acute phase of disease was performed. Clinical severity of UC was based on Mayo score assessment. Endoscopic (EI) and histological (HI) indexes were evaluated. Melatonin containing EC-cells were identified by Sevka's method. Immunohistochemistry was performed using monoclonal mouse antibodies raised against the mucins (Muc2, Muc3, Muc4), trefoil factor-3 (TFF3) and CD3, CD20, CD34, CD68. All patients received standard treatment of UC (5-ASA, topical steroids) during 30 days. 32 patients were treated with melatonin (2 mg per day orally) in addition to the base therapy (1-st group). 30 patients who didn't receive melatonin were considered as 2-nd group.
RESULTS: Before the therapy total Mayo index in all UC patients's group consisted 7.6+0.9 score points. The severity of UC correlated with the extensive of inflammation in the large intestine. The level of staining of Muc2 and Muc3 in all patients with UC was low, up to its complete absence (59.2% and 53.1% cases, p=0.05). Muc4 and TFF3 had high and medium staining intensity. Low quantity of EC-cells in the colon mucosa was found. After the treatment the most pronounced improvement was found in patients who received melatonin in addition to the standard treatment. Clinical remission was achieved earlier in the 1-st group (day 12.2+4.1) with Mayo index 1.9+0.5 score points in contrast to the 2-nd group: remission on 18.3+7.2 days, index Mayo 2.7+0.8 ($p\leq0.05$). The significant evidence of mucosal healing was mentioned in patients with melatonin: EI 1.1+0.5, HI 1.8+0.8, which were accompanied with increasing of Muc2 and Muc3 production (up to 75% cases), quantity of EC-cells, changes of CD3, CD20, CD34, CD68 in the colon mucosa.
CONCLUSION: melatonin application in addition to the standard treatment of UC was more effective than standard therapy alone. Melatonin showed significant improvement in the course of disease, earlier achievement of remission phase, evidence of deep histological remission in patients with UC.

P909 THE MAJORITY OF PATIENTS ARE NOT AWARE OF INFLAMMATORY BOWEL DISEASE MEDICATION SIDE EFFECTS

S. Bakkari[1,*], K. I. Kroeker[1], R. N. Fedorak[1]. [1]*Division Of Gastroenterology, University Of Alberta, Edmonton, Canada*

INTRODUCTION: Inflammatory bowel disease (IBD) is a chronic condition requiring long-term treatment with potentially toxic medications. It is not known how much patients know about the potential medications that they are being prescribed to treat their inflammatory bowel disease.
AIMS&METHODS: To assess patients' knowledge of medication side effects.**Methods:** This is a questionnaire-based, cross-sectional study of 204 adult IBD patients attending the gastroenterology and biologic clinics in the University of Alberta Hospital. Multiple-choice questionnaires assessed patient knowledge of side effects of commonly used IBD treatments (amino salicylates, corticosteroids, immunomodulators (imuran and methotrexate) and biologics)
RESULTS: Questionnaire response rate was 98% (200/204). Sixty-eight percent had Crohn's disease (136), 29% =ulcerative colitis, and 3% indeterminate colitis). The average age was 41.1±SD, range 18-79years. Half the patients were male (100/200).
Medication Side Effect % (N) Knowledge Respective
Sulfasalazine Reversible male infertility 7.8% (4/51)
Leukopenia 9.8% (5/51)
Mesalamine Kidney problem 14.5% (23/159)
Hepatitis 12.6% (20/159)
Prednisone Osteoporosis 47.3% (88/186)
Risk of infection 24.1% (45/186)
Thiopurine Analogue (Imuran, 6-MP)
Leukopenia 41.9% (67/160)
Pancreatitis 22.5% (36/160)
Hepatitis 35.6% (57/160)
Lymphoma 9.3% (15/160)
Methotrexate
Folate deficiency 24.6% (15/61)
Reversible male infertility 8.2% (5/61)
Anti-TNF (Infliximab, Adalimumab) Risk of infection 57% (86/151)
Lymphoma 24.5% (37/151)
Tuberculosis 23.2% (35/151)
Sulfasalazine :Reversible male infertility 7.8% (4/51) Leukopenia 9.8% (5/51). Mesalamine: Kidney problem 14.5% (23/159) Hepatitis 12.6% (20/159). Prednisone :Osteoporosis 47.3% (88/186) Risk of infection 24.1% (45/186):Thiopurine Analogue (Imuran, 6-MP) Leukopenia 41.9% (67/160) Pancreatitis 22.5% (36/160) Hepatitis 35.6% (57/160) Lymphoma 9.3% (15/160). Methotrexate: Folate deficiency 24.6% (15/61) Reversible male infertility 8.2% (5/61). Anti-TNF (Infliximab, Adalimumab) :Risk of infection 57% (86/151) Lymphoma 24.5% (37/151) Tuberculosis 23.2% (35/151)
CONCLUSION: Fewer patients were aware of the potential side effects of mesalamine and sulfasalazine than of prednisone and immunosuppressive medications. . The majority of IBD patients are not aware of important side effects of medications they have been prescribed for treatment of their IBD.

P910 PREDICTIVE FACTORS OF RESPONSE TO ORAL TACROLIMUS THERAPY IN REFRACTORY ULCERATIVE COLITIS: THE DEVELOPMENT OF A NOVEL PREDICTION FORMULA

S. Minemura[1,*], K. Saito[1], S. Sazuka[1], K. Okimoto[1], A. Oyamada[1], D. Maruoka[1], T. Matsumura[1], T. Nakagawa[1], M. Arai[1], T. Katsuno[1], O. Yokosuka[1]. [1]*Department of Gastroenterology, Chiba University Hospital, Chiba, Japan*

INTRODUCTION: Tacrolimus has been shown to be effective and safe as salvage therapy for steroid-refractory or steroid-dependent patients with ulcerative colitis (UC). However, some patients fail to respond and need to consider other treatments including colectomy. To predict effectiveness of tacrolimus therapy should contribute to early clinical decision-making.
AIMS&METHODS: The aim of this study is to identify predictive factors and to develop a reliable prediction formula of response to oral tacrolimus treatment. Included patients were those with moderate to severe steroid-refractory or steroid-dependent UC who had undergone oral tacrolimus treatment between July 2009 and April 2012 at a tertiary referral centre in Japan. Oral tacrolimus was started at a dose of 0.1 mg/kg body weight per day and trough levels were maintained at 10-15 ng/ml for 14 days. Then the trough levels were decreased and maintained at 5-10 ng/ml for 3 months. Primary endpoint of this study was clinical remission (Lichtiger score ≤ 4) at week 12 after starting oral tacrolimus. Demographic and clinical parameters obtained in 14 days after starting oral tacrolimus treatment were analysed by univariate (Chi-squared test or Mann-Whitney U test) and multivariate (multiple logistic regression analysis) statistics.
RESULTS: Thirty-six patients were included in this study (41.7% male with the average age of 41.0 ± 13.1 years). The average Lichtiger score when starting oral tacrolimus was 10.0 ± 3.2 (6-17). Nineteen patients (52.8%) had obtained remission at week 12 after starting oral tacrolimus and all of them avoided colectomy, 17 patients (47.2%) had failed to obtain remission and six of them underwent colectomy. Stepwise multiple logistic regression analysis identified three independent predictive factors of response to oral tacrolimus: stool frequency on the first day (="SF"), platelet count ($\times10^4/\mu$L) on day 14 (="PLT") and C-reactive protein value (mg/L) on day 14 minus that on the first day (="ΔCRP"). The calculation formula [$49.0 - 1.7 \times SF - 1.3 \times PLT - 0.27 \times \Delta CRP > 0$] was shown to predict remission with an accuracy of 88.9%, positive predictive value of 94.7% and negative predictive value of 82.4%.
CONCLUSION: This study indicates that disease remission status at week 12 can be predicted with a high accuracy by combination with three simple clinical items obtained in 14 days after starting oral tacrolimus therapy for UC. This

finding should be useful for acceralating early clinical decision-making when treating patients with UC.

P911 LOCALISED PHARMACOLOGICAL ACTIVATION OF MUCOSAL HYPOXIA INDUCIBLE FACTOR REVERSES COLITIS THROUGH ACCELERATED EPITHELIAL RESTITUTION

B. J. Goggins[1,2], S. Cole[1,2], R. Shalwitz[3], A. Kotsakis[4], S. Keely[1,2,*]. [1]*School of Biomedical Science and Pharmacy, University of Newcastle, Callaghan,* [2]*Gastrointestinal Research Group, Hunter Medical Research Institute, New Lambton Heights, Australia,* [3]*Aerpio Therapeutics, Ohio,* [4]*Aerpio Therapeutics, Cincinnati, United States*

INTRODUCTION: Crohn's disease (CD) is characterised by repeated wounding and inflammation of the intestinal mucosa. During mucosal inflammation, changes in metabolic activity and vascular damage, lead to a reduction in tissue-oxygen tension (hypoxia), in which healing processes such angiogenesis, cell migration and re-epithelialisation occur. Previous work has shown that pharmacological induction of hypoxia-inducible factor (HIF), a global transcriptional regulator of the hypoxic response, by prolyl hydroxylase inhibitors (PHDi) is protective in murine models of colitis. This appears to involve increased epithelial barrier function and restitution. Little is known about the role of HIF in mucosal wound healing. In a series of *in vitro* assays we identified induction of integrin $\beta1$ (ITGB1) during hypoxia. As integrins play critical roles in epithelial wound healing, we hypothesised that HIF activation accelerates epithelial restitution.
AIMS&METHODS: Employing chemically-induced Trinitrobenzene sulfonic acid (TNBS) murine models of colitis, our aims were to 1) investigate the relative induction of ITGB1 in epithelial cells with the mucosal protection afforded by PHDi, 2) examine the efficacy of PHDi with oral and systemic delivery. Colitis was induced in C57/Blk6 mice by rectal instillation of TNBS. Disease severity was monitored endoscopically over 7 days. At the peak of disease, as measured by endoscopy, mice received PHDi ([5mg/Kg] Akebia-4924, Aerpio Therapeutics) by i.p. injection or oral gavage. Mucosal healing was monitored and mice were euthanised at daily timepoints, where tissue was harvested for qPCR and western blot analysis.
RESULTS: TNBS colitis led to a significant increase in mucosal ITGB1 transcript and protein (7-fold increase). Integrin induction was most prominent in the epithelium (3-fold). A clear association (R2=0.78) between peak ITGB1 expression and mucosal recovery as measured by endoscopy score was observed across all groups. Mice treated with PHDi demonstrated increased epithelial HIF expression and an earlier, increased induction of ITGB1, which led to mucosal healing by day 7. Administration of PHDi by oral gavage led to a localisation of HIF and ITGB1 expression to the GI tract, with reduced HIF expression in the lungs, kidney and heart compared to i.p. injection.
CONCLUSION: These results suggest that epithelial HIF activation, through oral delivery of PHDi, promotes mucosal healing by accelerating the induction of ITGB1 expression in the epithelium and may represent a new therapeutic strategy for the management of IBD.

P912 THIOPURINE METABOLITES MEASUREMENT MORE EFFECTIVE IN GUIDING IBD MANAGEMENT WHEN DONE DURING DISEASE FLARE AS SUPPOSED TO DURING REMISSION.

T. A. Tandiari[1,*], G. D. Eslick[2]. [1]*Department of Gastroenterology and Liver services, Concord Repatriation Hospital,* [2]*Department of Surgery, The Whiteley-Martin Research Centre, Sydney, Australia*

INTRODUCTION: In the setting of inflammatory bowel diseases (IBD), measurement of the thiopurine metabolites; 6-thioguanine nucleotide (TGN) and 6-methyl mercaptopurine (MMP) has been proposed to help explain the failure of therapeutic efficacy and toxicity. The levels associated with efficacy is within 235 to 450 pmol/8x10^8 for 6-TGN and hepatotoxicity for 6MMP is >5700 pmol/8x10^8. There is a scarcity of guidelines in terms of the timing of measurement
AIMS&METHODS: AIMS
The aims of this analysis are to determine the effect of measuring thiopurine metabolites on subsequent management strategy during disease flare and remission and to compare metabolite-based thiopurine dosing versus weight-based dosing.
METHODS
Metabolites were prospectively performed on consecutive IBD patients taking thiopurines and their medical records reviewed. Disease activity at the time of metabolite measurements (categorised to ''flare'' or ''remission'' based on blood tests, endoscopy and physician assessment) and any subsequent management decision (thiopurine dose increase/adjust, use of allopurinol, therapy escalation, no action) were assessed. Weight based dosing (calculated at 1mg/kg 6-Mercaptopurine, 2mg/kg Azathioprine) were compared to metabolites-determined thiopurine maintenance dose.
RESULTS: In total, 30.9% of patients (44/142) reviewed were on thiopurines and 126 metabolites levels were measured between the years 2008 to 2012. Of these, 47.6% (60/126) were done during disease flare and 52.3% (66/126) during remission. Measurement of thiopurine metabolites was subsequently followed by increasing/adjusting thiopurine dose in 38% (23/60) during flare and 13.6% of tests (9/66) during remission ($p<0.001$). 15% (9/60) and 4.5% (3/66) of patients were identified as metabolite 'shunters' and started on allopurinol during flare and remission, respectively ($p<0.001$). Therapy escalation (ie. biological agent, drug trial, surgery) followed metabolites measurement in 20% (12/60) during flare and 0% of tests (0/66) during remission. No action was taken after 26.6% (16/60) and 81.8% (54/66) ($p<0.001$) of tests when done during flare and remission, respectively. 68% (30/44) of patients were on a lesser thiopurine dose when determined by metabolites level as supposed to weight. On average, patients on 6-MP were taking 48% less (71.2% less on 6-MP/allopurinol) and patients on azathioprine 27.1% less dose (70% lower on azathioprine/allopurinol).
CONCLUSION: Measurement of metabolites level during IBD flare plays a useful role prior to management change. Metabolite-based thiopurine dosing may allow more patients to be on thiopurine due to potentially less toxicity risk.

P913 SERUM VITAMIN D LEVELS IN INFLAMMATORY BOWEL DISEASE, EFFECT OF ORAL SUPPLEMENTATION

V. Kojecky[1,*], T. Salek[2]. [1]*Interni klinika,* [2]*Dep. of clinical biochemistry, Krajska nemocnice T Bati a.s. , Zlin, Czech Republic*

INTRODUCTION: Vitamin D (vitD) has multiple physiologic effects. Deficit may predispose to inflammatory bowel disease (IBD) or disease activity. Epidemiology of vitD levels was studied on relatively small sample sizes and little information is available on effect of oral supplementation and optimal dose in IBD.
AIMS&METHODS: Aim of this study was to assess levels of vitD in patients with inflammatory bowel disease in late winter with and without vitD supplementation.
Methods: Study included 126 IBD patients (91 Crohńs disease [CD], 35 ulcerative colitis [UC]). Serum 25 hydroxyvitamin D (25OHD) levels were determined by chemiluminescent assay (cut off > 75 nmol/l) during late winter (February to April). Demographic data and information dealing with vitD supplementation, steroid therapy and IBD were retrospectively obtained from patients electronic database.
RESULTS: Group of 52 women and 74 men, mean age 39.3 ± 15.2 years, duration of the disease 8.5 ± 7.4 years was studied. Active disease was present in 22.2 % CD and 19.2 % UC, steroid therapy in 15% patients (prednisone mean dose 11.7± 6.1mg/day). Mean 25OHD level was 51.8 ± 6.8 nmol/l in unsubstituted group without difference between men and women (p=0.57), CD and UC (p=0.53), on /off steroids (p=0.01), disease activity (p=0.27) and did not correlated with age (p =0.89) or disease duration (p=0.38). Only 13.8% subjects had normal levels of 25OHD and in 57.4 % of patients were levels < 50 nmol/l. 32 patients recieved oral cholecalciferol (mean 25OHD 56.6 ± 18.7 nmol/l) in dose 1337 ± 961 IU/day. In 41% was deficit relevant (< 50 nmol/l). There was no significant difference between levels in supplemented and unsupplemented group (p= 0.27). 25OHD levels do not correlated with supplementation dose of vitD (p= 0.31).
CONCLUSION: Vitamin D deficit is very common in IBD patients in late winter. Oral vitamin D supplementation even in doses about 1300IU/day has no significant influence on plasmatic levels. This result supports recommendation of higher supplementation dose in patients with IBD. Insufficient patients compliance must be however taken into account in such situation.

P914 CLINICAL PHARMACOLOGY AND SAFETY OF AMG 181, A HUMAN ANTI-A4B7 ANTIBODY FOR TREATING INFLAMMATORY BOWEL DISEASES

W.-J. Pan[1,*], B. Sullivan[2], W. Rees[3], C. Evangelista[2], D. Doherty[1], P. Prince[1], K. Reynhardt[3], K. Zhou[4], D. Han[5], J. Lee[2], Z. Yu[2], D. Borie[6]. [1]*PKDM, Amgen Inc., Seattle,* [2]*Medical Sciences, Amgen Inc., Thousand Oaks,* [3]*Medical Sciences, Amgen Inc., Seattle,* [4]*Biostatistics, Amgen Inc., South San Francisco,* [5]*California Clinical Trials, PAREXEL International, Glendale,* [6]*Clinical Development, Amgen Inc., Thousand Oaks, United States*

INTRODUCTION: AMG 181 is currently in Phase 2 clinical trials for treating subjects with Crohn's disease (CD) and ulcerative colitis (UC).
AIMS&METHODS: To evaluate the safety and pharmacokinetics/pharmacodynamics (PK/PD) of AMG 181 in healthy volunteers (HVs) and CD and UC, we have conducted a randomized, double-blinded, placebo-controlled, ascending multiple-dose study. 36 male HVs (age 18-44 yr, weight 57-113 kg) were randomized 6:2 to receive AMG 181 (7, 21, 70, or 210 mg) or placebo SC monthly for 3 months. 8 CD and 8 UC subjects were to be randomized 3:1 into 4 groups (N=4/group) to receive AMG 181 (21 or 210 mg) or placebo SC monthly for 3 months. Subjects were followed for 3-9 months after the last dose. AMG 181 PK and binding anti-AMG 181 antibodies (ADAs) were quantified. ADA positive samples were analyzed for neutralizing anti-AMG 181 antibodies (nADA) using a cell based assay. Blood was collected to assess $\alpha_4\beta_7$ receptor occupancy (RO) and CD4+ T cell counts using a validated whole blood 6-color flow cytometric assay with complete blood cell counts obtained from a hematology analyzer.
RESULTS: In HVs (completed), time to C_{max} was 1-14 days after dosing, with 1.22-2.03-fold accumulation from Dose 1 to 3. Both C_{max} and $AUC_{(0–4weeks)}$ increased dose-proportionally within the 21-210 mg dose range. The linear elimination half life was 30 (range: 20-46) days. The target-mediated disposition phase occurred at concentrations <1 μg/mL. The $\alpha_4\beta_7$ RO on CD4+ naïve T cells was maintained ~80-90% at 7 mg for 3 months, and >90% for 3.5, 5, and 7

months at 21, 70, and 210 mg, respectively. Absolute counts of CD4+ total, naïve, or memory T cells did not change significantly from baseline. Two HVs tested ADA positive for binding and neutralizing antibodies, and were followed until negative. To date, the AMG 181 PK profiles from the enrolled UC subjects (N=4; on-going) were contained within the range observed in HVs under the same doses. No ADAs were detected in UC. Blinded safety data showed no AMG 181-related serious adverse events, deaths, dose-limiting toxicities, or withdrawals due to adverse events. No clinically significant changes in electrocardiograms or neurological examinations were observed.
CONCLUSION: The safety and PK/PD profiles of AMG 181 under once-a-month multiple fixed SC doses of 7 to 210 mg have supported its further clinical development in Phase 2 clinical trials in UC and CD.

INTRODUCTION: The human monoclonal anti-IL-23 antibody AMG 139 has been developed for treating inflammatory diseases. It is in Phase 2 clinical trial in Crohn's disease (CD) subjects (Clinicaltrials.gov: NCT01714726).
AIMS&METHODS: To evaluate safety, pharmacokinetic/pharmacodynamic (PK/PD), and effects of AMG 139, we conducted 2 randomized, double-blind, placebo controlled studies. In the single-ascending-dose (SAD) study (NCT01094093; completed), 56 healthy volunteers (HV) and 17 psoriasis (PsO) subjects received AMG 139 or placebo (PBO) (6:2 HV; 3:1 PsO) subcutaneously (SC; 7 [HV only], 21, 70, or 210 mg) or intravenously (IV; 210 [HV only], 420 [HV only], or 700 mg). In the multiple-ascending-dose (MAD) study (NCT01258205), AMG 139 or PBO (6:2) was administered once-a-month for a total of 3 doses to 40 HV at 70, 210, 420, or 700 mg IV or 210 mg SC, and will be administered to 8 CD subjects (3:1; on-going) at 210 or 700 mg IV. Safety, PK/PD, anti-AMG 139 antibodies (ADAs), psoriasis area severity index (PASI; single-dose), and Crohn's disease activity index (CDAI; multiple-dose) were measured.
RESULTS: In the SAD study, AMG 139 PK was linear within the 21-700 mg range (half-life=22-37 days; SC bioavailability 64-86%). AMG 139 effects in PsO was achieved as PASI 90 to 100 was reached by Day 85-113 and fewer differentially regulated genes were observed between lesional and nonlesional tissues vs. PBO. AMG 139 also led to decreased serum IL-22, which was typically higher in PsO vs. HVs. In the MAD study, AMG 139 accumulated between 1.51- to 2.15-fold from Dose 1 to 3. Preliminary blinded evaluations of the ongoing CD part of the study indicate PK in CD to be similar to HV. Clinical response was determined by decreases in CDAI, serum C-reactive protein, and fecal calprotectin. No ADAs, serious adverse events, or deaths have been reported in either study.
CONCLUSION: Initial assessments of available PK/PD and safety data in HV, PsO, and CD support further testing of AMG 139 in subjects with inflammatory diseases.

P916 A MULTICENTER RANDOMIZED DOUBLE BLIND PLACEBO CONTROLLED TRIAL TO EVALUATE THE EFFICACY OF A PROBIOTIC PREPARATION AS MAINTENANCE THERAPY IN PATIENTS WITH ULCERATIVE COLITIS.

Y. Suzuki[1,*], N. Yoshimura[2], T. Katsuno[3], K. Fukuda[4]. *[1]Division of Gastroenterology, Department of Internal Medicine, Sakura Medical Centre, Faculty of Medicine, Toho Unversity, Chiba, [2]Department of Internal Medicine, Social Insurance Central General Hospital, Tokyo, [3]Department of Internal Medicine, Chiba University, Chiba, [4]Department of Gastroenterology, St Luke's International Hospital, Tokyo, Japan*

INTRODUCTION: Probiotics are live microorganisms which when administered in appropriate amounts are expected to produce therapeutic effects in the gut. Accordingly, hitherto, we have reported that probiotics have significant therapeutic effect in the prevention of relapse of ulcerative colitis (UC), notably patients who were found not to have adequate gut microbiota cluster.
AIMS&METHODS: In a multicentre, double blind placebo controlled setting, we were interested to determine if a commercially prepared probiotic called BIO-THREE has efficacy in the prevention of UC relapse. Each tablet of BIO-THREE contained 2mg of Streptococcus faecalis T-110, 10mg Clostridium butyricum TO-A and Bacillus mesenterium TO-A. Outpatients with quiescent UC (n=251) were recruited at 4 medical institutions. Faecal samples from these 251 patients were examined by the "Terminal Restriction Fragment Length Polymorphism" (T-RFLP), which is a molecular biology technique for profiling microbial communities. Additionally, we were interested to determine if patients' faecal microbiota had a high ratio of Bifidobacterium, which was an exclusion criterion in this study. Patients were randomly assigned to two groups: receiving 9 BIO-THREE tablets per day for 12 months or 9 placebo (lactose) tablets per day for 12 months. Patients in both arms could continue with their ongoing medications if had started well in advance of entry. Patients' symptoms were evaluated at every hospital visit up to 12 months. Patients' faecal samples were again examined after 12 months.
RESULTS: Among the 251 patients who were screened for eligibility, 170 were excluded because T-RFLP showed their faecal microbiota to have a high ratio of Bifidobacterium. Eighty-one patients were available for evaluation, and 5 patients were excluded for not adhering to the treatment protocol. The overall rates of sustained clinical remission after 12 months were 74.4% in the BIO-THREE group and 70.3% in the placebo group. The Kaplan-Meier analysis did not show any significant difference between the two groups. However, when patients under 45 years of age were considered, the rates of sustained clinical remission after 12 months were an 83.3% in the BIO-THREE group and 53.6% in the placebo group (P=0.034).
CONCLUSION: In this multicenter placebo controlled trial, the probiotic BIO-THREE showed significant efficacy in the prevention of UC relapse in young patients who had their faecal microbiota not to contain a high ratio of Bifidobacterium as determined by T-RFLP.

P917 CIRCULATING B CELL SUBSETS CORRELATE WITH CLINICAL RESPONSE TO ANTI-TNF THERAPY IN IBD

Z. Li[1,2,*], on behalf of IBD group of Catholic University of Leuven, S. Vermeire[2], D. Bullens[1], M. Ferrante[2], K. Van Steen[2,3], M. Noman[2], P. Rutgeerts[2], J. L. Ceuppens[1], G. Van Assche[2], IBD group , Catholic University. *[1]Clinical Immunology Unit, [2]IBD group, Catholic University of Leuven, Leuven, [3]Dept of Bioinformatics -Statistical Genetics, Université de Liège, Liège, Belgium*

INTRODUCTION: Various immune disorders, such as systemic lupus, Sjögren's syndrome and rheumatoid arthritis (RA), are associated with marked reductions of B-cell subtypes, notably of IgM^+CD27^+ pre-switched B cells , and anti-TNF therapy specifically upmodulates this population in RA. In active Crohn's disease(CD) and ulcerative colitis (UC) Ig M memory and $CD5^+$ B cells decrease. An increase in mucosal $CD19^+$ B cells in CD predicts long remission after Infliximab(IFX) therapy. We aimed to study the kinetics of B cell subsets during IFX therapy in patients (pts) with IBD.

AIMS&METHODS: Whole blood was taken from healthy controls (HC, n= 15) and pts with IBD (9 UC, 42 CD) before or after start of IFX (5mg/kg IV 0-2-6 and q8 wks). N=28 and 23 before therapy(BT) and after therarpy(AT). B cell subsets were assessed by flow cytometry for CD19, CD5,CD27, IgD and IgM. Assessments of symptoms, endoscopic healing and histological improvement were used to classify pts as responders (RS, n=17) or non-responders (NRS, n=6). To monitor biological response to IFX, serum C-reactive protein (CRP) was collected.
RESULTS: Active IBD pts had lower levels of circulating $CD19^+$, $CD5^+CD19^+$, total memory and pre-switched B cell subsets compared to HC (Table1). IFX therapy increased these 4 populations above and decreased post-switched memory B cells in RS. NRS had lower levels of the 4 populations than RS during after IFX therapy. CRP negatively correlated with $CD5^+$, 27^+memory, IgM^+CD27^+ pre-switchedmemory B cells(r=-0.47, p=0.01;-0.67,0.01; -0.51,0.01), and positively with 27^-naïve, IgD^+27^-naïve, $IgM^-IgD^-27^+$ post-switched B cells (r=0.32, p=0.03; 0.31,0.04; 0.30,0.04) respectively.
Table 1

Mean±SEM	HC	BT	RS	NRS	
(p value)		(p value vs. HC)	(vs. HC, BT)	(vs. HC,BT,RS)	UNIT
CD19+	0.25±0.04	0.16±0.02 (0.02)	0.25±0.04 (0.99,0.02)	0.15±0.02 (0.02,0.94,0.02)	10e9/L blood
CD19+ CD5+	6.66±0.85	2.44±0.47 (<0.001)	12.56±2.32 (0.03, <0.001)	2.03±0.69 (0.004, 0.3859,0.02)	% of CD19
Naive	67.16±2.34	72.11±3.01 (0.29)	68.43±4.56 (0.81,0.49)	73.36±3.47 (0.17, 0.85,0.55)	% of CD19
Memory	32.55±2.24	23.74±2.27 (0.01)	34.13±4.52 (0.76,0.03)	16.69±2.67 (0.0007, 0.067,0.03)	% of CD19
Pre-Switched	47.42±3.19	36.11±3.26 (0.03)	53.86±2.73 (0.13, <0.001)	41.99±5.512 (0.39, 0.44,0.04)	% of CD19+ CD27+
Post-Swtched	44.86±3.25	53.33±3.48 (0.06)	40.68±3.69 (0.42,0.02)	31.58±4.12 (0.03, 0.009,0.12)	% of CD19+ CD27+

CONCLUSION: $CD5^+$, pre-switched and total memory B cells in active IBD pts are lower than in healthy controls, and increases correlate with clinical and biological response to IFX, suggesting a role for these cells in IBD associated inflammation and in the molecular response to anti TNF therapy.

P918 CHARACTERISTICS OF CMV ENTEROCOLITIS IN PATIENTS WITH OR WITHOUT INFLAMMATORY BOWEL DISEASE

A. Y. Seo[1,*], C. M. Shin[1], Y. H. Choi[2], J. P. Im[2], D. H. Lee[1], N. Kim[1], Y. S. Park[1], H. Yoon[1]. [1]*Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si,* [2]*Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: The objective is to evaluate the differences in clinical characteristics of CMV enterocolitis with or without inflammatory bowel disease (IBD).
AIMS&METHODS: From 2003 to 2013 at Seoul National University Bundang Hospital and Seoul National University Hospital, a total of 84 patients with symptoms including hematochezia or diarrhea or abdominal pain diagnosed as CMV enterocolitis based on the pathologic findings were reviewed retrospectively.
RESULTS: Among the 84 patients, 26 had IBD [21 with ulcerative colitis (UC), 4 with Crohn's disease and 1 with Behcet's colitis] treated with steroids or other immunosuppressive agents. CMV enterocolitis in patients without IBD (n = 58) was mainly associated with immunocompromised or critically-ill non-immunosuppressed conditions. As for symptoms, hematochezia (84.6 % and 34.5 % in IBD and non-IBD groups, respectively) and weight loss (30.8 % and 5.2 %) were more common in IBD group than non-IBD group (all *P*-values < 0.01); fever was a common symptom in non-IBD group (11.5% and 50.0 %, $P < 0.001$). Non-IBD group showed a higher positivity of CMV antigenemia testing, which was not statistically significant (58.3 % and 82.4 %, $P = 0.097$). Endoscopic findings were varied, but not different between the two groups. In patients with UC (n = 21), 17 patients (80.9 %) were treated with antiviral agents, but 6 of them (35.3 %) underwent total proctocolectomy despite antiviral therapy; spontaneous remission occurred in 3 out of 4 patients who were not given antiviral agents and 1 patient had undergone total proctocolectomy. Forty-seven patients (81.0 %) in non-IBD group were treated with antiviral agents, but 19 patients (40.4 %) died of underlying disease; 7 out of 11 patients (63.6 %) who did not receive antiviral treatment recovered spontaneously.
CONCLUSION: CMV enterocolitis sometimes can cause serious illness and be associated with poor outcomes. However, it also can be cured naturally in both groups of patients who have IBD or not.

P919 PPIS ARE ASSOCIATED WITH HIGHER C. DIFFICILE INFECTION IN CRITICALLY ILL PATIENTS COMPARED TO H2RA

C. S. Eun[1], H. S. Kim[1,*], D. S. Han[1], S. M. Kim[1], K.-S. Yoo[1]. [1]*Hanyang University Guri Hospital, Guri, Korea, Republic Of*

INTRODUCTION: Proton pump inhibitors (PPI) and histamine-2 receptor antagonists (H2RA) are commonly prescribed for stress ulcer prophylaxis (SUP) among critically ill patients. Several studies suggested that the use of PPI is a potential risk factor for *Clostridium difficile* infection (CDI). We compared the CDI incidence of PPI treatment group and H2RA group for SUP in critically ill patients.
AIMS&METHODS: The aim of this study was to compare the CDI incidence of PPI treatment group and H2RA group for SUP in critically ill patients. From August 2005 to July 2012, the incidence of CDI were retrospectively analyzed in patients more than 18 years of age who were directly admitted and stayed more than 3 days in ICU. Patients who received gastric acid suppressants less than 3 days or crossover use were excluded. CDI was diagnosed when patients complained diarrhea with any positive results in *C. difficile* toxin assay, stool culture or endoscopy. SUP-related CDI was defined as a CDI diagnosed during SUP. Patients demographic and clinical data were analyzed to find potential risk factors for SUP-related CDI.
RESULTS: Among 1,005 patients (444 patients received PPI and 561 received H2RA) enrolled, 48 patients (4.8%) were diagnosed as a SUP-related CDI. The incidence of SUP-related CDI was higher in patients receiving PPI than in patients receiving H2RA (6.73% vs 1.82%). PPI use relative to H2RA (OR 2.67; CI95 1.25-5.72; p=0.012) and diabetes mellitus (OR 2.13; CI95 1.07-4.23; p=0.031) were independent risk factors for SUP-related CDI.
CONCLUSION: Our study showed PPIs are associated with higher risk of SUP-related CDI compared to H2RA in critically ill patients.

P920 EFFICACY OF RIFAXIMIN COMPARED TO CIPROFLOXACIN IN THE TREATMENT OF TRAVELER'S DIARRHEA: A META-ANALYSIS

J. P. G. Malenab[1,*], Ma Fatima, Sabaten Sophia ZamoraMDMD. [1]*Gastroenterology, Manila Doctors Hospital, Manila, Philippines*

INTRODUCTION: Background: Flouroquinolones are the mainstay of treatment for traveler's diarrhea (TD) but its wide spread use have led to increased resistance rates especially in Asia. Rifaximin, a non-absorbable antibiotic for TD caused by noninvasive strains, has significant efficacy against placebo, good tolerability profile and with no relevant bacterial resistance.
AIMS&METHODS: Objectives: This study aims to determine the efficacy of Rifaximin compared to Ciprofloxacin in the treatment of TD by evaluating time to last unformed stools (TLUS), clinical wellness and treatment failure.
Methods: Extensive article search was done using Medline/Pubmed; Cochrane central register for Controlled trials, EMBASE, HERDIN; outcomes analyzed using Review Manager software and assessed for heterogeneity.
RESULTS: Results: Three (3) randomized, double-blind, prospective clinical trials were reviewed. A total of 610 patients were included; 354 and 256 in the rifaximin and ciprofloxacin arm. The TLUS favors ciprofloxacin (MD 3.20 95% CI [-1.58, 7.98], $I^2 = 41\%$); Clinical wellness favors rifaximin (RR=0.96, 95% CI [0.89, 1.03], $I^2 = 0\%$); and low Treatment failure favors ciprofloxacin (RR=1.28, 95% CI [0.50, 3.27], $I = 68\%$). However, the prevalence of pathogens causing TD differs between geographic locations and up to 40% of cases are of unknown etiology despite comprehensive microbiological evaluation.
CONCLUSION: Conclusion: There is a trend towards earlier time to unformed stools and less treatment failure in the ciprofloxacin arm, while there is a trend towards rifaximin in earlier clinical wellness in the setting of traveler's diarrhea. However, more studies should be done regarding geographic location, enteropathogens involved and resistance patterns.

P922 FECAL MICROBIOTA TRANSPLANTATION FOR RECURRENT CLOSTRIDIUM DIFFICLE IN PATIENTS WITH PROLONGED IMMUNOSUPPRESSION

M. Fischer[1,*], D. K. Rex[1], G. K. Cook[1]. [1]*Medicine, IUPUI, Indianapolis, United States*

INTRODUCTION: Safety and efficacy of fecal microbiota transplantation (FMT) is not known in immunosuppressed patient. The only published prospective control trial excluded patients with immunodeficiency due to concerns of potential bacterial translocation and infectious complications. Immunodeficiency is associated with high burden of C. difficile infection (CDI).
AIMS&METHODS: Between 5/2012 and 2/2013, a total 33 patient underwent fecal microbiota transplantation for recurrent CDI using patient selected donors at our institution. Of these, 12 patients were immunosuppressed at the time of the procedure and during the follow-up period (1 month). Patients received vancomycin (125 mg po four times per day) for 14 days stopping it 48 hours before FMT. Following a bowel lavage with 4L of polyethylene glycol, emulsified fresh stool (<6 hrs.) was delivered in the terminal ileum or cecum during colonoscopy. Patient follow-up consisted of stool testing for C. difficile by PCR and recording of stool frequency, consistency, and adverse effects on days 7 and 30.
RESULTS:

Baseline characteristics of the patients	N = 12
Age – year (SD)	46 ± 17
Body mass index (SD)	27 ± 7
Female sex – N (%)	5 (42)
Use of PPI – N (%)	6 (50)
Median stool frequency (range)	5.5 (2-15)
Median CDI recurrences (range)	4 (3-7)
Previous failure of tapered vancomycin therapy (%)	11 (92)
WBC median (range)	6.9 (2.7-20.7)
Albumin –g/dl (SD)	3.7 ± 0.7

The underlying medical conditions requiring prolonged immunosuppression were the following: 3 patients with ulcerative colitis, 1 patient with ulcerative colitis and liver transplant for PSC, 3 patients with Crohn's disease, 2 patients with multivisceral transplant, 1 patient with multiple myeloma, 1 patient with lung transplant, and 1 patient with renal transplant. Immunosuppression included one of the following medications as a single therapy or in combination: azathioprine, prednisone, infliximab, tacrolimus, sirolimus, mycophenolate mofetil, and lenalidomide.
Stool test was negative for C. diff on day 7, and day 30 in 8 (75%) after 1 FMT, and in 11 (92%) patients after 2 FMTs. In comparison, the cure rate in patients without immunosuppression was higher 20/21 (95%) after 1 FMT (p=0.047). One patient became an asymptomatic carrier. One patient continued to have diarrhea despite CDI clearance. No significant adverse effects were reported.
CONCLUSION: FMT is a highly efficacious and safe therapy for recurrent CDI in immunosuppressed patients. A second stool infusion may more frequently be required in immunosuppressed patients for cure.

P923 ADULT ACUTE DIARRHOEA: IS RACECADOTRIL EFFECTIVE? ANSWER FROM A META-ANALYSIS

J.-M. Vetel[1], P. Baumer[2,*], P. Lehert[3]. [1]*Geriatric Service, Hospital, 72037 Le Mans,* [2]*Department of Gastroenterology, Saint-Antoine Hospital 75012, Paris, France,* [3]*Fucam, Louvain, Belgium*

INTRODUCTION:
The efficacy of racecadotril, an intestinal antisecretory drug acting *via* an enkephalinase inhibition, was reviewed in paediatric acute diarrhoea but not yet in adults.
AIMS&METHODS:
Aims: to estimate the effectiveness of racecadotril in the symptomatic treatment of acute diarrhoea in adults.
Methods: all randomised trials performed in adults suffering from acute diarrhoea with racecadotril as the studied group, whatever the control group. All pooled analyses were based on random-effects models. The only commun efficacy criteria was the duration of diarrhoea. According to available data, hazard ratio racecadotril / control with 95% confidence interval were adjusted for baseline predictors, calculated from individual raw data or estimated from Kaplan-Meier curves.
RESULTS:
Twelve randomised trials (2619 patients) met inclusion criteria. Results are summarized in the table. The diarrhoea duration in the racecadotril groups was significantly lower as compared to placebo groups and was not different as compared as in loperamide groups. The frequency of constipation in the racecadotril groups was not different as compared as in placebo groups and was significantly lower as compared to loperamide groups.

Criteria	Studies	N	population	Ratio	95% CI	*P*
Diarrhoea duration	*versus* placebo	5	1001	1.65	1.38 to 1.97	< 0.0001
	versus loperamide	7	1618	1.08	0.95 to 1.22	0.24
Constipation frequency	*versus* placebo	5	1070	1.02	0.29 to 3.57	0.97
	versus loperamide	7	1637	0.27	0.18 to 0.40	< 0.0001

CONCLUSION:
As compared to placebo, racecadotril induced a significant 65% reduction of the diarrhoea duration among one thousand adults. As compared to loperamide, diarrhoea was not significantly shorter but secondary constipation was significantly less frequent.

P924 IN PATIENTS WITH CLOSTRIDIUM DIFFICILE ASSOCIATED DIARRHOEA: DOES STOPPING PROTON PUMP INHIBITORS REDUCE RELAPSE?

K. Welch[1], M. Popescu[1], R. Cunningham[2], S. Cochrane[1,*], S. Lewis[1]. [1]*Gastroenterology,* [2]*Microbiology, DERRIFORD HOSPITAL, Plymouth, United Kingdom*

INTRODUCTION: Hypochlorhydydria due to proton pump inhibitor (PPI) therapy is associated with increased susceptibility and propensity to relapse from infection due to *Clostridium difficile*. We have done a retrospective audit of patients with *C difficile* - Associated Disease (CDAD) examining PPI use and any benefit achieved by stopping the PPI.
AIMS&METHODS: All patients with CDAD between 2010-12 were reviewed by infection control nurses who advised the attending doctors to stop any PPI therapy where a clear indication was not obvious. We have retrospectively audited patient's relevant baseline characteristics pertaining to other risk factors for CDAD, clinical outcome, length of hospital stay and PPI prescription at hospital discharge. In addition we followed patients up post discharge recording PPI prescription and further CDAD.
RESULTS: 99 patients with CDAD identified. No difference was seen regarding CDAD risk factors; antibiotic use, co-morbidity, immunosuppression, recent surgery, enteral feeding or place of residence.

PPI status at admission	None	Taking & not stopped	Taking & stopped
Number	47	25*	20*
Age mean (st dev)	76.7 (12.4)	69.2 (21.5)	73.4 (18.4)
LHS mean (st dev)	27 (26)	26.2 (23.4)	36.4 (32.8)
Died in hospital	7	-*	-*
At discharge :Number	40	25	20
Further diarrhoea C diff +ve	6 (15%)	4 (16%)	5 (25%)
Further diarrhoea C diff -ve	5 (12.5%)	1 (4%)	1 (4%)
Died	1	0	0

*7 patients taking a PPI died, thus were not discharged
No differences were seen between those patients who never took a PPI vs those who did irrespective if the PPI was stopped.
CONCLUSION: It was possible to stop PPI prescription in 44% of patients presenting with CDAD. We found no evidence of reduced recurrence of CDAD in patients who had stopped taking their PPI or had never taken it.

P925 TRENDS IN UPTAKE OF THE BOWEL CANCER SCREENING PROGRAMME IN THE EASTERN REGION OF ENGLAND

A. Field[1,*], M. Vogler[1], R. F. Logan[1,2]. [1]*Eastern Bowel Cancer Screening Hub, Nottingham University Hospitals Trust,* [2]*Nottingham Digestive Diseases Centre, Nottingham University, Nottingham, United Kingdom*

INTRODUCTION: Bowel cancer is more common in men than women with age-adjusted incidence in the UK being over 50% higher in men and mortality 63% higher. However uptake of the Bowel Cancer Screening Programme in England (BCSP) has been generally about 5% lower in men[1]. We have examined whether with increasing familiarity with the BCSP there have been changes in uptake of screening invitations over the past 4 -5 years.
AIMS&METHODS: Analysis of uptake of screening invitations by sex and 2 year age bands of people invited for screening by the Eastern Hub which covers the East of England and East Midlands (total population 10.6 million) between 1 Jan 2008 and 30 June 2012 by 6 month periods.

RESULTS: Over the 4.5 years >2.8 million invitations were sent by the Eastern Hub. For those aged 60-61 years uptake by men was 9-10% lower than that by women (uptake 60%) with no evidence of any change over the 4 years. In women uptake remained over 60% for the 62-63, 64-65 and 66-67 age bands with a small increase over time reaching 65% in 2012. In men uptake showed a steady increase with age such that by age 68-69 uptake was 3% lower than in women. For those aged 70-71 uptake in men was only 2% lower than in women and for those aged 72-73 and those aged 74 uptake was around 1-2% higher in men than women. This was partly accounted for by a decline in uptake in women to below 60%. Analysis of time trends in those over 70 was unreliable because of only partial roll-out ('age extension') of the BCSP to this group in the Eastern region.

Uptake

	60-61yr	62-63yr	64-65yr	66-67yr	68-69yr	70-71yr	72-73yr	74yr
Men	**51.2%**	**53.9%**	**56.4%**	**57.6%**	**56.9%**	**60.3%**	**61.5%**	**55.7%**
Women	**60.0%**	**61.5%**	**62.9%**	**62.2%**	**60.1%**	**62.3%**	**59.9%**	**54.5%**
All	**55.6%**	**57.7%**	**59.6%**	**60.0%**	**58.5%**	**61.2%**	**60.5%**	**55.1%**

CONCLUSION: While the small decline in uptake in women >70 years is a concern the increasing uptake in men with age is encouraging and suggests that the introduction of simpler screening approaches using faecal immunochemical tests will see substantial increses in uptake of the BCSP[2].

P926 HOW OFTEN IS BOWEL CANCER DETECTED FROM A POSITIVE 3RD KIT IN THE ENGLISH BCSP?

A. Field[1,*], M. Vogler[1], R. F. Logan[1,2]. [1]*Eastern Bowel Cancer Screening Hub, Nottingham University Hospitals Trust,* [2]*Nottingham Digestive Disease Centre, Nottingham University, Nottingham, United Kingdom*

INTRODUCTION: In the English Bowel Cancer Screening Programme (BCSP) subjects returning a weak positive kit (1-4 of the 6 windows positive) are invited to do a 2nd kit and if none of the windows are positive they are invited to complete a 3rd kit. If any windows are then positive subjects are referred for possible investigation; if no windows are positive subjects are discharged from that screening round. This testing algorithm has been criticised for making the screening process too prolonged thereby producing anxiety and drop-outs and the Scottish BCSP has abandoned asking for a 3rd kit on the grounds that the yield was negligible.

AIMS&METHODS: We have analysed the outcomes from the 3rd kits returned to the Eastern BCSP Hub from subjects invited for screening between 1 Jan 2011 and 31 March 2012.

RESULTS: Over this period over 850,000 subjects aged 60-74 yrs were invited for screening. 4% (20,021) completed 3 kits and of these 16% (3192) had a positive 3rdkit and were referred for further investigation. Of those investigated (2830) 4.4% (125) were found to have bowel cancer compared with 17.8% (298) with cancer found after a single kit and 8.1% (483) with cancer found after completing 2 kits. A further 7% and 12% completing 3 kits were found to have high and intermediate risk adenomas. The mean time from selection for screening to obtaining a definitive result for those completing 3 kits was 63 days compared to 34 days for those completing a single kit (95% of all subjects returning kits) and 49 days for those completing 2 kits (1% of all subjects returning kits).

Patient Test Outcome according to number of kits completed

1 kit (n=1673) 2 kits (n=5939) 3 kits (n=2830)
Cancer 298 17.8% 483 8.1% 125 4.4%
High-risk Adenoma 137 8.2% 589 9.9% 199 7.0%
Intermediate-risk Adenoma 246 14.7% 978 16.5% 336 11.9%

CONCLUSION: A significant number (14%,125/906) of bowel cancers are detected in those completing 3 kits but this is at the cost of having a screening episode prolonged to almost twice that for subjects obtaining a definitive result after one kit. The intended introduction of faecal immunochemical tests to replace guaiac faecal occult blood tests should allow the use of a simpler and shorter testing algorithm.

P927 RISK OF BOWEL CANCER INCREASES WITH NUMBER OF WINDOWS POSITIVE ON GUAIAC FAECAL OCCULT BLOOD TESTING

A. Field[1,*], M. Vogler[1], R. F. Logan[1,2]. [1]*Eastern Bowel Cancer Screening Hub, Nottingham University Hospitals Trust,* [2]*Nottingham Digestive Disease Centre, Nottingham University, Nottingham, United Kingdom*

INTRODUCTION: Bowel (colorectal) cancer screening programmes using a 6 window guaiac faecal occult blood test kits (gFOBt) are now in operation in the UK and in several countries in Europe and elsewhere. In the UK subjects returning kits with 5-6 windows positive are referred immediately for colonoscopy while subjects with only 1-4 windows positive are asked to repeat the gFOBt up to twice and are referred for colonoscopy only if one or more windows are positive on the repeat kits.

AIMS&METHODS: To determine the relationship between the number of positive gFOBt windows and subsequent cancer detection we have examined data collected by the Eastern Bowel Cancer Screening Hub covering the Eastern region of England (total popn. 10m) for the period Jan 2011-July 2012

RESULTS: Over this period more than 1.1million people aged 60-74yrs were sent gFOBt kits with 760,000 returning them. Of the kits returned 14020 were deemed abnormal and 12,198 subjects were investigated (>90% by colonoscopy). Overall cancer was detected in 1005 and 'high' risk adenomas in 1081. The table shows the cancer detection rate according to the number of windows positive on the *first* gFOBt kit returned.

	1 Window Positive*	2 Windows Positive*	3 Windows Positive*	4 Windows Positive*	5 Windows Positive	6 Windows Positive
Total Abnormals	4827	4202	1444	1196	1012	1339
Number investigated (n)	4310	3694	1257	1017	863	1057
Cancers Detected	191	219	128	134	123	210
%	4.4%	5.9%	10.2%	13.2%	14.3%	19.9%

*only referred for investigation if one or more windows positive on repeat gFOBt For subjects with only 1-4 windows positive on the first gFOBt kit the likelihood of returning a positive second gFOBt kit increased with the number of positive windows on the first kit and in these the cancer detection rate increased according to the total number of positive windows on both gFOBt kits.

CONCLUSION: These findings are consistent with occult blood loss from colorectal neoplasia being prolonged but variable over time. They also suggest that for bowel cancer screening programmes where the availability of colonoscopy is a major constraint a testing and investigation algorithm based on repeat testing of subjects with 'weak' positive results will result in higher cancer detection rates than a testing algorithm based on a single test for a defined colonoscopy capacity.

P928 REDUCED 5-YEAR MORTALITY IN SCREEN-DETECTED COLO-RECTAL CANCERS DIAGNOSED AT THE 1ST BIENNIAL ROUND OF A FIT-BASED MASS SCREENING PROGRAMME IN COMPARISON WITH NON-SCREENING CANCERS IN NORTHERN ITALY.

F. Parente[1], C. Vailati[1,*], E. Bonoldi[2], A. Ardizzoia[3], A. Ilardo[4], F. Tortorella[4], M. E. Pirola[5], M. Cremaschini[6], G. Achille[4]. [1]*Gastroenterology,* [2]*Pathology,* [3]*Oncology, A. Manzoni Hospital,* [4]*Preventive Medicine, Local Health Care Centre, Lecco,* [5]*Screening Unit, Regional Health Centre, Milan,* [6]*Epidemiology, Local Health Care Centre, Bergamo, Italy*

INTRODUCTION: Population-based colorectal cancer(CRC) screening programmes aim to reduce disease-related mortality by detection of cancers at an earlier stage and by removal of its precursors. To date, however, no study has specifically focused on the effect of a single FIT screening round with respect to a reduction in CRC-related mortality among average risk subjects.

AIMS&METHODS: We aimed to compare 5-year mortality rates of screen-detected CRCs with those of non-screening cancers diagnosed in the same northern Italian province. We determined tumour characteristics and mortality of asymptomatic CRCs detected by faecal immunochemical testing (FIT) at the 1st biennial round of mass screening programme of Lecco province addressed to 50-70 years old resident population of the province (78,083 individuals) and characterized by a FIT uptake of 50% and colonoscopy compliance of 92%. TNM stage at diagnosis, anatomical distribution of cancers along the colon and 5-year survival were compared with those of non-screening CRCs detected in the same age-range population during the screening period(January 2006-January 2008) as well as with those of CRCs diagnosed in our province in 2003-2004(pre-screening biennium), whose data were retrieved from the Regional cancer registry. Kaplan-Meyer survival estimates and Log-rank test for equality of survivor functions were used for statistical analysis.

RESULTS: Stage distribution significantly differed between screening and non-screening CRCs. Indeed, among screen-detected cancers 73% were stage A or B as compared to 43% and 40% among non-screening CRCs detected in the same or previous biennium, respectively. Cumulative 5-year CRC-related

mortality was significantly lower in screening CRC patients as compared to non-screening cancers detected in the same biennium (*19% versus 41%*, $p<0.001$) or in the biennium preceding screening implementation (44%). No significant difference in anatomical distribution of cancers nor in the presence of synchronous lesions were found between screening and non-screening CRC patients.
CONCLUSION: CRCs are detected at earlier stages in asymptomatic individuals with positive FIT compared to non-screening patients. As a consequence, the cumulative 5-year disease-related mortality rate among screened patients is significantly reduced, already from the 1st round of screening as compared to non-screening patients.

P929 THE POSITIVE PREDICTIVE VALUE OF FAECAL IMMUNOCHEMICAL BLOOD TEST FOR CANCER AND ADVANCED ADENOMA, BUT NOT FOR LOW-RISK ADENOMA, PROGRESSIVELY DECREASES WITH REPEATED SCREENING ROUNDS. A PILOT EXPERIENCE IN NORTHERN ITALY

D. Cereda[1,*], F. Radaelli[2], F. Parente[3], M. E. Pirola[1], C. Vailati[3], L. Bertizzolo[4], C. Crosta[5]. *[1]Asl Milano 1, Rho, [2]AO Valduce Como, Como, [3]AO provincia di Lecco, lecco, [4]Università degli Studi di Milano, [5]European Institute of Oncology, Milano, Italy*

INTRODUCTION: Colorectal cancer (CRC) screening programs based on a biennial faecal immunochemical blood test (FIT) are widely adopted in many European countries. Whether the positive predictive value (PPV) for either carcinoma or advanced adenoma decreases through repeated rounds of FIT is still a matter of debate. Sharp fluctuation of this value could have a great clinical and socio-economic impact.
AIMS&METHODS: We aimed to assess variations of PPV for CRC and advanced adenoma in subjects testing positive at repeated screening rounds of a Regional FIT-based mass screening program in Northern Italy, addressed to average-risk subjects aged 50-69 years, which has been running since 2006. In particular, we analyzed data from subjects participating to the CRC screening campaign in one large metropolitan area (Milan 1 area) from 2006 to 2012. The PPV of FIT for CRC, advanced adenoma and low- risk adenoma was calculated for tests performed at the 1st round and for those performed at 2nd and 3rd rounds in subjects with one or two previous negative tests.
RESULTS: A total of 274,165 FITs were done in 150,512 subjects during the study period. 55% of these tests were performed at the first round, 30% at the 2nd round, and 13% at the 3rd round. The FIT positivity rate progressively reduced from 6% in 1st round to 4.4% in the 3th round. Colonoscopy was performed in 12,715 patients; the adherence to colonoscopy remained consistent through different rounds of FIT (82% > 86%). The diagnosis of cancer showed a downward trend (6% in the 1st, 3% in the 2nd, 2% in the 3rd round); a similar trend was demonstrated for high risk adenoma (30% > 21% > 18%); conversely, low risk adenoma diagnosis remained unchanged (15% and 16%). As a result, the PPV for carcinoma or advanced adenoma progressively decreased, from 36% for the 1st round to 24% and 20% for the 2nd and the 3rd round, respectively. Otherwise, the frequency of a negative result at colonoscopy increased after each subsequent round of screening, from 43% in the 1st round to 53% and 57% in the 2nd and the 3rd round, respectively.
CONCLUSION: A substantial and progressive decrease of the PPVs of FIT for either cancer and advanced adenoma, but not for low-risk adenoma, was observed in subjects undergoing repeated rounds of FIT. More data after the 3th biennial FIT are needed to verify the capacity of our Regional CRC screening program to reduce CRC incidence.

P930 IMMUNOLOGIC FECAL OCCULT BLOOD TESTING (IFOBT) IN OPPORTUNISTIC SCREENING FOR COLORECTAL CANCER (CRC) – SINGLE CENTER EXPERIENCE IN 3571 PATIENTS

F. Renner[1,2,*], R. Emminger[2], C. Auzinger[1], B. Jagdt[1]. *[1]Internal medicine, [2]Central Laboratory, BHS Ried, Ried im Innkreis, Austria*

INTRODUCTION: Based on higher sensitivity and convenience at appropriate specificity iFOBT has replaced guajac FOBT in major CRC screening guidelines. Despite intense efforts to increase acceptance for health maintainance plan based CRC screening it still takes place oftenly as socalled opportunistic screening on the occasion of hospital contacts for a variety of reasons. In this mostly older and sicker patients frequently treated with anticoagulants iFOBT has not been evaluated so far. We therefore investigated prospectively performance (cut off values at different levels, sensitivity, specificity, NPV, PPV) for CRC and precancerous lesions.
AIMS&METHODS: All consecutive iFOBT results in a 10 month period were correlated with demoscopic data, colonoscopy findings as far as available (colonoscopy was on the decision of referring phycision) and anticoagulant medication. Standard statistical methods were applied.
RESULTS: Fecal samples of 3519 patients were studied. The mean age was 63,6 ± 35,3 years. 50,8 % were female. 2717 patients (77,2%) had negative iFOBT, 802 patients tested positive (22,8%) at the lowest cut off level of 50 ng/ml. In iFOBT positive patients 232 colonoscopies (28,9%), in iFOBT negatives 356 colonoscopies (13,1%) were performed. In those 588 endoscopies 17 CRC (2,9%) and 173 precursors (29,4%) were dedected. Performance characteristics are summarized at different cut off levels below.

CutOff Levels		50 ng/ml		75 ng/ml		100 ng/ml	
%	CI	%	CI	%	CI		
Sensitivity	for CRC	88.2	64 - 98	82.4	58 - 95	82.4	58 - 95
	for Precursors	48.6	41 - 56	41.0	34 - 48	32.4	26 - 40
Specificity	for CRC	62.0	58 - 66	66.7	63 - 70	71.6	68 - 75
	for Precursors	66.6	62 - 71	70.1	65 - 74	73.6	69 - 78
NPV	for CRC	99.4	98 - 100	99.2	98 - 100	99.3	98 - 100
	for Precursors	74.4	70 - 79	72.6	68 - 77	71.1	67 - 75
PPV	for CRC	6.5	4 - 10	6.9	4 - 11	8.0	5 - 13
	for Precursor	52.7	35 - 48	41.7	35 - 49	40.4	34 - 48

Anticoagulants and antithrombotic agents increased sensitivity at all cut off levels reaching 100% at 50 ng/ml for CRC.
CONCLUSION:
iFOBT is also highly effective in opportunistic screening. A cut off level of 50 ng/ml haemoglobin is recommended in this population. The extraordinary high negative predictive value for CRC may help to reduce the burden of colonoscopies especially in older patients where early detection and not secondary prevention is the major goal of CRC screening.

P931 SIGNIFICANT SUSCEPTIBILITY MARKERS FOR COLORECTAL CANCER (CRC) MAY INDICATE A SCREENING PRIORITY

G. Mahon[1,*], M. Pauly[1], B. Metzger[1], M. Dicato[1], A. Menzel[2], B. Weber[2]. *[1]Fondation recherche sur le cancer et maladies du sang, Centre Hospitalier, Luxembourg, [2]Recherche, Laboratoires Réunis, Junglinster, Luxembourg*

INTRODUCTION: Recommendations for screening for colorectal cancer (CRC) specify a colonoscopy at age 50 and if normal a repeat after 10 years. The yield of the follow-on colonoscopy in this setting is poor. There is a highly significant association between a SNP variant at the TGFBR1 (tumour growth factor beta, receptor 1) locus and CRC and we have suggested that TGFBR1 could be useful to screen for CRC (ASCO 2013, abstract e14591). We now present results on the association between variants of TGFBR1 and mutants at the GSTT1 (glutathione S-transferase theta 1) locus, and CRC and consider the implications for screening.
AIMS&METHODS: Tumour samples were obtained from 185 CRC patients and from 98 healthy control subjects, all Caucasian. After gDNA extraction, selected amplicons were amplified by PCR, followed by melting curve analysis. Samples were typed for the rs334348 SNP at the TGFBR1 locus and mutant vs. wild-type at the GSTT1 locus. Statistical significance was assessed using logistic regression. Sensitivity was calculated as the ratio of test-positive cases to total cases, and specificity as the ratio of test-negative controls to total controls.
RESULTS: The association between CRC and TGFBR1 variant was highly significant ($P<0.00005$) as was that of CRC with GSTT1 mutant ($P<0.00005$) in a multivariate analysis. For TGFBR1, contrasting homozygous variants (VV) versus heterozygotes plus homozygous normals (VN+NN) for CRC cases and controls, the sensitivity was found to be 43.2% and specificity 89.8%. Comparing TGFBR1 (VV+VN) with (NN) gave a sensitivity of 83.2% and a specificity of 45.9%. For GSTT1, the sensitivity and specificity were 49.7% and 83.7%. Contrasting TGFBR1 (VV+VN) or GSTT1 mutants with TGFBR1 (NN) and GSTT1 wild-type gave a sensitivity of 90.8% and a specificity of 35.7%.
CONCLUSION: There is a trade-off between sensitivity and specificity depending on how the TGFBR1 heterozygotes are considered. When they are combined with the homozygous normals, sensitivity is low and specificity is high; when combined with homozygous variants the sensitivity is high and specificity low. Sensitivity relates to the test's ability to identify positive results. Thus we conclude that the heterozygotes should be included with the homozygous variants in any eventual screening test. Including GSTT1 raises the sensitivity. Using a test to predict cancer risk would be cost-saving and easier on patients and could possibly, in patients at risk, call for a colonoscopy sooner and more often while increasing yield. A prospective clinical trial to prove the cost-benefit is indispensable.

P932 BODY MASS INDEX AS A PREDICTOR OF ADVANCED COLONIC NEOPLASIA

H. J. Kim[1,*], Y. S. Park[1,2], H. J. Kwon[1], J. H. Lim[1], K. J. Park[1], C. M. Shin[1,2], J.-H. Hwang[1,2], J.-W. Kim[1,2], S.-H. Jeong[1,2], N. Kim[1,2], D. H. Lee[1,2]. *[1]Departments of Internal medicine Seoul National University Bundang Hospital, Seongnam, [2]Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Colorectal cancer (CRC) was the third frequent cancer in Korea. There are several risk factors such as male sex, older age, smoking and family history of colon cancer. And advanced colon polyp larger than 1cm is a definite precancerous lesion of CRC. Recently, obesity is thought to be a risk factor of CRC and advanced colon polyp.

AIMS&METHODS: From this background the aim of cross-sectional study to determine the association BMI and advanced colorectal neoplasia. A total of 256 patients with advanced colorectal neoplasia who were diagnosed with colonoscopy during between May, 2004 and December, 2011 were included in this study. An advanced colorectal neoplasia is defined as large (≥1 cm) adenoma or adenocarcinoma. We compared these patients to control group consisted of 217 subjects with normal colonoscopic finding during the same period.
RESULTS: Of the 256 patients, men were 132 (51.6%) and mean age was 56.4 ± 12.3 years. The advanced colorectal neoplasia had a larger percentage of males, alcohol consumption and current smokers. Body mass index (BMI, kg/m^2) and age were significantly higher in advanced colorectal neoplasia than control group in female group. However, there was no significant difference except age in male group. Multiple logistic regression analysis identified overweight (BMI 23.0–24.9 kg/m2, odds ratios (OR) = 2.022) and obesity (BMI ≥ 25 kg/m2, OR = 2.383) as independent risk factors for advanced colorectal neoplasia.
CONCLUSION: BMI looks like to be an independent risk factor for advanced colonic neoplasia and the screening colonocoscopy could be recommended earlier in this group.

P933 BLEEDING-RELATED SYMPTOMS IN COLORECTAL CANCER: A 4-YEAR NATIONWIDE POPULATION-BASED STUDY

J. P. Hreinsson[1,*], J. G. Jonasson[2], E. S. Bjornsson[1]. [1]*Department of Gastroenterology,* [2]*Department of Pathology, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland*

INTRODUCTION: Little is known about the major presenting features of patients with colorectal cancer in a population-based setting, especially regarding bleeding-related symptoms.
AIMS&METHODS: We aimed to determine the proportion of colorectal cancer patients presenting with bleeding-related symptoms, compare bleeders and non-bleeders, and to explore the role of anticoagulants in bleeders. This was a nationwide, population-based, retrospective study, including all colorectal cancers diagnosed in Iceland from the year 2008-2011. Medical records were reviewed and relevant data collected. Bleeding-related symptoms were defined as overt bleeding, iron deficiency anemia or a positive fecal occult blood test. Obstructive symptoms were defined as a confirmed diagnosis of ileus and dilated intestines on imaging.
RESULTS: Data were available for 472/496 (95%) patients, males 51%, with a mean age of 69 (±13) years. In all, 348 (74%) patients had bleeding-related symptoms, and of those 348 patients 208 (60%) had overt bleeding. Bleeders were more likely to use warfarin than non-bleeders 9% vs. 3% (p = 0.031). The use of low-dose aspirin was the same (24%) in bleeders and non-bleeders. Bleeders were less likely than non-bleeders to have metastasis at diagnosis, 19% vs. 34% (OR 0.31, CI 0.15-0.64), respectively. Overt bleeders were less likely than non-bleeders to have obstructive symptoms, 2% vs. 16%, respectively, (OR 0.13, CI 0.042-0.42). Occult bleeders were more likely to have proximal cancer (69%) than overt (17%) and non-bleeders (44%) (p < 0.0001).
CONCLUSION: The majority of patients with colorectal cancer present with bleeding-related symptoms. Bleeders with colorectal cancer present earlier than non-bleeders. Warfarin use may induce bleeding in some patients, resulting in an earlier diagnosis.

P934 HIGH IMPACT REGIONAL COLORECTAL CANCER SCREENING PROGRAM OF AVERAGE RISK POPULATION IN NORTH-EASTERN ITALIAN REGION OF FRIULI-VENEZIA-GIULIA

M. Marino[1,*], M. Bulajic[1], D. Berretti[1], R. Maieron[1], I. Lodolo[1], M. Zilli[1]. [1]*Gastroenterology Unit, UNIVERSITY HOSPITAL OF UDINE, Udine, Italy*

INTRODUCTION: Average-risk population screening for colorectal cancer (CRC) using fecal occult blood tests is aimed to detecting cancer in an early stage. We analyze data of 3 consecutive years experience of Bowel Cancer Screening Program (BCSP) of subjects from North-Eastern Italian Region of Friuli-Venezia-Giulia.
AIMS&METHODS: We evaluate data from 2009-2011 of 450.153 subjects referred for BCSP, aged 50-69 years, invited to complete one single qualitative immunochemical fecal test (FIT, cut-off level 100ng/ml) every 2 years. Only in 2009 the BCSP decided to give priority to subjects aged 60-69 (about 70% of all FIT invitations). Those positive were referred to colonoscopy in 11 regional hospitals and detected polyps were removed in most of the cases in the same session (88.4%).
RESULTS: We report the overall adherence to FIT being 147.485 subjects (32.76%), which resulted positive in 8060 cases (5.46%). The adherence to colonoscopy was 77.8%. All colonoscopies were performed with a completion rate of 96% (caecal or terminal ileum intubation). The positive finding on colonoscopy (initial adenoma, advanced adenoma and/or cancer) was reported in 68.02%. Colorectal cancer (CRC) was diagnosed in 529 subjects (8.43%), with most detected cases in the first year (265), followed by decreasing trend in 2010 and 2011 (148 and 116 CRC respectively). On a total of 3738 subjects, we detected 1074 with advanced adenomas (17.12%) and 2664 with initial adenomas (42.47%). Adenoma detection rate (ADR) was reported to be 59.6%, while advanced ADR was 17.12%. The highest advanced ADR was observed in subjects aged 60-69 years, varying from 11.4-12.8%. Most of the polyps were removed in the same session in 88.4% of subjects. The most of advanced adenomas were treated endoscopically by polypectomy and endoscopic mucosal resection (94.8%), while cancerized polyps and pT1 cancers were treated endoscopically in 5.4% cases. Regarding the T stadiation, the most frequent finding among cancers was pT3 stage (37.06%).
CONCLUSION: The extremely high rate of cancer/adenoma detected can partly be explained by: initial BCSP in our local population, higher incidence of colon cancer/adenomas in our region, relative initial older age of the involved population (most of them older than 60 years), the performance of FIT and the good bowel preparation in almost all the subjects. The initial low adherence to FIT could be explained with a low intensity public action campaign. The decreasing trend of detected CRC over years supports the strategy of screening in regions with high CRC incidence.

P935 OBESITY AND HEAVY ALCOHOL CONSUMPTION ARE INDEPENDENTLY ASSOCIATED WITH AN INCREASED RISK OF COLORECTAL CANCER : A NESTED CASE-CONTROL STUDY

M. Fabbri[1], R. M. Zagari[1], D. Colussi[1], N. Garavelli[1], F. Bazzoli[1], L. Ricciardiello[1,*]. [1]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy*

INTRODUCTION: Colorectal cancer (CRC) is one of the leading causes of cancer incidence and death worldwide. Epidemiological studies obtained from several world areas have shown that obesity increases the risk for the disease because of insulin resistance and elevated circulating pro-inflammatory mediators. Obesity is the fastest growing risk factor, and its incidence has increased by 1% every year, including Southern Europe. Thus, it could represent an important risk factor also in this area.
AIMS&METHODS: To evaluate the association between a number of lifestyle factors including obesity, smoking, alcohol use, dyslipidemia and CRC in the population aged 50-70 years who were part of a colorectal cancer screening program in Northern Italy. One hundred seventy two colorectal cancers were diagnosed among 3819 subjects who underwent total colonoscopy, between March 2005 and January 2013, at a center participating to a region-wide screening program based on biannual immunochemical fecal occult blood test. A nested case-control study was performed on 161 eligible CRC patients and 322 age- and sex-matched negative controls (polyps were excluded as well). Adjusted conditional logistic regression was used to estimate odds ratios.
RESULTS: Obesity and drinking >35 gr/daily (drinkers) of alcohol were the only factors significantly and independently associated with an increased risk of colorectal cancer: odds ratio was 1.79 (95% CI, 1.01-3.17; *P*=0.043) for individuals with a BMI ≥ 30 kg/m^2 and 2.39 (95% CI, 1.06-5.42; *P*=0.036) for heavy alcohol drinkers, respectively. When considering cancer location, the odds ratio for obesity and right sided colon cancer was 5.51 (95% CI, 1.59-19.08; *P*=0.007), while no association was found between obesity and cancer of the left colon and rectum. Finally, the odds ratio between drinkers and cancer of the left colon and rectum was 3.60 (95% CI, 1.33-9.71; P=0.011). Smoking (OR 1.13, 95%CI 0.67-1.91; P=n.s.) and dyslipidemia (OR 1.45, 95%CI 0.83-2.52; P=n.s.) were not associated with CRC.
CONCLUSION: In our population undergoing a CRC screening program in Northern Italy, obesity is a significant risk factor for right-sided colon cancers. Heavy drinking has an independent relationship with CRC that is more significant in left colon and rectum. It is possible that in the future an earlier screening strategy should be adopted among obese subjects and advise should be given to people actively drinking alcohol.

P936 COLORECTAL POLYP CHARACTERISTICS IN IRAN, AN AGE SPECIFIC TREND WITH HIGH RISK POLYP

M. Abdollahi[1,*], M. Somi[2], H. Ashktorab[3], S. M. Nouraie[4]. [1]*Young Researchers and Elite Club,Tabriz Branch, Islamic Azad University,* [2]*Liver and Gastrointestinal Diseases Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic Of,* [3]*Department of Medicine,* [4]*Department of Internal Medicine, Howard University Cancer Center, Washington D.C., United States*

INTRODUCTION: Asian countries are experiencing a dramatic increase in colorectal cancer which is associated with rapid life style changes in specific age groups. Information about the age specific characteristic of colorectal polyp in these countries is limited. In this study we assessed the age specific trend of colorectal polyp and their baseline risk in a large sample from Iran.
AIMS&METHODS: During 2000-2012, demographic and clinical data of all colonoscopies performed in 2 university hospitals of Tabriz (Northwest of Iran) were collected. Colonoscopies were performed by 5 experienced gastroenterologists who followed a standard protocol. The collected data were checked by a questionnaire and then were analyzed.
RESULTS: In 10327 adult colonoscopies, 47% were female and median (interquartile) age was 49 (35-63) years. The main reasons for colonoscopy were GI bleeding (32%), change in bowel habit (21%), and abdominal pain (17%). The screening comprise of 1% of all colonoscopies. The frequency of polyp diagnosis was 17%, which increased from 7% in patients younger than 31 to 25% in patients 60-65 years (p<0.001), this frequency decreased to 24% in older patients. Male gender was associated with higher frequency of polyp (OR=1.2, p<0.001). Fifty percent of polyps were located in rectosigmoid followed by 12% in descending and 11% ascending colon. Five percent of polyps were multiple, and 29% were larger than 1 cm. The frequency of high risk polyp (multiple or >

1cm) increased from 28% in patient younger than 31 to 38% in 51-60 years and decreased to 33% in older patients. Frequency of high risk polyp was more in rectosigmoid (OR=1.6, p=0.038). Frequency of high risk polyps was not different between male and female. The highest frequency of high risk polyp were observed in patient who were visited for follow-up (50% vs. 33% for other reason, p=0.003). Among all polyps 49% were sessile which was higher in older age (OR=2.7, p=0.014) but not associated with gender, location or symptom.
CONCLUSION: This study reveals some identical characteristics of colorectal polyp in developing countries, including importance of sessile, high risk and rectosigmoid polyp besides importance of middle age in polyp prevalence and risk. Our results could indicate that in these countries population younger than 60 years old are more prone to high risk polyps. High risk of polyps in this population is also an alarm sign for future of colorectal cancer.

P937 POSITIVE COLONOSCOPY FINDINGS FOR COLORECTAL CANCER IN RELATION WITH AGE AND GENDER

M. Somi[1,*], M. Abdollahi[2]. [1]*Liver and Gastrointestinal Diseases Research Center, Tabriz University of Medical Sciences,* [2]*Young Researchers and Elite Club,Tabriz Branch, Islamic Azad University, Tabriz, Iran, Islamic Republic Of*

INTRODUCTION: Colorectal cancer (CRC) is a major cause of morbidity and mortality throughout the world. It is the third most common cancer worldwide and the fourth most common cause of death. Colonoscopic screening has been recommended for all persons who have had a colorectal adenoma or carcinoma. Colonoscopy has the advantage of allowing biopsy and/or removal of lesions during the same procedure.
AIMS&METHODS: Aim: In this study we aimed to analyze the colonoscopy results of 3650 patients for CRC risk factors and find the relation of them with age and gender.
Methods: All records (n=3650) patients undergoing colonoscopy from 2008 to 2012 at Tabriz University of Medical science were analyzed. We also evaluated the age, gender, having polyp, signs and symptoms, other colonoscopy findings and relationship between them. We used t-test for descriptive variables and Chi-square tests to compare categorical variables.
RESULTS: In this study 3650 patients were enrolled and all of them underwent complete examination of the colon. From 1984 males (54.3%) and 1666 females (45.7%), mean age of our patients was 48.7±18.6 [5-100]. The risk factors most likely to be associated with a finding of colorectal cancer were rectorrhagia (34%), abdominal pain (18.4%), diarrhea (17.9%), constipation (12.6%), anemia (9.1%), history of CRC (7.3%) and positive fecal occult blood test (0.7%), respectively. From those who had rectorrhagia 52.7% were males and 47.3% were females. Polyps were detected in 545 patients (15%). From those who had polyp 326 patients were male (59.8%) and 219 patients were female (40.2%). Most common location of polyp was in rectum (26.5%). Other colonoscopy findings were hemorrhoid (78.1%), skin tag (8.7%), anal fissure (6.5%), diverticule (4.6%) and lesions (2.1%), respectively. From those who had hemorrhoid 52.6% were males and 47.4 were females. From those who had history of colorectal cancer 56.4% were males and 43.6% were females.
CONCLUSION: There was a significant relation between CRC risk factors and male gender. Most frequently associated with positive colonoscopy findings were rectorrhagia, presence of abdominal pain and history of CRC. A history to include these risk factors can serve to prioritize the need for a colonoscopic examination.

P938 FIRST CYCLE OF NATIONAL COLORECTAL CANCER SCREENING PROGRAMME IN CROATIA-PRELIMINARY RESULTS

N. Antoljak[1,*], M Katičić, M Kujundžić, M Strnad, D Štimac, M Šamija, Z Ebling, D Skoko Poljak, V Stamenić, T Brkić, M Kalauz. [1]*Croatian national public health institute, Zagreb, Croatia*

INTRODUCTION: Colorectal cancer (CRC) was the second leading cause of cancer mortality in men and women respectivelly in Croatia, (n_m=1164, 49.77/100000; n_w=845, 34.89/100000). It is also on a second place of incidence among malignant neoplasms with 3068 cases in 2010. The National Colorectal Cancer (CRC) Screening Program was established by the Ministry of Health, and started at the beginning of 2008.
AIMS&METHODS: The fecal occult blood test (FOBT) was performed by guaiac Hemognost card-test. Each participant was required to fulfill the questionnaire and to send it together with the stool specimen on 3 test cards to the county public health institute for further reading. All positive persons had to be invited to colonoscopy within 6-8 weeks. A descriptive analysis of was performed.
RESULTS: A total of 1418103 individuals (100% of eligible) were invited to screening by the end of 2012. In total, 288347 (20.3%) persons returned the envelope with a completed questionnaire, and 247362 of them returned it with a correctly applied stool specimen on FOBT cards. Until now, 15516 (6.3%) FOBT positive patients have been found. Colonoscopy was performed in 10428 cases (67%), and identified colorectal cancers in 564 patients (5.4% of colonoscopied, 3.7% of FOBT-positive, and 0.23% of all screened individuals). Polyps were found and removed in 4107 (39% of colonoscopied) patients.
CONCLUSION: First cycle implementation characteristics are: relatively low FOBT compliance, higher number of FOBT-positive persons but still in the range for population-based programs, and higher number of pathologic findings (polyps and cancers). These results suggest a need for intervention strategies which include organizational changes and educational activities to improve awareness of CRC screening usefulness.

P939 VITAMIN D AND PARATHYROID HORMONE LEVELS IN PATIENTS WITH COLON POLYPS.

Ö. T. Yürekli[1,*], F. E. Akın[1], A. Demirezer Bolat[1], T. solakoğlu[1], R. atalay[1], N. S. Büyükaşık[1], E. Selvi[1], O. Ersoy[1]. [1]*gastroenterology, Ankara Atatürk Research and Teaching Hospital, ankara, Turkey*

INTRODUCTION: Calcium and Vitamin D have been shown to act against cancer by inducing differentiation, inhibiting proliferation and inducing apoptosis. Studies have revealed that serum vitamin D levels were inversely correlated with the colorectal carcinoma incidence. Similar findings have been reported from studies involving colonic polyps.
AIMS&METHODS: Patients undergoing colonoscopy between January -March 2012 were included. Serum 25 (OH) vitamin D, PTH, serum calcium, phosphorus, creatinine, albumin and hemoglobin levels were measured. Patients in whom entire colon could not be visualized, inflammatory bowel disease patients were excluded. Also patients with creatinine clerences < 50 ml/min were left out of the study. History was taken from all patients about family history of colorectal carcinoma, previous medical history about colon polyps. They were also asked about alcohol intake or smoking and whether they get nonsteroidal anti-inflammatory drugs or calcium and vitamin D supplements. All patients' body mass indexes were calculated
RESULTS: 620 colonoscopies were performed during the study period. 325 colonoscopies were excluded. Of 295 patients analysed 122 were female. Average age was 53,39±12,38 years. 98 patients had colon polyps (33,2 %). Mean vitamin D levels in polyp group were 14,30±11,10 ng/ml and PTH levels were 61,32±35,40 pg/ml while mean vitamin D levels in normal colonoscopy were 12,70±6,74, and PTH levels were 55,84±24,34 (p > 0,05). Only age was found to be moderately correlated with polyp risk. Vitamin D levels did not correlate with polyp number, diameter, localization or type. 16 colorectal carcinoma cases were identified. Vitamin D and PTH levels were not different from noncancer group. Patients with polyps were further classified as high and low risk polyp(high risk polyp: more than 3 adenomatous polyps, polyp diameter > 1 cm or presence of villous component). Only age was found to be related with the probability of having high risk polyp. Analyses failed to show any effect of NSAID intake, smoking or family history on probability of having high risk polyp.
CONCLUSION: We could not find any relationship between colorectal polyp incidence and 25 (OH) vitamin D and PTH levels. Vitamin D and PTH levels also did not affect polyp characteristics. Our study was performed during winter months in Ankara. Vitamin D levels were low in all groups. This might have prevented any relation to be detected. One measurement of serum vitamin D levels may not be reflecting long term vitamin D status . Since it was a cross sectional study long term follow up of these patients may reveal different results.

P940 AGE RELATED INCREASE IN THE PREVALENCE OF PROXIMAL ADVANCED NEOPLASIA IN THREE ROUNDS OF A POPULATION BASED COLORECTAL CANCER SCREENING BY IMMUNOCHEMICAL FECAL OCCULT BLOOD TESTING

S. Crotta[1,*], R. Lolli[1], C. Cerrato[1], F. Valle[1], S. Paganin[1], B. Dagnes[1], C. Senore[2]. [1]*Aosta Hospital, Gastrointestinal Unit, Aosta,* [2]*AOU S. Giovanni Battista, CPO Piemonte, Turin, Italy*

INTRODUCTION: There is a growing interest about the anatomical site of screen-detected colorectal cancer (CRC). Some recent data suggested that both colonoscopy and fecal immunochemical test (FIT) might be less sensitive for cancer located in the right side of colon. Moreover right-sided CRCs seem to be diagnosed more frequently in older compared to younger age. We analysed a screened population looking for age-related differences in the colonic location of advanced neoplasia (AN) (carcinomas and advanced adenomas).
AIMS&METHODS: In Aosta Valley Region (Italy) between 2006 and 2010, about 38,000 average-risk subjects, 50–74 years old, were invited for 3 rounds of a biennial screening program for CRC, based on 1-day FIT (OC Sensor, cut-off set at 100 ng Hb/ml buffer). We estimated the cumulative detection rate (DR) of AN over 3 rounds among people who attended the initial screening invitation, stratified by two age group (50-54 years vs 65-69 years) and by two colonic site (right vs left colon) at colonoscopy in FIT positive subjects. Adenomas with at least one of the following features – size > 9 mm; villous component >20%; high-grade dysplasia – were classified as advanced.

RESULTS: About 75% out of 12,944 subjects attending the initial screening performed 2 consecutive tests and 50% had 3 consecutive FITs (average: 2.2 tests per person). In the 8,708 subjects in the younger cohort 464 (5.3%) had at least 1 positive FIT compared to 535 (12.6%) of the 4,236 subjects in the older cohort. Table I reports the results of the cumulative DR and the site distribution of CRCs and advanced adenomas in the two age groups. The relative risk in the cumulative DR for older cohort, compared to younger subjects, was 5.02 (95% CI: 3.15-8.00) for right-sided and 2.20 (CI: 1.68-2.87) for left-sided AN.

Tab I - Cumulative Detection Rate of AN over 3 FIT screening rounds **by colonic site and screenees age**

50-54 years	CRC	Advanced Adenoma	Total	65-69 years	CRC	Advanced Adenoma	Total
Distal N %	9 0,10	93 1,07	102 1,17	**Distal N %**	10 0,24	99 2,34	109 2,57
Proximal N %	3 0,03	22 0,25	25 0,29	**Proximal N %**	15 0,35	46 1,09	61 1,44
Total N %	12 0,14	115 1,32	127 1,46	**Total N %**	25 0,59	145 3,42	170 4,01

CONCLUSION: Over 3 CRC screening rounds with FIT subjects aged 65 to 69 showed a near 3 fold increased cumulative DR of AN compared to subjects aged 50 to 54. The increase was about twice as high for proximal than for distal AN. These findings would confirm a shift from left toward right side of colon of advanced neoplasia with age.

P941 SOCIOECONOMIC STATUS IS ASSOCIATED WITH INEQUALITIES IN SURGICAL TREATMENT AND SHORT-TERM OUTCOMES IN PATIENTS WITH NON-METASTATIC COLORECTAL CANCER

V. K. Dik[1,*], M. J. Aarts[2], V. E. Lemmens[2,3], P. D. Siersema[1]. *[1]Gastroenterology & Hepatology, UMC Utrecht, Utrecht, [2]Eindhoven Cancer Registry, Comprehensive Cancer Center South (IKZ), Eindhoven, [3]Dept. of Public Health, Erasmus MC, Rotterdam, Netherlands*

INTRODUCTION: Low socioeconomic status (SES) is associated with lower survival in colorectal cancer (CRC) patients. Factors responsible for these inequalities include disease stage, access to and use of medical care and comorbidities. However, only a few studies have focused on the association between SES, surgical treatment and short-term outcomes.

AIMS&METHODS: We aim to investigate whether SES is associated with surgical treatment and short-term outcomes after surgery in patients with stage I-III CRC. All patients diagnosed with stage I-III CRC in the period 2005-2010 in the Eindhoven Cancer Registry area in the Netherlands (~2.4 million inhabitants) were included in this study. Demographic and clinical data were routinely collected from medical charts. Multivariable logistic analyses were used to estimate adjusted odds ratios (OR) for 1-year mortality, undergoing resection of the primary tumor, emergency surgery, open vs. laparoscopic surgery, residual tumor after surgery, ≥12 lymph nodes examined, and anastomotic leakage/abscess formation. Analyses were adjusted for age, gender, comorbidities, disease stage, tumor characteristics and, in case of 1-year mortality for chemo- and radiotherapy.

RESULTS: A total of 4,814 colon and 2,500 rectal cancer patients were included. Compared to low SES, high SES colon cancer patients had a lower likelihood to undergo open surgery (OR 0.61, 95% > CI 0.46-0.82), develop anastomotic leakage/abscess formation (OR 0.70, 95% > CI 0.49-0.99) and urgent stoma/stent placement (OR 0.19, 95% > CI 0.04-0.93). No associations with regard to SES and outcome of rectal cancer were observed. One year mortality risk was lower in high vs. low SES patients for both colon (OR 0.48, 95% > CI 0.38-0.61) and rectal (0.62, 95% > CI 0.43-0.90) cancer. The latter associations attenuated after adjustment for clinical characteristics and (neo)adjuvant treatment for both colon cancer (OR 0.68, 95% > CI 0.53-0.88) and rectal cancer (OR 0.78, 0.95% > CI 0.52-1.17), while further adjustment for surgical treatment characteristics and complications had no effect.

CONCLUSION: Marked SES specific differences exist with regard to type of surgical treatment (open vs. laparoscopic) and (short-term) outcomes in stage I-III CRC. However, it remains to be elucidated whether these findings can be attributed to patient- or physician-related factors that were not studied. Meanwhile, in a society where health care is available to the same extent for the whole population, low SES patients may benefit from specific attention with regard to the surgical technique used and the monitoring of post-operative complications.

P942 AUTOMATED WORKFLOW FOR MRNA BIOMARKER ANALYSIS OF COLORECTAL CANCER DEVELOPMENT USING BIOPSY, FRESH FROZEN AND FORMALIN-FIXED, PARAFFIN EMBEDDED (FFPE) SPECIMENS

A. Kalmar[1,*], B. Wichmann[2], O. Galamb[2], S. Spisák[2], F. Sipos[1], K. Tóth[1], K. Leiszter[1], A. V. Patai[1], A. Schöller[1], B. K. Barták[1], Z. B. Nagy[1], Z. Tulassay[2], B. Molnár[1,2]. *[1]2nd Department of Internal Medicine, SEMMELWEIS UNIVERSITY, [2]Molecular Medicine Research Unit, Hungarian Academy of Sciences, Budapest, Hungary*

INTRODUCTION: Recently a colorectal cancer-specific transcript set (including COL12A1, CXCL2, IL1B, MMP3) was identified on colonic biopsy samples using whole genomic microarrays[1].

AIMS&METHODS: Our aim was to evaluate the applicability of these markers on independent biopsy and also on fresh frozen and formalin-fixed, paraffin-embedded (FFPE) tissue specimens from healthy and CRC patients by expression arrays and RT-PCR. Furthermore, automated RNA isolation was introduced and evaluated with increased sample number. Total RNA from 3 normal and 3 CRC FFPE specimens were analyzed by using Affymetrix HGU133Plus 2.0 whole genome expression arrays. Total RNA was isolated from 30 biopsy samples stored in RNALater (15 CRC, 15 normal), 20 fresh frozen surgically removed colonic tissues (10 CRC, 10 adjacent normal) and 60 FFPE (30 CRC, 30 adjacent normal using fresh (≤6 months) and archive (≥5 years) old FFPE blocks) samples with the automated MagNA Pure 96 system using MagNA Pure 96 Cellular RNA Large volume kit (Roche) and reverse transcription was done using Transcriptor First Strand cDNA Synthesis Kit (Roche). Gene expression analysis was performed with real-time PCR using RealTime ready assays and the LightCycler 480 system (Roche).

RESULTS: The FFPE specimens could be clustered correctly by the results of the microarray analysis. According to the gene expression levels of the set of 11 transcripts the biopsy, fresh frozen and fresh FFPE samples could be distinguished by 100% sensitivity and 100% specificity by RT-PCR. The discriminatory power of the marker set was proved to be high also on archive FFPE samples. The automated RNA isolation technique has not influenced the classification power of the markers, but decreased the handling time.

CONCLUSION: The analyzed set of markers in an automated environment could correctly characterize the healthy and the tumorous colonic tissue samples on biopsy, fresh frozen and also on FFPE tissue samples by microarrays and RT-PCR. On the basis of these results, FFPE samples can serve as valuable source for retrospective gene expression studies and these markers can enhance the automated, early and differential detection of colorectal cancer.

P943 INCREASE IN PARTICIPATION RATE IN SUCCESSIVE ROUNDS OF FIT SCREENING

A. Kapidzic[1,*], E. Grobbee[1], L. Hol[1], A. H. van Roon[1], A. J. van Vuuren[1], W. Spijker[2], K. Izelaar[2], M. van Ballegooijen[3], E. J. Kuipers[1], M. E. van Leerdam[1]. *[1]Department of Gastroenterology & Hepatology, Erasmus MC University Medical Centre, [2]Stichting Bevolkingsonderzoek Zuid-West Nederland, [3]Department of Public Health, Erasmus MC University Medical Centre, Rotterdam, Netherlands*

INTRODUCTION: Faecal immunochemical test (FIT) based screening for colorectal cancer requires successive screening rounds for an optimal preventive effect. However, data on multiple rounds of FIT screening are lacking until so far. We therefore conducted a third round of FIT screening in a population-based trial.

AIMS&METHODS: Average-risk subjects aged 50-75 years were approached for screening with a single FIT (OC-sensor). They were excluded from further FIT screening when they had a positive FIT in the previous screening round, when they had a previous history of CRC or inflammatory bowel disease and in case of imaging of the bowel in the former three years. Subjects with a FIT ≥50 ng/ml were referred for colonoscopy.

RESULTS: A total of 9228 subjects were invited for consecutive screening with a maximum of 3 rounds of FIT screening. Participation was 62.6% in the first, 63.2% in the second and 64.6% in the third screening round (p=0.013). In total, 2910 participants attended all screening rounds. The overall positivity rate (PR; proportion of participants with a positive FIT) was 8.4% in the first, 6.0% in the second and 5.8% in the third screening round (p<0.001). The overall detection rate (DR; proportion of participants with advanced neoplasia) was 3.3% in the first, 1.9% in the second and 1.1% in the third screening round (p<0.001). The overall positive predictive value (PPV; proportion of participants who underwent colonoscopy with advanced neoplasia) was 40.7% in the first, 33.2% in the second and 21.5% in the third screening round (p=0.007).

Table 1: FIT characteristics per screening round

	Round 1	Round 2	Round 3	*P*
Attendance	62.6%	63.2%	64.6%	0.013
Positivity rate	8.4%	6.0%	5.8%	<0.001
Detection rate	3.3%	1.9%	1.1%	<0.001
Positive predictive value	40.7%	33.2%	21.5%	0.007

CONCLUSION: The participation to FIT screening increases with successive screening rounds. This implies that repeated FIT screening is acceptable on a population level. A decline in detection rate is seen over three successive screening rounds, suggesting that consecutive FIT screening has a beneficial effect on decreasing the prevalence of advanced neoplasia. The majority of these lesions are detected in the first screening round.

P944 COMPARISON OF TWO FAECAL OCCULT BLOOD TEST CUT-OFF VALUES IN COLORECTAL CANCER SREENING

D. Santare[1,2,*], I. Kojalo[1,2], T. Huttunen[3], M. Leja[1,2]. [1]*Faculty of Medicine, University of Latvia,* [2]*Riga East University hospital, Riga, Latvia,* [3]*4 Pharma, Turku, Finland*

INTRODUCTION: Faecal immunological blood tests (FITs) are the recommended tests for colorectal cancer (CRC) screening, yet the standardization of the tests, including the cut-off values is still remaining an open issue.
Objective is to compare the positivity and lesion detection rates between two FITs with identical cut-off values.
AIMS&METHODS: Within the pilot-study conducted in Latvia two target groups aged 50-74 years were offered FIT testing; 4899 individuals were offered FOB Gold (Sentinel Diagnostics, Milan, Italy), but 4871 – OC-Sensor (Eiken Chemical Co., Tokyo, Japan) tests. Here, we report the test-positivity rates with the following cut-off values – 50, 75, 100, 150 and 200 ng Hb/ml buffer as well as advanced lesion detection rates (cancer+advanced adenoma) in each of the subgroups.
RESULTS:

Faecal immunological blood test

	Cut-off value (ng Hb/ml buffer)	50	75	100	150	200
FOB Gold	Positive tests*	305	233	198	162	134
	Adequately reported colonoscopies**	150	117	97	76	60
	Advanced lesions**	27	25	23	21	20
OC-Sensor	Positive tests*	191	136	119	96	80
	Adequately reported colonoscopies**	94	61	50	38	31
	Advanced lesions**	26	20	16	14	12

* p between tests <0.001 with all cut-off values
** p between tests >0.05 with all cut-off values

44.7% of FOB Gold and 47.4% OC-Sensor tests got returned. The positivity rate with 50 ng/ml cut-off was 13.9% for FOB Gold and 8.3% for OC-Sensor ($p<0.001$), similarly with all the other cut-off values FOB Gold showed substantially higher positivity. At the same time there was no difference in advanced lesion detection rates between the groups – 27 cases with advanced lesions were detected in the FOB Gold group, but 26 – in the OC-Sensor group. To detect these lesions 150 adequately reported colonoscopies were performed in the FOB Gold group and 94 – in the OC-Sensor group.
CONCLUSION: Similar numbers of advanced colorectal lesions were identified with identical cut-off levels with FOB Gold and OC-Sensor tests at the cost of higher test positivity rate and necessary colonoscopy number in the FOB Gold group.

P945 DNA METHYLATION BIOMARKERS FOR NON-INVASIVE DIAGNOSTIC OF COLORECTAL CANCER

D. Azuara[1,*], F. J. Carmona[2], T. Berenguer[3], A. Fernández[2,4], S. Biondo[5], J. de Oca[5], F. Rodríguez-Moranta[6], R. Salazar[1], A. Villanueva[1], M. Fraga[7], J. Guardiola[6], G. Capellá[1], M. Esteller[2], V. Moreno[3]. [1]*Translational Research Laboratory,* [2]*Cancer Epigenetics and Biology Program (PEBC),* [3]*Biomarkers and Susceptibility Unit, Catalan Institute of Oncology (ICO-IDIBELL), Barcelona,* [4]*Cancer Epigenetics Laboratory, IUOPA-HUCA-Universidad de Oviedo, Oviedo,* [5]*General and Disgestive Surgery,* [6]*Department of Gastroenterology, University Hospital of Bellvitge (HUB-IDIBELL), Barcelona,* [7]*Department of Immunology and Oncology, CNB-CSIC, Madrid, Spain*

INTRODUCTION: The aim of the present study was to identify a panel of methylation markers useful for diagnosis of colorectal cancer (CRC) in stool DNA. Additionally, we analyze the methylation status of selected genes as a risk marker for CRC in IBD patients.
AIMS&METHODS: For the *discovery phase* we assessed DNA methylation levels using the Illumina® GoldenGate Methylation Cancer Panel I microarray (to assay 1.505 CpG sites selected from 807 genes) in 92 sporadic CRC patients. An *in silico* validation was performed for the selected probes using public datasets GSE17648 and GSE29490 (Infinium HumanMethylation27 BeadChip array). The *biological validation* of the selected methylation biomarkers was performed by pyrosequencing in three independent groups of samples: 1) 62 tumors, 32 normal-appearing adjacent mucosa and 87 stool samples were tested from 126 sporadic CRC patients. 2) 25 FFPE biopsies from surgical resections of patients with IBD-associated neoplasia. 3) colonic biopsy specimens from 39 healthy subjects. As a reference we also evaluate two previously described methylation-based markers (*Vimentin* and *Septin 9*) in a subset of these samples.
RESULTS: After *discovery phase* and *in silico* validation, three genes (*AGTR1, WNT2* and *SLIT2*) were validated in stool DNA of affected patients with a detection sensitivity of 78% (50/64). DNA methylation of *VIM* and *SEPT9* in stool samples yield sensitivities of 55% (18/33) and 20% (7/35) respectively. In tissue 95% of sporadic carcinomas (57/60) were positive for at least one methylation marker. In IBD-associated neoplasia we found 93% of neoplastic tissues (13/14) positives. The prevalence of methylation in adjacent non-neoplastic mucosa in IBD-associated neoplasia was also higher than in mucosa from healthy controls (14/17; 82% vs 4/38; 11%; $p<0.001$).
CONCLUSION: This novel panel of specific methylation markers can be useful for diagnosis of CRC using stool DNA from CRC patients, and may help in the follow-up of high-risk IBD patients.

P946 PREVALENCE AND VARIABILITY OF SERRATED ADENOMA DETECTION RATES IN GREEK PATIENTS UNDERGOING SCREENING COLONOSCOPY

K. Soufleris[1,*], D. Tzilves[1], G. Lazaraki[1], I. Pilpilidis[1], D. Paikos[1], P. Xirou[2], A. Tarpagos[1]. [1]*GASTROENTEROLOGY,* [2]*PATHOLOGY, THEAGENION ANTICANCER HOSPITAL THESSALONIKI, THESSALONIKI, Greece*

INTRODUCTION: Adenoma detection rate (ADR) is a validated quality indicator of screening colonoscopy. The emerging problem of missed lesions in the right colon has prompted the study of nonhyperplastic serrated adenoma detection rates (SDR), and especially proximal serrated polyps detection rate (PDR).
AIMS&METHODS: All 1445 screening colonoscopies performed by 5 experienced endoscopists in the years 2011-2012 were retospectively reviewed, as part of an internal quality enhancement programm. Examinations with poor preparation were excluded, only if the endoscopist suggested that the examination should be repeated immediately. Colonoscopies performed by an endoscopist with less than 50 examinations per year were also excluded. Completion rates and withdrawal times were not taken into account. ADR, SDR, PSDR were assessed and Pearson linear coefficients were calculated to explore possible assosiations between them.
RESULTS: 1393 average risk patients were evaluated: mean age was 63.6 years, 57% were female. Mean adenoma detection rates were 35% in men, 23% in women, and 28% in total. SD: 5.9%, LDL (95%): 21%, UDL (95%): 36%. SDR and PSDR were 1.8% and 0.8% respectively. No correlation between ADR and SDR (r:-0.334 p:0.583) or between ADR and PSDR (r:-0.470 p:0.425) was observed.

	ADR male	ADR female	ADR total	SDR	PSDR
Endoscopist A	36/98	36/128	72/226	6/226	1/226
Endoscopist B	57/157	31/175	88/332	2/332	0/332
Endoscopist C	60/131	41/145	101/276	5/276	3/276
Endoscopist D	43/124	45/216	88/340	5/340	3/340
Endoscopist E	23/115	31/156	47/219	6/219	3/219
Total	215/599	181/794	496/1393	24/1393	10/1393

CONCLUSION: Lack of any correlation between ADR and SDR/PSDR poses limitations to the use of ADR as a sole quality indicator of screening colonoscopies in a real life setting. Further improvement in the histopathologic and endoscopic recognition of serrated lesions is required. PSDR/SDR may be an additional, more stringent marker of high quality colonoscopy.

INTRODUCTION: Endocytoscopy (EC) is an ultra-magnification technique, which can be performed to evaluate structural and cellular atypia with observation of lumens and nuclei in the surface layer of the mucosa[1,2]. EC has made it possible to diagnose living tumor cells in vivo and to obtain an ultra-magnification pathological image simply by applying the scope to the target mucosa during an endoscopic examination. On the other hands, analysis of the surface microvessels of colorectal lesions using magnifying narrow-band imaging is useful for identifying the appropriate treatment method for colorectal lesions. In addition, the surface microvessels can be analyzed using EC.
AIMS&METHODS: The aim of this study was to investigate whether the observation of surface microvessels using EC was useful in predicting the histopathology of colorectal lesions. The study included 193 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April

Table: P948

	Dukes' Stage A		Dukes' Stage B		Dukes' Stage C		Dukes' Stage D	
	Screen	**Interval**	**Screen**	**Interval**	**Screen**	**Interval**	**Screen**	**Interval**
Gender	No Difference		No Difference		**More Men**	**More Women**	No Difference	
Deprivation Level	No Difference		No Difference		No Difference		No Difference	
ASA Grade	No Difference		No Difference		No Difference		No Difference	
T Stage	No Difference		**More T3**	**More T4**	No Difference		No Difference	
N Stage	N/A		N/A		**More N1**	**More N2**	No Difference	
Tumour Site	No Difference		No Difference		**More Left-Sided**	**More Right-Sided**	No Difference	
Survival Rate	No Difference		No Difference		**Better**	**Worse**	**Better**	**Worse**

2006 and January 2013. A total of 220 lesions (10 normal mucosae, 10 hyperplastic polyps, 135 adenomas, and 65 submucosally invasive cancers) were retrospectively evaluated. The colonic surface micro-vascular patterns observed using EC were classified into the following 3 groups: EC-V1, the surface microvessels were obscure ; EC-V2, the surface microvessels were clearly observed, and their caliber and arrangement were uniform; and EC-V3, the surface microvessels were thick, and their caliber and arrangement were non-homogeneous.
RESULTS: The EC-V1 group included all the normal mucosae and hyperplastic polyps, whereas 88.5% (131/148) of EC-V2 lesions were adenomas and 94.1% (48/51) of EC-V3 lesions were invasive cancers.
CONCLUSION: Vascular patterns of colorectal cancers observed by endocytoscopy were useful in predicting the histopathology of colorectal lesions.

P948 SCREEN-DETECTED COLORECTAL CANCERS ARE ASSOCIATED WITH AN IMPROVED OUTCOME WHEN COMPARED WITH INTERVAL CANCERS WHEN MATCHED FOR STAGE

M. D. Gill[1,2,*], M. Bramble[2], M. Hull[3], S. Mills[1], E. Morris[3], M. Bradburn[1], Y. Bury[4], C. Parker[5], T. Lee[6], C. Rees[6]. [1]*Northern Colorectal Cancer Audit Group, Northumberland,* [2]*University of Durham, Durham,* [3]*University of Leeds, Leeds,* [4]*Royal Victoria Infirmary, Newcastle,* [5]*South Tyneside General Hospital, South Tyneside,* [6]*Northern Region Endoscopy Group, North East England, United Kingdom*

INTRODUCTION: Colorectal cancers detected through the NHS Bowel Cancer Screening Programme (BCSP) have been shown to have a more favourable outcome compared to non-screen detected cancers. The aim of this study was to identify whether this was solely due to the earlier stage shift of these cancers, or whether there were other factors involved.
AIMS&METHODS: A combination of a regional colorectal cancer registry (Northern Colorectal Cancer Audit Group) and the BCSP database were used to identify screen detected cancers and interval cancers (diagnosed after a negative faecal occult blood test, before the next screening round). All cancers were diagnosed between April 2007 and March 2010, within the North East of England. For each Dukes' stage, patient demographics, tumour characteristics, and survival rates were compared between the screen detected and interval cancer groups.
RESULTS: 322 screen detected cancers were compared against 192 interval cancers.
Significant differences highlighted in bold, $p < 0.05$. Mean follow-up 32 months.
CONCLUSION: With equivalent patient demographics and tumour characteristics, the improved survival of screen detected cancers over interval cancers for Stages C and D suggest that there may be a biological difference in the cancers in each group. Although lead-time bias may have a role, this may be related to a tumours propensity to bleed and therefore may reflect detection through current screening tests.

P949 EFFECT OF MEDICATION USE ON FAECAL OCCULT BLOOD TEST POSITIVITY IN THE NHS BOWEL CANCER SCREENING PROGRAMME

M. D. Gill[1,2,*], M. Bramble[2], C. Rees[3,4]. [1]*Northern Colorectal Cancer Audit Group, Northumberland,* [2]*University of Durham, Durham,* [3]*South Tyneside Foundation Trust, South Tyneside,* [4]*Northern Region Endoscopy Group, North East England, United Kingdom*

INTRODUCTION: Faecal occult blood test (FOBt) positivity is linked with both tumour site and gender. Left sided cancers, and cancers in men are detected in significantly greater proportions by screening. The aim of this study was to evaluate for an association with certain medication use at time of test, with the FOBt result, in patients diagnosed with a colorectal cancer.
AIMS&METHODS: Using a regional colorectal cancer dataset (Northern Colorectal Cancer Audit Group) and Bowel Cancer Screening Programme database, all screen detected and interval cancers (diagnosed after a negative faecal occult blood test, before the next screening round) were identified. Diagnosis date was between April 2007 and March 2010. General Practitioners for each patient were asked to complete a proforma detailing use of hormone antagonists, hormone replacement therapy, anticoagulants, aspirin, non-steroidal anti-inflammatory drugs (NSAIDs), and pre cancer diagnosis cholecystectomy. Medication use within two months of performing a FOBt was deemed positive. Chi-squared and logistic regression analyses were used.
RESULTS: Of 514 patients, 346 (67.3%) proformas were returned and suitable for analysis. 120 patients analysed were in the interval cancer group, with 226 in the screen detected cancer group. Between screen detected and interval cancers groups, no difference was found in the use of hormone antagonists, hormone replacement therapy, anticoagulants, and aspirin. Rates of cholecystectomy were equivalent. The use of non-aspirin NSAIDs within two months of test was seen in a significantly greater proportion in the screen detected cancer group (10.6% vs. 4.2%, p=0.039). For the population who used NA-NSAIDs, there was no difference between groups in gender, tumour location, or stage of tumour.
CONCLUSION: The use of NA-NSAIDs around the time of test was associated with a greater rate of positivity of the FOBt. This finding adds to our understanding of factors influencing the positivity of FOB testing, and may be useful in understanding the rates of interval colorectal cancers within the screening programme.

Hospital, Jinju,* [8]*Internal medicine, Daegu Fatima Hospital, Daegu, Korea, Republic Of*

INTRODUCTION: The risk of cancer varies with the subtype of the colorectal laterally spreading tumors (LST). However, there are variable visual interpretations among endoscopists.
AIMS&METHODS: The aim of this study was to evaluate interobserver agreement and accuracy for endoscopic classification of LST subtypes among experts and trainees. Forty LST images were collected and independently reviewed by 14 gastroenterology experts and 10 trainees. All investigators recorded their findings as one of the four categories (homogeneous, nodular mixed, flat elevated, and pseudodepressed). Agreement was expressed by a kappa estimate (k). The accuracy was assessed by agreement with gold standard which was based on the gross morphology of resected specimen.
RESULTS: 41 (45.1%) out of the possible 91 pairwise k estimates among experts were greater than 0.75, indicating excellent agreement while only 2 (4.44%) out of the 45 pairwise k estimates among trainees were greater than 0.75. The mean kappa value was 0.73 (range 0.54–0.86) for experts and 0.56 (range 0.36–0.83) for trainees. The agreement for individual LST subtype in trainee group were significantly lower than those in the expert group, except LST subtype of flat elevated which showed similar agreement between two groups (0.96 vs. 0.94). Also, the overall accuracy of LST was higher in experts ($k = 0.811$) than in trainees ($k = 0.620$).
CONCLUSION: The interobserver agreement and accuracy for LST subtype classification were different between experts and trainees. Implementation of adequate training system is necessary for beginners to better identify colorectal LST.

P951 A COMPARISON OF ENDOSCOPIC TREATMENTS IN RECTAL CARCINOID TUMORS

A. Y. Seo[1,*], C. M. Shin[1], S. B. Kim[1], D. H. Lee[1], N. Kim[1], Y. S. Park[1], H. Yoon[1]. [1]*Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic Of*

INTRODUCTION: Various endoscopic techniques for rectal carcinoid tumor have been developed recently. In this study, we compared the outcomes among conventional endoscopic mucosal resection (EMR), two-channel EMR, and EMR after circumferential precutting (EMR-P).
AIMS&METHODS: From March 2004 to January 2013, the medical records of 140 patients who were treated by endoscopic procedure for rectal carcinoid tumor in Seoul National University Bundang Hospital were investigated retrospectively. The characteristics of patients and tumors, selection of treatment method, complete resection rate and complication were analyzed retrospectively.
RESULTS: The mean age was 45.5 (range, 28-74 yrs), and the number of male patients was 88 (62.9 %). The mean tumor size was 5.1 ± 2.4 (1-14) mm and mean distance from anal verge was 7.0 ± 2.9 (1-16) cm. Forty-two patients were treated by EMR, 65 by 2 channel-EMR and 33 by EMR-P. The mean procedure time of EMR, 2 channel-EMR and EMR-P was 291.6 ± 220.0 sec, 389.4 ± 237.3 sec and 442.9 ± 179.7 sec, respectively. Post hoc analysis showed a significant difference in the mean procedure time between EMR and EMR-P ($P = 0.012$). Endoscopic complete resection was achieved in all cases. But histologic examination showed positive lateral or deep resection margins in 38 out of 140 patients (27.1 %). Multivariate analysis showed that 2-channel EMR method and EMR-P method were independent factors for the prediction of margin positive, with odds ratios of 0.11 and 0.11 with 95% confidence interval [CI], 0.04-0.32 and 0.03-0.38, respectively.
CONCLUSION: For the optimal endoscopic treatment of rectal carcinoid tumor, 2-channel EMR and EMR-P are more effective than conventional EMR in the meaning of margin status. Although EMR-P needs more time than the conventional EMR, the effectiveness of treatment offsets EMR-P's disadvantage of time consumption.

P952 LONG-TERM OUTCOME OF BRIDGE-TO-SURGERY COLONIC STENTING STRATEGY IN PATIENTS WITH MALIGNANT LARGE BOWEL OBSTRUCTION.

A. Repici[1,*], A. Mussetto[2], L. Fuccio[3], P. Cassoni[4], M. Jovani[1], G. Strangio[1], O. Triossi[5], T. Casetti[2], V. Cennamo[3], A. Gatti[6], M. Montorsi[6], A. Malesci[1]. [1]*Gastroenterology and Endoscopy, Istituto Clinico Humanitas, Milan,* [2]*Gastroenterology, Hospital S. Maria delle Croci , Ravenna,* [3]*Gastroenterology and Endoscopy, Sant'Orsola-Malphigi Hospital, Bologna,* [4]*Department of Medical Sciences, Torino,* [5]*Gastroenterology, Hospital of Ravenna, Ravenna,* [6]*General Surgery III, Istituto Clinico Humanitas, Milan, Italy*

INTRODUCTION: Bridge-to-surgery stenting (BTSS) has been advocated as a potential strategy to manage obstructing colonic cancer. Stent-related tumor-cell seeding and dissemination is the main long-term safety concern.
AIMS&METHODS: Long-term outcome and survival of patients treated with BTSS.
This is a retrospective, cohort, multicenter study. Patients operated with curative intent after BTSS from January 2003 to April 2008 in four tertiary referral centers were included. Data were extracted from medical records, updated after telephone contact with the patients, their relatives or family physician, and analyzed on an intention-to-treat basis according to the study outcomes.
RESULTS: Overall 68 consecutive patients (pt) were included (38 male; 30 female, median age at the onset of obstruction 73 years) which were followed for a median of 41 months (range 1-89). Tumor staging resulted as follows: stage I: 2 pt (2.9%); stage II: 20 pt (29.5%); stage III: 30 pt (44.1%;); stage IV: 16 pt (23.5%). Technical success of stent placement was 97.1%. Median time from stent placement to surgery was 8 days (range 1-257). Four patients (5.9%) underwent laparoscopic surgery while 94.1% pt underwent open surgery. In 4 pt (5.9%) a temporary stoma was effectuated following stent-induced perforation or incomplete relief of obstruction. Early perforation rate following BTSS was 4.4% (3/68). Six patients (8.8%) received neo-adjuvant chemotherapy whilst adjuvant therapy was administered in 39 patients (57.3%; six pt received biologic drugs). Tumor recurrence was observed in 24 patients (35.2%) after a median of 20 months (range 3-40) from surgery, sooner on the group receiving adjuvant chemotherapy (median 14 months; range 3-40). Twenty-nine patients (42.6%) had died at the end of follow-up. Of these 19 (65.5% of deaths; 27.9% of total pt) died from disease progression. Five-year overall survival was 57.4% while five-year disease-free disease was 44.1%. At multivariate analysis, only advanced stage of disease (stage III and IV) was significantly associated to tumor recurrence and fatal outcome.
CONCLUSION: To date this is the largest study reporting the 5-year outcome after bridge-to-surgery stenting. More than 50% of patients in this study were still alive at the end of follow-up. Overall survival, disease-free survival and death are comparable to literature data on patients with same stage of disease, operated in an elective manner.
Disclosure of Interest: None Declared

P953 CURCUMIN POTENTIATES AN ANTIPROLIFERATIVE EFFECT OF 5-AZA-CDR WITHOUT INTERFERING WITH ITS DNA HYPOMETHYLATING EFFECT

A. Link[1,*], M. Drechsel[1], F. Balaguer[2], A. Poehlmann[3], A. Goel[4], T. Wex[1], P. Malfertheiner[1]. [1]*Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke University Hospital Magdeburg, Magdeburg, Germany,* [2]*Gastroenterology, Hospital Clínic, Centro de Investigación Biomédica en Red en Enfermedades Hepáticas y Digestivas (CIBEREHD), IDIBAPS, University of Barcelona, Barcelona, Spain,* [3]*Institute of Pathology, Otto-von-Guericke University Hospital Magdeburg, Magdeburg, Germany,* [4]*Epigenetics and Cancer Prevention, Baylor Research Institute and Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX, United States*

INTRODUCTION: Colorectal cancer (CRC) is the result of multiple genetic and epigenetic alterations. Accumulating evidence indicates that epigenetic-modifying drugs may be useful in cancer prevention and treatment of malignant conditions. DNMT inhibitors, such as 5-aza-2'-deoxycytidine (5-aza-CdR) induce reactivation of the silenced genes through promoter DNA hypomethylation, however are associated with dose-dependent toxicity. Curcumin is one of the most effective dietary polyphenols and has been also shown to modify DNA methylation in CRC. Yet, concurrent application of both compounds has not been studied before.
AIMS&METHODS: The aim of our study was to evaluate the interaction of 5-aza-CdR and curcumin treatment on proliferation and on the DNA methylation in the CRC. Two CRC cell lines (RKO and HCT116) were treated with different concentrations of curcumin and 5-aza-CdR and alone and in combination. Proliferation analyses were performed using MTT assay. Global (LINE-1), and gene-specific methylation analysis was carried out using quantitative bisulfite pyrosequencing. The functional validation of the methylation-dependent gene expression changes was determined by quantitative RT-PCR (ex. miR-137, MLH1, UCHL1).
RESULTS: Both 5-aza-CdR and curcumin inhibited proliferation of CRC cells in concentration-dependent manner in vitro. However, the combination of both drugs in comparison to single drug treatment, resulted in stronger inhibition of proliferation (60% and 45% vs. 32% for RKO and 42% and 49% vs. 26% for HCT116, $p<0.001$, for 5-aza-CdR and Curcumin vs. combination, respectively). As expected, 5-aza-CdR, but not curcumin, lead to global (LINE-1) and gene-specific hypomethylation and subsequently to re-expression of genes (ex. miR-137, MLH1 etc.). The simultaneous treatment of CRC cells with 5-aza-CdR and curcumin was associated with similar or stronger induction of DNA hypomethylation and corresponding gene expression changes, but not when curcumin was given 24h prior to the 5-aza-CdR treatment.
CONCLUSION: Our results provide valuable information on the interaction of 5-aza-CdR and curcumin in CRC cells in vitro supporting concurrent use of those drugs. Simultaneous application of 5-aza-CdR and curcumin leads to a stronger inhibition of tumor cell proliferation without affecting the effectiveness of 5-aza-CdR to induce promoter DNA hypomethylation and gene expression. This study provides rational for the further systematic analyses in vivo.

P954 DEPTH OF INVASION IS A SIGNIFICANT PROGNOSTICATOR IN STAGE II COLORECTAL CANCER.

C. Maeda[1,*], S.-E. Kudo[1], Y. Mori[1], S.-I. Kataoka[1], K.-I. Takeda[1], K. Ichimasa[1], S. Mukai[1], K. Miyahara[1], Y. Sugihara[1], H. Miyachi[1], E. Hidaka[1], F. Ishida[1], S. Hamatani[1]. [1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama, Japan*

INTRODUCTION: The clinicopathological factors of recurrence in stage II colon cancer have been investigated.
AIMS&METHODS: This study aimed at investigating the factors which affect recurrence and survival in patients with stage II colorectal cancer. Our study comprised 206 stage II colorectal cancer patients that were surgically resected at our center from January 2005 to December 2009. Median observation period was 44 months. The patients were divided into 2 groups: recurrence group and non-recurrence group. Further, the following clinicopathological factors were retrospectively compared between two groups: lymphatic invasion, venous invasion, tumor size, depth of invasion, histological type, the number of dissected lymph node, tumor location and adjuvant chemotherapy.
RESULTS: See the table. Multivariate logistic regression analysis revealed that depth of invasion was related to a higher incidence of recurrence.
Table: Univariate analysis of factors

	Recurrence group (n=25)	Non-recurrence group (n=181)	P value
Lymphatic invasion	22 (88%)	133 (71%)	0.142
Venous invasion	21 (84%)	150 (83%)	0.999
Tumor size (more than 39mm)	16 (64%)	102 (56%)	0.469
Depth of invasion (pT4)	7 (28%)	16 (9%)	0.004
Histological type (muc, por)	1 (4%)	9 (5%)	0.999
Preoperative CEA level (more than 5.0 ng/ml)	3 (12%)	34 (19%)	0.999
The number of dissected lymph node (more than 11)	18 (72%)	131 (72%)	0.935
Tumor location (Rectum)	7 (32%)	35 (19%)	0.174
Adjuvant chemotherapy	5 (20%)	38 (21%)	0.908

CONCLUSION: Depth of invasion is a significant prognosticator in stage II colorectal cancer.

P955 SENSITIZATION OF COLON CANCER STEM CELLS TO CHEMOTHERAPY BY ER STRESS INDUCED DIFFERENTIATION

M. C. Wielenga[1,*], S. Colak[2], J. Heijmans[1], J. F. van Lidth de Jeude[1], S. L. Rosekrans[1], J. P. Medema[2], G. R. van den Brink[1]. [1]*Gastroenterology, Academic Medical Center, Amsterdam, Tytgat Institute for Liver and Intestinal Research,* [2]*Laboratory of Experimental Oncology and Radiobiology, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: In cancer, a small subpopulation of cells, is responsible for tumor-initation and -growth. These so called cancer stem cells (CSCs) are more resistant to chemotherapy than differentiated tumor cells, that represent the bulk of the tumor. We recently showed that normal intestinal epithelial stem cells experience very low levels of Er stress and that ER stress induces the earliest steps in stem cell differentiation (Heijmans et al Cell Rep. 2013). We hypothesized that induction of ER stress may force CSCs into a more differentiated state, which could sensitize them to the effects of chemotherapy.
AIMS&METHODS: We used a previously described cancer stem cell culture (Vermeulen et al Nat Cell Biol 2010) with a TCF/LEF driven GFP reporter for Wnt signaling activity. This allowed us to compare cancer stem cells (GFP-high) with more differentiated cancer cells (GFP-low) within the same experiment. ER stress was induced with SubAB (1000ng/μl), a toxin that specifically depletes GRP78, the major ER chaperone. Stemness of the GFP-high cells was determined using gene arrays to examine expression of a previously published colon cancer gene set (De Souza Cell Stem Cell 2011), qPCR, a matrigel differentiation assay and a limiting dilution assay. Sensitivity to oxaliplatin (50 uM) induced apoptosis was determined using a FACS based cleaved Caspase-3 assay.
RESULTS: Induction of ER stress revealed loss of stem cell markers OLFM4 and LGR5 and downregulation of the previously described colon cancer stem cell gene set, NES -1.54, $P<0.001$. When treated with subAB for 24 hours, clonogenic capacity of GFP-high cells was markedly reduced (1.3% vs 20.8% sphere initiating cells). In matrigel 3D culture SubAB treatment dramatically increased the percentage of differentiated spheres (90% vs 11%, $p<0.001$). GFP-high cells where more resistant to oxaliplatin induced apoptosis that GFP-low cells (23% vs 47% respectively). Treatment for 24 hours with SubAB alone did not induce apoptosis in GFP-high cells but increased their sensitivity to oxaliplatin induced apoptosis to that observed in GFP-low cells (42% vs 51%).
CONCLUSION: ER-stress forces colon cancer stem cells into differentiation and sensitizes CSCs to oxaliplatin induced apoptosis. ER stress inducing agents may be developed as adjuvants in chemotherapy of colorectal cancer.

P956 SURGICAL OUTCOME OF SCREEN-DETECTED ENDOSCOPICALLY-TREATED MALIGNANT POLYPS: DATA FROM A NORTHERN ITALIAN REGISTER

R. Fasoli[1,*], E. Guido[2], F. Monica[3], D. Di Piramo[4], F. Valiante[5], M. Lo Mele[6], P. Cassoni[7]. [1]*Department of Gastroenterology and Digestive Endoscopy, Ospedale Santa Chiara, Trento,* [2]*Department of Medicine, Gastroenterology Unit, Ospedale Sant'Antonio, Padova,* [3]*Department of Gastroenterology, ULLS 3 Veneto, Bassano del Grappa,* [4]*Department of Gastroenterology and Digestive Endoscopy, ULLS 22 Veneto, Bussolengo,* [5]*Department of Gastroenterology and Digestive Endoscopy, ULLS 2 Veneto, Feltre,* [6]*Department of Diagnostic, Medical Sciences and Special Therapies, Surgical Pathology and Cytopathology Unit, University of Padova, Padova,* [7]*Department of Biomedical Sciences and Human Oncology, University of Torino, Torino, Italy*

INTRODUCTION: Although more and more experience is being gained and published concerning indications to surgical radicalization after endoscopic resection of colo-rectal polyps or flat lesions considered at high risk, the issue still relies on clinical experience with no prospective controlled trials available. Residual disease at surgery in such patients has been recently reported in the region of 18% (Gill, Scotland, 2012) and 15% (Kim-Kwang, South Korea, 2013).
AIMS&METHODS: We have collected and evaluated data on endoscopically-resected malignant polyps coming from the first round of colo-rectal screening series of a few centres of Northern Italy, with the aim of creating a common register, analysing endoscopic and surgical results and the future intent to homogenize histological reports and clinical behaviours.
RESULTS: Six centres have so far participated to the study: Trento/Rovereto, Padova (Ospedale Sant'Antonio), Bussolengo (Verona), Torino (Ospedale Molinette), Bassano (Vicenza) e Feltre (Belluno).
251 malignant polyps have been treated endoscopically during the first round of respective screening campaigns.
133 have been sent to radicalization surgery, according to high risk attribution (53%).
Their site distribution was the following: rectum 24.2%, left colon 56.1%, right colon 19.7%.
The mean number of resected lymph-nodes at surgery was 7.8 (range 0-37)
At surgical intervention the Dukes' classification was the following: A: 91.7%; B1: 1.5%; C1: 6.8%.
CONCLUSION: In this multicentre northern Italian screening series, site distribution and rate of surgical radicalization in endoscopically-resected colo-rectal malignant polyps is in keeping with most international data. The number of lymph-node removed at surgery is sub-optimal according to published guidelines, which suggest to resect and send to pathologist at least 12 nodes. The rate of residual disease at surgery in high-risk malignant polyps turned out to be lower than reported in recently published series.
These last data deserve particular attention in a screening environment and – in this regard - a multicentre histological re-evaluation of endoscopic samples prior to risk attribution is in progress.

P957 FAMILIAL ADENOMATOUS POLYPOSIS: WHICH SURGICAL OPTION?

R. Küttner Magalhães[1,*], R. Marcos-Pinto[1], R. Pimentel[1], A. Rocha[2], M. Santos[2], I. Pedroto[1]. [1]*Gastroenterology,* [2]*General Surgery, Hospital Santo António, Porto, Portugal*

INTRODUCTION: Prophylactic surgery in patients with Familial Adenomatous Polyposis (FAP) comprises two approaches: total colectomy with ileo-rectal anastomosis (IRA) and total proctocolectomy with ileo-pouch anal anastomosis (IPAA). The choice can be determined by the experience of the center, as well as the age, phenotype and the wish of the patient to have children.
AIMS&METHODS: Our objective was to evaluate surgical option (IPAA vs IRA) in FAP patients in a specialized center and relate preoperative variables to postoperative outcomes. Demographic and clinical data on patients with FAP submited to surgical treatment and followed in regular consultation were retrospectivelycollected.
RESULTS: Of 67 patients with a mean age of 47.3 years (20-83), 58.2% were female and in 83.6% of cases APC gene mutation was identified. In 16.4% desmoid tumors were recognized and 26.9% had duodenal adenomas. With an mean age of 34.2 years-old, 77.6% (n=52) underwent total colectomy with IRA and 22.4%(n=15) underwent total proctocolectomy with IPAA. Among patients submitted to IRA or IPAA, there were no differences related to sex, age, identification of APC mutation, severity of colonic polyposis, rectal polyposis and postoperative follow-up polyps. IRA patients had less desmoid tumors when compared to patients with IPAA (9.3% vs. 40.0%, $p = 0.012$), less duodenal adenomas (15.4% vs. 67.7%, $p < 0.001$), had fewer complications related to surgery (5.8% vs 46.7%, $p = 0.001$), fewer surgical reinterventions (11.5% vs. 40.0%, $p = 0.020$), needed more endoscopic surveillance (12.5 vs 4.3 exams, $p < 0.001$) and did not have lower birth rates (7.7% vs 40.0%, $p = 0.006$). Only one patient submited to IRA required reoperation for rectum adenocarcinoma.
CONCLUSION: We didńt verify a clear association with some classic factors related to IRA and IPAA indication. IPAA patients had more complications related to the pouch, higher need for surgical reintervention, but not a lower birth rate. Similar long-term results are achieved with both options.

P958 CZECH NATIONAL COLORECTAL CANCER SCREENING PROGRAM: QUALITY CONTROL OF 107,876 PREVENTIVE COLONOSCOPIES

S. Suchanek[1,*], O. Majek[2], B. Seifert[3], L. Dusek[2], M. Zavoral[4]. [1]*Department of Gastroenterology, 1st Faculty of Medicine of Charles University and Military University Hospital, Prague,* [2]*Institute of Biostatistics and Analyses, Masaryk University, Brno,* [3]*Institute of General Medicine, 1st Faculty of Medicine of Charles University,* [4]*Department of Gastroenterology, 1st Medical Faculty of Charles University and Military University Hospital, Prague, Czech Republic*

INTRODUCTION: The National Colorectal Cancer Screening Programme in the Czech Republic has been introduced in 2000, focused on asymptomatic individuals. Since the beginning of 2013, only immunochemical fecal occult blood tests (FIT) and preventive colonoscopies are recommended. In age 50 – 54, annual FIT is offered, followed by FOBT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10 years interval.
AIMS&METHODS: Three main indicators have been used to assess the quality control of screening colonoscopies – adenoma detection rate (ADR), advanced adenoma detection rate (aADR) and cecal intubation rate (CIR). These indicators have been compared to European guidelines (published in 2010). Other quality indicators of all preventive colonoscopies (positive predictive value, endoscopic complications) have been measured.
RESULTS: Between January 2006 and April 2013, there have been 107,876 preventive colonoscopies performed: 92,449 FOBT+ colonoscopies (86.7%) and 15,457 screening colonoscopies (14.3%). Adenomas have been diagnosed in 31,497 patients within FOBT+ colonoscopy (34.0%; 48.1% of them with advanced adenomas) and in 3,874 patients within screening colonoscopy (25.1%; 29.4% of them with advanced adenomas). In all preventive colonoscopies 4,227 cancers have been registered. The overall cecal intubation rate has reached 96.2%. In years 2006 – 2012, there were 92 cases of perforations

(0.09% of all examinations) and 361 cases of bleeding during endoscopic polypectomies (0.76% of all therapeutic procedures) reported.
Table: Quality indicators of screening colonoscopies: comparison of Czech CRC Screening Program and European Guidelines

	Adenoma detection rate (ADR)	Advanced adenoma detection rate (aADR)	Cecal intubation rate
European Guidelines	14.9 – 37.5%	4.9 – 8.6%	90.0%
Czech Republic	25.1%	7.4%	97.7%

CONCLUSION: Preventive colonoscopies performed within the Czech National Colorectal Cancer Screening Program are safe diagnostic and therapeutic procedures. All of three main quality indicators of screening colonoscopies are comparable to European guidelines.

P959 EICOSAPENTAENOIC ACID (EPA) EFFICACY FOR COLORECTAL ABERRANT CRYPT FOCI (ACF): A DOUBLE-BLIND RANDOMIZED CONTROLLED TRIAL

T. Higurashi[1,*], S. Uchiyama[1], E. Yamada[1], E. Sakai[1], H. Ohkubo[1], H. Endo[1], H. Takahashi[1], A. Nakajima[1]. [1]*Gastroenterology, Yokohama City University, Yokohama, Japan*

INTRODUCTION: Colorectal cancer (CRC) is one of the most commonly occurring neoplasms and a leading cause of cancer death worldwide, and new preventive strategies are needed to lower the burden of this disease. Eicosapentaenoic acid (EPA), the omega-3 polyunsaturated fatty acid that is widely used in the treatment of hyperlipidemia and prevention of cardiovascular disease, has recently been suggested to have a suppressive effect on tumorigenesis and cancer cell growth. Aberrant crypt foci (ACF), defined as lesions containing crypts that are larger in diameter and stain more darkly with methylene blue than normal crypts, are considered as a reliable surrogate biomarker of CRC. We conducted a prospective randomized controlled trial as a preliminary study prior to a CRC chemoprevention trial to evaluate the chemopreventive effect of EPA against colorectal ACF formation and the safety of this drug.
AIMS&METHODS: This study is a multicenter, double-blind, placebo-controlled, randomized controlled trial to be conducted in patients with both colorectal ACF and colorectal polyps scheduled for polypectomy. Twenty-four eligible patients were recruited for the study and the number of ACF in the rectum counted at the baseline colonoscopy. Then, the participants were allocated randomly to either one of two groups, the EPA group and the placebo group. Twelve patients in the EPA group received oral 900 mg EPA capsules thrice daily (total daily dose, 2.7 g per day), and 12 patients in the placebo group received oral placebo capsules thrice daily. After one month's treatment with EPA/placebo, colonoscopic examination and polypectomy were performed to evaluate the formation of ACF, and the cell-proliferative activity and cell-apoptotic activity in normal colorectal mucosa and colorectal polyps.
RESULTS: At polypectomy, the EPA group had a significant decrease in the mean number of ACF per patient (8.9 ± 4.5 before treatment versus 4.8 ± 2.3 at 1 month, $P = 0.003$), whereas the mean ACF number did not change significantly in the placebo group (7.7 ± 5.2 versus 8.9 ± 8.0, $P = 0.347$). The proliferating cell nuclear antigen index was significantly decreased and the apoptotic cell index was significantly increased in both normal rectal epithelium and polyps in EPA group patients.
CONCLUSION: This is the first study proposed to explore the chemoprevention effect of EPA against colorectal ACF formation in humans. For the future, we plan to conduct a long-term chemoprevention trial of EPA for colorectal adenoma or cancer.

P960 FROM THE POPLAR MECHANO-PERCEPTION TO VISCERAL SENSITIVITY IN MICE: ROLE OF UBIQUITOUS TRANSCRIPTION FACTOR EGR-4?

A. Accarie[1,*], Y. Aissouni[1], E. Muller[1], A. Eschalier[1], D. Ardid[1], A. Gelot[1]. [1]*Pharmacologie Fondamentale et Clinique de la Douleur, UMR1107 NEURO-DOL Inserm/UdA, Clermont-Ferrand, France*

INTRODUCTION: In a pathophysiological context such as inflammatory bowel disease or irritable bowel syndrome, perception of mechanical stimuli may be impaired in the colon, leading to colonic hypersensitivity. The perception of mechanical stimuli is common to many species whether animal or plant. Initially, works done on poplar by the MECA team of UMR PIAF identified a transcription factor involved in mechano-perception in plants. Bioinformatics analysis has then highlighted a homologous gene in mice, named EGR-4. The encoded protein has been described as a transcription factor which appeared to be involved in early perception of mechanical stimuli.
AIMS&METHODS: The aim of this study is to determine the EGR-4 localization and its involvement in the mouse colon sensitivity to a mechanical stimulus. For that purpose, wild-type and healthy mice were subjected or not to a colorectal distension (mechanical stimulus) for 10 seconds *via* inflation of a balloon inserted at 1cm from the anal margin. Then, we analyzed the expression of EGR-4 at different time points after the distension at the mRNA level in the colon, dorsal root ganglia (DRG) and spinal cord by quantitative RT-PCR and its cellular localization in DRG, and in colon after whole-mount dissection, by immunohistochemistry. We also identified targeted genes of this transcription factor in mouse colonic epithelial cells transfected by an EGR-4 expressing vector after microarray analysis.
RESULTS: EGR-4 transcription factor is localized in the colon, DRG and spinal cord cells. In addition, its expression is modified after colorectal distension in a time dependent manner. In the sub-mucosal plexus and myenteric plexus EGR-4 is co-localized with PgP9.5, a neuronal marker.
CONCLUSION: Our study indicates that EGR-4 is involved in colonic mechano-sensitivity and suggests its contribution to colonic hypersensibility, mainly associated to visceral chronic pain. Its co-localization with nervous fibers suggests a role in nervous transmission of mechanical perception and hypersensibility. This study opened new avenues in treatment of abdominal pain, by proposing new therapeutic targets to correct mechanical sensitivity disturbance.

P961 ABNORMAL INTESTINAL PERSISTENCE OF CD-ASSOCIATED ADHERENT-INVASIVE ESCHERICHIA COLI ENHANCES SPONTANEOUS VISCERAL HYPERSENSITIVITY

A. Lashermes[1,*], A. Gelot[1], N. Barnich[2], A. Darfeuille-Michaud[2], A. Eschalier[1], D. Ardid[1], F. A. Carvalho[1]. [1]*Pharmacologie Fondamentale et Clinique de la Douleur, UMR1107 NEURO-DOL Inserm/UdA,* [2]*Bacteriology, UMR1070 M2ISH Inserm/UdA, Clermont-Ferrand, France*

INTRODUCTION: Crohn's disease is characterized by acute phases with moderate to severe intestinal inflammation, and chronic phases with colonic hypersensitivity and abdominal pain. This intestinal disease is believed to result from breakdown of homeostasis between intestinal microbiota and the mucosal immune system, with both environmental and genetic influencing factors. A number of studies of IBD in humans have described a functional class of *Escherichia coli* referred to as adherent invasive *E. coli* (AIEC) to be abnormally present in the ileum and associated with overexpression of the bacterial colonizing receptor CEACAM6.
AIMS&METHODS: We hypothesized that, depending on the level of intestinal AIEC colonization, mice will spontaneously develop a visceral hypersensitivity which will persist even after bacterial clearance and intestinal inflammation alleviation.
Transgenic mice overexpressing the human form of CEACAM6 protein and their wild-type littermates were orally infected by CD-associated AIEC bacteria (reference strain LF82) or by a non-pathogenic *E. coli* (MG1655). At 3, 9 and 21 days after infection, visceral hypersensitivity was assessed using a technique based on measuring electromyographic abdominal contractions induced by colorectal distension. This test is to induce, by progressive inflation of a balloon inserted into the colon, abdominal cramps whose amplitude is proportional to the colon sensitivity. Moreover, mice were euthanized and were assayed for intestinal inflammation level. Inflammation was monitored using anatomical indicators of colitis such as spleen and colon weight, and assessed by determination of the colonic myeloperoxidase activity and expression of systemic pro-inflammatory cytokines.
RESULTS: Human CEACAM6 overexpression in mice induced a significant decrease of the visceral hypersensitivity in comparison to their housekeeping WT mice. Otherwise, CD-associated AIEC LF82, but not non-pathogenic *E. coli* MG1655, infection dramatically quickly (D3) increased levels of visceral hypersensitivity in comparison to their housekeeping WT. Such visceral hypersensitivity persisted in mice overexpressing CEACAM6 receptor after bacterial clearance and did not match with intestinal inflammation.
CONCLUSION: Direct involvement of CD-associated AIEC LF82 infection in colonic hypersensitivity has been demonstrated. Thus, due to abnormal expression of their intestinal colonization receptor CEACAM6, increased intestinal persistence of such AIEC bacteria in CD patients may impact on colonic sensitivity.

P962 INCREASED COLONIC BILE ACID EXPOSURE: A RELEVANT FACTOR FOR SYMPTOMS AND TREATMENT IN IRRITABLE BOWEL SYNDROME (IBS).

A. Bajor[1,*], M. Rudling[2], H. Törnblom[1], K.-A. Ung[3], M. Simrén[1]. [1]*Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg,* [2]*Metabolism Unit, Centre for Metabolism and Endocrinology, Department of Medicine and Molecular Nutrition Unit, Centre for Nutrition and Toxicology, NOVUM, Karolinska Institute at Huddinge University Hospital, Stockholm,* [3]*Department of Internal Medicine, Kärnsjukhuset, Skövde, Sweden*

INTRODUCTION: Bile acids may play a role in the pathophysiology of irritable bowel syndrome (IBS). Bile acid malabsorption (BAM) is commonly diagnosed by use of the ^{75}SeHCAT retention test or by measurement of the ratio between plasma C4 and cholesterol (C4/chol) as an expression of bile acid synthesis.
AIMS&METHODS: The aims of this study were to investigate if any GI symptoms (GSRS-IBS and bowel habits) in patients with IBS (Rome II criteria) correlated with ^{75}SeHCAT retention values or C4/chol ratio. Results were compared with healthy controls (^{75}SeHCAT n=29, C4/chol n=419). Stool frequency

and form (Bristol Stool Form Scale) was registered and oro-anal transit time (OATT) measured with radio-opaque markers. We also offered 8 weeks open label treatment with colestipol to patients with a ^{75}SeHCAT retention value <20%. Registration of IBS symptom severity (IBS-SSS) at baseline and every other week and a weekly question about adequate relief of IBS symptoms (yes/no) was done for evaluation.

RESULTS: We included 141 patients (102 females; mean age 35.3 (range 17-71) years) where 18.5% had ^{75}SeHCAT retention <10% and 16% had high C4/chol ratio. Patients had lower ^{75}SeHCAT retention and higher C4/chol ratio (p=.0001 for both) compared to controls. ^{75}SeHCAT retention was lower in IBS-D and IBS-A compared to IBS-C and healthy controls (p<.0001). There were no differences between IBS subtypes regarding C4/chol ratio. Positive correlations were seen between ^{75}SeHCAT retention and stool frequency (r=0.27; p=.001), stool form (r=0.19; p=.03) and OATT (r=0.496; p=.001), but not with any of the GSRS-IBS parameters. C4/chol ratio did not show any relevant correlations to bowel habits or other GI symptoms. Fifteen of the 27 patients who agreed to participate in the colestipol treatment were responders (55%) defined by adequate relief of IBS symptoms at week 7 and/or 8. IBS Symptom severity was reduced at the end of the last treatment week compared to baseline (IBS-SSS 220±109 vs. 277±106 (mean±SD); p<.0001).

CONCLUSION: Increased colonic bile acid exposure measured by ^{75}SeHCAT retention influence bowel habits and OATT in patients with IBS. Symptom reduction and a high response rate to open label treatment with colestipol supports this, but placebo-controlled studies are warranted.

P963 A REGIONAL STUDY IN THE HUNT FOR ENTERIC NEURAL STEM CELLS

C. Tzivinikos[1,*], D. Natarajan[1], J. Cooper[1], A. J. Burns[1], N. Thapar[1].
[1]*Gastroenterology and Neural Development Units , University College London, Institute of Child Health , London, United Kingdom*

INTRODUCTION: Enteric neuropathies remain a challenging group of diseases. Current management is mainly palliative driving research towards enteric nervous system (ENS) cell replenishment therapies using enteric neural stem cells (ENSCs). Human ENSCs have been isolated from colonic full thickness and mucosal biopsies, while mouse ENSCs have been derived from entire gut. It remains unclear as to which gut region should be targeted in order to best harvest ENSCs for transplantation.

AIMS&METHODS: The aim of this study was to determine the optimal region of the gut for the harvesting of ENSCs. The study used both wild-type as well as transgenic mice (Rosa26YFPstop:TgWnt1Cre), in which all the neural crest cells (NCCs) and their derivatives constitutively express yellow fluorescent protein (YFP). The presence and relative proportion of ENSCs was compared between Oesophagus, Stomach, Small intestine,Colon and Caecum. Methods used to determine this were,1. Fluorescence-activated cell sorting (FACS), which calculated the % of YFP+ cells per region (therefore % of NCC as a total of all cells derived from each region);2. Immunohistochemistry on gut sections and entire gut to characterise and calculate the proportion of NCC cells that were presumptive ENSCs (based on a Sox10+/S100- immunostaining profile; Sox 10 is a transcription factor expressed by neural crest cells and S100 a glial marker) and to count cells per high power field in each region.

RESULTS: The study revealed qualitative and quantitative differences in ENS across the regions. Gut wholemount and section immunochemistry revealed the most YFP, p75^{NTR} (NCC marker), Tuj1 (neuronal marker), Sox10 and S100 stained cells in the colon and caecum followed by small intestine then stomach and oesophagus. In all regions more immunostained cells (all markers) were noted in the myenteric rather than submucosal plexus. FACS sorting (n=3) demonstrated the highest percentage of YFP+ cells in the large intestine (colon - 6.33% and caecum - 7.96%) and lowest in the stomach (2.21%). Counting of Sox10 only cells from Sox10/S100 double-labelled sections in each region of gut also revealed that the caecum contained the highest number of progenitor cells (7.6%) followed by colon (2.2%) and the least in the stomach (0.7%) and oesophagus (0.4%).

CONCLUSION: Although present in all regions, ENSCs have the greatest density within caecum, followed by colon, progressively decreasing more proximally in the gut. Considering these findings and the balance between which region are likely to contain more progenitors as well as be easily accessible to harvest tissue, we suggest that future ENSCs studies should focus on the colonic region, including the appendix, which may be a potential niche for ENSCs.

P964 DOES SHIFT WORK AFFECT COLONIC MOTILITY? A STUDY PERFORMED IN THE OCTODON DEGUS.

F. E. Martín Cano[1,*], D. Hernández Moreno[1], L. F. Barriga Sánchez[1], P. J. Camello[1], M. J. Pozo Andrada[1]. [1]*Physiology, University of Extremadura, Cáceres, Spain*

INTRODUCTION: Recent evidences suggest that the circadian rhythm disruption that occurs in aging also plays a role in cellular senescence. Modern life is increasing the gap between personal habits and natural synchronizers, as people increasingly adopt nocturnal life modes. Premature aging in these conditions could be responsible for several digestive disturbances and associated pathologies. Contrary to humans, most rodents have nocturnal habits. *Octodon degus*, which mainly shows diurnal rythms, represents a valuable tool in order to make circadian cycle studies translational to human research.

AIMS&METHODS: To study whether lighting simulating rotating shift work causes changes in colonic.

18 *Octodon degus,* split into two groups, were used in this study. In order to emulate shift work, the chronodisrupted group was under weekly shifting illumination for three weeks, going back to standard light during the weekends. Control group received a standard 12h-light pattern. The physical activity and internal temperature of the animals were continuously recorded in order to determine their biological rhythms. Colonic motility was studied using isometric contractile recordings from proximal and distal colonic strips without the mucosal layer and spatiotemporal mapping of distal colonic segments.

RESULTS: Animal activity and internal body temperature were uncoupled from the light/dark cycle due to the weekly changes in the illumination. This circadian alteration translates into changes in the contractility of colonic strips. Thus, distal colon strips showed lower spontaneous activity in the chronodisrupted animals. In addition, the contractile response to depolarization induced by KCl was differentially affected depending on the region: proximal response decreased by 68% whereas distal strips showed an increase of 125%. Similar results were obtained with muscarinic agonist bethanechol. Regarding the response to electrical field stimulation (EFS), chronodisruption induced an overall decrease for all the frequencies tested. Pharmacological dissection suggests that circadian alteration predominantly affects the adrenergic and cholinergic components of the neural response. Finally, spatiotemporal mapping of distal colonic segments revealed that motility patterns remained mainly unaffected in the chronodisrupted animals.

CONCLUSION: Chronodisruption alters contractility in colonic muscular strips; however these changes do not necessary translate into colonic motility alterations. It could be possible that functional redundancy counteracts the effects observed in the strips, preventing alterations at colonic function levels.

P965 LINACLOTIDE INDUCES SECRETION OF CGMP FROM MOUSE COLONIC EPITHELIUM

G. Hannig[1,*], B. Tchernychev[1], S. Jacobson[1], C. B. Kurtz[1], M. G. Currie[1], I. Silos-Santiago[1]. [1]*Ironwood Pharmaceuticals, Inc, Cambridge, United States*

INTRODUCTION: Linaclotide is a novel receptor guanylyl cyclase C (GC-C) agonist approved for treatment of abdominal pain and constipation in patients with irritable bowel syndrome with constipation (IBS-C). Linaclotide effects on bowel movements are mediated by intracellular cGMP produced upon activation of GC-C. It is hypothesized that the effects of linaclotide on abdominal pain are mediated by extracellular cGMP, which was shown to decrease the activity of pain-sensing nerves [1].

AIMS&METHODS: We used an *ex vivo* Ussing chamber assay to measure cGMP secretion from the mouse colonic mucosa in response to linaclotide treatment. Linaclotide-induced ion transport and epithelial barrier function were monitored by measuring short-circuit current (I_{sc}) and trans-epithelial electrical resistance (TEER).

RESULTS: Stimulation with linaclotide (1 uM) elicited a robust short-circuit current across mouse colonic epithelium. I_{sc} reached a maximum within ten minutes following stimulation with linaclotide and remained steady during the duration of the study (60 min). Treatment of colonic mucosa with linaclotide induced release of cGMP from the apical as well as the basolateral side of the epithelium. The time course of cGMP accumulation in the basolateral bath of the Ussing chamber was linear with an estimated cGMP secretion rate equal to 23 fmol/mińcm^2. The trans-epithelial electrical resistance of the colonic mucosa did not change over the course of the study indicating that the cGMP measured in the basolateral compartment after linaclotide stimulation is not diffusing from the apical compartment.

CONCLUSION: These findings demonstrate that linaclotide-stimulated mouse colonic epithelium secretes cGMP from both the apical and basolateral sides and that cGMP is present in the submucosal space to inhibit colonic nociceptors.

P966 RADIAL STRETCH TO HUMAN COLONIC SEGMENT IN VITRO IDENTIFIES DIFFERENT FUNCTION BETWEEN THE RIGHT AND LEFT COLON

H.-K. Oh[1,2,*], S.-B. Ryoo[2], S. A. Yu[2], E.-K. Choe[2], S.-H. Moon[2], K. J. Park[2]. [1]*Department of Surgery, Seoul National University Bundang Hospital, Seongnam-si,* [2]*Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: We previously demonstrated that the propagation patterns of contractions were different between the right and left colon in human. Since stretch is an important stimulus to evoke contractions in colon, we intended to determine whether there are any differences between the right and left colon with regards to the stretch reflex in human.
AIMS&METHODS: Colon segments of 5x3cm in size were obtained from the specimen of elective colon resections. Four steel clips were attached to each lateral margin of the colon in a direction that was orthogonal to the segment so as to record the activity of muscular contractions. Radial stretch was applied by intraluminal balloon distension of 9 Fr Foley catheters. Frequency (/min), amplitude (mN), and area under the curve (AUC, sec×mN/min) of muscle contractions were recorded before and after stretch intervention at the proximal and distal side of colon. Conventional microelectrode recordings for membrane potentials were performed using sharp microelectrodes.
RESULTS: Tension recordings on colonic segments were analyzed in tissues obtained from 50 patients (21 from the right and 29 from the left colon). Frequency (/min), amplitude (mN), and AUC (AUC, sec×mN/min) of contraction were 0.5±0.2, 13.9±7.0, and 263.2±128.5 in the right colon and 0.4±0.2, 21.9±16.3, and 357.5±225.5 in left colon, respectively. After radial stretch in the right colon, these variables increased to 0.6±0.2 (p=0.02), 22.5±16.6 (p=0.01), 387.4±129.5 ($p<0.001$) at the proximal side, and 0.6±0.2 (p=0.39), 19.6±10.1 ($p<0.001$), 369.0±197.7 ($p<0.001$) at the distal side, respectively. In the left colon, excitation of contractility after radial stretch was also observed at the proximal side, 0.6±0.2 ($p<0.001$), 23.1±16.1 (p=0.001), and 388.9±241.6 ($p<0.001$), but on the contrary, at the distal side, inhibition of contractions were recorded as follows, 0.4±0.1 (p=0.007), 17.5±11.0 ($p<0.001$), and 293.3±162.4 ($p<0.001$). The pattern of the contractility changes at the distal side were also significantly different between right and left colon segment (all $p<0.05$). In intracellular recordings after stretch intervention from the circular muscles, hyperpolarization (from -54.8±12.0 to -55±3.1mV) was noted at the distal side of the left colon, in contrast to depolarization at all other sites.
CONCLUSION: Our results indicate that radial stretch in human colon *in vitro* evoke excitatory contractions at both proximal and distal sides in the right colon and proximal side of left colon, but inhibits contractions in the distal side of the left colon. This may reflect the differences in functions between the right and the left colon.

P967 DEPLETION OF MURINE INTESTINAL MICROBIOTA BY ANTIBIOTICS: EFFECTS ON GUT TRANSIT AND TOLL-LIKE RECEPTORS EXPRESSION.

L. Grasa[1,*], M. Castro[1], E. Latorre[1], E. Layunta[1], S. Gonzalo[1], A. Gimeno[1], J. E. Mesonero[1], M. P. Arruebo[1], M. A. Plaza[1], A. I. Alcalde[1], M. D. Murillo[1]. [1]*Pharmacology and Physiology, University of Zaragoza, Zaragoza, Spain*

INTRODUCTION: Alteration of intestinal microbiota, induced by infection, diet or antibiotics, is involved in intestinal disorders like Irritable Bowel Syndrome. In fact, disruption of the intestinal microbiota by antibiotics induces changes in gut sensory-motor function and immune activity[1]. Toll-like receptors (TLRs) play a pivotal role in sensing both pathogenic and commensal microorganisms. Thus, TLRs are critical for the initiation of inflammatory and innate immune responses.
AIMS&METHODS: The aim was to investigate the effects of the alteration of murine intestinal microbiota induced by antibiotics on gut transit. We also examined the expression of TLRs (1, 2, 3, 4, 5, 6, 7, 9 and 11) in the intestine from mice treated with antibiotics.
Female C57BL/10 mice of 5-8 weeks old were divided into two groups: control and treated with antibiotics (n=8). Mice were gavaged for 7 days with water (controls) or a combination of antibiotics (bacitracin 20 mg and neomycin 20 mg) and the antifungal substance pimaricin 5 μg per mouse and day (treated mice). Alteration of the gut microbiota was confirmed by measuring the load of bacterial DNA in feces by 16S rRNA gene quantitative PCR. The colonic transit was studied in mice fasted for 14 h and anesthetized with isoflurane before a glass bead was inserted 2 cm intrarectally. The latency to the expulsion of the bead was recorded. Afterwards, mice were individually housed and gavaged with an Evans blue marker and the latency to the detection of Evans blue in the droppings was recorded to determine the whole gut transit. TLRs gene expression (mRNA) was determined in ileum and colon by quantitative RT-PCR.
RESULTS: Mice treated with antibiotics had 370 fold less bacterial DNA in feces than controls, demonstrating depletion of the colonic microbiota. The treatment with antibiotics delayed the colonic (711.2 ± 147.6 s vs. 329.2 ± 90.2 s; $P \leq 0.05$) and whole gut transit (341.4 ± 13.9 min vs. 177.4 ± 21.08 min; $P \leq 0.001$) respect to controls. Mice treated with antibiotics showed a reduced expression of TLR2, TLR3 and TLR6 in ileum and TLR2 and TLR9 in colon. On the contrary, these animals showed an increased expression of TLR4, TLR5 and TLR9 in ileum and TLR3, TLR4, TLR6 and TLR7 in colon.
CONCLUSION: The treatment with antibiotics depletes the murine colonic microbiota and induces delay in gut transit. These functional changes are accompanied by downregulation or upregulation of TLRs mRNAs, depending on the segment of the gut.

P968 IN CONSTIPATED IRRITABLE BOWEL SYNDROME (IBS-C) RESPONSE TO PRUCALOPRIDE IS ASSOCIATED TO A NORMALIZATION OF POSTPRANDIAL MODIFICATION OF RECTOSIGMOID TONE: PRELIMINARY DATA

M. DI STEFANO[1], M. BERGONZI[1,*], C. MENGOLI[1], A. ZANABONI[1], E. PAGANI[1], E. MICELI[1], G. R. CORAZZA[1]. [1]*1st Medical Department, IRCCS S Matteo Hospital Foundation, Pavia, Italy*

INTRODUCTION: Increased postprandial rectal tone is related to the occurrence of postprandial defecation (1): when contractions of the sigmoid colon present stool to the rectum in a high tone status (2), an increase in parietal tension occurs, heightening sensation, and providing the call to stool. In IBS, we have previously shown that postprandial recto-sigmoid tone modification is impaired, due to an altered activation of neural pathways (3). Moreover, in IBS-C patients, we have shown that the administration of serotoninergic agents improves this abnormality (4).
AIMS&METHODS: The aim of this work was to verify if responder patients to prucalopride treatment show an improvement of intestinal tone regulation. Eight female patients (mean age 33 years, range 25-38) with constipation-predominant IBS (IBS-C), diagnosed according to Rome III criteria, were studied. In all subjects, presence and severity of symptoms, number and consistency of daily evacuations (Bristol Stool Form Scale) and recto-sigmoid barostat test were evaluated. After an overnight fast, a double lumen polyvinyl tube with an adherent, infinitely compliant plastic bag (1200 ml capacity), finely folded, was inserted through the anus as far as the recto-sigmoid junction. The perception and discomfort thresholds were investigated during fasting and the postprandial period (200 Kcal, 200 ml liquid meal) by a series of isobaric distentions; at the end of each distention, patients were asked to assess the sensation using a standardized scale from 0 (no sensation) to 6 (pain), were 1=perception and 5=discomfort. During the test, we evaluated modification of rectosigmoid tone, as the difference between mean 60-min post-prandial volume and mean 30-min fasting volume. After prucalopride 2 mg/day for 4 weeks, a second evaluation of symptom assessment and recto-sigmoid tone was performed. A patient was considered as a responder if ≥3SCBM/week were achieved.
RESULTS: Four out of 8 patients showed a clinical response to prucalopride. In all, postprandial modification of recto-sigmoid tone improved at the end of the treatment (postprandial modification tone from +8±35% to -64±22%). No modification of sensitivity thresholds was evident after treatment. In the 4 non responder patients, no modification of postprandial rectosigmoid tone nor of sensitivity thresholds was evident.
CONCLUSION: These preliminary data show that in IBS-C, in responder patients to prucalopride treatment, the improvement of symptom severity is accompanied by an improvement of regulation of intestinal tone.

P969 RECIPROCAL MYENTERIC NEUROTRANSMISSION IN THE CIRCULAR AND LONGITUDINAL MUSCLE LAYERS IN AGED HUMAN SIGMOID COLON

M. J. Pozo[1,*], F. Martín-Cano[1], C. Camello[1], D. Henandez[1], F. Barriga[1], T. Espin[2], F. Santos[3], J. Gonzalez[3], P. J. Camello[1]. [1]*Physiology, University of Extremadura, Cáceres,* [2]*Genaral Surgery, Hospital Infanta Cristina, Badajoz,* [3]*Genaral Surgery, Hospital S Pedro de Alcantara, Cáceres, Spain*

INTRODUCTION: The postprandial propulsion of intestinal contents depends on the coordinated activity of circular and longitudinal smooth muscle brought about by the peristaltic reflex. The role of neuromuscular function in the contractility of the circular muscle layer has been extensively studied, but studies in the control of the human longitudinal one are lacking, specially in humans.
AIMS&METHODS: To unveil possible differences in the myenteric neurotransmission between both muscular layers of human sigmoid colon.
Macroscopically normal samples of human sigmoid colon were obtained from 6 patients (aged 60-87 yrs) who underwent surgery for rectal cancer. After removing mucosa and submucosal layers, circular muscle strips (10 x 4 mm) were cut with the long axis lying in the direction of the muscle fibres. Longitudinally orientated strips were taken after removing the circular muscle. *In vitro* contractility was recorded under basal conditions and electrical field stimulation (EFS, 0.3 ms, 350 mA, 0.2-10 Hz, for 60 s every 9 min). Statistical differences were determined by two-way ANOVA, followed by Bonferroni post-hoc test.
RESULTS: Isolated strips contracted rhythmically in the absence of stimuli, but circular strips had spontaneous contractions of higher frequency and amplitude than the longitudinal ones. The longitudinal muscle presented long-lasting giant contraction every 5 min. In the longitudinal muscle, EFS-induced responses at all tested frequencies but in the circular layer 2, 5 and 10 Hz had an inhibitory character, indicating a predominant inhibitory myenteric neurotransmission to the circular muscle. In keeping with this, after EFS a significant decrease in the basal tone and spontaneous activity was present only in the circular muscle. Blockade of excitatory cholinergic and adrenergic innervations caused a strong reduction in EFS-induced responses of the longitudinal layer, and the residual contraction was abolished by GR94800, a substance P blocker . However, in the circular layer these inhibitors had little effects and EFS-induced responses were reverted by blockade of nitrergic and purinergic inhibitory nerves that present mutual inhibition.
CONCLUSION: Activation of myenteric plexus of aged human sigmoid colon causes relaxation of the circular muscle but contraction of the longitudinal layer, which will favor peristaltic reflexes. The giant contractions that appear in the longitudinal layer could contribute to the progression of colonic content or act as a braking mechanism.

P970 INHALED METHANE IS PREVENTING AN INCREASE IN NITRERGIC MYENTERIC NEURON DENSITY AND ENHANCED OXIDATIVE AND NITROSATIVE STRESS AFTER MESENTERIC ISCHEMIA-REPERFUSION IN RATS

N. Bódi[1,*], P. Talapka[1], G. Varga[2], T. Tőkés[2], M. Z. Poles[1], A. Pál[1], M. Bagyánszki[1], J. Kaszaki[2], É. Fekete[1], M. Boros[2]. INTRODUCTION: The gastrointestinal tract is highly susceptible to hypoxic insults; therefore, the intestinal vascular failures are often accompanied by enteric neuropathy. We recently demonstrated that inhaled methane (CH_4) has potent anti-inflammatory effects in experimental mesenteric ischemia-reperfusion (IR), however, the impacts of exogenous CH_4 on the IR-induced enteric neuropathy has not been studied yet.
AIMS&METHODS: Therefore, we aimed to investigate the neuroprotective potential of inhaled CH_4 and to determine the parallel biochemical signs of reactive oxygen and nitrogen species generation in a rat model of mesenteric IR. Anesthetized rats were randomly divided into sham-operated control, IR and CH_4 treated IR groups. Superior mesenteric artery occlusion was maintained for 30 min and the subsequent reperfusion was monitored for 120 min. The animals inhaled normoxic artificial air (21% O_2) with or without 2.5% CH_4 during the last 10 min of ischemia and in the first 5 min of reperfusion. At the end of reperfusion, segments of the duodenum, ileum and colon were processed for quantitative histochemical and biochemical studies. The nitrergic and total neuronal density and the number of neurons containing neuronal and endothelial nitric oxide synthase (nNOS and eNOS, respectively) were evaluated by single and double-labelling immunohistochemistry on whole-mounts from different gut segments. The tissue content of nitrite/nitrate (NO_x) and nitrotyrosine (NTyr), and xanthine oxidoreductase (XOR) activity were determined, from small intestinal biopsies.
RESULTS: As a consequence of IR the density of nitrergic myenteric neurons, nNOS and eNOS immunoreactive neurons was significantly elevated in the duodenum only, while the number of total myenteric neurons did not change. The levels of NO_x, NTyr and XOR were significantly increased in the intestinal biopsies as compared to control samples. The inhalation of CH_4 kept the nitrergic neuronal density as well as the levels of oxidative and nitrosative stress markers at the control level.
CONCLUSION: These results demonstrate that CH_4 inhalation can neutralize the reactive oxygen and nitrogen species during the early phase of reperfusion, and therefore may contribute to the resetting of nitrergic myenteric neuronal density and restore the nitrergic function in gut motility after mesenteric IR.

P971 CELLULAR ALTERATIONS INDUCED BY ENTEROGLIAL S100B ON HUMAN COLONIC SMOOTH MUSCLE CELLS.

S. Rosati[1,*], A. Scirocco[1], G. Tellan[2], B. Ascione[3], P. Matarrese[3], W. Malorni[3], G. Esposito[4], E. Corazziari[1], C. Severi[1]. INTRODUCTION: S100B, a Ca^{2+}-binding protein, is predominantly expressed and secreted by enteroglia in inflammatory conditions. As an extracellular factor, S100B engages RAGE (Receptor for Advanced Glycation End-products) with different outcomes (i.e. beneficial or detrimental, pro-proliferative or pro-differentiative) depending on the concentration attained. At micromolar concentrations, S100B exerts toxic effects on neurons via activation of the NADPH oxidase complex that, through theoverproduction of reactive oxygen species (ROS), induces inflammatory cytokines production and apoptosis. The expression of enteroglial-derived S100B and its possible contribution to inflammatory motor disorders has been poorly investigated
AIMS&METHODS: Aim of this study is to evaluate the effects induced by S100B on nearby gut smooth muscle. A primary highly pure human colonic smooth muscle cells (HSMC) culture was exposed to 1μM of S100B up to 24h. Total RNA was isolated and expression of S100B, RAGE and proinflammatory cytokines IL-6 and MCP-1 were determined by q-PCR. ROS (Hydrogen peroxide) (H_2O_2), cytoskeleton and apoptosis were measured by cytofluorometry and biological activity by scanning micrometry. Results are expressed as mean±SE and analysed by ANOVA, $p<0.05$ considered statistically significant.
RESULTS: HSMC presented a resting length of 75.06 ± 2.66 μm and a maximal contractile response to the muscarinic agonist acetylcholine of $24.94 \pm 1.27\%$. qPCR analysis showed that HSMC constitutively express mRNA encoding for RAGE and S100B. Exposure to S100B for 24h induced a dose dependent decrease in cell length (21.46±2.01% $p<0.05$) and contraction (64,02±7.08% $p<0.005$). In addition quantitative flow cytometry analysis indicated that S100B induced an increase of ROS generation, in particular an over-production of hydrogen peroxide (437.00±4.01, $p<0.0005$) without concomitant increase in the apoptosis factor caspase-3 activity. Moreover, S100B induced a peculiar dose-dependent rearrangement and redistribution of the contractile filament actin (23.30±0.12, $p<0.05$), and an increase of pro-inflammatory cytokines MCP-1 and IL-6 expression. The effects of S100B were abolished in the presence of Ab antiRage (1:10000) or of the NADPH oxidase inibhitor apocynin (60μM).
CONCLUSION: S100B can induce HSMC dysfunction through interaction with Rage coupled to the NADPH oxidase transduction signalling. Taken together, these results increase our understanding of the molecular mechanisms of RAGE signaling in muscle cells and could lead to the identification of novel therapeutic targets for motor disorders.

P973 THE SHORT HEALTH SCALE QUESTIONNAIRE VALIDATION IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

A. Krarup[1,*], E. Peterson[1], G. Ringström[1], H. Törnblom[1], H. Hjortswang[2], M. Simrén[1]. [1]*Department of Internal Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg,* [2]*Division of Gastroenterology and Hepatology, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden*

INTRODUCTION: Subjective health assessment is central when treating patients with irritable bowel syndrome (IBS). The "Short Health Scale" (SHS) is a simple 4-item questionnaire covering most aspects of subjective health that has been validated for inflammatory bowel disease.
AIMS&METHODS: to evaluate validity, reliability and responsiveness of the SHS in IBS patients. To test validity, 451 patients with IBS (mean age 38 years; 81% females) completed the SHS and questionnaires assessing IBS symptom severity (IBS-SSS), gastrointestinal (GI)-specific anxiety (VSI) and quality of life (IBSQOL). To evaluate reliability and responsiveness to changes, the questionnaires were repeated after 2 weeks in 18 patients, and after 12 weeks in 212 patients who had completed a patient education program.
RESULTS: Validity was documented with 1) gradually increasing mean scores for all four SHS items with increasing IBS symptom severity, ($P<0.0001$), and 2) positive correlations between the four SHS item and the corresponding items from the other subjective health assessment tools (item 1 rho= 0.67, item 2 rho=-0.44;-0.46, item 2 rho=-0.51;0.57, item 4=-0.34;-0.46, $P<0.0001$). Reliability was confirmed (Spearman's rho >0.7, and intraclass correlations >0.7). Responsiveness was good with patients defined as being responders after the patient education (reduction of IBS-SSS≥50 points) having significant reductions in three of the SHS items ($P<0.05$), and borderline change for the fourth SHS item ($P=0.06$).
CONCLUSION: The SHS is a valid, reliable, and responsive health measure in IBS patients. It can be rapidly completed and evaluated, which supports its usefulness in clinical practice and clinical trials.

P974 ADEQUATE RELIEF ASSESSMENT: MEASUREMENTS OF SUBJECTIVE HEALTH IN PATIENTS WITH IRRITABLE BOWEL SYNDROME AND RELATIONSHIP TO OTHER VALIDATED QUESTIONNAIRE OUTCOMES

A. Krarup[1,*], G. Gingström[1], H. Hjortswang[2], M. Simrén[1]. [1]*Department of Internal Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg,* [2]*Division of Gastroenterology and Hepatology, Department of Clinical and Experimental Medicine, Linköping University, Linköbing, Sweden*

INTRODUCTION: Subjective health assessment is necessary when treating patients with irritable bowl syndrome (IBS). The simple 2-item questionnaire "IBS Adequate Relief" (IBS-AR) has been proposed as standard for primary outcome assessment in IBS trials. It has been proposed that the baseline results of IBS-AR may confound treatment results[1].
AIMS&METHODS: The aim of this study was to compare the IBS-AR outcomes with outcomes using other validated IBS questionnaires. Before and after treatment 584 IBS patients (mean age 40 years; 79% females) completed IBS-AR, "IBS Severity Scoring System" (IBS-SSS), IBS specific Gastrointestinal Symptom Rating Scale (GSRS-IBS), "IBS disease-specific Quality Of Life" (IBSQOL), and "Gastrointestinal-Specific Anxiety" (VSI).
RESULTS: At baseline 19.3% of the 579 patients completing IBS-AR reported adequate relief (*baseline responders*). They had a higher distribution of women (87% versus 77%, P=0.01), milder IBS severity (6.6% versus16.1%, P=<0.01), lower symptom scores (261.7 versus 311.7, P>0.001) and better quality of life (domains; sleep, energy, physical role and function, all P<0.05) compared to *baseline non-responders*. After treatment the 253 (43.7%) IBS-AR responders had improvement in IBS-SSS severity, (-86.6 ± 83 versus -1.4 ±112, P<0.001), and in several of the GSRS and IBS-QOL scores (P<0.02). When excluding IBS-AR *baseline responders* these differences were even more pronounced. Only when excluding IBS-AR *baseline responders* did the proportion of IBS-AR *responders* follow the IBS-SSS severity scores (P=0.004 versus P=0.3). There were no strong agreement between treatment *responders* defined by IBS-AR versus IBS-SSS and GSRS (Kappa 0.13-0.45, all P<0.05).
CONCLUSION: IBS-AR *baseline responders* differ significantly from *baseline non-responders* and this may confound treatment results if *baseline responders* are not excluded. Different commonly used IBS treatment endpoints do not strongly agree on definitions of *responders*.

P975 IRRITABLE BOWEL SYNDROME PATIENTS DIAGNOSED IN PRIMARY AND SECONDARY CARE; WHAT EXPLAINS THE DIFFERENCE IN HEALTH CARE COSTS?

C. Flik[1,*], W. Laan[1], A. Smout[2], N. de Wit[1]. [1]*Julius Centre, Health Sciences and Primary Care, UNIVERSITY MEDICAL CENTRE, Utrecht,* [2]*department of Gastroenterology and Hepatology, Academic Medical Centre, Amsterdam, Netherlands*

INTRODUCTION: Irritable Bowel Syndrome (IBS) is a chronic condition that is often accompanied by other chronic or functional comorbidities. IBS is reported to initiate substantial health care expenditure, but the background of these costs is unknown.
AIMS&METHODS: The aims of this study were to compare the costs of healthcare consumption of patients diagnosed with IBS in primary and secondary care before and after diagnosis and to specify the origin of additional costs in further detail. All patients diagnosed with IBS by a general practitioner or specialist between 2006 and 2009 and a control group of individuals without IBS, matched for age and gender, were extracted from the database of a Dutch health insurance company, with over 2 million members. Direct medical costs for general practitioner consultations, drug prescription and hospital care were compared between the two groups. Hospital costs were further divided into costs for IBS, for other chronic diseases, for other functional disorders and for all other disorders.
RESULTS: Data of 326 primary care IBS patients, 9274 IBS patients diagnosed in secondary care and 652 respectively 18548 non IBS control patients were included in the analysis. For primary care IBS patients the mean (± SD) total annual health care costs were 1648 (± 2898) € in the two years before diagnosis and 2134 (± 3258) € annually in the three years after the diagnosis was made, as compared to 1320 (± 2840) and 1492 (± 3120) € for control patients. For secondary care IBS patients mean annual costs in the three years before diagnosis were 2003 (± 3863) and 4331 (± 6958) € in the three years after diagnosis; costs for control patients were 1951(± 6002) respectively 1976 (± 5692) €. For primary care patients the increase after diagnosis could be mainly attributed to costs for 'non-IBS'-medication, to specialist costs for 'all other disorders' and to the increase in general practitioners' consultations. For secondary care patients the increase in costs after IBS was diagnosed was almost completely caused by additional costs for specialist care for 'all other disorders'.
CONCLUSION: Mean annual health care costs per patient increase with 30% after the diagnosis of IBS in primary care and over 100% for patients diagnosed in secondary care. Costs of control patients are higher in secondary care than in primary care, but do not change in time. The increase in costs after the IBS diagnosis is mainly due to non IBS related health care expenditure.

P976 EFFECT OF TRANSCRANIAL MAGNETIC STIMULATION ON RECTAL SENSITIVITY IN IRRITABLE BOWEL SYNDROME: A RANDOMIZED, PLACEBO-CONTROLLED PILOT STUDY

C. Melchior[1,*], G. Gourcerol[1], N. Chastan[1], E. Verin[2], J.-F. Ménard[3], P. Ducrotté[1], A.-M. Leroi[1]. [1]*INSERM U1073,* [2]*Handicap Research Group, UPRES EA 3830/IFRMP23,* [3]*Biostatistics Unit, Rouen University Hospital, ROUEN, France*

INTRODUCTION: Repetitive transcranial magnetic stimulation (rTMS) applied to the motor cortex can induce analgesic effects in patients with chronic pain syndromes through its effect on central pain modulatory systems. Our aim was to evaluate the effect of rTMS on rectal sensitivity in irritable bowel syndrome (IBS) patients.
AIMS&METHODS: In this randomized, sham-controlled trial, 21 IBS patients (11 women, 10 men, mean age 44 ± 12.6 years) were randomized using a double-blind crossover protocol to active or sham rTMS for five days of treatment. The primary outcome measure was the increase in the pressure pain threshold after rTMS. Secondary outcomes were the changes in maximum tolerated rectal volume, rectal compliance, and average pain intensity between baseline and the end of the treatments.
RESULTS: There were no statistically significant differences between active and sham rTMS in terms of an increase in the pressure pain threshold, maximum tolerated volume, and rectal compliance at the end of the treatments compared to baseline. However, in the subgroup of patients with the most marked rectal hypersensitivity, the volume threshold was significantly improved by active but not by sham rTMS (p=0.03). Patients experienced a significant improvement in pain regardless of the type of stimulation.
CONCLUSION: This pilot study failed to demonstrate any benefit of rTMS on our primary endpoint. However, the effect of rTMS on rectal tolerated volume in the most hypersensitive patients was encouraging enough to plan more powered studies.

P977 CALCIUM ANTAGONISTIC EFFECTS OF ETHANOLIC MYRRH EXTRACT IN INFLAMED INTESTINAL SMOOTH MUSCLE PREPARATIONS

C. Vissiennon[1,*], K.-H. Goos[2], O. Goos[2], K. Nieber[1]. [1]*Institute of Pharmacy, University of Leipzig, Leipzig,* [2]*REPHA GmbH, Langenhagen, Germany*

INTRODUCTION: Myrrh is the oleo-gum resin of mainly *Commiphora molmol* ENGLER (Burseraceae) and as powdered substance one compound in the traditional medicinal product Myrrhinil-INTEST®, which has been used for the treatment of unspecific and inflammatory intestinal disorders. To date only limited data is available regarding its mechanism of action. Besides antimykotic and antiphlogistic properties calcium antagonistic and antidiarrhoic effects have been discussed [1].
AIMS&METHODS: The aim of the present study was to evaluate the calcium antagonistic effect of myrrh. Therefore, an ethanolic myrrh extract (MY) was tested for its effects on muscle tone and acetylcholine (ACh)-induced contractions in untreated and inflamed rat ileum/jejunum preparations. Inflammation was experimentally induced by 2,4,6-trinitrobenzene sulfonic acid (TNBS, 10 mM, 30min). Additionally, the effect of the calcium channel agonist Bay K8644 in presence of varying MY concentrations was examined to confirm the calcium antagonistic effect.
RESULTS: MY suppressed the ACh-induced contraction down to 25,75 % (0,99 mg/ml MY). MY (0,15; 0,25 and 0,35 mg/ml) induced a concentration-dependent right-ward shift of the Bay K8644 concentration-response curve in untreated and inflamed preparations with a significant EC50 shift. Schild analyses resulted in a pA2 value of 0,93 for untreated preparations. Increasing MY concentrations induced a concentration-dependent decrease of the agonistic maximum effect in untreated and inflamed preparations down to 15,84% and 25,78% respectively for the highest concentration leading to a pD2 value of 0,58.
CONCLUSION: MY reduced intestinal muscle tone and ACh-induced contraction of untreated and inflamed ileum/jejunum preparations based on dual calcium antagonism characterised by a right-shift of the agonistic dose-response curve and a depression of maximum effect. The resulting reduction of intestinal motility and spasmolytic effects provide a rationale for the treatment of intestinal disorders.

P978 IRRITABLE BOWEL SYNDROME AND PSYCHOLOGICAL COMORBIDITY – LONG-TERM SUCCESS OF GUT-DIRECTED GROUP HYPNOSIS

J. Peter[1], U. S. Tran[2], M. Michalski[1], G. Moser[1,*], Working Group for Psychosomatics in Gastroenterology, Medical University of Vienna.
[1]*Gastroenterologie, MEDIZINISCHE UNIVERSIÄT WIEN,* [2]*Fakultät für Psychologie, Universität Wien, Vienna, Austria*

INTRODUCTION: A recent long-term study (Moser et al., Am J Gastroenterol 2013) has shown gut-directed group-hypnosis (GGH) to have a positive effect on refractory irritable bowel syndrome (IBS). Patients with severe psychological disorders were excluded from that study. However, IBS is frequently associated with psychological co-morbidity.
AIMS&METHODS: Aim of this study was to examine a) if patients with psychiatric diagnoses do also profit by GGH, and b) if GGH can lead to higher resilience. **Methods:** nA=37 Gastroenterology outpatients with IBS (Rome III criteria), 26 (70%) of which had psychiatric co-morbidity and participated in 7 to 10 GGH-sessions were included. Quality of life, physical and psychological wellbeing (visual analogue scales; 0="extremely bad", 100="excellent") as well as anxiety and depression (HADs) were measured before first, fifth, last GGH-session, and at follow-up (after 10,3 months averagely). Additionally, at follow-up, IBS-severity and factors of resilience were measured. The same data was collected for a control group of nB=37 IBS patients not undergoing GGH-treatment.
RESULTS: Comparison between begin of GGH and follow-up revealed significant improvement in physical wellbeing (mean: 33.8 vs. 57.3; $p<.001$), psychological wellbeing (43.0 vs. 57.0; $p<.01$), quality of life (38.3 vs. 58.9; $p<.001$), and showed reduction in anxiety (HADs: 9.8 vs. 7.45; $p<.001$) and depression (6.6 vs. 5.0; $p<.01$). Thirty patients (81%) indicated considerable improvement after GGH-treatment. This responder-subgroup showed lower IBS-severity and higher resilience ($p<.001$ respectively) than the control group.
CONCLUSION: GGH presents a valuable therapy even for IBS-patients with psychological co-morbidity. Lower IBS-severity and higher resilience after treatment indicate better coping.

P979 EFFECT OF LINACLOTIDE ON IBS-QOL SEXUAL SUBSCALE SCORES IN PATIENTS WITH IRRITABLE BOWEL SYNDROME WITH CONSTIPATION: RESULTS FROM 2 PHASE 3 TRIALS

M. G. Currie[1], S. J. Shiff[2], X. Hao[1], R. Carson[2], M. J. Baird[1], J. Johnston[1,*].
[1]*Ironwood Pharmaceuticals Inc., Cambridge,* [2]*Forest Research Institute, Jersey City, United States*

INTRODUCTION: Linaclotide (LIN) is a minimally absorbed guanylate cyclase-C agonist approved for treatment of IBS with constipation (IBS-C). IBS often results in diminished quality of life (QOL), including decreased sexual desire and activity. This post hoc analysis aimed to determine if LIN treatment improved IBS-QOL sexual subscale scores in IBS-C patients, compared to placebo (PBO).
AIMS&METHODS: Data from 2 randomised, double-blind Phase 3 trials of LIN in IBS-C were pooled. The IBS-QOL was administered at baseline and Week 12. The sexual subscale includes items on difficult sexual activity and reduced sexual desire, both rated on a 5-point scale (1=not at all, 2=slightly, 3=moderately, 4=quite a bit, 5=extremely/a great deal), with the sum of both items scaled to 0 (worst) to 100 (best). Scores for LIN- vs PBO-treated patients in the intent-to-treat (ITT) population and the Impaired Sexuality (IS) subgroup (patients with baseline sexual subscale scores $\leq$50) at Week 12 were compared to baseline.
RESULTS: Of 1598 ITT patients with baseline sexual subscale scores, 522 (33%) had a score $\leq$50 indicating IBS significantly impacted their sexual desire and activity (34% of females [484/1439] and 24% of males [38/159]). LIN significantly improved change-from-baseline sexual subscale scores at Week 12 vs PBO in both the ITT population and the IS subgroup (Table, $P<0.001$ for both). Although baseline scores for males were higher (better) than those of females, improvement vs PBO for males compared to females was similar in the ITT population and greater for the IS subgroup. However, the sample size for males was too small to establish statistical significance.
IBS-QOL Sexual Subscale Results

	PBO (ITT)	LIN (ITT)	Change from baseline Δ	P-value (ITT)	PBO (IS)	LIN (IS)	Change from baseline Δ	P-value (IS)
Overall (n)	795	803	5.2	<0.0001[a]	249	273	7.2	0.0007[a]
Baseline	68.9 (31.9)	66.9 (30.9)			27.2 (17.8)	29.5 (17.7)		
Week 12	79.7 (25.9)	83.1 (23.6)			57.8 (29.9)	67.9 (28.1)		
Females (n)	706	733	5.2	<0.0001[a]	228	256	6.7	0.0016[a]
Baseline	68.0 (32.3)	66.1 (31.1)			26.6 (17.8)	29.5 (17.8)		
Week 12	79.8 (25.8)	83.2 (23.4)			58.5 (30.2)	68.6 (27.7)		
Males (n)	89	70	4.2	0.3129[a]	21	17	10.2	0.2389[a]
Baseline	76.3 (28.1)	74.5 (28.7)			32.7 (16.5)	30.1 (17.7)		
Week 12	78.9 (26.7)	81.5 (26.0)			50.0 (25.7)	57.8 (33.2)		

Data are mean (SD)
[a]P values based on change-from-baseline treatment difference for LIN vs PBO in an ANCOVA model
CONCLUSION: LIN treatment significantly improves IBS-QOL sexual subscale scores in IBS-C patients, compared with PBO in both the total population and in patients with impaired sexuality at baseline.

P980 IS RESPONSE TO LINACLOTIDE AFTER 4 WEEKS OF TREATMENT PREDICTIVE OF 12-WEEK IMPROVEMENT?

W. D. Chey[1], B. J. Lavins[2], S. J. Shiff[3], J. E. MacDougall[2], C. B. Kurtz[2], M. G. Currie[2], J. M. Johnston[2,*]. [1]*Division of Gastroenterology, University of Michigan, Ann Arbor,* [2]*Ironwood Pharmaceuticals Inc., Cambridge,* [3]*Forest Research Institute, Jersey City, United States*

INTRODUCTION: Linaclotide (LIN) is a minimally absorbed guanylate cyclase C agonist approved in the US and EU for irritable bowel syndrome with constipation (IBS-C). A question for prescribing physicians is whether to continue LIN in patients who do not improve during early weeks of therapy. This post hoc analysis assessed if response to LIN at Week 4 predicts Week 12 improvement, and if LIN should be continued in IBS-C patients not responding by Week 4.
AIMS&METHODS: Pooled data from 2 Phase 3 IBS-C trials of LIN were analysed. For Degree of Relief of IBS Symptoms, Degree of Relief of Abdominal Pain, and Spontaneous Bowel Movement [SBM] frequency, a patient's Week 4 clinical response was used to predict improvement at Week 12. For the purposes of determining a patient's Week 4 response, the 7-point balanced Degree of Relief scale was collapsed into 3 categories: Improved (completely, considerably, or somewhat relieved), Unchanged, and Worse (somewhat worse, considerably worse, or as bad as I can imagine) compared to baseline. For SBM frequency, a dichotomous end point was used: SBMs increased by $\geq$2/week or not increased by $\geq$2/week from baseline.
RESULTS: The proportion of patients who had response at Week 4 was significantly greater for LIN- vs placebo (PBO)-treated patients: 72% vs 47% for Degree of Relief of IBS Symptoms, 70% vs 47% for Degree of Relief of Abdominal Pain, and 59% vs 33% for SBM frequency (all comparisons: $P<0.0001$). For all parameters, most LIN-treated patients ($\geq$70%) who had response at Week 4 were improved at Week 12. For LIN-treated patients whose symptoms were unchanged at Week 4 for Degree of Relief of IBS Symptoms and Degree of Relief of Abdominal Pain, 36% and 39% were improved at Week 12, compared with 19% and 21% of the PBO group, respectively ($P<0.05$). For SBM frequency, 30% of LIN-treated patients vs 17% of PBO-treated patients without response at Week 4 were improved (SBMs $\geq$2) at Week 12 ($P<0.05$).
CONCLUSION: Patients whose IBS symptoms improved with LIN after 4 weeks were likely to maintain improvement. At least 30% of LIN patients who were unchanged at Week 4 experienced symptom improvement by Week 12. The significant differences between LIN and PBO in the percentage of patients improved at Week 12 who were unchanged at Week 4 indicates that $\geq$1 month of LIN therapy may be required for improvement in some patients. As such, an initial course of LIN therapy in IBS-C patients should be >4 weeks.

P981 A RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED STUDY: EFFECTS OF THE ENZYME ALPHA-GALACTOSIDASE ON GASTROINTESTINAL SYMPTOMS IN IBS PATIENTS.

L. Böhn[1,*], S. Störsrud[1], H. Törnblom[1], M. Simrén[1]. [1]*Department of Internal Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

INTRODUCTION: IBS is a functional gastrointestinal (GI) disorder. Gas-related symptoms, e.g. abdominal distension and bloating are common. Certain foods that contain large amounts of incompletely absorbed carbohydrates (IAC) enhance gas-formation. α-Galactosidase (αG) is an enzyme that is able to digest IAC to smaller entities, thereby facilitating uptake and minimizing the bacterial fermentation in the colon. αG has been shown to reduce GI symptoms when combined with meals in healthy subjects, but has not been evaluated in IBS.
AIMS&METHODS: The aim of the study was to assess if αG is superior to placebo in reducing GI symptoms and production of hydrogen and methane gas in IBS patients after ingestion of meals rich in IAC. The patients were served breakfast and lunch together with capsules containing either αG or placebo according to a randomization schedule with a two weeks washout period in-between. A breath test measuring hydrogen and methane was performed at baseline and every 30 min during 7.5 h. The patient completed a questionnaire assessing GI symptom severity (gas, bloating, discomfort, distension, nausea, rumbling, urgency, abdominal pain) and general well-being, ranging from 0= no symptoms to 20= worst imaginable symptoms at baseline and after every breath test. Area under the curve (AUC) was calculated for hydrogen, methane and GI symptoms. Abdominal pain, bloating/distension and dissatisfaction with bowel habits were assessed on a visual analogue scale in the morning at each visit and in the morning the day after.
RESULTS: Twenty IBS patients (19 women, age 50 years (20-75) (median (range)) were included. There were no significant differences between AUC concerning hydrogen (ppm) (5543 (2085-29040) vs. 8198 (2700-20280); p=0.47) or methane (ppm) (1823 (750-17265) vs. 1815 (660-16560); p=0.64) between αG or placebo. Furthermore, no differences regarding AUC for GI symptoms or general well-being were noted between the study days. There was a significant reduction in the severity of bloating/distension the morning after intake of αG compared with placebo (z=1.94, p=0.05, *r*=0.31), but not for abdominal pain or satisfaction with bowel habits.
CONCLUSION: Based on this study, α-Galactosidase cannot be recommended to IBS patients in order to alleviate GI symptoms caused by meals rich in IAC. However, a positive effect on bloating/distension the following day was noted, which need to be further evaluated in long-term studies.

P982 ROLLING OUT FODMAP DIET –SYMPTOM IMPROVEMENT IN TERTIARY REFERRAL AND SELF-REFERRAL POPULATION

L. M. Jackson[1,*], T. Ferguson[1], J. o keefe[1], W. A. Stack[1], K. Macken[1]. [1]*Gastroenterology, Bon Secours Hospital . Cork, Ireland, Cork, Ireland*

INTRODUCTION: Low FODMAP dietary approach which minimizes consumption of dietary factors that distend the intestine, has been recommended as a useful strategy in the management of patients with functional GI disease.
AIMS&METHODS: The aim of this study is to review the outcomes of Irish patient cohort instructed re low FODMAP diet over 17month period. Individually tailored instruction in low FODMAP diet was provided by 2 trained dieticians. Patients completed questionnaire scoring symptom severity at baseline assesment and at 8 weeks after FODMAP elimination
RESULTS: 54 patients received instruction re low FOD MAP diet over study period; 31/54 were referred by consultant gastroenterologist, 6/54 by primary care physican and 17/54 self-referred. After 8 weeks dietary intervention 87%(39/45) patients self reported score improved for symptoms of bloating symptoms, 76%(35/46) reported an improvement in abdominal pain and 69%(11/16) of patients with >4 BO daily noted reduction in bowel frequency. There was no significant difference in outcomes between tertiary referral and self referral /GP referral patients. 40%(20/50) patients considered diet difficult but 76%(38/50) patients advised that they would definitely recommend diet to other IBS patients
CONCLUSION: Our study confirms the benefit of FODMAP elimination for functional GI symptoms in unselected Irish population.

P983 TARGETING MECHANISMS OF IRRITABLE BOWEL SYNDROME: EFFECTS OF LACTOBACILLUS REUTERI ON EPITHELIAL BARRIER DYSFUNCTION

N. L. Lilli[1,2,*], P. Aubert[1], G. Barbara[2], R. Restignoli[3], G. Moretti[3], V. Stanghellini[2], R. De Giorgio[2], M. Neunlist[1]. [1]*Inserm U913, Nantes, France,* [2]*Department of Clinical Medicine and Digestive Diseases and Internal Medicine, University of Bologna, Bologna,* [3]*Noos S.r.l., Rome, Italy*

INTRODUCTION: The irritable bowel syndrome (IBS) is a complex disorder characterized by abdominal symptoms including chronic abdominal pain or discomfort and alteration of bowel habit. Increasing evidence demonstrates a central role of intestinal epithelial barrier (IEB) dysfunction, and especially increased paracellular permeability, in the pathophysiology of IBS. Therefore, enhancing the IEB may become a valuable therapeutic option in IBS.
AIMS&METHODS: The purpose of this study was to investigate the effects of the probiotic strain *Lactobacillus reuteri* (DSM 17938; NOOS S.r.l., Italy) upon intestinal paracellular permeability using an *in vitro* model of IEB induced dysfunction. Caco-2 cell monolayers were incubated with *L.reuteri* (live; dead or supernatant of bacteria culture) for 8h (10^6 or 10^7CFU/100 µl) prior to treatment with a PAR-2 agonist (SLIGRL 100µM) for 24h. At the end of this period, Caco-2 monolayer paracellular permeability was measured using fluorescein sulfonic acid (FSA). Finally, Caco-2 monolayers were processed for quantitative PCR, Western blot or ELISA analysis of key tight junctions protein (ZO-1) and/or cytokines (IL-8).
RESULTS: Treatment of Caco-2 monolayers with PAR-2 agonist significantly increased paracellular permeability. Pre-incubation of Caco-2 with live, heat inactivated and supernatant of *L. reuteri* prevented PAR-2 agonist-induced increase in paracellular permeability. Incubation of Caco-2 monolayer with PAR-2 agonist caused a significant increase and decrease in the expression of ZO-1 mRNA and protein expression, respectively. Pre-incubation of Caco-2 monolayers with *L. reuteri* (10^7 CFU/100 µl) prevented PAR-2 induced reduction in ZO-1 protein expression. Incubation of Caco-2 monolayer with PAR-2 agonist increased apical and baso-lateral IL-8 secretion. Pre-incubation of Caco-2 with live bacteria (but not heat inactivated and bacteria supernatant) prevented PAR-2 agonist-induced increase in IL-8 levels.
CONCLUSION: Our study demonstrates that *L.reuteri* is able to prevent barrier dysfunction induced by PAR-2 agonists probably in part via a mechanism involving modulation of tight junction protein expression. Additional studies need to be performed to validate its putative therapeutical use in the treatment of IBS associated symptoms.

P984 THE EFFECTIVENESS OF GUIDED AFFECTIVE IMAGERY FOR TREATMENT OF IRRITABLE BOWEL SYNDROME

S. Nadav[1], E. Gil[1], S. Aisic[1], K. Hod[1], Y. Niv[1], R. Dickman[1,*]. [1]*Gastroenterology, Rabin Medical Center, Petach Tikva, Israel*

INTRODUCTION: Methods of guided affective imagery (GAI) have been suggested to be effective in the treatment of irritable bowel syndrome (IBS). GAI is a form of psychotherapy yet to be fully researched in the treatment of IBS.
AIMS&METHODS: To compare the efficacy of combined GAI with standard medical treatment versus standard medical treatment only in patients with IBS. 32 IBS patients, age- and gender-matched, were randomly assigned to two treatment groups for 9 weekly appointments. The first group (N= 19) received standard dietary consultation and medical treatment and served as the control group. The second group (N= 13) received the same basic treatment in addition to GAI therapy from the same trained medical psychologist. All patients completed a demographic questionnaire as well as the Irritable Bowel Syndrome Quality of Life (IBS QOL) and the SF-36 at entry and at the last treatment for the assessment of their quality of life. We used the Welch two sample t-test (testing the hypothesis of equality of means) to compare results of IBS QOL and SF-36 between first and last meeting and then between groups.
RESULTS: At the end of treatment, IBS patients that were treated with standard medical care and GAI scored higher than controls on 3 domains of SF-36: physical functioning (p=0.04), general health perceptions (p= 0.001) and social role functioning (p=0.04). However, no significant differences between the groups were found for the IBS QOL domains. erun:yes'> All patients completed a demographic questionnaire as well as the Irritable Bowel Syndrome Quality of Life (IBS QOL) and the SF-36 at entry and at the last treatment for the assessment of their quality of life. We used the Welch two sample t-test (testing the hypothesis of equality of means) to compare results of IBS QOL and SF-36 between first and last meeting and then between groups.
CONCLUSION: Guided affective imagery improved several domains of quality of life and may become a promising therapeutic option in patients suffering from IBS. A larger study will be required to confirm our findings.

P985 THE ANTI-INFLAMMATORY COMMENSAL BACTERIUM FAECALIBACTERIUM PRAUSNITZII ALSO EXHIBIT ANTI-NOCICEPTIVE EFFECT IN A NON-INFLAMMATORY VISCERAL IBS-LIKE PAIN MODEL

S. Miquel[1,*], R. Martin-Rosique[1], A. Gelot[2], A. Eschalier[2], D. Ardid[2], M. Thomas[1], P. Langella[1], F. A. Carvalho[2]. [1]*Commensal and Probiotics-Host Interactions Laboratory, INRA UMR1319 Micalis, Jouy-en-Josas,* [2]*Pharmacologie Fondamentale et Clinique de la Douleur, UMR1107 NEURO-DOL Inserm/UdA, Clermont-Ferrand, France*

INTRODUCTION: Visceral pain is a diffuse and stabbing sensation which may be associated with functional gastrointestinal disorders, such as IBS, or with direct inflammation of a visceral organ as in IBD. This common complaint is a crucial feature because of its significant impact on patients' quality of life and lack of efficient therapies. In IBS, as in IBD, patients, dysbiosis have been recently detected suggesting a long term impact of the intestinal microbiota on inflammation, but also on colonic hypersensitivity (CHS). Diminished prevalence and abundance of *F. prausnitzii*, an extremely oxygen sensitive (EOS) Firmicute, have been reported in intestinal disorders as IBD, IBS and colorectal cancer. This bacterium was the first anti-inflammatory commensal bacterium identified on the

basis of human clinical data. The aim of this study was to determine if *F. prausnitzii* could also have a direct impact on CHS, independently to its anti-inflammatory properties.
AIMS&METHODS: We assessed the effect of *F. prausnitzii* in Neonatal Maternal Separation (NMS) CHS mouse model. After birth, wild-type C57Bl/6J pups were isolated from their mother from D2 to D14, three hours per day. At eight-week old age, male mice were orally treated each day with 10^{10} *F. prausnitzii* (A2-165 reference strain) bacteria for nine days. Visceral pain due to CHS was assessed using a technique based on measure of electromyographic abdominal contractions induced by colorectal distension. In this test, abdominal contractions (whose amplitude is proportional to the colon sensitivity) are induced by progressive inflation of a balloon inserted into the colon. These data were expressed as visceromotor response (VMR) reflecting CHS. After euthanasia, inflammation was monitored using anatomical indicators of colitis and assessed by expression of the colonic myeloperoxidase activity or colonic pro-inflammatory cytokines.
RESULTS: NMS treatment induced an increased VMR in the absence of any significant alteration in gut wall macroscopic integrity or colonic mucosa inflammation. Only a slight increase of colonic permeability has been measured after this stress-induced CHS. *F. prausnitzii* treatment significantly decreased VMR in NMS model, without affecting the VMR in non NMS control mice.
CONCLUSION: All of these results suggested a specific protective role of this commensal bacterium on CHS in a non-inflammatory NMS model. This study could facilitate and optimize the potential future use of *F. prausnitzii* as a novel probiotic to treat abdominal pains observed in IBS patients.

P986 THE EFFICACY OF A MULTISPECIES PROBIOTICS MIXTURE ON THE IBS SYMPTOMS AND CORRELATION BETWEEN CHANGE OF FECAL FLORA AND IBS SYMPTOMS

Y. S. Park[1,*], D. H. Lee[1], J. H. Lim[1], H. J. Kim[1], N. Kim[1], C. M. Shin[1], H. J. Jo[1], J.-G. Seo[2]. [1]*Department of Internal Medicine, Division of Gastroenterolgy, Seoul National University Bundang Hospital, Seongnam,* [2]*R&D Center of Cell Biotech Co. Ltd, Seoul, Korea, Republic Of*

INTRODUCTION: Some clinical trials tried to reveal the efficacy of probiotics in irritable bowel syndrome (IBS), but the use of probiotics in IBS is still contentious. According to previous report multispecies probiotic mixture had an effect on the symptoms in diarrhea-dominant IBS patients.
AIMS&METHODS: We tried to evaluate the effects of probiotics mixture on IBS symptoms and the relation between IBS symptoms and change of fecal micorbiota. 100 patients were enrolled and 11 patients were dropped out during screening and trial period. 89 patients were randomized into placebo (n=42) or probiotic mixture (n=39) (*Lactobacillus acidophilus, Lactobacillus plantarum, Lactobacillus rhamnosus, Bifidobactrium breve, Bifidobactrium actis, Bifidobactrium longum, and Stretococcus thermophius* 1.0 x 10^{10} CFU) groups. Probiotics and placebo were taken daily for 4 weeks. The primary outcome was relief of overall IBS symptoms assessed after 4 weeks treatment. Relief of symptoms was defined as a patient who experienced adequate relief at least half of IBS symptoms during study period. Secondary outcomes included the effects on individual symptoms, stool parameter, change of fecal flora and relations between change of symptoms and fecal flora. The fecal floras were quantized by polymerase chain reaction denaturing gradient gel electrophoresis (DGGE).
RESULTS: The proportion of symptom relief seemed to be higher in probiotics group than placebo group (72.7% vs 60.5%, p=0.278). Percent changes on individual IBS symptom scores were not different in both groups. The mean score on the Bristol Stool Scale has decreased in probiotics group whereas increased in placebo group (-0.14 vs 0.09, p=0.245). Denaturing gradient gel electrophoresis profiles of fecal flora showed that *B. bifidum, B. lactis, L. rhamnosus, L. acidophilus* increased significantly in probiotics group comparing to placebo group. Analyzing probiotics group separately, the *Lactobacillus* species increased higher in patients experienced with relief of symptoms than the patients without relief of symptoms (n=24 vs 9, p=0.027).
CONCLUSION: The probiotic mixture might be effective in providing relief of overall IBS symptoms and make the Bristol Stool Score decreased in IBS patients, even if it had no significant effect on individual IBS symptoms. And in the patients with relief of IBS symptoms of probiotics group, *Lactobacillus* species has increased higher than the patients without relief of IBS symptoms in fecal flora analysis. The therapeutic effect of probiotics could be expected in subgroup IBS patients whom probiotics might settle down well in their intestine.

P987 LONG TERM MANAGEMENT OF PATIENTS WITH MESENTERIC INFARCTION: A 10 YEAR EXPERIENCE

F. Adaba[1,*], A. Patel[1], A. Rajendran[1], Y. Cheung[2], J. Nightingale[1], J. Warusavitarne[1]. [1]*Intestinal Failure,* [2]*Pharmacy, St Marks Hospital, Harrow, United Kingdom, London, United Kingdom*

INTRODUCTION: Morbidity and mortality from mesenteric infarction is still high despite advances in diagnostic and therapeutic measures. The management of patients who survive their initial emergency operation has not been extensively investigated. The aim of this study was to review our experience in long term management of patients with mesenteric infarction.
AIMS&METHODS: A retrospective review of hospital database of patients treated with mesenteric infarction from 2000 to 2010.
RESULTS: 115 patients (61 females, median age 54) were referred to our institution following emergency resection in the referring institution. Aetiology breakdown: superior mesenteric artery thrombosis (SMA) in 40 (34%), SMA embolism in 36 (31%), superior mesenteric vein thrombosis in 25 (21%) and unknown in 10 (8%). Of the 115 patients, 57 (49%) were suitable for restoration of bowel continuity. 25 (43%) of these patients stopped their parenteral nutrition within a month after restoration of bowel continuity. Multivariate analysis did not show any factors that would alter survival in this group.
CONCLUSION: In this cohort of patients with mesenteric infarction, careful patient selection for consideration of bowel continuity following an emergency resection is a feasible option that reduces parenteral nutrition requirements and may improve quality of life.

P988 A SIMPLE SCORE FOR PREDICTING MORTALITY IN PATIENTS WITH PNEUMATOSIS INTESTINALIS

K.-J. Kim[1,*], H.-S. Lee[1], S. S. Lee[2], J. S. Lee[2], S.-K. Yang[1]. [1]*Gastroenterology,* [2]*Radiology, Asan Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: This study was conducted to identify simple computerized tomography (CT)and clinical predictors of mortality in patients with pneumatosis intestinalis (PI). We tried todefine the clinical characteristics and outcomes of PI and to identify the predictors thatassociate with mortality retrospectively.
AIMS&METHODS: The medical records of 123 patients with PI were reviewed. Multivariate logisticregression models were constructed to determine independent predictors of mortality. Thesedata were used to develop a simple score that would predict mortality on the first and seventhday after diagnosis.
RESULTS: The median age at diagnosis was 62 years (range, 20–91). The most common causeof PI was mesenteric vascular ischemia (n=43, 35.0%). Twenty-nine (23.6%) disease-relateddeaths occurred during the index admission. The presence of peritoneal irritation signs onphysical examination (HR: 4.57, 95% CI: 1.99–10.39, P = 0.0003) and decreased or absentenhancement of the bowel wall on CT (HR: 9.43, 95% CI: 3.18-27.98, P <0.001) were bothassociated with increased mortality. If both factors were absent, the in-hospital mortality wasless than 5% on the first and seventh days after the diagnosis of PI. However, if both factorswere present, the in-hospital mortality was 57% on the first day and 59% on the seventh day.
CONCLUSION: A simple and novel risk score that predicts mortality in patients with PI wasproposed. Patients with both peritoneal irritation and decreased or absent enhancement ofbowel wall on CT should be observed vigilantly and early intervention should be instituted.

P989 CLINICAL FEATURES AND ENDOSCOPIC FINDINGS OF PATIENTS WITH ACTIVE BLEEDING COLONIC ANGIODYSPLASIA

N. Nishimura[1,*], H. yamamoto[1], K. matsueda[1]. [1]*kurashiki central hospital, kurashiki, Japan*

INTRODUCTION: Colonic angiodysplasia (AGD) is an important cause of lower gastrointestinal bleeding. However, most of bleeding from colonic AGD stops spontaneously. To date few data are available on the endoscopic findings of bleeding colonic angiodysplasia.
AIMS&METHODS: To clarify the clinical features and endoscopic findings of active bleeding colonic AGD, we conducted a retrospective study of colonoscopies undertaken at our hospital. From November 2006 to March 2013 inclusive, 32,586 colonoscopies were undertaken at this hospital. Thirteen patients with bleeding colonic AGD were enrolled in the study. Criteria to define bleeding from colonic AGD were, active bleeding from AGD without any other major colonic lesion or the bleeding site being identified on colonoscopy.
RESULTS: The mean age was 84 years (range 69-90 years), and eight patients were women (62%). The mean follow-up period was eight months (range 1-52 months). All patients had chronic heart disease. Other coexisting diseases were

chronic uremia undergoing dialysis for two patients and liver cirrhosis in one patient. All patients were using anticoagulant and/or antiplatelet drugs.
Bleeding AGD was localized in the left colon of two patients (15%) and in the right colon of the remaining patients (85%). 77% of lesions (10/13) were 2 mm, and two lesions were 4 mm. Only one lesion was larger than 5 mm.
Endoscopic treatment by argon plasma coagulation and/or hemoclip had a therapeutic success rate of 100%. In 85% of patients (11/13), bleeding did not reoccur after treatment. During the study period, two patients presented with bleeding from residual AGD and underwent endoscopic treatment.
CONCLUSION: In most instances, the size of the bleeding colonic AGD was smaller in our study compared to previous reports. Targeted colonoscopic treatment for active bleeding AGD was effective and safe. It is essential that physicians consider active bleeding colonic AGD when performing colonoscopy in elderly patients with a history of cardiovascular disease, and anticoagulant and/or antiplatelet therapy.

P990 PREDICTIVE FACTORS FOR REBLEEDING AND MORTALITY IN NON-VARICEAL UPPER DIGESTIVE BLEEDING

D. Lazar[1,*], A. Goldis[1], I. Ratiu[1], M. Matei[1], D. Koukoulas[1], I. Sporea[1]. [1]*Gastroenterology, UNIVERSITY OF MEDICINE AND PHARMACY , Timisoara, Romania*

INTRODUCTION: Non-variceal upper digestive bleeding represents an important cause of morbidity and mortality.
AIMS&METHODS: To assess the predictive factors for rebleeding and mortality in patients with non-variceal upper digestive bleeding (UDB).
We have performed a retrospective study including 1842 patients with non-variceal UDB (644 women and 1198 men), mean age 61±15 years admitted in the Department of Gastroenterology and Hepatology, Emergency County Hospital Timisoara during 2003-2012. We have analyzed the variables that might influence the rebleeding and mortality rate of these patients: demographic characteristics, pre-endoscopic aspects of severity-haemorrhagic shock (tachycardia, hypotension), consumption of NSAIDs or anticoagulants, severity of anemia, Forrest classification (for the 1293 patients with UDB of ulcerous etiology), as well as Rockall, Baylor (pre-endoscopic, endoscopic and total) and Cedar-Sinai scores used for stratifying the risk in patients with UDB. For the statistical analysis we have used the method of multivariate regression.
RESULTS: Of the 1842 patients, a number of 151 have rebled (8.2%), and 115 died (6.2%). The rebleeding rate was not influenced by the consumption of NSAIDs/anticoagulants ($p>0.05$). The presence of active bleeding during endoscopy was significantly correlated with the risk of rebleeding, and it was noticed in 73/151 patients that have rebled (48.3%) vs. 231/1407 patients without rebleeding (16.4%) ($p<0.0001$). The independent variables that presented a statistically significant correlation with the death of the patients were the following: Aspirine consumption ($p=0.03$), tachycardia ($p=0.01$), rebleeding ($p=0.04$), hypotension ($p<0.0001$). The consumption of other AINS, anticoagulants, the level of haemoglobin and the age didn't influence the survival ($p>0.05$). By comparing the three risk scores, the Rockall score proved to be statistically significant more useful regarding the prediction of mortality ($p=0.004$). For the subgroup of patients with UDB of ulcerous etiology, the presence of active bleeding/sitgns of recent bleeding at endoscopy (Forrest classification I and II) was correlated significantly with the risk of death: active bleeding was noticed in 64% of the patients that died (48/75 patients) vs. 51,7% of the patients that survived (630/1218 patients) ($p=0.03$).
CONCLUSION: The factors that were correlated significantly with death in patients with non-variceal UDB are represented by the Aspirine consumption, the presence of haemorrhagic shock and rebleeding. The Rockall score proved to be the most reliable in predicting mortality. The presence of active bleeding at endoscopy was correlated with an increased risk of rebleeding and death.

P991 MORTALITY IN HIGH-RISK PATIENTS WITH BLEEDING MALLORY-WEISS SYNDROME IS SIMILAR TO THAT OF PEPTIC ULCER BLEEDING - RESULTS OF A PROSPECTIVE DATABASE STUDY

N. Ljubičić[1], I. Budimir[1], T. Pavić[1], A. Bišćanin[1], A. Bratanić[2], B. Troskot[1], **M. Gomerčić Palčić**[1,*]. [1]*Division of Gastroenterology, Department of Internal Medicine, «Sestre milosrdnice» University Hospital Center, Medical and Dental Faculty, University of Zagreb, Zagreb,* [2]*Division of Gastroenterology, Department of Internal Medicine, «Split» University Hospital, Split, Croatia*

INTRODUCTION: Mallory-Weiss syndrome and peptic ulcer disease remains an important cause of nonvariceal gastrointestinal bleeding.
AIMS&METHODS: The aim of this study was to identify the predictive factors influencing mortality in patients with bleeding Mallory-Weiss syndrome in comparison with peptic ulcer bleeding.
Between January 2005 and December 2009, 281 patients with endoscopically confirmed Mallory-Weiss syndrome and 1530 patients with peptic ulcer bleeding were consecutively evaluated. The 30-day mortality and clinical outcome were related to patient's demographic data, endoscopic and clinical characteristics.
RESULTS: The one-year cumulative incidence for bleeding Mallory-Weiss syndrome was 7.3 cases/100,000 people and for peptic ulcer bleeding 40.4 cases/100,000 people. The age-standardized incidence for both bleeding Mallory-Weiss syndrome and peptic ulcer bleeding remained unchanged during the observational five-year period. The majority of patients with bleeding Mallory-Weiss syndrome were male patients with significant overall comorbidities (ASA class 3-4). Overall 30-day mortality rate was 5.3% for patients with bleeding Mallory-Weiss bleeding and 4.6% for patients with peptic ulcer bleeding ($p = 0.578$). In both patients with bleeding Mallory-Weiss syndrome and peptic ulcer bleeding, mortality was significantly higher in patients over 65 years of age and those with significant overall comorbidities (ASA class 3-4).
CONCLUSION: The incidence of bleeding Mallory-Weiss syndrome and peptic ulcer bleeding has not changed over a five-year observational period. The overall 30-day mortality was almost equal for both bleeding Mallory-Weiss syndrome and peptic ulcer bleeding and was positively correlated to older age and underlying comorbid illnesses.

P992 POTENTIATION BY CO-ADMINISTRATION OF ANTIPLATELET DRUGS OF ASPIRIN-INDUCED GASTRIC BLEEDING AND ULCEROGENIC RESPONSES IN RATS: COMPARISON WITH CLOPIDOGREL, TICROPIDINE AND CILOSTAZOL

K. Takeuchi[1,*], S. Takayama[1], C. Izuhara[1], K. Amagase[1]. [1]*Division of Pathological Sciences, Department of Pharmacology and Experimental Therapeutics, Kyoto Pharmaceutical University, Kyoto, Japan*

INTRODUCTION: Although antithrombotic therapy plays a central role in the treatment of apoplexy, cardiac disorders and peripheral arterial diseases, recent studies suggest that the risk of upper gastrointestinal bleeding is increased by the concomitant use of anti-platelet drugs with low-dose aspirin (ASA). We recently reported that an antiplatelet drug clopidogrel, the $P2Y_{12}$ receptor antagonist, increased gastric bleeding induced by intraluminal perfusion with acidified low dose ASA in the rat stomach.
AIMS&METHODS: We examined the effects of other antiplatelet drugs, such as ticlopidine and cilostazol, on gastric bleeding and lesion formation induced by

intraluminal perfusion with low-dose ASA in rats, in comparison with those of clopidogrel.
Under urethane anesthesia, a catheter was inserted into the rat stomach through an incision in the esophagus and another cannula was provided in the stomach through the pylorus. Then, the gastric lumen was perfused with saline through a catheter, and the perfusate was collected. After an equilibration period with saline perfusion, the stomach was perfused with acidified ASA (25 mM in 50 mM HCl) for 60 min. Gastric bleeding was evaluated as the hemoglobin concentration in the perfusate. Clopidogrel (10-100 mg/kg, PO), ticlopidine (10-300 mg/kg, PO) or cilostazol (3-30 mg/kg, IP) was given twice, 24 h and 0.5 h before ASA perfusion.
RESULTS: Perfusion of the stomach with acidified ASA alone caused slight bleeding and lesions in the stomach. Pretreatment of the animal with clopidogrel, despite provoking by itself neither bleeding nor damage, dose-dependently increased gastric bleeding and damage after intraluminal perfusion with acidified ASA, and these responses were significantly prevented by PGE_2. Likewise, ticlopidine also dose-dependently aggravated the severity of damage with an increase of gastric bleeding, the effects at 300 mg/kg being equivalent to those of clopidogrel at 100 mg/kg. On the other hand, cilostazol, unlike other two antiplatelet drugs, dose-dependently decreased gastric bleeding and lesions in response to acidified ASA, the inhibition of hemoglobin output and lesion score at 30 mg/kg being 68.2% and 46.8%, respectively.
CONCLUSION: These results suggest that the antiplatelet drug ticlopidine increases gastric bleeding and ulcerogenic responses to low-dose ASA, similar to clopidogrel, while ciloztazol suppresses these responses, yet the mechanism for the protective action remains unknown. It is assumed that cilostazol may be safely used as a dual antiplatelet therapy combined with low-dose ASA, without increase of the risk of gastric bleeding.

P993 EFFECT OF SURGICEL® (FIBRILLAR) ON PREVENTING DELAYED BLEEDING AFTER ESD FOR GASTRIC EPITHELIAL TUMORS

S. J. Hong[1,*], J. P. Han[1], H. J. Jung[1], M. H. Choi[1], T. H. Lee[1], B. M. Ko[1], J. Y. Cho[1], J. S. Lee[1], M. S. Lee[1]. [1]*Internal medicine, Soonchunhyang University College of Medicine, Bucheon, Korea, Republic Of*

INTRODUCTION: Endoscopic submucosal dissection (ESD) provides larger gastric epithelial tumors to be completely resected, compared endoscopic mucosal resection (EMR). However, ulcer bleeding after ESD can occur more frequently. Proton pump inhibitor (PPI) has used to prevent bleeding from the post-ESD ulcer. Surgicel® (Fibrillar) is oxidized regenerated cellulose and absorbable hemostats, and has used to control of oozing bleeding. We assessed the effect of Surgicel® on preventing bleeding after ESD.
AIMS&METHODS: From January through September 2012, patients scheduled for ESD to treat the gastric epithelial tumors were prospectively enrolled in this study. Patients were assigned to combination therapy with Surgicel® and H2RA or monotherapy with PPI after ESD procedure. Bleeding rate and change of hemoglobin (Hb) were assessed to evaluate the effect on preventing ulcer bleeding after ESD.
RESULTS: A total of 116 patients (87 male, 29 female) were enrolled in this study. Fifty-nine patients were assigned to combination therapy with Surgicel® and H2RA and 57 patients to monotherapy with PPI. There were no significant differences between the two groups in terms of age, sex, underlying disease, antiplatelet medication, location of lesion, and histological result from ESD. There was no significant difference in major bleeding including active bleeding on follow-up endoscopy, unstable vital sign, decreasing Hb of more than 2 g/dL, or need for transfusion (combination therapy 5.1%, monotherapy 3.6%, P=1.000). However, the laboratory result showed there was significant change of Hb (7 days after ESD) between two groups (-0.6±1.3 in combination therapy, -1.2±1.3 in monotherapy , P=0.013).
CONCLUSION: Combination therapy with Surgicel® and H2RA had similar effect on preventing major ulcer bleeding after ESD for gastric epithelial tumors, compared to monotherapy with PPI. Moreover, Surgicel® enables oozing bleeding to be discontinued, resulting in preventing reduction of Hb.

P994 CLINICAL MARKERS INDICATING THE NEED FOR EMERGENCY ENDOSCOPY FOR UPPER GASTROINTESTINAL BLEEDING ARE USEFUL TO REDUCE MEDICAL EXPENSES: A PROSPECTIVE COHORT STUDY IN JAPAN

T. Dokoshi[1,*], M. Fujiya[1], N. Ueno[1], Y. inaba[1], K. moriichi[1], Y. kogo[1]. [1]*asahikawa medical university, asahikawa, Japan*

INTRODUCTION: Upper gastrointestinal bleeding (UGIB) is frequently indicative for an emergency endoscopy (EE) and hospital admission. Indeed, it has been estimated that the prevalence of gastric ulcers is 353.9/100,000, and the incidence of bleeding is 3.3% in Japan. However, EE is associated with disadvantages including the labor of the medical staff and is time-consuming, particularly after office hours. The Glasgow-Blatchford Score (GBS) was introduced for UGIB to help avoid unnecessary EE and admission. However, the patients with UGIB usually show high GBS scores in Japan, thus resulting in it having a lower impact for decreasing the rate of EE. We have proposed that a high blood urea nitrogen (BUN) level and low blood pressure (BP) were significant markers as an indication for EE in UGIB.
AIMS&METHODS: The aim of this prospective cohort study was to investigate the medical expenses associated with EE, and to determine the efficacy of using clinical markers to provide the indications for EE with regard to decreasing the medical expenses. From January 2011 to August 2012, 83 patients with hematemesis, melena and/or anemia who underwent EE were enrolled in this study. Clinical factors and the results of blood examinations were investigated to determine whether they are associated with the need for endoscopic treatment. The medical expenses included the costs of the devices and agents used and the personnel expenses, which were estimated from mean staff salaries.
RESULTS: Endoscopic treatments were needed in 32 cases (38.5%) because of the hemostasis (Forrest I or IIa), but were not needed in 51 cases (61.5%) (Forrest IIb or III). The average time of all EE was 24.8 minutes, and the hospital stay was 4.1 days. A high BUN level and a low BP were significantly associated with the need for intervention, whereas the other clinical factors were not. The average costs of EE during overtime and normal office hours were calculated to be 272 and 239 dollars, respectively. If only patients with a high BUN level and/or low BP were considered to be indicated for EE, 42% patients with UGIB would not undergo EE. If the indications for EE had been limited to UGIB patients with a high BUN level and/or low BP, it is estimated that more than 4,600,000 dollars would have been saved in a year.
CONCLUSION: In the Japanese population, the average cost to treat the patents with EE was estimated to be 1040 dollars. The cost of EE was higher after hours than during office hours. If only the patients with a high BUN level and/or low BP are considered to be indicated for EE, then the medical expenses for EE will be greatly reduced.

P995 DOES PROTON PUMP INHIBITORS ARE SUFFICIANT FOR GASTROPROTECTION DURING ANTIPLATELET THERAPY WITH CLOPIDOGREL AND ACETYLSALICYLIC ACID?

I. Paliy[1], V. Vavrinchuk[1,*], S. Zaika[1]. [1]*Vinnitsya national medical university, Vinnitsya, Ukraine*

INTRODUCTION: The dual antiplatelet therapy may increase the risk of damage to the mucous membrane of the stomach with the development of complications such as bleeding. For gastroprotection during dual antiplatelet therapy widely used proton pump inhibitors. However, remains little studied gastroprotective properties of proton pump inhibitors with dual antiplatelet therapy.
AIMS&METHODS: To study in rats gastro protective properties of pantoprazole with a double (acetylsalicylic acid + clopidogrel) antiplatelet therapy. The study was conducted on 30 white male rats. Control group received no medication, group #1 received clopidogrel 6.8 mg/kg body weight (recalculated 75 mg for an adult human) + acetylsalicylic acid 6.8 mg/kg body weight (75 mg allocation adult), group #2 received clopidogrel 6.8 mg/kg body weight + acetylsalicylic acid 6.8 mg/kg body weight + pantoprazole 3.6 mg kg (40 mg allocation for an adult). Drugs were administered intragastrically once a day. On the 14th day of the study degree of destruction of the gastric mucosa was studied in rats. For this purpose gastric mucosa was homogenated to determinate the level of malondialdehyde (MDA) and phospholipids. Study was conducted according to the rules of humane treatment of experimental animals.
RESULTS: The level of MDA in the gastric mucosa homogenate was significantly greater ($p < 0.001$) in the group #1 as compared to control (8,73 ± 0,43 nmol/mg against LCA b e 6,26 ± 0,42 nmol/mg b e LCA), and level of phospholipids in group #1 was significantly lower ($p < 0.01$) compared with control (57,96 ± 6,03 mkg/mg b e LCA vs. 77,06 ± 6,61 mkg / mg b e LCA). In group #2 MDA level in homogenates of gastric mucosa did not differ significantly ($p > 0.05$) from the control group (6,84 ± 0,34 nmol/mg b e LCA vs. 6,26 ± 0,42 nmol/mg b e LCA). When the level of phospholipids in gastric mucosa group #2 was significantly lower ($p < 0.01$) compared to controls (45,19 ± 3,83 mkg / mg against b e LCA 77,06 ± 6,61 mkg/mg b e LCA). In group #2 level of MDA in homogenates of gastric mucosa was significantly lower ($p < 0.01$) compared with the group #1 (6,84 ± 0,34 nmol/mg b e LCA vs. 8,73 ± 0,43 nmol/mg b e LCA), and the level of phospholipids in group #2 and group #1did not differ ($P > 0.05$) between them (45,19 ± 3,83 mkg / mg b e LCA vs. 57,96 ± 6,03 mkg/mg b e LCA).
CONCLUSION: We found that taking dual antiplatelet therapy leads to the destruction of the gastric mucosa of rats. Adding pantoprazole to therapy partially fulfills gastroprotective properties. Experimental data can help in the further development of new schemes for the prevention of gastro protective gastropathies with dual antiplatelet therapy.

P996 HER2 HETEROGENEITY IN GASTRIC CANCER: THE COMPARISON BETWEEN BIOPSY AND RESECTED SPECIMENS

Y. Niwa[1,*], T. Ohbayashi[2], M. Tajika[1], T. Tanaka[1], M. Ishihara[1], H. Goto[2], K. Yamao[3], N. Mizuno[3], K. Hara[3], S. Hijioka[3], H. Imaoka[3]. [1]*Department of Endoscopy, Aichi Cancer Center Hospital,* [2]*Department of Gastroenterology, Nagoya University Graduate School of Medicine,* [3]*Department of Gastroenterology, Aichi Cancer Center Hospital, Nagoya, Japan*

INTRODUCTION: The importance of human epidermal growth factor receptor 2 (HER2) in the tumor is well established in breast cancer (BC). According to the ToGA trial in gastric cancer (GC), molecular-targeted drugs, such as traszumab, are recognized to prolong overall survival and progression-free survival in patients with HER2-positive gastric cancer. However, it is well known that the

HER2 overexpression in GC in is different from that BC and that the heterogeneity is GC is high. In this study, we investigated the HER2 overexpression between biopsy and resected specimens in GC.
AIMS&METHODS: This retrospective study was conducted in 87 patients with GC between April 2009 and May 2012. These specimens were obtained from biopsy and resected specimens. The clinicopathlogical features and HER2 imunohistochemistry (IHC) were investigated in these gastric cancers. We divided the specimens into two groups: the HER2 0/1+ group and the HER2 2+/3+ group. In the HER2 score, the intratumoral heterogeneity of 2+/3+ resected specimens was assessed from the viewpoint of the distribution in the resected specimen. To study the heretogenity in detail, we added 11 GC cases with HER2+/3+. The heterogeneity was defined as those positive in at least 5% and under 50% of nuclei overexpression.
RESULTS: Eighty seven patients with GC (male 56/ female 31, median age 65.0) were enrolled in this study. There were 15 early and 72 advanced GCs; 42 were intestinal type and 45 diffuse type. Seventy-one fell into the HER2 0/1+ group, and 16 into the HER2 2+/3+ group. The ratio of the intestinal / diffuse type in the HER2 0/1+ group was lower than that in the HER2 2+/3+ group. Even in early gastric cancer, HER2 2+/3+ overexpression was observed. The concordance of HER2 score was 89.7% (78/87) between biopsies and resected specimens. In 27 gastric cancers with HER2+/3+, the heterogeneity was investigated as the distribution of HER2 overexpression. Seventeen were diffuse type and 11 were focal type. The four patterns of HER2 overexpression observed were: diffuse / complete, diffuse / incomplete, focal patchy, and focal localized. False negative cases were observed in focal positive cases.
CONCLUSION: The HER2 score in biopsy specimens was almost equal to that in resected specimens. However we have to recognize the intratumoral heterogeneity of HER2 overexpression and take care of the site and numbers of biopsy.

P997 OBESITY CAUSES ALTERATIONS OF GASTRIC HUMAN SMOOTH MUSCLE CELLS

A. Scirocco[1,*], M. Carabotti[1], M. Rizzello[2], S. Rosati[1], G. Silecchia[2], E. Corazziari[1], C. Severi[1]. *[1]Department of internal medicine and medical specialties,, [2]departement of medical surgical sciences and biotechnology, University Sapienza, rome, Italy*

INTRODUCTION: In obese patients motor alterations have a higher prevalence than in normal-weight controls likely through an increased production and secretion of pro-inflammatory molecules by inflamed adipose tissue. These cytokines cause morpho-functional alterations of smooth muscle cells (SMC) *in vitro* and affect G protein–coupled receptors transmembrane signaling regulation. This has been reported for the cAMP-dependent transduction pathway in human airway smooth muscle cells which is the main pathway involved in relaxation of human smooth gastric antrum through activation of VIP_2 receptors
AIMS&METHODS: Aim of this study was to evaluate morpho-functional and molecular alterations in gastric muscle tissue in obese. Smooth muscle cells (SMC) were isolated from muscle specimen of terminal antrum obtained from 5 normoglycemic-normocholesterolemic morbid obese patients (BMI$\geq$40 Kg/m^2) submitted to bariatric surgery and 5 patients submitted to gastrectomy for gastric cancer (19$\leq$BMI$\geq$25 Kg/m^2)(control). Analysis of morpho-functional parameters (length and biological response to contractile and relaxant neurotransmitters) and mRNA expression encoding for VIP_2, inflammatory (IL-1β, TNFα, COX2) and anti-inflammatory (IL-10) molecules were performed on isolated SMC. Data are expressed as mean±SE, $p<0.05$ considered significant.
RESULTS: Obese and control SMC presented similar resting lengths (75.8±0.6 μm and 72.7±1.6 μm respectively) and maximal contractile responses to the muscarinic agonist carbachol (24.2±1.8% and 26.0±1.4% respectively). In turn, differences were found in VIP-induced relaxation, the effect of which was tested on maximal carbachol induced-contraction. While 1μM VIP induced a 70.6±8.5%relaxation in control SMC, no effects were observed in obese SMC. RT-PCR analysis and densitometric comparison of amplified cDNA, showed however a similar distribution of mRNA expression for VIP_2 between obese and control SMC. Relaxation induced by the 2nd messenger cAMP (1mM) instead was similar between obese and control SMC (86.10±0.1 and 71.7±8.2 respectively). Finally the qPCR analysis for inflammatory molecules showed a 5-fold increase in expression of cyclooxygenase 2 in obese SMC in respect to control ($p<0.05$). No difference were instead observed in mRNA expression of TNFα, IL-1 β or IL-10.
CONCLUSION: During obesity gastric muscle present an uncoupling in relaxant transmembrane signaling and an over-expression in COX-2. These myogenic cellular alterations might contribute to the genesis of motor alterations observed in obese patients

P998 EFFECT OF DIFFERENT VOLUME CHALLENGE ON THE GASTRIC MYOELECTRIC ACTIVITY IN EXPERIMENTAL PIGS

I. Tacheci[1,*], J. Kvetina[1], M. Pavlik[2], M. Kunes[3], S. Rejchrt[1], M. Kopacova[1], J. Bures[1]. *[1]2nd Department of Internal Medicine - Gastroenterology, Charles University Faculty of Medicine and University Teaching Hospital, [2]Centre of Advanced Studies, University of Defence, Faculty of Military Health Services, [3]Biomedical Research Center, University Teaching Hospital, Hradec Kralove, Czech Republic*

INTRODUCTION: Surface electrogastrography (EGG) is a non-invasive method for the assessment of gastric myoelectrical activity. Porcine EGG is fully comparable with that recorded in healthy humans with normal rhythm of 3 cycles per minute (3-cpm) (1). There were no data on EGG with water load test in experimental pigs so far.
AIMS&METHODS: The aim was to evaluate the effect of different volume challenge on the gastric myoelectric activity. Five mature female experimental pigs (*Sus scrofa f. domestica*, mean weight 30.9±1.6 kg) entered the study three-times within 3 weeks. After a 15-minute baseline EGG was recorded, tap water (23 °C) was administrated into the stomach by a gastric tube: 500 mL (part A) or 1000 mL (part B) or 1500 mL (part C). A total of twenty 15-minute intervals were recorded afterwards. Surface cutaneous EGG was recorded under general anaesthesia using an Electrogastrography System (MMS, Enschede, the Netherlands). The results were expressed as running spectrum percent activity and the dominant frequency and amplitudes of slow waves were set.
RESULTS: The dominant frequency of slow waves decreased from baseline values (3.34±0.69; 3.25±0.72; 3.30±0.68 cpm) to 2.97±0.52 (part A; p=0.004) or 3.16±0.48 (part B; p=0.116) or 3.09±0.28 (part C; p=0.013) 15 min. after intragastric water administration. Dominant frequency returned back to baseline values within 30 to 60 min. In the part A, the amplitudes of waves increased from basal values (2611±3726 μV^2) to their maximum after 15 min. (7733±1246; p=0.001), subsequently decreased to their minimum after 90 min. (312±283; $p<0.001$) and finally equalised after 160 min. In the part B, the amplitudes of waves increased from basal values (1851±2795) to their maximum after 30 min. (12450±1428; $p<0.001$), subsequently decreased to their minimum after 90 min. (554±460; NS) and finally equalised after 210 min. In the part C, the amplitudes of waves increased from basal values (1991±2713) to their maximum after 60 min. (9070±1258; $p<0.001$), subsequently decreased to their minimum after 180 min. (1154±1177 μV^2; $p<0.001$) and finally equalised after 255 min.
CONCLUSION: Water load test is feasible in experimental pigs. The EGG rhythm remained in a 3-cpm pattern after the water load. After the administration of water, there were 3-cpm EGG waves with initially increased amplitudes, subsequently decreased values and with their final equalisation.

P999 MODALITY SPECIFIC ALTERATIONS OF ESOPHAGEAL SENSITIVITY CAUSED BY LONGSTANDING DIABETES MELLITUS

J. Brun[1,*], C. Brock[2], J. Frøkjær[3], E. Söfteland[4], H. Gregersen[5], A. Drewes[2], M. Simrén[1]. *[1]Dept of Gastroenterology & Hepatology, Institute of Medicine, Gothenburg, Sweden, [2] Mech-Sense, Department of Gastroenterology, Aalborg University Hospital, [3]Mech-Sense, Mech-Sense, Department of Radiology, Aalborg University Hospital , Aalborg, Denmark, [4]Department of Endocrinology and the Hormone Laboratory, , Haukeland University Hospital, , Bergen, Norway, [5]Sino-Danish Centre for Research & Education, Aarhus University , Aarhus, Denmark*

INTRODUCTION: A substantial proportion of patients with diabetes mellitus (DM) suffer from diabetic autonomic neuropathy (DAN), which involves upper and lower GI symptoms. The enteric nervous system (ENS) is not easily accessible and this has called upon new techniques to study the pathophysiology, such as *multimodal pain stimulation* (MMPS) (e.g. mechanical, electrical, thermal) in the oesophagus.
AIMS&METHODS: To further explore ENS alterations in patients with DAN, we compared 30 healthy volunteers (11 M) and 26 patients (8M) with longstanding DM and gastrointestinal (GI) symptoms refractory to medical treatment. Subjects underwent MMPS and HOLTER-ECG, as a measure of ANS function. We used the Gastrointestinal Cardinal Symptom Index to reflect GI symptom severity, and the Short Form-36, (SF-36) to assess quality of life.
RESULTS:

Multimodal Pain Stimulation (MMPS) in the oesophagus

	Electrical (mA)		**Mechanical** (mmHg)		**Mechanical** (bag vol. ml)		**Heat** (sec x °C)	
VAS	**Patients**	**Healthy**	**Patients**	**Healthy**	**Patients**	**Healthy**	**Patients**	**Healthy**
1(SD)	21(12)	16(6)	14(13)	25(29)	16(9)	23(14)	107(164)	178(161)
3	27(13)	21(5)	21(17)	33(32)	27(13)	35(17)	172(197)	268(207)
5	32(13)	29(5)	31(20)	33(33)	38(20)	48(20)	353(233)	473(289)
7	35(13)	36(6)	44(29)	42(36)	52(25)	58(27)	554(297)	602(450)
P	P=0.02		P=0.02		P<0.001		P<0.001	

The patients were more sensitive to heat and mechanical stimulation than controls, but less sensitive to electrical stimulation (see table). There was a positive correlation between heat stimulation and RR(beat-to-beat)-interval (measure of parasympathetic tone) (P=0.04), and physical health (SF-36) (P=0.03). Furthermore patients reported reduced physical (median: 33 vs. 54; $P<0.001$) and mental health (median 34 vs. 54; $P<0.001$) according to SF-36, and reported more severe nausea and vomiting ($P<0.001$), post prandial fullness ($P<0.001$) and bloating ($P<0.001$).

CONCLUSION: Patients with diabetic autonomic neuropathy demonstrate signs of altered oesophageal sensitivity, which may be of relevance for their upper GI symptoms. The complex pattern with *hyper*sensitivity to mechanical and heat stimulation, but *hypo*sensitivity to electrical stimulation implicates that different receptors may respond differently under the influence of long-standing diabetes mellitus.

P1000 NEUROTICISM & ANXIETY RETARDS AUTONOMIC NERVOUS SYSTEM RECOVERY FOLLOWING ESOPHAGEAL INTUBATION

A. D. Farmer[1,*], S. Coen[1], M. Kano[1], Q. Aziz[1]. [1]*Barts and the London School of Medicine, WINGATE INSTITUTE OF NEUROGASTROENTEROLOGY, London, United Kingdom*

INTRODUCTION: Esophageal intubation activates a complex stress response, mediated in part by the Autonomic Nervous System (ANS) (1). Measurement of ANS tone at intubation is thus a useful method of assessing the duration of the physiological stress response which may influence any measurements of esophageal sensory-motor function. For instance, it is known that both ANS tone and psychological factors such as the personality trait of neuroticism and anxiety levels, influence esophageal sensitivity to distension (1). However, factors that influence recovery of ANS tone following intubation are incompletely understood.
AIMS&METHODS: To evaluate the ANS response to esophageal intubation and to identify whether personality traits influence its recovery to baseline. 50 healthy subjects (25 male, mean age 38.1 years, range 21-59 years) had personality traits, using the validated Big-Five Inventory (BFI), and anxiety levels, using the validated Spielberger State/Trait Anxiety Inventory (STAI). ANS tone was assessed using cardiac vagal tone (CVT) which is a measure of brain stem mediated parasympathetic (PNS) efferent tone at baseline (10 minutes) & continuously thereafter in addition to heart rate (HR) and mean arterial blood pressure (MBP) which are mixed measures of PNS and sympathetic tone. Subjects were then intubated with a naso-esophageal catheter, without the aid of local anaesthetic, and monitored for a further 20 minutes.
RESULTS: All subjects tolerated the study well. The mean BFI neuroticism score (BFI-N) was 2.86 (range 1-5). The mean baseline HR, MBP and CVT was 65 beats per minute (range 48-88), 87 mmHg (range 68-104) and 7.8 (range 2.2-14.1) respectively. As expected, naso-esophageal intubation caused a significant elevation in HR ($p<0.0001$) and MBP ($p<0.0001$) with associated CVT withdrawal ($p=0.001$). The mean recovery time of CVT to baseline was 4.5 minutes (range 1.1 – 14.9). BFI-N, state STAI and trait STAI were positively correlated with recovery time (r=0.86, $p<0.0001$; r=0.48, $p<0.0001$; r=0.58, $p<0.0001$).
CONCLUSION: Naso-esophageal intubation results in the withdrawal of PNS tone and an increase in HR and MBP and the speed of recovery to baseline of PNS tone is correlated with neuroticism. Future studies should allow for at least 15 minutes of recovery time after intubation before any physiological assessments are made and consideration should be given to psychological trait measures as these can influence the recovery of stress response to intubation.

P1001 NORMAL VALUES AND REPRODUCIBILITY OF THE REAL TIME BEAT-TO-BEAT INDEX OF CARDIAC VAGAL TONE IN HEALTHY HUMANS

A. D. Farmer[1,*], M. Kano[1], S. J. Coen[1], Q. Aziz[1]. [1]*Barts and the London School of Medicine, WINGATE INSTITUTE OF NEUROGASTROENTEROLOGY, London, United Kingdom*

INTRODUCTION: The vagus nerve is the primary neuroanatomical substrate within the brain gut axis (1). Vagal dysfunction is considered to be a central pathophysiological feature in many functional gastrointestinal (GI) disorders (2). In humans, surrogate measures of vagal tone are most commonly evaluated using heart rate variability (HRV) albeit with considerable methodological limitations, particularly with respect to temporal resolution. However, recent advances have allowed the measurement of a novel non-invasive validated measure of efferent vagal activity from the brainstem, known as cardiac vagal tone (CVT). CVT is measured on a linear vagal scale (LVS) where 0 represents full atropinization and has improved temporal resolution compared to HRV. CVT is increasingly being utilised in a diverse array of GI research (3,4,5).
AIMS&METHODS: The aim of this study was to define the normal range of CVT and to assess its reproducibility. 120 healthy subjects (68 males, median age 29 years, range 19-55 years) were studied in a temperature controlled, constantly lit, quiet laboratory. After attachment of CVT recording equipment (Neuroscope), 20 minutes of CVT data (resting/no stimulation) was acquired. 30 subjects, selected at random, were restudied after 1 year. Reproducibility was assessed using a two-way, random effects, single measure intra-class correlational coefficients (ICC) model and Bland Altman plots.
RESULTS: All subjects completed the study. The mean CVT was 8.2 LVS with a standard deviation of 3.0. Thus, the normal range (mean +/- 2 standard deviations (SD)) for CVT based on this data is therefore 2.2 LVS to 14.2 LVS. Age correlated negatively with CVT (r=-0.36, $p<0.0001$) but there was no discernable effect of gender, body mass index or ethnicity. The ICC for CVT was 0.81 (95% confidence interval 0.64-0.91), indicating excellent reproducibility. Figure 1 shows the Bland-Altman plot that demonstrate that 29 out of the 30 measurements lie within +/- 2 SDs of the differences between measurements suggesting that there was no bias or systematic error and that the parameter of CVT is reproducible at a period of 1 year.
CONCLUSION: The normal range for CVT should be considered to be 2.2 – 14.2 LVS. CVT is a reproducible measure over the period of 1 year. Future research utilising CVT should refer to these values.

P1002 A PROSPECTIVE STUDY OF COGNITIVE PERFORMANCE IN IRRITABLE BOWEL SYNDROME: VISUOSPATIAL MEMORY DEFICITS AS A STABLE FEATURE

P. J. Kennedy[1,2], G. Clarke[1,2], A. P. Allen[1,2,*], A. O'Neill[2], J. A. Groeger[3], E. M. Quigley[2,4], F. Shanahan[2,4], J. F. Cryan[2,5], T. G. Dinan[1,2]. [1]*Department of Psychiatry,* [2]*Alimentary Pharmabiotic Centre, University College Cork, Cork, Ireland,* [3]*Department of Psychology, University of Hull, Hull, United Kingdom,* [4]*Department of Medicine,* [5]*Department of Anatomy and Neuroscience, University College Cork, Cork, Ireland*

INTRODUCTION: The cognitive neurobiological model of irritable bowel syndrome (Kennedy et al., 2012a) proposes that key pathophysiological features, such as altered hypothalamic-pituitary-adrenal (HPA) axis function, may lead to impaired cognitive performance. Recently IBS patients were found to exhibit visuospatial memory deficits (Kennedy et al., 2012b). However, a prospective assessment is essential to confirm if cognitive dysfunction is a stable feature of IBS.
AIMS&METHODS: Aim: To prospectively assess visuospatial memory performance in participants with IBS, in comparison to disease controls [Crohn's disease (CD)] and healthy controls (HC).
Method: Age and IQ-matched participants were assessed at baseline and 6-month follow-up. IBS patients (baseline n = 39), CD patients (baseline n = 18), and HC (baseline n = 40), were assessed using a selection of cognitive tests from the Cambridge Neuropsychological Test Automated Battery (CANTAB) and Stroop test. Abdominal pain severity at time of testing was reported by IBS patients on a scale ranging from 0-100. Cortisol awakening response was taken as a measure of activity in the hypothalamic-pituitary-adrenal axis.
RESULTS: At both baseline and follow-up, IBS patients displayed visuospatial memory deficits [assessed using the Paired Associates Learning (PAL) test]. IBS patients made more errors at the 6 pattern recall stage (baseline: $p < 0.05$), which also approached significance across baseline and follow-up ($p = 0.05$), and they required a greater number of trials to complete the PAL [baseline and follow-up ($p < 0.05$)]. Both patients with IBS and those with CD displayed reduced morning cortisol. However, pain severity did not correlate with PAL performance ($p > 0.05$).
CONCLUSION: Visuospatial memory dysfunction is a stable feature of IBS. These results may inform future management of this debilitating disorder in which there is a great unmet medical need.

P1003 THE ESOPHAGEAL MULTIMODAL PAIN MODEL: EXPLORATION OF GENDER DIFFERENCES IN PAIN THRESHOLDS IN THE NORMAL AND SENSITIZED STATE OF HEALTHY VOLUNTEERS

A. Krarup[1,2,*], J. Gunnarsson[3], J. Brun[3], G. Ringström[1], A. M. Drewes[4], M. Simrén[1]. [1]*Department of Internal Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden,* [2]*Department of Internal Medicine, Randers Hospital, Randers, Denmark,* [3]*Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden,* [4]*Mech-Sense, Department of Gastroenterology, Aalborg University Hospital, Aalborg, Denmark*

INTRODUCTION: Clinical data suggests gender differences in gastrointestinal pain, but very little experimental data exists. With the esophageal multimodal pain model gender differences in pain perception to distension, heat, cold, electric current and acid can be measured.
AIMS&METHODS: Using the esophageal pain model, the aim was to measure the effect of gender and mild esophagitis on esophageal pain perception. 35

healthy volunteers (19 males, median age 29 (22-56 years)) underwent gastroscopy, 24h pH metry, and esophageal multimodal pain stimulation. Stimulus intensities at painful thresholds were measured.
RESULTS: Men had a higher pain detection threshold (PDT) to distension (mean volume: men 20.9 ± 10 ml versus women 15.2 ± 6.8 ml, P=0.02. There were no differences between the PDT for men and women to 1) thermal stimulation (mean stimulation time (men, women): heat; 20±5 sec versus 21±6 sec or cold; 33.3 ± 20.1 sec versus 20.7 ± 21.4 sec, $P>0.2$), 2) electrical current (mean current: men 17.6±9.2 mA versus women 12.9±3.7 mA, P=0.11), or 3) tolerated volume acid (median volume: men 200 (20;200) ml versus women 133 (40;200) ml, P=0.2). However, more men compared to women tolerated the maximum volume of acid, P=0.03. Fifteen asymptomatic subjects had mild esophagitis (10 men, all Los Angeles grade A). There were no differences in any esophageal PDT between subjects with normal endoscopy or subjects with mild esophagitis (all $P>0.3$)
CONCLUSION: Esophageal pain thresholds for young men and women have been compared. The results suggest that gender but not mild esophagitis tend to influence esophageal pain perception.

P1004 THE EFFECT OF SILDENAFIL CITRATE ON GASTRIC MOTILITY AND SATIATION IN HEALTHY VOLUNTEERS.

F. Carbone[1,*], S. Verschueren[1], J. Tack[1]. [1]*Gastroenterology, KULeuven, Leuven, Belgium*

INTRODUCTION: Sildenafil induces an intense and prolonged relaxation of smooth muscle cells by blocking phosphodiesterase type 5, which inactivates the nitric oxide-stimulated cyclic guanosine monophosphate. Studies have shown that dyspepsia is one of sildenafil most frequent reported adverse event next to headache and flushing. Therefore, sildenafil might have important effects on gastric motility.
AIMS&METHODS: The **aim** of this study was to examine the effect of sildenafil on gastric accommodation and gastric emptying in humans. **Methods:** Sildenafil (50 mg) or placebo was orally administered to 20 fasted healthy volunteers (HVs) in a single-blind manner. After a manometry probe and an infusion catheter were positioned in the proximal stomach, the intragastric pressure (IGP) was measured before and during nutrient drink infusion (60 ml per minute). Volunteers were asked to fill in a visual analogue scale for hunger and satiation and 6 epigastric symptoms (fullness, nausea, belching of air, cramps in the abdomen, bloating and pain) at 5-minute intervals. The experiment ended when the volunteers scored maximal satiation at 1-minute intervals by using a graphic rating scale that combines verbal descriptors on a scale graded from 0–5 (1, threshold; 5, maximum satiety). Additionally, a breath test was used to measure gastric emptying rate. The volunteers ingested a standardized solid meal consisting of one non-radioactive ^{13}C-octanoic acid labeled pancake. Breath samples were collected every 15 minutes for 6 hours after the meal.
RESULTS: Nutrient drink infusion induced a rapid drop in proximal stomach IGP, which was suppressed by sildenafil compared to placebo. The average AUC change from baseline was -34.7±8.2 mmHg after sildenafil compared to -81.3±17.1 mmHg after placebo (p=0.001) (see Figure 1). Sildenafil-treated volunteers scored maximal satiation at a significantly lower volume compared to placebo treated subjects (837±86.6 vs. 663±64.8 mL, p=0.002). Finally, gastric half emptying time was significantly slower after sildenafil (76.8±6.1 vs. 90.1±5.9 minutes, p=0.04).
CONCLUSION: Sildenafil inhibits gastric accommodation, leading to significantly decreased nutrient tolerance, and slightly delays gastric emptying rate in man.

P1005 OESOPHAGEAL BIOFEEDBACK USING BALLOON DISTENSION OF THE OESOPHAGUS AND SWALLOWING-RELATED VISUAL, OLFACTORY, AND GUSTATORY STIMULI IN THE TREATMENT OF SEVERE DYSPHAGIA WITH TUBE FEEDING

R. A. Awad[1,*], S. Camacho[1], D. Manjarrez[1]. [1]*Experimental Medicine and Motility Unit U107, Mexico City general Hospital, Mexico City, Mexico*

INTRODUCTION: Tactile, gustatory and visual biofeedback stimuli modulate neural substrates of deglutition (1). Sacral nerve stimulation activates a region of the frontal cortex, which is normally active during focused attention, while subsequent stimuli activate the caudate nucleus, which is involved in learning and reward processing (2). The purpose of this pilot study was to modulate the altered neuronal substrate of swallowing through the stimulation of tensoreceptors with esophageal balloon distension combined with visual, olfactory, and gustatory stimuli in patients with severe dysphagia and feeding tube.
AIMS&METHODS: Seventeen patients with severe dysphagia (Castell dysphagia severity scale = 6±2) after unsuccessful prior therapies were studied [clinical, radiology, endoscopy, and esophageal manometry (MMS, Netherlands)] and compared with 12 healthy subjects for manometry studies. Biofeedback: 1) Inflation of the balloon in the mid esophagus was performed three times in a single session. 2) The patients received a graphic description of how a normal person swallowing mechanism functions. 3) On waking, they rinsed out their mouths with water. 4) Patients were asked to look at, smell, chew and then discharge the food. 5) Then they were asked to try and swallow food while bearing in mind the working of the swallowing system that had been explained to them. Steps 3-4-5 were followed at home, every morning until healing. Mean±SD, binominal 95% confidence interval, and nonpaired Student two-tailed t test with alpha=0.05.
RESULTS: All patients recovered completely the mechanism of swallowing in 36.9±25 (CI: 24-49) days. The 3 patients who were initially feeding tube dependent progressed to total oral intake after 13±10.5 (CI: -1.6-27.6) days of treatment. Patients with dysphagia compared with healthy subjects showed impaired peristalsis (p=0.008), lesser esophageal medial amplitude [47±21 (CI: 35-59) Vs. 88±54 (CI: 57-119) mmHg, respectively; p=0.022), and lesser esophageal upper duration [3±0.7 (CI: 2.5-3.4) Vs. 3.6±0.5 (CI: 3.3-3.9) s, respectively; p=0.034). Lower esophageal sphincter pressure was not different between patients with dysphagia (14±6 (CI: 10.2-17.7) mmHg and healthy subjects (20.8±11.2 (CI: 14.4-27.2) mmHg, p=0.082.
CONCLUSION: This successful outcome with our innovative Dysphagia Therapy Program suggests that the stimulation of oesophageal tensoreceptors combined with visual, olfactory, and gustatory biofeedback stimuli, can modulate the neural substrates of swallowing reprogramming the physiological mechanism of swallowing in patients with severe dysphagia.

P1006 OUTCOMES OF INTRAPYLORIC BOTULINUM TOXIN INJECTION FOR REFRACTORY GASTROPARESIS - A SINGLE CENTER EXPERIENCE.

A. Murawska[1,*], A. Ukleja[1], A. Schneider[1]. [1]*Gastroenterology, CLEVELAND CLINIC FLORIDA, Weston, United States*

INTRODUCTION: Refractory gastroparesis (GP) constitutes a major therapeutic challenge. Drug therapy for GP is often ineffective and intolerance to drugs is common. Two small controlled studies suggested a limited value of endoscopic intrapyloric Botox (BTX) injections. In clinical practice we found that some patients noticed significant improvement in symptoms and quality of life. With limited treatment options, Botox injections can still be considered for treatment of refractory GP when drug therapy failed.
AIMS&METHODS: The aim of this study was to evaluate the long-term outcomes of intrapyloric Botulinum toxin injection for patients with proven GP by gastric emptying study. Retrospective medical records review was performed. Patients with GP who received intrapyloric BTX injection from 1/2008-7/2012 were included. Demographics, comorbidities, diagnosis, past surgical history, amount of BTX injected, intraprocedural complications, and medication were collected. The questionnaire was sent to all patients. Symptoms, the overall improvement after procedure, gastric stimulator placement, complications related to BTX injection and number of visits to ER/hospitalizations were analyzed. BTX was injected into 4 quadrants into the pyloric channel.
RESULTS: 25 of 32 pts. were included (refused participation 1, no response 6) 19 females (♂), 6 males (♀). Mean age: 46.1 (range 21-71). Causes of GP: idiopathic (IGP) 17 (13F, 4M), Diabetes (DGP) 6 (4F, 2M), postsurgical (PGP) 2F. Number of BTX injections: 1-15 pts. (13F, 2M), 2-5 pts.(4F, 1M); 3-3 pts. (1F, 2M), 4-2 pts. (1F, 1M). The mean follow up: 31months. Overall symptom improvement: 0% (2F), 25% (5F), 50% (8F, 2M), 75% (3F, 4M), 100% (1F). Improvement (>50%) based on Dx: IGP 82% (14/17); DGP: 67% (4/6), PGP 0% (0/2). Reduced ER/hospital visits: 24% pts. (6/19). Gastric stimulator placement: 28% pts. (7/25).
Symptom Improvement with BTX injections (GCSI).

Response	Bloating		Abdominal distention	Early satiety	Nausea*	Vomiting*
No improvement	(♂)	9	10	11	6	4
	(♀)			1	1	
Partial improvement	(♂)	9	8	6	10	9
	(♀)	4	3	2	2	3
Complete	(♂)	1	1	2	2	5
	(♀)	2	3	3	3	3
improvement						

*1 patient no nausea/vomiting
CONCLUSION: Approximately 72% of our GP patients noticed significant (>50%) symptom improvement. This response rate does not exclude BTX therapy from the armamentarium for treatment of refractory GP. There may be a role for BTX therapy in properly selected GP patients. The subgroup of GP patients who benefited the most were males and those with IGP. Further studies with a larger sample size are needed.

P1007 FACTORS THAT EFFECT THE DISRUPTION OF OESOPHAGOGASTRIC JUNCTION AND ITS RELATION WITH HIGH RESOLUTION MANOMETRY ALTERATIONS AND ACIDIC REFLUX

C. Ciriza De Los Ríos[1,*], F. Canga[1], I. Castel[1], M. Ortiz[1], G. Castellano[1].
[1]*Gastroenterology, HOSPITAL 12 DE OCTUBRE, Madrid, Spain*

INTRODUCTION: The oesophagogastric junction (OGJ) is a mobile structure and several factors contribute to its disruption. High resolution manometry (HRM) facilitates the investigation of the OGJ and its progressive disruption which favors gastroesophageal reflux (GOR).
AIMS&METHODS: To evaluate the risk factors associated with OGJ disruption and the relationship between OGJ type, manometric alterations and acid reflux. 115 patients with GOR symptoms included. HRM (Manoscan; Given) and 24 hour pH-metry were performed on all. They were classified according to the OGJ type based on the axial separation between the lower oesophageal sphincter (LOS) and crural diaphragm (CD) (type I: normal; type II: 1-2 cm LOS-CD separation; type III or hiatus hernia: LOS-CD separation > 2 cm). Statistical analysis: regression logistic models; Kruskal-Wallis; Chi-Square.
RESULTS: Epidemiological data, HRM and pH-metry parameters are expressed in the table. Age (Odd Ratio (OR) 1.03 [1.01-1.06]; p=0,016), body mass index (BMI) (OR 1.09 [1.02-1.17]; p=0,01) and abdominal perimeter (AP) (OR 1.03 [1.01-1.06]; p=0,021) were independent risk factors for OGJ type III (area under the curve 0.70). OGJ disruption is associated with lower pressure (p=0,006), greater length (p < 0.001) and oesophageal body (OB) shortening (p<0.001), noting that the increase of one unit in the length of the hernia decreases the length of the oesophagus in 0.963 (p=0,013). Higher acid exposure was found in OGJ type II and III with respect to type I (p =0,015).

	OGJ I (n=56)	OGJ II (n=44)	OGJ III (n=15)	P value
	Epidemiological data			
Age	49,3 [45,4-53,2]	54,3 [49,6-58,9]	64,9 [58,5-66]	**0,001**
Sex (F)	33 (58,9%)	28 (63,6%)	10 (66,7%)	0,815
BMI (kg/m2)	25,2 [23,9-26,4]	27,9 [26,3-29,7]	31,4 [25,4-37,4]	**0,001**
AP (cm)	88,5 [84,8-92,2]	95,6 [91,5-99,6]	98,4[92,6-104,2]	**0,003**
	HRM parameters			
OGJ pressure	16,3 [13,8-18,8]	10,6 [9-12,3]	13,9 [9,8-18,1]	**0,006**
IRP-4s	8,7 [7,4-9,9]	7,5 [5,8-9,3]	11,3 [7,9-14,7]	0,133
OGJ length (cm)	4 [3,9-4,2]	4,7 [4,5-4,9]	8,5 [6,9-10,2]	**<0,001**
OB length (cm)	24,6[24,1-25,1]	23,6[23-24,1]	20,5[18,5-22,4]	**<0,001**
DCI(mmHg.cm.s	2525,5	1981,4	1865,4	0,204
VFC (cm/s)	4,9 [3,1-6,7]	4,1[3,1-5,1]	2,9 [2,5-3,4]	**0,027**
Latency (s)	6,3 [5,7-6,9]	6,9[5,6-8,3]	5,8 [2,4-14,1]	0,577
	pH-metry			
% pH < 4 total	2,3[1,6-2,9]	4,9[3,6-6,4]	8,1[3,4-12,8]	**0,015**
% pH < 4 upright	2,6[1,9-3,4]	5,9[4,3-7,6]	7,2[3,2-11,3]	**0,022**
% pH< 4 supine	1,3[0,6-2,1]	3,8[1,8-5,8]	8,9[2,5-15,2]	**0,001**
DeMeester score	9,8[6,6-13]	19,8[14,2-25,3]	30,9[13,6-48,3]	**0,014**

CONCLUSION: Age, overweight and central obesity pose a greater risk for hiatus hernia. The greater OGJ disruption is associated with lower pressure, oesophageal shortening, and higher acid exposure in pH-metry.

P1008 INTEGRATED RELAXATION PRESSURE IN ACHALASIA IN SITTING POSITION

J. Perez De La Serna[1,*], A. Ruiz de León[1], S. CASABONA FRANCÉS[1], B. MATEOS MUÑOZ, V. ROALES GÓMEZ[1], B. SERRANO FALCÓN[1], I. PEREZ AMARILLA[1], E. REY DIAZ-RUBIO[1]. [1]*GASTROENTEROLOGY, HOSPITAL CLINICO SAN CARLOS, MADRID, Spain*

INTRODUCTION: One of the criteria used to diagnose achalasia by means of high resolution manometry is an Integrated relaxation pressure >15 mmHg of the esophago-gastric junction measured in supine position. Normal values in upright position have been published but by now there is not a cut-off value in order to diagnose achalasia.
AIMS&METHODS: The aim of the study was to determine the usefulness of the 15 mm. Hg. integrated relaxation pressure (IRP) value of the esophago-gastric junction (EGJ) in patients with achalasia studied by High Resolution Manometry (HRM) in the sitting position.
MATERIAL AND METHODS: The HRM (ManoScan A100, Given / Sierra Scientific Instruments Inc.) records of consecutive patients diagnosed with achalasia from december 2007 to december 2012 in our unit were retrospectively analyzed. All of the studies were done with the patient in the sitting position in fasting state. After a 5 min adaptation period, subjects were provided with ten swallows of 5 mL water. The proximal and distal esophageal margins of the EGJ were adjusted manually to ensure accuracy for every swallow. A descriptive analysis of the data was made.
RESULTS: The records of 97 patients were analyzed. 29 records were excluded because of poor quality studies (artifacts, impossibility to get a gastric record), history of associated disease that can affect esophageal motility, previous treatment of achalasia, esophageal or gastric surgery, and those in whom a secondary achalasia could not be ruled out.
The final group was composed of 68 patients (39 M (57%): 29 F, with a mean age of 49 years (range: 15-92). The mean age of male was 45 years (range: 17-83) and 54 years in female (range: 15-92).
The average value of the IRP in the 68 patients was 26.4 (SD 10.65) mm. Hg. In 9 patients (13.2%) the IRP was <15 mm. Hg, of which 6 were men, and none had an IRP <10 mm. Hg.
The IRP patients >15 mm. Hg. had a higher mean resting pressure (32.2 (11.7 to 88.8) mm. Hg.) than those with an IRP <15 mm. Hg. (16.9 (6.7 to 40.9) mm. Hg.).
CONCLUSION: Our results show that using IRP values >15 mm.Hg. in diagnosing patients with achalasia by HRM in the sitting position may produce up to 13% false negatives.
With the limitations imposed by the small number of patients with achalasia and IRP <15 mm.Hg, there is a significant relationship between resting pressure and IRP values. Although further studies will be necessary to confirm our data to formally establish the cutoff point, we consider that values of IRP ≥ 10 mm.Hg. would be more appropriate.

P1009 PNEUMATIC DILATION IN ACHALASIA: 30 YEARS EXPERIENCE

M. Müller[1,*], C. Keck[1], S. Werling[1], A. J. Eckardt[1], T. Wehrmann I[1], V. Gockel[2], F. Eckardt[1]. [1]*Gastroenterology, German Diagnostic Clinic, Wiesbaden,* [2]*Department of General and Abdominal Surgery, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany*

INTRODUCTION: The success rate, of pneumatic balloon dilatation (PD) in achalasia varies.
AIMS&METHODS: This longitudinal cohort study investigated the long term clinical after pneumatic dilatation, with a focus on possible predictors for the time of recurrence. Between 1982-2012, 99 patients with a mean age of 49.7 ± 16 years were treated with PD and followed-up at regular intervals for a median of 13 years. Remission was determined with the use of a structured interview and the Eckardt score. Patient's characteristics, manometry, barium swallow results and PD characteristics were evaluated as predictors for the need of a second treatment.
RESULTS: One perforation occurred with no mortality, and 84 (84.4%) of the 99 patients were symptom-free 12 weeks after dilation. The mean time of remission was 87 months. However, later on, 51 (51.5%) patients required a second treatment (39 PD, 12 cardiomyotomy). Lower esophageal sphincter pressure (LES) (mean 21.2 mmHg vs. 15.5 mmHg; *P*=.001), width of esophageal corpus (mean 4.2cm vs. 3.4cm; *P*=.007) post PD and young age at presentation are predictive factors of recurrence. Neither clinical, manometric or radiological findings, nor gender determined the need for a second treatment.
CONCLUSION: Single pneumatic dilation in achalasia is a safe and effective therapy. However, half of the patients will need a second treatment in the long term. Young age at presentation, a high LES pressure and a wide esophageal corpus 3 months after PD are predictive factors for the need for repeated treatment.

P1010 ACUPUNCTURE FOR DIABETIC GASTROPARESIS - A FEASIBILITY COMPARATIVE STUDY

N. Danielli Miller[1], E. Schiff[2], J. Singer[3], N. Sahar[1], T. Tsadok Perets[1], S. Flaut[1], Y. Niv[1], R. Dickman[1,*]. [1]*Gastroenterology, Rabin Medical Center, Petach Tikva,* [2]*Internal Medicine, Bnai Zion Medical Center, Haifa,* [3]*Endocrinology, Rabin Medical Center, Petach Tikva, Israel*

INTRODUCTION: Available medical treatments for diabetic gastroparesis (DG) are less than satisfactory. Acupuncture treatment has been used for various gastrointestinal conditions with effects noted on gastrointestinal motility.
AIMS&METHODS: To compare the degree of symptoms, gastric emptying rate (GER) and glucose control improvement before and after domperidone followed by acupuncture treatment.
Eight patients with long-standing, uncontrolled diabetes mellitus and gastroparesis were enrolled in this pilot, prospective case-crossover study. All patients received domperidone (20 mg QID) for 12 weeks and after a wash-out period of 2-3 weeks, received acupuncture treatments for 16 weeks. All patients completed a demographic questionnaire as well as the Gastroparesis Cardinal Symptom Index (GCSI), Satisfaction with Life Scale (SWLS) and the 36-item short-form (SF-36) at entry and at the end of each treatment period. Gastric emptying rate (GER) measurement, glucose level and HbA1C were performed at entry and at the end of each treatment period as well.
RESULTS: Mean age, M/F ratio and mean BMI (kg/m^2) were 57.1 ± 9.9 yrs, 1/7 and 25.2, respectively. Treatment with domperidone did not improve symptoms, GER or glucose control. Acupuncture treatment was associated with improvement of almost all cardinal symptoms scores of GCSI, SWLS (p=0.002) Social Functioning (SF) score (p=0.054) but not with GER or glucose control.
CONCLUSION: Acupuncture was associated with improvement in symptoms related to gastroparesis. A larger trial is warranted for the evaluation of acupuncture in patients with diabetic gastroparesis.

P1011 ROLE OF GASTROESOPHAGEAL REFLUX IN PROTON PUMP INHIBITORS-REFRACTORY NON-EROSIVE REFLUX DISEASE PATIENTS WITH ESOPHAGEAL MOTILITY DISORDERS

S. Izawa[1,*], Y. Funaki[1], Y. Tamura[1], M. Mizuno[1], A. Iida[1], N. Ogasawara[1], M. Sasaki[1], K. Kasugai[1]. [1]*Department of Gastroenterology, Aichi Medical University School of Medicine, Nagakute, Japan*

INTRODUCTION: A high proportion of non-erosive reflux disease (NERD) patients do not respond to proton pump inhibitors (PPI) therapy. Various underlying mechanisms have been shown to contribute to the failure of PPI treatment. Although esophageal motility disorders (EMD) are considered to be one of the most important factors causing PPI-refractory NERD, there is no report of EMD related with the frequency, classification, symptom and gastroesophageal reflux in patients with NERD.
AIMS&METHODS: The aim in this study is to evaluate the relationship between symptoms of PPI-refractory NERD patients with EMD and their gastroesophageal reflux. Seventy six patients (44 males and 32 females) whose heartburn symptoms did not improve despite taking PPI at the standard dose for at least 8 weeks (PPI-refractory NERD patients) underwent intraesophageal pressure test and were divide into 2 groups; normal esophageal motility and EMD. Twenty-four -hour multichannel intraluminal impedance-pH (MII-pH) monitoring examination and medical interview such as reflux symptoms were assessed using the Questionnaire for the Frequency Scale for the Symptoms of GERD (FSSG) were performed in all patients to analyze patient's backgrounds, gastroesophageal reflux and their symptoms between the groups.
RESULTS: Of 76 PPI-refractory NERD patients, 19 patients (25%) had EMD. In 17 patients except 2 patients with achalasia, there were 6 patients with ineffective esophageal motility (IME), 9 patients with non-specific esophageal motility disorder (NEMD) and 2 patients with hypertensive lower esophageal sphincter (HLES). Fifty seven patients had no esophageal motility disorders. There were no significant differences related with gender, age, BMI, duration of 24-hour esophageal pH < 4, mean frequency of gastroesophageal and proximal reflux between the 2 groups. The MII-pH monitoring examination revealed that symptom index (S.I.≧50%) exactly coincided with reflux of gastric contents in 12 patients (70.5%) with EMD and 43 patients (75.0%) with normal esophageal motility. The FSSG scores of normal esophageal motility and EMD were 17.8±8.9 and 17.0±2.1, respectively, and there was no significant difference. Of patients with EMD the questionnaire No.10 of FSSG was significantly related with the rate of gastric reflux (r=0.58, p=0.02) and proximal reflux (r=0.63, p=0.02). The questionnaire No.9 of FSSG was also related with the rate of gastric reflux (r=0.44, p=0.06).
CONCLUSION: PPI-refractory NERD involved some prevalence of EMD, and symptoms of patients with EMD were considered to be caused by gastroesophageal reflux.

P1012 CORRELATION OF NOVEL ESOPHAGEAL PRESSURE-FLOW METRICS WITH BOLUS TRANSPORT AND ESOPHAGO-GASTRIC JUNCTION FLOW DURING BARIUM SWALLOW

T. Omari[1,*], M. Szczesniak[2], J. Maclean[2], N. Rommel I[3], I. Cook[2]. [1]*Gastroenterology, Child, Youth and Women's Health Service, Adelaide,* [2]*Gastroenterology, St George Hospital, Sydney, Australia,* [3]*3Translational Research Center for Gastrointestinal Diseases, University of Leuven, Leuven, Belgium*

INTRODUCTION: Esophageal pressure-flow analysis derives metrics that better describe the interactions between bolus transport and pressure generation. Pressure-flow metrics detect abnormal bolus pressurisation in dysphagia patients with apparently normal peristalsis (1-4). To date there are no data correlating esophageal pressure-flow metrics with videofluroscopic (VF) measures. To address this knowledge gap we undertook a pilot study in dysphagia patients undergoing VF + impedance-pressure assessment of swallowing.
AIMS&METHODS: We analysed simultaneous VF + impedance-pressure recordings in 9 dysphagia patients (62-82y, 7m) during liquid barium swallows. A 3.2mm catheter with 25 1cm pressure/12 2cm impedance was used (Solar GI system, MMS). We derived metrics of bolus pressurisation (Pressure Flow Index, PFI), bolus clearance (Impedance Ratio, IR) and bolus flow timing relative to pressure generation (time from nadir impedance to peak pressure, TZnPp). Peristaltic break size (20mmHg iso-contour defect, ICD) and 4 sec integrated relaxation pressure (IRP4s) were also measured. Bolus transport was assessed by 7-point VF scale (5); high score = abnormal. The cumulative time of flow across the EGJ was also measured (bolus flow time, BFT). Age-match control swallows were used as a normal comparator for pressure-impedance derived variables.
RESULTS: Patients compared to controls had larger peristaltic breaks, higher Impedance Ratio and reduced EGJ relaxation (ICD 8 [2, 13] vs. 2 [0, 2] cm, p = 0.027; IR 0.5 ± 0.1 vs. 0.3 ± 0.0, p=0.019; IRP4s 11 ± 2 vs. 6 ± 1 mmHg, p = 0.070). In patients, a higher VF score correlated with larger ICD (Spearman r = 0.895, p<0.001) and a higher IR (r = 0.661, p<0.05). Diminished EGJ BFT correlated with a shorter TZnPp (r = -0.733, p<0.05) and a higher IR (r = -0.750, p<0.05). IRP4s did not correlate with either VF score or BFT. Patients could be separated into three distinct groups on grounds of abnormal bolus pressurisation (high pressure flow index) and/or clearance (high Impedance ratio); Grp1 normal PFI/normal IR (n=4), Grp2 abnormal PFI/normal IR (n=2) and Grp3 normal PFI/abnormal IR (n=3). Comparisons among these groups showed that VF scores were most abnormal for Group 3 (ANOVA p = 0.014) and BFT shortest in Groups 2 and 3 (ANOVA p=0.04).
CONCLUSION: Peristaltic breaks (large ICD) and incomplete clearance (high IR) correlate with bolus transport abnormalities on VF, however PFI in combination with IR, may better discriminate abnormalities due to over-pressurisation of the bolus when bolus transport is nomal. The metric TZnPp appears to be an indirect marker of EGJ flow time.

P1013 DELAYED GASTRIC EMPTYING IS THE REASON OF EARLY GASTRO-ESOPHAGEAL REFLUX DISEASE RELAPSE.

V.V. Chernyavskyi[1,*]. [1]*Internal medicine #1, National Medical University, Kyiv, Ukraine*

INTRODUCTION: Gastro-esophageal reflux disease (GERD) relapses occur commonly and call for maintenance therapy (1). Early relapse possibly caused by hiatal hernia or rebound of acid hypersecretion after PPI-treatment stopping, other reasons have to be investigated (1,2,3). Searching and correction of possible individual factors causing the reflux could be beneficial for long remission of GERD symptoms. Delayed gastric emptying (DGE) is known as possible reason of GERD, but gastric emptying time is not measured routinely. Use of 13C-octanoate breath test (13C-OBT) (4) could be reasonable for this topic in part of GERD patients.
AIMS&METHODS: Our aims were to detect DGE in GERD patients as a possible reason of early symptoms relapse and to define appropriate treatment regimen using 13C-OBT with infrared stable isotope spectrometer (IRIS,Wagner-Analysen-Technik) for measure the gastric emptying half-time ($T_{1/2}$) in those patients. 42 (27 male, 15 female) patients with erosive GERD and without hiatal hernia were examined and treated. Egg-13C-OBT $T_{1/2}$ was previously validated in 18 healthy volunteers. Gastric emptying half-time was measured with egg-13C-OBT before treatment with single dose of PPI (esomeprasole 40 mg) and after 8 weeks. Those patients, who have DGE after 8 weeks divided to 2 groups. Group 1 patients received prokinetic drug itopride hydrochloride 50 mg 3 times a day during 2 weeks, group 2 were informed untreated controls. Symptoms frequency and severity (0 to 5 points) were assessed in groups after 2 and 6 weeks from itopride start. ''Statsoft 7,0'' was used for statistics.
RESULTS: Median $T_{1/2}$ in healthy volunteers was 74,5 minutes (95% CI=67-85). 32 patients had grade A of esophagitis, 10 – grade B. DGE was revealed in 33 of 42 (78,6%) patients at start. After 8 weeks esophagitis was healed in 40 pts (95,2%±3,3%), 22 of 40 successfully treated patients (55,0%) had DGE. Healing influences on $T_{1/2}$ improving: OR (0,6 95% CI=0,4-0,9). Heartburn relapsed in 1 patient of 11 during 2 weeks period of itopride treatment in group 1 and in 3 of 11 patients in group 2, p=0,09. After 1 month from treatment stop in group 1 were 2 patients, who noticed heartburn, in group 2 – 8 patients had heartburn. Impact of itopride on early (within 6 weeks) relapse prevention was significant: OR 3,0 (95%CI=1,0-5,0). Long-term observation is continued.
CONCLUSION: 13C-ODT is good tool for gastric emptying time measure, an it is beneficial for GERD patients. DGE is highly prevalent among erosive GERD patients. The probability of early symptomatic relapses is dependent on impaired gastric emptying speed. Search for individual reason of DGE is needed. Additional prokinetic treatment is useful in part of GERD patients.

P1014 DURATION OF UNTREATED INFLAMMATION REPRESENTS THE MAIN RISK FACTOR FOR STRICTURE DEVELOPMENT IN EOSINOPHILIC ESOPHAGITIS

A. Schoepfer[1,*], E. Safroneeva[2], C. Bussmann[3], T. Kuchen[4], S. Portmann[5], A. Straumann[5]. [1]*Gastroenterology and Hepatology, University Hospital Lausanne / CHUV, Lausanne,* [2]*Institute of Social and Preventive Medicine, University of Bern, Bern,* [3]*Institute of Pathology, Viollier AG, Basel,* [4]*University of Zurich, Zurich,* [5]*Gastroenterology and Hepatology, University Hospital Basel, Basel, Switzerland*

INTRODUCTION: Eosinophilic Esophagitis (EoE) is a chronic-inflammatory condition presenting either as inflammatory-phenotype (IP), as stenosing-phenotype (SP) or as an overlap form. The IP is endoscopically characterized by whitish exudates, furrows and edema, whereas the SP shows signs reflecting tissue remodeling, such as rings and strictures. There is some evidence that SP develops over time, but the precise evolution of stricture formation during the disease course remains largely unknown.
AIMS&METHODS: We aimed to correlate the prevalence of esophageal strictures with the duration of untreated disease and to evaluate risk factors for stricture formation. We analyzed data from the Swiss EoE Database (SEED), extended by a review of patients charts, endoscopy and pathology records. Strictures were assessed endoscopically at first diagnosis of EoE and defined as a narrowing leading to problems passing a standard adult upper endoscope (outer diameter 9mm). Diagnostic delay was defined as period from onset of EoE symptoms to diagnosis.
RESULTS: Two hundred EoE patients were analyzed (153 males, mean age at index visit 39 ± 15 years, all Caucasians). All patients were symptomatic; dysphagia was present in 94% and chest pain in 35% of patients. Allergies were identified in 132 (66%) of patients. An endoscopic bolus removal was performed in 56 patients (28%), whereof 28 prior and 28 at the time of EoE diagnosis. Median diagnostic delay was 6 years (IQR 2-12, range 0-36 years). We observed the following stricture prevalence at EoE diagnosis according to the following intervals of disease duration: 0-2 years (n=58) 17.2%, 3-5 years (n=39) 30.8%, 6-8 years (n=18) 38.9%, 9-11 years (n=29) 37.9%, 12-14 years (n=12) 41.7%, 15-17 years (n=14) 64,3%, 18-20 (n=6) 66.7%, >20 years (n=24) 70.8% ($p < 0.001$). Logistic regression modeling detected a long duration of untreated disease (defined as diagnostic delay ≥ 7 years) to be strongly associated with the presence of strictures at the index visit (Odds Ratio 3.24, 95% confidence interval 1.75-5.97, $p < 0.001$). No association of strictures at the index visit was found with gender, presence of allergies, age at EoE diagnosis, positive family history of EoE, blood eosinophilia, elevated serum IgE, and peak eosinophil count at index histology.
CONCLUSION: Strictures in EoE develop over time. The frequency of stricture formation is proportional to the duration of the untreated disease. These findings underscore the need to reduce the diagnostic delay in EoE and to control the underlying inflammation in order to prevent esophageal remodeling.

P1015 PATIENTS WITH EOSINOPHILIC ESOPHAGITIS TRIGGERED BY NATIVE PROTEINS TOLERATE COW'S MILK-BASED HYDROLYZED FORMULA

A. J. Lucendo[1,*], Á. Arias[2], J. González-Cervera[3], T. Mota-Huertas[4], J. L. Yagüe-Compadre[4], S. González-Castillo[1], T. Angueira[1]. [1]*Gastroenterology, Hospital General de Tomelloso, Tomelloso,* [2]*Research Support Unit, Complejo Hospitalario Mancha Centro, Alcázar de San Juan,* [3]*Allergy, Hospital General de Tomelloso, Tomelloso,* [4]*Pathology, Complejo Hospitalario Mancha Centro, Alcázar de San Juan, Spain*

INTRODUCTION: Eosinophilic esophagitis (EoE) is an emerging gastrointestinal disorder characterized that usually persists from childhood to adulthood. Its high response rate to food-elimination diets implies that the disease involves allergic sensitization to commonly consumed foods. Cow's milk protein is the main food trigger for EoE in both children and adults and should be continuously avoided once identified as such.
AIMS&METHODS: We aim to evaluate tolerance of a cow's milk-based extensively hydrolyzed formula (eHF) with regard to disease remission maintenance in adult patients with milk-triggered EoE. Seventeen adult patients in whom cow's milk was consecutively demonstrated to trigger EoE after an empiric six-food elimination diet-based study protocol and who subsequently maintained disease remission were prospectively recruited. They were given 400 mL of a cow's milk-based eHF daily for 8 weeks. Intraepithelial peak eosinophil and blood esosionophil counts, esophageal related symptoms, serum total and specific IgE to major milk proteins, and eosinophil cationic protein were monitored before and after eHF intake.
RESULTS: Thirteen male and 4 female patients aged 17 to 56 completed the study protocol. 15 patients (88.24%) achieved and maintained EoE remission, while an infiltration >15 eosinophils/hfp reappeared in the remaining two patients. No differences in age, gender, symptoms and endoscopic appearance at baseline conditions, or personal/family allergic background were observed between those patients who tolerated the eHF and those who did not. Symptom scores did not significantly change after eHF intake and were significantly lower than those documented at baseline conditions or after cow's milk challenge. No differences were documented in blood eosinophil counts or serum markers after eHF intake.
CONCLUSION: Most adult patients with EoE triggered by cow's milk tolerate a cow's milk-based eHF, thus providing them with a safe, economical alternative to cow's milk.

P1016 OESOPHAGEAL BASELINE IMPEDANCE VALUES ARE DECREASED IN PATIENTS WITH EOSINOPHILIC OESOPHAGITIS

B. D. Van Rhijn[1,*], B. Kessing[1], A. Smout[1], A. Bredenoord[1]. [1]*Gastroenterology & Hepatology, Academic Medical Center, Amsterdam, Amsterdam, Netherlands*

INTRODUCTION: Gastro-oesophageal reflux has been suggested to play a role in eosinophilic oesophagitis (EoO). Oesophageal acid exposure decreases baseline impedance, a marker of mucosal integrity, in patients with gastro-oesophageal reflux disease.
AIMS&METHODS: The aim of this study was to assess oesophageal baseline impedance levels in EoO patients and to investigate their relationship with oesophageal acid exposure in EoO.
Ambulatory 24-h pH-impedance monitoring was performed in 11 EoO patients and in 11 healthy controls with matched oesophageal acid exposure. We assessed baseline impedance levels in the distal, mid and proximal oesophageal impedance channels every 2 hours during a 30-second time window. The median baseline impedance level during all 2-hour periods was considered to be the baseline impedance level for the measurement.
RESULTS: Patients did not differ from controls with regard to acid exposure time (4.7 (2.0-9.2)% vs 4.8 (4.4-5.6)%, $p = 0.693$), the total number of reflux episodes (50 (21-74) vs 56 (41-71), $p = 0.622$) and the number of proximal reflux episodes (13 (1-21) vs 31 (22-58), $p = 0.148$). Baseline impedance levels in EoO patients were markedly lower compared to healthy controls in the distal oesophagus (988 (757-1978) Ω vs 2259 (1767-2896) Ω, $p = 0.015$), mid oesophagus (1420 (836-2164) Ω vs 2614 (2374-3879) Ω, $p = 0.003$), and proximal oesophagus (1856 (1006-2625) Ω vs 2868 (2397-3439) Ω, $p = 0.005$). In EoO patients, distal, mid and proximal oesophageal baseline impedance values were not correlated with acid exposure at these levels ($r = 0.427$, $p = 0.190$, $r = 0.136$, $p = 0.689$, and $r = 0.027$, $p = 0.937$, respectively). Whereas baseline impedance decreased from proximal to distal in healthy subjects ($p = 0.037$), no such gradient was seen in EoO patients ($p = 0.123$).
CONCLUSION: Throughout the oesophagus baseline impedance values are decreased in EoO patients, indicating impaired mucosal integrity. Our findings suggest that factors other than acid reflux are the cause of low baseline impedance in EoO.

P1017 SWALLOWED FLUTICASONE RESTORES OESOPHAGEAL MUCOSAL INTEGRITY BY REDUCING EOSINOPHILIC INFLAMMATION IN ADULTS WITH EOSINOPHILIC OESOPHAGITIS

B. D. Van Rhijn[1,*], J. Verheij[2], M. A. van den Bergh Weerman[2], A. J. Smout[1], A. J. Bredenoord[1]. [1]*Gastroenterology & Hepatology,* [2]*Pathology, Academic Medical Center, Amsterdam, Amsterdam, Netherlands*

INTRODUCTION: It has been shown that the oesophageal mucosal integrity is impaired in patients with eosinophilic oesophagitis (EoO). It is unknown whether this is the cause or a result of eosinophilic inflammation. Inflammatory cytokines and degranulation products of eosinophilic inflammation may impair the mucosal integrity. However, the latter may also facilitate transmucosal allergen flux leading to inflammation. An improvement of the mucosal barrier function with the anti-inflammatory drug fluticasone would suggest that barrier dysfunction is a result and not the cause of eosinophilic inflammation.
AIMS&METHODS: To evaluate the effect of swallowed fluticasone on the mucosal integrity in EoO, we included 8 adult EoO patients (>15 eosinophils/hpf, no response to PPI). Patients underwent upper endoscopy at baseline and after 8 wks of swallowed fluticasone 500 μg BID. As a measure of mucosal integrity *in vivo*, electrical tissue impedance spectroscopy (ETIS) measurements 5 cm proximal to the LOS were performed during endoscopy. Four biopsies taken at the same level were transferred to Ussing chambers to measure transepithelial electrical resistance (TER) and transmucosal flux of small fluorescein and large rhodamine molecules during a 1-hour period. Intercellular spaces were measured with electron microscopy.
RESULTS: Eosinophil and mast cell counts decreased after fluticasone (table 1). The mucosal integrity was substantially improved after fluticasone, as shown by increased extracellular impedance and TER. In line, transmucosal flux of fluorescein and rhodamine molecules decreased, however significance was not reached. Intercellular spaces were not affected by fluticasone(p=.263). Dysphagia and endoscopic signs were decreased by fluticasone (both $p<.05$). After fluticasone, the peak eosinophil count correlated with the extracellular impedance (r=-.778, $p<.05$), TER (r=-.874, $p<.01$), and transepithelial flux of rhodamine molecules (r=.741, $p<.05$).
Table 1

	Baseline, median (IQR)	After fluticasone, median (IQR)	p
Extracellular impedance (Ω•m)	2057 (1715-3971)	5852 (4973-9510)	.036
TER (Ω•cm^2)	31.6 (26.2-45.7)	68.9 (50.1-102.0)	.017
Fluorescein flux (μmol/cm^2/h)	2419 (834-2826)	157 (0-2132)	.093
Rhodamine flux (μmol/cm^2/h)	69 (25-83)	0 (0-26)	.310
Peak eosinophilia (n/hpf)	70.0 (30.0-78.8)	6.5 (1.0-32.0)	.069
Peak mastocytosis (n/hpf)	21.5 (11.5-46.3)	6.0 (3.5-17.3)	.036

CONCLUSION: Fluticasone treatment decreases eosinophilic inflammation and improves mucosal integrity in EoO. Our study suggests that esophageal mucosal barrier dysfunction is a consequence and not the cause of eosinophilic inflammation in EoO.

P1018 SAFETY OF PROPOFOL ADMINISTRATION IN ADULT EOSINOPHILIC OESOPHAGITIS PATIENTS SENSITIZED TO EGG, SOY OR PEANUT

J. Molina-Infante[1,*], A. Arias-Arias[2], D. Vara-Brenes[1], R. Prados-Manzano[1], A. J. Lucendo[3]. [1]*Gastroenterology, Hospital San Pedro de Alcantara, Caceres,* [2]*Research Unit, Hospital Alcazar de San Juan,* [3]*Gastroenterology, Hospital Tomelloso, Ciudad Real, Spain*

INTRODUCTION: Propofol administration in a fatty emulsified formulation containing egg lecithin and soybean oil is often contraindicated in patients with allergies to egg and/or soy. However, Intralipid, a fat emulsion prepared for intravenous administration, which contains soybean oil and egg lecithin as well, can be safely administered in egg- or soy-allergic patients.
AIMS&METHODS: To investigate the safety of propofol for procedural sedation in adult eosinophilic oesophagitis (EoE) patients sensitised to egg, soy or other foods showing cross-reactivity with them. A prospective cohort study of the safety of propofol for procedural sedation during upper endoscopies in consecutive adult EoE patients was conducted in two secondary referral hospitals between January 1, 2007 and March 1, 2013. Propofol was administered by an endoscopist in all procedures excepting two 14-yrs old male with food impaction who underwent general anesthesia. Food-specific serum IgE measurements and skin prick/prick prick tests for egg, chicken, soy, peanut and other legumes (including lentils, chickpeas, beans and peas) were carried out.
RESULTS: Sixty consecutive EoE adult patients, mostly on empirical six-food elimination diet, were evaluated. Mean age was 28 years-old (14-56), with a clear male predominance (54/6, 90%). Atopy was present in 52/60 (87%) of patients, being the most prevalent allergic comorbidities rhinoconjunctivitis (75%) and seasonal asthma (61%). The rate of food sensitisation in the cohort, measured by either blood or skin testing, was egg (41%), soy (41%), chicken (23%), peanut (52%), lentils (64%), chickpea (17%) and pea (17%). A total of 404 upper endoscopies (mean 6.78 (3-17)) were performed under propofol sedation (mean dose 175 mg (90-282)), including 7 stricture dilations. No anaphylactic or allergic adverse events were reported in the entire cohort excepting a transient bronchospasm episode after orotracheal intubation in one of the 14-yrs old male undergoing anesthesia. This patient, who suffered from severe asthma, received as well ketamine and midazolam for anesthesia induction and further allergic work-up ruled out sensitisation neither to propofol nor to Intralipid.
CONCLUSION: Propofol was safely administered for procedural sedation in a large series of adult EoE patients sensitised to egg, soy or cross-reactant foods. These findings may warrant further reconsideration of warning labels regarding propofol administration in egg or soy-allergic patients

P1019 TOPICAL CORTICOSTEROIDS DO NOT RESTORE A HEALTHY BLOOD EOSINOPHIL PHENOTYPE IN PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

H. Bergquist[1], C. Lingblom[2], M. Johnsson[3], M. Bove[1,*], C. Wennerås[2]. [1]*Department of ENT|H&N Surgery,* [2]*Microbiology,* [3]*Clinical Chemistry, Sahlgrenska University Hospital, Göteborg, Sweden*

INTRODUCTION: Eosinophilic esophagitis (EoE) is an allergic disorder in which eosinophilic granulocytes invade the esophagus. Patients typically suffer from dysphagia and food bolus impaction. Swallowed corticosteroids are the standard therapy. Eosinophils in the circulation of untreated patients display a particular pattern of surface molecules.
AIMS&METHODS: The objectives of this study were to examine if topical corticosteroid therapy restores the phenotype of eosinophils to a healthy phenotype.
Blood eosinophils from adult EoE patients before (n=13) and following a 2-month course of topical corticosteroids (n=7) were investigated, and compared to healthy controls (n=10). Eosinophilic surface molecule expression was determined by 4-color flow cytometry. Data was processed by multivariate pattern recognition methods to reveal specific patterns.
RESULTS: Eosinophils from all EoE patients, independent of treatment, had decreased expression of CD44 and CCR3, and enhanced expression of CD23, CD40 and CD54 relative to control persons. Corticosteroids decreased the expression of CD18 on eosinophils, but did not otherwise alter the phenotype of blood eosinophils in EoE patients.
CONCLUSION: Topical corticosteroids did not reverse the phenotype of blood eosinophils to a healthy profile. The diminished expression of CD18 on blood eosinophils may explain the reduced entry of eosinophils into the esophagus following corticosteroid treatment of EoE patients.

P1020 STEROID THERAPY FOR EOSINOPHILIC ESOPHAGITIS: A META-ANALYSIS AND SYSTEMIC REVIEW

M. chen[1,*], Y. xiao[1], N. tan[1]. [1]*gastroenterology, the first affiliated hospital of SYSU, China, guangzhou, China*

INTRODUCTION: Eosinophilic esophagitis (EoE) is an inflammatory disorder of the esophagus causing upper gastrointestinal symptoms with distinctive endoscopic and histologic features. Although many therapies are advocated, there is currently no consensus on its appropriate treatment protocol.
AIMS&METHODS: To clarify the benefits and harms of steroid therapy for EoE, we performed a meta-analysis and systemic review with the published literatures. PubMed, EMBASE, Medline, ISI Wed of Science were searched to obtain relevant randomized controlled trials (RCTs) with comparison of steroid therapy vs. non-steroid therapy, retrospective and prospective trails on steroid therapy for EoE till March 2013. Two reviewers independently screened the trials and extracted the related information from the included studies, and RevMan 5.2 was used.
RESULTS: Six RCTs fulfilled inclusion criteria of meta-analysis, with 193 subjects (55 children); And 3 RCTs, 2 prospective and 5 retrospective trials fulfilled criteria of systemic review. All of them were of high quality evaluated via Cochrane collaboration's tool for assessing risk of bias or Newcastle-Ottawa Scale. Meta-analysis showed topical steroids significantly decreased the mean and peak values of the esophageal eosinophils (eos) count (MD_{mean}= -23.41, 95%CI_{mean} -42.08~ -4.73, P=0.01 and MD_{peak}= -51.27, 95%CI_{peak} -78.62~ -23.92, P=0.0002 respectively), compared to the non-steroid therapy. The decease of mean value of eos was more pronounced in the adult group and when compared to the placebo group (P=0.02 and P= 0.002 respectively). And the decrease of peak value of eos remained significant independent of patient age, types of steroids (both $P<0.05$). There were 14 trials showing the effectiveness of steroids on decreasing eos count, 10 trials showing improvement of symptoms, and 5 trials showing endoscopic improvement after steroids therapy. Only mild adverse effects (esophageal or oral candidiasis) were reported for topical steroids, but severe systemic side effects for systemic steroids.
CONCLUSION: This meta-analysis and systemic review demonstrated the effectiveness of steroids on decreasing the mean and/ or peak value of eos count for EoE, especially among the adult patients and when compared to the placebo group, but regardless of the types of steroids. As lack of unified standards, we yet couldn't determine its value of improving symptoms and endoscopic changes.

P1021 INFLUENCE OF LONG-TERM TREATMENT WITH TOPICAL CORTICOSTEROIDS ON NATURAL COURSE OF EOSINOPHILIC ESOPHAGITIS AND CORRELATION BETWEEN SYMPTOMS AND ENDOSCOPY, HISTOLOGY, AND BLOOD EOSINOPHILS

S. Portmann[1,*], A. Schoepfer[2], T. Kuchen[3], E. Safroneeva[4], C. Bussmann[5], A. Straumann[1]. *[1]Gastroenterology and Hepatology, University Hospital Basel, Basel, [2]Gastroenterology and Hepatology, University Hospital Lausanne / CHUV, Lausanne, [3]University of Zurich, Zurich, [4]Institute of Social and Preventive Medicine, University of Bern, Bern, [5]Institute of Pathology, Viollier AG, Basel, Switzerland*

INTRODUCTION: Natural history studies on Eosinophilic Esophagitis (EoE) have shown that the disease remains clinically, endoscopically and histologically active over years. However, whether this course can be altered by treatment with swallowed topical corticosteroids (TCS) is completely unclear. Furthermore, the association between clinical, endoscopic, histologic, and biochemical features of EoE needs further elucidation.

AIMS&METHODS: We aimed to assess the influence of treatment with TCS on disease activity and to determine the association between clinical and endoscopical, histological and biochemical activity in the long term run in a well characterized cohort of adult EoE patients. Patients from the Swiss EoE Database (SEED) were analyzed.

RESULTS: Hundred fifty two patients with a total of 511 visits were analyzed (115 males, mean age at EoE diagnosis 39 ± 14 years). The median follow-up time was 5 years (IQR 2-6), patients had on average 3.4 follow-up visits. In the follow-up period, patients were during 424 (83%) of visits clinically active (94% dysphagia, 22% thoracic pain) and in 87 (17%) of visits inactive. The following risk factors for clinical activity were evaluated: peripheral eosinophilia (OR 2.49, 95%>CI 0.69-8.94, p=0.16), presence of whitish exudates and/or furrows (OR 6.23, 95%>CI 3.79-10.26, p<0.001), presence of rings and/or strictures (OR 4.32, 95%>CI 2.66-7.01, p<0.001), histologic activity (OR 5.93, 95%>CI 2.65-13.29, p<0.001), therapy with topical steroids (OR 0.30, 95%>CI 0.17-0.54, p<0.001), and endoscopic dilation (OR 1.58, 95%>CI 0.80-3.11, p=0.185). In the multivariate logistic regression model (factors entered if p<0.1) clinical activity was significantly associated with active endoscopic and fibrotic activity (OR 4.01, 95%>CI 2.15-7.49, p<0.001 and OR 4.37, 95%>CI 2.42-7.90, p<0.001, respectively), and histologic activity (OR 0.25, 95%>CI 0.11-0.54, p<0.001), while therapy with topical steroids was significantly negatively associated (OR 0.25, 95%>CI 0.11-0.54, p<0.001) with clinical activity.

CONCLUSION: This is the first study demonstrating that long-term use of TCS in EoE is associated with symptom resolution. In addition, a good correlation between symptoms and endoscopic and histologic activity was found, but not with peripheral blood eosinophilia.

Disclosure of Interest: None Declared

P1022 TOPICAL STEROID THERAPY EFFICIENTLY REDUCES THE RISK FOR LONG LASTING FOOD IMPACTIONS REQUIRING ENDOSCOPIC REMOVAL IN EOSINOPHILIC ESOPHAGITIS

S. Portmann[1,*], T. Kuchen[2], E. Safroneeva[3], C. Bussmann[4], A. Schoepfer[5], A. Straumann[1]. *[1]Gastroenterology and Hepatology, University Hospital Basel, Basel, [2]University of Zurich, Zurich, [3]Institute of Social and Preventive Medicine,*

University of Bern, Bern, [4]Institute of Pathology, Viollier AG, Basel, [5]Gastroenterology and Hepatology, University Hospital Lausanne / CHUV, Lausanne, Switzerland

INTRODUCTION: Long lasting food impactions requiring endoscopic bolus removal occurs frequently in Eosinophilic Esophagitis (EoE) and are risky and frightening for patients. So far it is unknown whether the risk of impaction can be reduced by therapy with swallowed topical steroids (TCS).
AIMS&METHODS: To assess the frequency of impactions requiring endoscopic bolus removal in EoE patients under therapy with topical corticosteroids compared to a group of untreated EoE patients. In addition, we aimed to identify other risk factors for bolus removal. We analyzed retrospectively data of the Swiss EoE Database (SEED).
RESULTS: Hundred fifty two patients with a total of 511 visits were analyzed (115 males, mean age at EoE diagnosis 39 ± 14 years). The median follow-up time was 5 years (IQR 2-6), patients had on average 3.3 follow-up visits. In the follow-up period, 32 (6.3% of all endoscopies) episodes with endoscopic bolus removal were observed in 25 patients (16.4% of the cohort). Therapy with topical swallowed steroids reduced the risk for bolus removals (OR 0.53, 95% > CI 0.27-1.05, p=0.069). The following risk factors for bolus removal were further evaluated by univariate logistic regression modeling: clinical activity (OR 1.07, 95% > CI 0.43-2.65, p=0.880), esophageal stricture (OR 2.66, 95% > CI 1.41-5.03, p=0.003), peak eosinophil count > 20 eosinophils/HPF (OR 0.62, 95% > CI 0.29-1.28, p=0.193), blood eosinophilia (OR 0.62, 95% > CI 0.29-1.28, p=0.193), adherence to steroid therapy 3 months before bolus removal (OR 1.14, 95% > CI 0.40-3.25, p=0.805), and esophageal dilation (OR 2.36, 95% > CI 1.16-4.79, p=0.018). Factors with $p < 0.1$ were entered into the multivariate logistic regression model. In the multivariate model therapy with topical steroids was signicantly negatively associated with the risk for endoscopic bolus removal (OR 0.34, 95% > CI 0.16-0.73, p=0.006), whereas the presence of esophageal strictures was positively associated with endoscopic bolus removal (OR 2.56, 95% > CI 1.12-5.84, p=0.025). Dilation was no longer associated with endoscopic bolus removal (OR 1.79, 95% > CI 0.75-4.28, p=0.190).
CONCLUSION: Treatment with swallowed topical steroids efficiently reduces long lasting bolus impactions requiring endoscopic intervention. A reduced esophageal diameter is associated with an increased risk for bolus impactions. Of note, clinical activity is clearly insufficient to predict the risk of bolus impactions.

P1023 DIFFERENCE OF SYMPTOM-RELIEF TO PROTON PUMP INHIBITOR BETWEEN NEW-ONSET OR RECURRENT GASTROESOPHAGEAL REFLUX DISEASE DURING THE ON-DEMAND VERSUS CONTINUOUS MAINTENANCE THERAPY IN JAPAN- A POST HOC ANALYSIS

A. Nagahara[1,*], M. Hojo[1], D. Asaoka[1], H. Sasaki[1], Y. Shimada[1], S. Watanabe[1]. [1]*Gastroenterology, JUNTENDO UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan*

INTRODUCTION: Gastroesophageal reflux disease (GERD) is considered as liable to show recurrence. Although a number of studies describe the clinical importance of maintenance therapy, no study focused on the difference of efficacy during maintenance therapy between patients with new-onset and recurrent GERD.
AIMS&METHODS: The aim of this study is to reveal whether there is any difference in symptom-relief between new-onset or recurrent GERD during the on-demand versus continuous maintenance therapy. Endoscopically proven GERD patients who completed 8-week initial therapy were sequentially randomized to continuous arm (Omeprazole 20mg od) or on-demand arm (Omeprazole 20mg on-demand). Patients filled in daily symptom and tablet usages on the daily chart for 24 weeks. Symptom relief was defined as no-symptom on >6 days during a week. Patients were divided into new-onset GERD and recurrent GERD. In this subgroup, the number of patients who achieved symptom-relief was compared between continuous and on-demand arm during a maintenance therapy. This study was approved by the ethical committee.
RESULTS: A total of 118 patients, 82 were new-onset GERD (mean age 59.6 years, men/women 53/29) consisting of 42 continuous and 40 on-demand arm, and 36 were recurrent GERD (mean age 57.6 years, men/women 22/14) consisting of 17 continuous and 19 on-demand arm. Among new-onset GERD, more patients in contentious arm achieved symptom-relief than on-demand arm only at 4,5,6 and 17week whereas among recurrent GERD, contentious arm achieved superior effect at 1,2,3,4,5,7,8,17 and 18 week respectively. For instance, percentages of symptom-relief in continuous/on-demand in new-onset GERD were 62.5%43.2% at 1week, 78.1%/54.1% at 4week, 78.1%/59.5% at 8week, 80.6%/67.6% at 16week and 76.7%/83.3% at 24week, respectively. In continuous/on-demand in recurrent GERD, percentages of symptom-relief were 84.6%31.2% at 1week, 84.6%/40.0% at 4week, 92.3%/46.7% at 8week, 83.3%/56.3% at 16week and91.7%/73.3% at 24week, respectively. The mean tablet consumption showed no difference between new-onset and recurrent GERD in on-demand therapy in each week.
CONCLUSION: In patients with recurrent GERD comparing to new-onset GERD, continuous therapy provided more satisfying symptom-relief than on-demand therapy during a maintenance therapy.

P1024 A PILOT STUDY OF AN ENDOSCOPIC SURGICAL STAPLER FOR THE TREATMENT OF GERD – FIVE YEAR FOLLOW UP RESULTS

A. Bapaye[1,*], S. Date[1], R. Pujari[1], S. Dorwat[1], A. Roy-Shapira[2]. [1]*Department of Digestive Diseases and Endoscopy, Deenanath Mangeshkar Hospital and Research Center, Pune, India, [2]Department of Surgery A, Ben Gurion University Faculty of the Health Science, Beer Sheva, Israel*

INTRODUCTION: From May - Oct 2007, an IRB approved pilot study of a new endoscopic stapling device (Medigus SRS^{TM} device) for GERD treatment was conducted on 13 subjects. Inclusion - h/o PPI use > 2y for pH-metry proven GERD & no co-morbidity. The device is a flexible endoscopic surgical stapler with ultrasonic sight & range finder. It fires a staggered quintuplet of standard titanium B shaped 4.8mm surgical staples. It is guided into the stomach through the esophagus like a standard gastroscope. Cartridge is positioned in esophagus 2-3 cm above GE junction. Distal 21 cm is flexed in fundus, pushing it toward cartridge in esophagus. Ultrasonic sight is used to align cartridge in esophagus, measure intervening gap & allow compression to optimize firing range. Procedure repeated after replacing cartridge for 2nd or 3rd stapling. Result is an anterolateral true fundoplication functionally similar to Dor-Thal operation. A single operator did all procedures under general anesthesia.
AIMS&METHODS: Aim: To evaluate the 5-year follow up results of Medigus SRS^{TM} fundoplication. As per original informed consent, subjects were contacted annually for 5 yrs, the final telephone interviews conducted in early October 2012. Following data were collected: Velanovich GERD-HRQL scores, PPI use, symptoms, satisfaction with the procedure & willingness to repeat procedure again. This data and the trends were compared to the 6-month & annual follow up data of these same subjects.
RESULTS: Each year, 11 / 13 subjects could be reached by phone (but not the same subjects each year). GERD-HRQL scores were reduced > 50% in all subjects but one. This subject had an initial score - 29, & had reported scores of 15 or 14 in different years. All subjects agreed to undergo the procedure again if required in future. Mean satisfaction score was 7.7 (6-10) on a scale 1-10 (1 – not satisfied, 10 – fully satisfied). None had dysphagia or gas bloat. In 1st 3 years, slight increase in PPI reuse was seen. 3 resumed daily PPI's (compared to 2 at 2y follow up), 3 need reduced dose PPI (<50%), 1 takes PPI only after large meal & 4 are off PPI. No deterioration of results was seen after 3rd year.
CONCLUSION: At 5 years, the SRS procedure remained effective to improve QOL in moderate to severe GERD without causing dysphagia. PPI use was eliminated / reduced > 50% in 73% subjects. All subjects remain satisfied with the procedure & would do it all over again. There was no deterioration of results after 3rd year. This study suggests that at 5-years, results of SRS fundoplication are similar to laparoscopic fundoplication in terms of PPI use & QOL improvement.

P1025 GAVISCON DOUBLE ACTION (ANTACID + ALGINATE) IS MORE EFFECTIVE THAN ANTACID ALONE IN CONTROLLING POST-PRANDIAL ACID REFLUX IN GERD PATIENTS; A DOUBLE-BLIND CROSSOVER STUDY

J. Chen[1], A. de Ruigh[2,*], J. Pandolfino[1], P. J. Kahrilas[1]. [1]*Gastroenterology and Hepatology, Northwestern University, Chicago, United States, [2]Gastroenterology and Hepatology, Academic Medical Center Amsterdam, Amsterdam, Netherlands*

INTRODUCTION: Recent studies have shown that Gaviscon (an alginate containing antacid) administered after a meal localizes in the postprandial acid pocket suggesting a targeted mechanism of action in GERD.
AIMS&METHODS: The aim of this study was to compare the effectiveness of Gaviscon to an equivalent strength non-alginate antacid on postprandial distal esophageal acid exposure in GERD patients. 14 GERD patients (LA A or B esophagitis or >5% distal esophageal acid exposure on BRAVO pH monitoring) not taking antisecretory medications were recruited for two 3.5-hour pH-impedance recording periods. After being instrumented with a high resolution manometry (Given Imaging) and a pH-impedance electrode (Sandhill Scientific) participants consumed a standardized meal (MacDonald's double quarter-pounder with cheese and small fries). In a double-blinded randomized crossover design they then received Gaviscon Double Action (alginate, sodium bicarbonate, calcium carbonate) or CVS Antacid Liquid Supreme (calcium carbonate, magnesium hydroxide), each at a volume containing ~20mEq acid neutralizing capacity. The recording was continued for 3 hours with patients scoring their symptoms q30 min with the GERDQ instrument. The primary outcome was the % time that the distal esophageal pH was <4; secondary outcomes were number of reflux events, proximal extent of reflux, and nadir pH of the refluxate. A paired t-test was used to compare the data.
RESULTS: 11 patients completed the study (mean age 47.3, 6 female); 9 had esophagitis and 2 had abnormal pH-metry. Mean baseline GERDQ scores were 9.5 (SD 1.20) and 7.3 (SD 1.70) on study days 1 and 2 respectively. Gaviscon studies had significantly less distal esophageal acid exposure and greater mean

pH of refluxate than CVS antacid studies (Table). There were no statistically significant differences between the total number of reflux events or the proximal extent of reflux.

	Antacid	Gaviscon	*p*
% time pH <4.0 median (IQR)	11.2 (5.9 - 17.85)	0.8 (0 - 8.95)	0.002
Total number of reflux median (IQR)	21 (16 - 31.5)	19 (14 - 32.5)	0.705
Nadir pH mean +/- SD	1.44 +/- 0.52	2.07 +/- 1.14	0.049
% reaching 17cm from LES median (IQR)	0.19 (0.12 - 0.33)	0.08 (0.026 - 0.17)	0.222

CONCLUSION: Gaviscon Double Action was more effective than antacid alone in controlling postprandial acid reflux. However, the number of reflux events and the spatial distribution of reflux within the esophagus were similar. This suggests that Gaviscon's effectiveness was related to its co-localization with and neutralization of the post-prandial acid pocket rather than by creating a barrier (raft) that prevents reflux.

P1026 EFFECT OF PROTON PUMP INHIBITORS IN ASTHMATICS WITH GASTROESOPHAGEAL REFLUX DISEASE

F. Dimoulios[1,*], E. Tsikrika[2], K. Kontotasios[3], C. Koutras[3], K. Panteleakis[1]. [1]*Gastroenterology Department,* [2]*Respiratory Medicine Department,* [3]*Internal Medicine Department, General Hospital of Veroia, Veroia, Greece*

INTRODUCTION: Prevalence of Gastroesophageal Reflux Disease (GERD) among patients with asthma has varied, according to different studies, from 33% to 90%[1]. Treatment with Proton Pump Inhibitors (PPIs) seems to improve asthma symptoms in some patients with asthma and GERD[2].

AIMS&METHODS: The objectives of this study was to investigate the presence of esophagitis in patients with asthma and GERD and to assess the effect of PPIs on pulmonary function. 51 patients with asthma and typical esophageal GERD symptoms (heartburn and/or regurgitation), according to the Montreal Consensus for GERD definition[3], were enrolled. All patients were submitted to upper gastrointestinal endoscopy, so that the presence of esophagitis could be recorded (according to Los Angeles classification). Patients were classified in two groups, according to the presence or absence of reflux esophagitis. Peak Expiratory Flow Rate (PEFR) was measured and then all patients began treatment with a double dose of PPI (omeprazole 20mg bid) for three months. PEFR was measured again at the end of the 3-month period. Response to treatment was defined a priori as positive if PEFR increased at least by >20%[4].

RESULTS: 44 patients (mean age 46±12 years, 24 women, 20 men) were finally investigated. 19 out of 44 patients (43.18%) had endoscopic findings of reflux esophagitis (grade A: 10, grade B: 5, grade C: 3, grade D: 1) and the rest 25 patients (56.82%) did not have reflux esophagitis. Among the esophagitis group, 4 out of 19 patients (21.05%) responded positively at the end of the 3-month treatment with the PPIs (PEFR increase >20%). Among the non-esophagitis group, 5 out of 25 patients (20%), improved their PEFR>20%. The difference between the two groups regarding positive response to PPI treatment was non significant (NS).

CONCLUSION: PPI treatment may improve pulmonary function in some patients with asthma and typical esophageal GERD symptoms. The presence or absence of reflux esophagitis does not seem to influence this response.

P1027 COMPARISON OF COMBINED THERAPY OF PROTON POMP INHIBITOR AND ALGINATES AND A MONOTHERAPY OF PROTON POMP INHIBITOR IN TREATMENT OF PATIENTS WITH EROSIVE ESOPHAGITIS AFTER USAGE OF NON-STEROID ANTI-INFLAMMATORY DRUGS

I. Pakhomova[1], Y. Uspenskiy[2,*], N. Baryshnikova[2]. [1]*Introduction into internal diseases, North-West State Medical University n.a. I.I. Mechnikov,* [2]*2Surgical gepatology with a gastroenterology course, St-Petersburg State Medical University n.a. I.P. Pavlov, Saint-Petersburg, Russian Federation*

INTRODUCTION: The serious medical problem is an esophagus pathology after usage of non-steroid anti-inflammatory drugs (NSAID). It is known that usage of NSAID (including low doses of the aspirin) is a risk factor of developing of damages of the esophageal mucous.

AIMS&METHODS: The aim: to evaluate the efficacy of proton pomp inhibitors (PPI) and combined treatment of PPI and alginates ("Gaviskon-Forte") in the treatment of erosive esophagitis after receiving NSAIDs. 68 patients with erosive esophagitis were observed. All of these patients use NSAIDs at least 1 month and have heartburn. These patients were divided into 2 groups: the 1st group (n=30) received PPI (pantoprasol) 40 mg once a day and "Gaviskon-Forte" 10 ml after a meal 3 times a day and 10 ml before sleeping within 14 days, the 2nd group (n=38) - PPI (pantoprasol) in the dose of 40 mg once a day. All patients responded to daily questionnaire for consideration of complaints; esophagogastroscopy and pH monitoring before and after the treatment were carried out.

RESULTS: Combination of PPI and "Gaviskon-forte" noted more persistent symptom control (heartburn to the 7th day disappeared in 53.3% of patients, to the 14th day - in 90.0% ($p<0.05$ in comparison to 2nd group)) compared with an isolated application of PPI (heartburn to the 7th day disappeared in 42.1% of patients, to the 14th day - in 68.4%). More pronounced positive dynamics of the endoscopic picture was observed in the group of patients receiving combination therapy (on 14th day full healing of erosion was observed in 73.3% in the 1st group and the 60.5% in the 2nd group ($p<0.05$)). Combined treatment of PPI and "Gaviskon-forte" improved results of pH monitoring (24 hours) and significantly reduces the period percent with intragastral pH less 4 during a day (from 23.5% to 7%), total reflux number decreased from 161 to 52.2 within 24h ($p<0.05$ in comparison to 2nd group). In the group of patients receiving only PPI the period percent with intragastral pH less 4 during a day reduced from 21.7% to 10.1%, total reflux number decreased from 143 to 72.2 within 24h. For a treatment period the side effects and allergic reactions were not registered.

CONCLUSION: Combination of PPI and «Gaviskon-Forte» showed the higher clinical and endoscopic efficiency in the treatment of the erosive esophagitis after usage of NSAID compared with monotherapy PPI. Also combination of PPI and "Gaviskon-forte" quite safety to consume. So we can recommend this combination to use in such patients

P1028 IMPROVEMENT IN SYMPTOM RELIEF WITH PANTOPRAZOLE MAGNESIUM 40MG VERSUS ESOMEPRAZOLE 40MG IN PATIENTS WITH EROSIVE ESOPHAGITIS AFTER 8 WEEKS

J. P. Moraes-Filho[1,*], M. Pedroso[2], E. M. Quigley[3]. [1]*Gastroenterology, Univ Sao Paulo School of Medicine,* [2]*Medical Department, Takeda Brazil, São Paulo, Brazil,* [3]*Gastroenterology and Hepatology, The Methodist Hospital, Weill Cornell Medical College, Houston, United States*

INTRODUCTION: The proton pump inhibitor (PPI), pantoprazole-Mg, has a prolonged elimination half-life, which may translate into extended inhibition of the proton pump with the potential for improved symptom relief.

AIMS&METHODS: Pantoprazole-Mg was compared with esomeprazole over 4 and 8 weeks for symptom relief in a multicentre (14 Brazilian sites), phase III, randomised, double-blind, controlled study in patients with erosive gastroesophageal reflux disease (GERD; Los Angeles grades A–D). Patients received pantoprazole-Mg (n=290) or esomeprazole (n=288), administered as 40 mg once daily for 8 weeks. GERD-related symptoms were assessed at baseline (BL) and after 4 and 8 weeks using ReQuest^{T}-GI, which includes acid-related complaints, upper abdominal/stomach complaints, lower abdomen/digestive tract complaints and nausea.

RESULTS: Symptom relief rates were significantly higher at Week 8 with pantoprazole-Mg (n=275) than with esomeprazole (n=264) (91.6% vs. 86.0%, p=0.0370). Significant improvements were seen in mean ReQuest^{T}-GI scores from BL to Weeks 4 and 8 (both $p<0.0001$), and from Week 4 to Week 8 (p=0.0206), in pantoprazole-Mg recipients. ReQuest^{T}-GI scores significantly improved from BL to Weeks 4 and 8 (both $p<0.0001$) with esomeprazole, but not from Week 4 to Week 8. A similar trend was seen for all individual ReQuest^{TM}-GI sub-scores (Table). This correlated with improvements in general well-being from BL to Weeks 4 and 8 for both pantoprazole-Mg (both $p<0.0001$) and esomeprazole (both $p<0.0001$), and improvements from Week 4 to Week 8 for pantoprazole-Mg (1.42 to 1.06) but not esomeprazole (1.42 to 1.36).

Table. Individual ReQuest^{TM}-GI dimension mean scores after 4 and 8 weeks' treatment (intent-to-treat efficacy population).

	Acid complaints			Upper abdominal/ stomach complaints			Upper abdominal/ stomach complaints			Nausea

P1029 EVALUATING THE CONTROL OF DAYTIME INTRAGASTRIC PH BY ESOMEPRAZOLE 20 MG (ESO 20): NEW COMPARATIVE ANALYSES WITH OTHER PROTON PUMP INHIBITORS OMEPRAZOLE 20 MG (OME 20), LANSOPRAZOLE 15 MG (LAN 15) AND PANTOPRAZOLE 20 MG (PAN 20)

P. Katz[1], J. Dent[2,*], P. Kahrilas[3], B. Traxler[4], T. Lind[5], K. Röhss[5], D. Johnson[6].
[1]Albert Einstein Medical Center, Philadelphia, PA, United States, [2]Royal Adelaide Hospital, Adelaide, Australia, [3]Northwestern University, Chicago, IL, [4]AstraZeneca R&D, Wilmington, DE, United States, [5]AstraZeneca R&D, Mölndal, Sweden, [6]Eastern Virginia Medical School, Norfolk, VA, United States

INTRODUCTION: It is well established that the oesophageal mucosal inflammatory component of the gastric refluxate and the associated symptoms of gastro-oesophageal reflux disease (GORD) are pH-dependent.[1] In untreated patients, the major burden of high rates of acid reflux and frequent heartburn symptoms occurs during waking hours.[2,3] Control of daytime pH provides relief of nighttime symptoms, presumably by making the oesophagus less sensitive to nighttime reflux.[4] Published studies have evaluated the 24-hour control of intragastric pH by ESO 20 and the OTC doses of other proton-pump inhibitors (PPIs).[5-8] Here we report new analyses of these studies, focusing on intragastric pH in the 14-hour awake period.
AIMS&METHODS: In one double-blind[5] and three open-label,[6-8] randomized, crossover studies, intragastric pH was monitored for 24 hours on Day 5 of treatment. Acid control was reassessed for the 14-hour daytime period. Mean percent times with pH > 4 were estimated using a linear mixed-effect model that included factors for treatment, treatment period, and treatment sequence as fixed effects and a factor of subject nested with treatment sequence as a random effect. Using the same model, geometric mean ratios were estimated based on log-transformed individual values.
RESULTS: The results are presented in Table 1.
Table 1. Mean time with pH > 4 during the 14-hour daytime period, and geometric mean ratios

Treatment	Mean (95% CI) time with pH > 4 (%)	Geometric mean (95% CI) ratio, ESO 20 / comparator
ESO 20 vs OME 20, N=36[a,5]	61.9 (53.9-69.9)** vs 51.7 (43.7-59.7)	1.45 (1.14-1.85)**
ESO 20 vs PAN 20, N=38[b,8]	55.2 (48.2-62.1)*** vs 27.5 (20.5-34.5)	2.57 (2.09-3.16)***
ESO 20 vs LAN 15, N=37[a,7]	51.2 (45.6-56.8)*** vs 31.5 (25.9-37.0)	1.69 (1.46-1.97)***
ESO 20 vs LAN 15, N=26[b,6]	55.8 (43.5-68.0)* vs 45.2 (33.0-57.5)	1.89 (1.05-3.37)*

[a]Patients with GORD; [b]Healthy subjects; *p < 0.05; **p < 0.01; ***p < 0.0001 vs comparator
CONCLUSION: During the period of daytime food-stimulated acid secretion and postprandial reflux, ESO 20 provides acid control for a significantly greater average portion of the time vs other PPIs at OTC doses. As the majority of reflux occurs during the day, we postulate that better control of daytime intragastric pH should translate to improved treatment of acid-related inflammation and sensitization of the oesophagus and thereby better directed symptomatic control of frequent heartburn.

P1031 THE EVALUATION OF THE EFFICACY OF WEIGHT LOSS IN CONTROLLING SYMPTOMS IN PATIENTS WITH GASTROESOPHAGEAL REFLUX SYMPTOMS .

N. de Bortoli[1,*], G. Guidi[1], E. Savarino[2,3], I. Martinucci[1], L. Bertani[1], R. Franchi[1], M. Furnari[3], M. Bellini[1], V. Savarino[3], S. Marchi[1].
[1]Gastroenterology Unit, University of Pisa, Pisa, [2]Division of Gastroenterology, University of Padua, Padua, [3]Division of Gastroenterology - DIMI, University of Genoa, Genoa, Italy

INTRODUCTION: An association between obesity and gastroesophageal reflux (GERD) symptoms has been reported in a large number of studies. A recent meta-analysis have concluded that individuals with BMI > 30 have an approximately twofold risk of GERD compared with individuals who have a normal BMI. Weight loss is commonly recommended as part of first-line management of GERD despite the paucity of published clinical trials.
AIMS&METHODS: The aim of the study was to evaluate the effect of weight loss in controlling symptoms in a group of patients with GERD. The secondary aim was to evaluate the progressive reduction of proton pump inhibitors (PPI) therapy after the weight loss.
We enrolled a group of 50 overweight and obese patients with typical and atypical GERD symptoms with previous erosive esophagitis endoscopically proven. These patients were evaluated with two validated questionnaires (QOLRAD and VAS) to detect the prevalence of GERD related symptoms and the ongoing PPI therapy. All patients underwent an anthropometric evaluation (BMI, height, weight, abdominal circumference) and received a personalized hypo-caloric diet with 1200–1500 kcal for women and 1500–1800 kcal for men. All patients were invited to perform a daily aerobic activity auto-evaluated by mean of a pedometer. It was considered effective if the step number was higher than 10 thousand. The hypocaloric diet was considered effective if at least of 10% weight loss was obtained in each patient. The hypocaloric diet was completed within 6 months. The same anthropometric evaluation and questionnaires were performed at the end of treatment. The PPI dosage per day was also evaluated. The results were evaluated with a Student paired t-test and considered statistically significant when p value was < 0.05.
RESULTS: Male/female ratio was 0.78 (22/28). Mean age was 49.3 (±11.8). Mean BMI decreased from 30.3 (sd ±4.1) to 25.7 (±3.1) ($p < 0.05$) and the mean weight loss from 82.1 (±16.9) to 69.9 (±14.4) after hypocaloric diet ($p < 0.05$). Symptoms perception decreased both with QUOLRAD and VAS scale ($p < 0.05$). In particular, heartburn decreased from 3.68 (±1.9) to 0.28 (±0.4) in QUOLRAD scale and from 5.7 (±1.8) to 0.6 (±0.6) in VAS scale ($p < 0.05$). PPI therapy was completely discontinued in 27/50 (54%) patients, was halved in 16/50 (32%) patients. Only 7/50 (14%) continued the same PPI dosage.
CONCLUSION: We can conclude that a 10% of weight loss is recommended in all patients with GERD-related symptoms. This weight reduction could be able to reduce not only symptoms perception but also the dose of PPI therapy.

P1032 PREDICTORS OF RAPID HEALING AND REFRACTORY REFLUX ESOPHAGITIS WITH POTENT ACID SUPPRESSION

P. J. Kahrilas[1,*], A. Jonsson[2], H. Denison[2], B. Wernersson[2], N. Hughes[3], C. W. Howden[1]. *[1]Feinberg School of Medicine, Northwestern University, Chicago, United States, [2]AstraZeneca R&D, Mölndal, Sweden, [3]Research Evaluation Unit, Oxford PharmaGenesis™ Ltd, Oxford, United Kingdom*

INTRODUCTION: Potent acid suppression heals reflux esophagitis (RE), but little is known about how patient characteristics affect the rapidity of healing.
AIMS&METHODS: We performed a *post hoc* analysis of a large, randomized trial of AZD0865 (a potassium-competitive acid blocker) 25–75 mg/day vs esomeprazole 40 mg/day for the treatment of RE.[1] Group A (n=732) were treated for up to 4 weeks (therapy stopped at 2 weeks if healed). Group B (n=747) were treated for up to 8 weeks (therapy stopped at 4 weeks if healed). All patients had frequent heartburn at baseline. Patients completed the RDQ e-diary during treatment, and the Quality Of Life in Reflux Disease and Dyspepsia (QOLRAD) questionnaire at baseline and at 2 and 4 weeks. Data from all treatment groups were pooled as there was no difference between treatments in symptom response or RE healing.
RESULTS: In group A, RE healed in 495/732 (68%) patients by 2 weeks (rapid healers). Rapid healers were more likely to have Los Angeles (LA) grade A–B RE at baseline vs those with unhealed RE at 2 weeks (Table). In group B, of those with unhealed RE at 4 weeks, 49/127 (39%) had unhealed RE at 8 weeks (refractory). Refractory patients were more likely to have LA grade C–D RE (Table), frequent (≥4 days/week) regurgitation (81% vs 63%) and lower mean QOLRAD scores (at baseline vs those healed by 8 weeks but not at 4 weeks (slow healers). However, the 95% confidence intervals for all mean QOLRAD scores overlapped. Age, *Helicobacter pylori* status and baseline heartburn or dyspeptic symptoms did not predict the rapidity of RE healing.
Table: Baseline demographics of patients with rapid and refractory healing of RE.

Baseline demographics	Group A (n=732) Rapid healers: RE healed at 2 weeks (n=495)	Group A (n=732) RE not healed at 2 weeks (n=237)	Group B (n=747) Slow healers: RE healed at 8 weeks (n=78)	Group B (n=747) Refractory: RE not healed at 8 weeks (n=49)
Mean age in years (standard deviation)	46.7 (13.2)	47.3 (11.8)	44.4 (12.2)	43.9 (12.3)
Men Women	290 (58.6) 205 (41.4)	160 (67.5) 77 (32.5)	60 (76.9) 18 (23.1)	32 (65.3) 17 (34.7)
LA grade A B C D	192 (38.8) 222 (44.8) 77 (15.6) 4 (0.8)	52 (21.9) 96 (40.5) 62 (26.2) 27 (11.4)	22 (28.2) 26 (33.3) 17 (21.8) 13 (16.7)	7 (14.3) 17 (34.7) 19 (38.7) 6 (12.2)
Hiatal hernia	316 (63.8)	171 (72.2)	54 (69.2)	25 (51.0)
H. pylori	66 (13.5)	34 (14.4)	9 (11.5)	4 (8.2)

Results are numbers and percentages unless stated otherwise.
RE, reflux esophagitis.
CONCLUSION: Rapid healers are more likely to have LA grade A–B at baseline. Patients with refractory RE are more likely to have LA grade C–D, frequent regurgitation and lower HRQoL at baseline than slow healers.

P1033 ELECTRICAL STIMULATION THERAPY (EST) OF THE LOWER ESOPHAGEAL SPHINCTER (LES) – AN EFFECTIVE THERAPY FOR REFRACTORY GERD – INTERIM RESULTS OF AN INTERNATIONAL MULTICENTER TRIAL

P. Siersema[1,*], A. Smout[2], J. Conchillo[3], J. Ruurda[1], N. Bouvy[3], M. van berge Henegouwen[2], A. Bredenoord[2], A. Escalona[4], M. Booth[5], D. N. Reddy[6], J. Wu[7]. *[1]UMC Utrecht, Utrecht, [2]Academic Medical Center, Amsterdam, [3]Academisch Ziekenhuis Maastricht, Maastricht, Netherlands, [4]Pontificia Universidad Catolica de Chile, Santiago, Chile, [5]Waitemata Specialist Centre, Auckland, New Zealand, [6]Asian Institute of Gastroenterology, Hyderabad, India, [7]Chinese University of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: A previous single-center trial showed that LOS-EST significantly improves esophageal acid and symptoms in GORD patients long-term.
AIMS&METHODS: The aim of this international multicenter trial was to evaluate the safety and efficacy of LOS-EST in refractory GORD patients.
We studied GORD patients partially responsive to PPI with off-PPI GORD HRQL >20, LOS end-expiratory pressures of >5 mmHg, % 24 hour oesophageal pH<4 for >5%, hiatal hernia < 3cm and oesophagitis < LA Grade C. Bipolar stitch electrodes and a pulse generator (EndoStim BV, Hague, Netherland) were implanted laparoscopically. EST at 20 Hz, 220usec, 5-8mAmp in 6-12, 30 minutes sessions was initiated post-implant. Patients are evaluated using GORD-HRQL, symptom diaries, SF-12, oesophageal pH and manometry at regular intervals. Stimulation sessions are optimized based on residual symptoms and oesophageal pH.
RESULTS: Twenty-four patients (median age 51; men=14) have been enrolled and implanted with the LOS stimulator. One patient suffered a trocar perforation of small bowel during the implant successfully repaired on POD#1 and device prophylactically explanted. The remaining 23 patients are continuing with LOS-EST; 18 patients have completed their 3 month and 14 their 6 month evaluation. The median (IQR) off-PPI GERD-HRQL scores at baseline were 31 (25-37), which improved to 4 (2-11) on EST at months 3, ($p<0.001$) and 5 (4-9) at month 6 ($p<0.01$). There was improvement compared to the on-PPI GORD-HRQL scores of 14 (8-22) at baseline. Patients median oesophageal pH was 11.3% (9-15.5) at baseline and improved to 3.3% (2.5-9.1, $p<0.01$) at 3 months and 2.6% (1.8-5.4, $p<0.01$) at 6 months. Thirty-six AEs including 2 SAE were reported in 14 patients. Nine were non-serious events, not device or procedure related. Fourteen were probable or definite device or procedure related, including pain at the implant site and post-op nausea.
CONCLUSION: Interim results show that LOS-EST can be effective in treating refractory GORD. There was a significant improvement in patients' symptom, PPI usage and trend in improvement in their oesophageal acid exposure. LOS-EST was safe with no GI or cardiac side-effects. Long-term results in a larger group of patients are being collected to establish safety and efficacy of LOS-EST in refractory GORD.

P1034 REFLUX-RELATED COUGH AND RESPONSE TO PPI TREATMENT: DIFFERENCE BETWEEN PRIMARY CARE EXPERIENCE AND TERTIARY CARE CLINICAL TRIAL OUTCOMES?

P. Woodland[1,*], J. Jafari[1], N. Barnes[2], I. Small[3], J. O'Malley[4], A. P. Hungin[5], D. Sifrim[1]. *[1]Barts & The London School of Medicine and Dentistry, Queen Mary University of London, [2]Royal London Hospital, London, [3]Department of General Practice and Primary Care, The University of Aberdeen, Aberdeen, [4]Wirral University Hospital Trust, Wirral, [5]School of Medicine, Pharmacy and Health, University of Durham, Durham, United Kingdom*

INTRODUCTION: Gastro-oesophageal reflux disease (GORD) has long been considered a cause of chronic unexplained cough. Despite this, multiple trials of proton pump inhibitor (PPI) in cough have consistently failed to show a significant therapeutic response. A possible reason for this is the tertiary care location (in either gastroenterology or respiratory departments) of many of these studies, where many patients will have already failed PPI treatment by family practitioners.
AIMS&METHODS: We **aimed** to evaluate the experience of UK primary care doctors in treating chronic cough with PPI.
A web-based questionnaire was sent to UK-wide general practitioners with an interest in gastroenterological or respiratory disease. The questionnaire asked for information including experience of PPI use for chronic cough, symptoms associated with a higher probability of cough resolution, PPI dose given, and perceived proportion of PPI-response.
RESULTS: 294 general practitioners (200 with interest in gastroenterology and 94 with interest in respiratory medicine) responded to the questionnaire. 88% regularly treated cough empirically with PPI. The strongest factor associated with decision to treat was the presence of accompanying heartburn (92% respondents) and regurgitation (83%). 54% used PPI when all other treatments for cough had failed. Most (65%) practitioners treated with once-daily PPI, and the most common duration of trial of therapy was one month (64%). 98% of responders considered a satisfactory PPI response to be a 50% or greater improvement in cough. Two thirds of respondents considered that a satisfactory response was seen in 40% or more of treated patients, with accompanying typical reflux symptoms being considered most associated with good response (88% of responders agreed).
CONCLUSION: Treatment of chronic cough with PPI therapy is common in UK primary practice in spite of lack of evidence based in clinical trial results. Most practitioners treat empirically with once daily PPI for one month. Perceived PPI-response rate was high, with most respondents agreeing that accompanying typical GORD symptoms are the best predictor of satisfactory response. These results suggest successful PPI outcome studies may best be performed in primary care.

P1035 SYSTEMATIC REVIEW: OBSERVATIONAL STUDIES ASSESSING THE ASSOCIATION BETWEEN CARDIOVASCULAR OUTCOMES AND THE CO-PRESCRIPTION OF PROTON PUMP INHIBITORS WITH CLOPIDOGREL

S. Johansson[1], S. Sweet[2,*], P. Nagy[1]. *[1]AstraZeneca R&D, Mölndal, Sweden, [2]Research Evaluation Unit, Oxford PharmaGenesis™ Ltd, Oxford, United Kingdom*

INTRODUCTION: Proton pump inhibitors (PPIs) are often co-prescribed with the antiplatelet agent clopidogrel to reduce the risk of gastrointestinal bleeding. Although some pharmacokinetic and pharmacodynamic studies have reported that PPIs, in particular omeprazole and esomeprazole, reduce the activity of clopidogrel by inhibiting its conversion from a pro-drug to an active metabolite, the results of studies assessing clinical outcomes in patients receiving both drugs are inconsistent. We conducted a systematic review of observational studies reporting cardiovascular (CV) outcomes in patients receiving clopidogrel with or without a PPI, focusing in particular on the differences between omeprazole and esomeprazole and other PPIs.
AIMS&METHODS: The Embase and Medline literature databases were searched for articles published before 9 July 2012. Studies identified through regular drug safety surveillance carried out by AstraZeneca were also included. Non-observational studies (including clinical trials, clinical pharmacology studies and guidelines) and reviews were excluded, as were congress abstracts when the study was also published as a full paper.

RESULTS: The final review comprised 68 observational studies. Overall, 31 (45.6%) reported a statistically significant increase in the risk of CV events in patients receiving clopidogrel with a PPI, compared with those receiving clopidogrel without a PPI. The remaining 37 studies (54.4%) reported no such increase. A total of 21 studies reported the results for different PPIs separately, 11 of which presented hazard ratios (HRs) for CV events in patients receiving clopidogrel with a PPI compared with those receiving clopidogrel without a PPI. HRs were 0.3–1.8 for esomeprazole, 0.8–4.2 for omeprazole, 0.4–1.4 for lansoprazole, 1.0–2.5 for pantoprazole and 0.5–1.8 for rabeprazole. All studies that showed a significant association between omeprazole or esomeprazole co-prescription with clopidogrel and an increased risk of CV events also showed an association of comparable magnitude (with overlapping 95% confidence intervals) for other PPIs.
CONCLUSION: In the 68 observational studies analysed, considerable variability was seen in their conclusions regarding the clinical outcomes associated with co-prescribing a PPI with clopidogrel. There was no consistent evidence of there being a greater likelihood of CV events in patients receiving both drugs. No evidence was found that omeprazole or esomeprazole are more likely than other PPIs to affect clinical outcomes in patients receiving clopidogrel.

P1036 LONG-TERM TREATMENT OF GASTRO-ESOPHAGEAL REFLUX DISEASE: DOES CARDIA-LIKE METAPLASIA OF THE DISTAL ESOPHAGUS MATTER?

Y. Mastykava[1,*], M. Konorev[1], M. Matveenko[2]. [1]*Basic and clinical pharmacology,* [2]*Pathology, VITEBSK STATE MEDICAL UNIVERSITY, Vitebsk, Belarus*

INTRODUCTION: Our previous study has established that patients with gastroesophageal reflux disease (GERD) and cardia-like metaplasia of the distal esophagus have a higher relative risk (3.2) in the development of the erosive esophagitis than patients with GERD and squamous epithelium in the distal esophagus [1].
AIMS&METHODS: The aim of our study was to assess the effectiveness of different types of long-term PPI therapy among patients with GERD who had cardia-like metaplasia of the distal esophagus and patients with GERD who had squamous epithelium in the distal esophagus. To assess the effectiveness of treatment the rate of endoscopically confirmed erosive esophagitis was estimated at the end of one year of follow up.
Prospective, comparative study was conducted. The first study group included 35 patients with GERD and cardia-like metaplasia of the distal esophagus (the mean age 56.2±13.7 years). The second group included 34 patients with GERD and squamous epithelium in the distal esophagus (the mean age 58.2±11.3 years). At the end of one year of follow-up all patients were endoscopically examined in order to assess the condition of the distal esophagus. The patients were randomly assigned to receive omeprazole 20 mg on-demand (14 patients in the first group and 17 patients in the second group) and omeprazole 20 mg 'weekend' therapy: on Friday, Saturday and Sunday (21 patients in the first group and 17 patients in the second group).
RESULTS: Among patients with GERD and cardia-like metaplasia of the distal esophagus the rate of erosive esophagitis was significantly ($\chi 2 = 11.81$, $P = 0.0006$) higher in on-demand group (64.3%, 95% CI: 39.1 – 89.5%) than in the group treated only on week-ends (4.7%, 95% CI: - 0-13.9%). Among patients with GERD and squamous epithelium in the distal esophagus there were no reliable differences ($\chi 2 = 0.06$, $P = 0.8$) among two treatment strategies (11.8%, 95% CI: 0 – 27.3% and 7.7%, 95% CI: 0 – 22.5% respectively).
CONCLUSION: The 'weekend' therapy is more effective treatment strategy for patients with GERD and cardia-like metaplasia of the distal esophagus than on-demand one. For patients with GERD and squamous epithelium in the distal esophagus on-demand treatment and 'week-end' treatment are both equally effective.

P1037 EVALUATION OF EFFICACY OF PROTON PUMP INIHIBITORS IN REFRACTORY GASTROESOPHAGEAL REFLUX DISEASE

E. H. Kim[1], D. Lee[2], K. Park[2], H. Chung[1], H. Lee[1], J. C. Park[1], S. K. Shin[1], S. K. Lee[1], J. B. Chung[1], Y. C. Lee[1,*]. [1]*Department of internal medicine,* [2]*Department of Pharmacology, Yonsei University college of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Many patients with gastroesophageal reflux disease (GERD) have persistent reflux despite treatment with proton pump inhibitors (PPIs). Treatment in clinical practice has been primarily focused on doubling the PPI dose or switching to another PPI. The purpose of this study was to assess whether PPI is effective in refractory GERD or not.
AIMS&METHODS: Forty-five patients with clinical reflux symptoms (heartburn, chest pain, and/or regurgitation) and a history of ineffective response to PPIs were enrolled in this study. At admission, patients performed ambulatory 24-h pH impedance monitoring to identify the reflux pattern. They received doubling the PPI or switching to another PPI. Clinical outcome was defined as responder (≤ 2 symptoms/week) or nonresponder (≥ 3 symptoms/week).
RESULTS: Demographic analysis of the refractory GERD group revealed a mean age of 50.4 years (19-75 years) with 42.5% males. The rates of hernia, alcohol intake, smoking and weight loss was not different between two groups, responder (n = 21) vs. nonresponder (n = 24). In univariate and multivariate analysis, doubling the PPI or switching to another PPI was not related to symptom relief. The causes of refractory GERD might be the weakly acidic reflux. In ambulatory 24-h pH impedance monitoring, there were fewer acid reflux episodes in refractory GERD group to control group (19.3 ± 15.2 vs. 4.4 ± 5.3) while more weakly acidic reflux episodes were identified (21.7 ± 14.6 vs. 28.0 ± 17.3).
CONCLUSION: PPIs do not affect the total number of reflux episodes. PPIs only decrease the acidity of refluxate. In refractory GERD patients, the treatment of weakly acid and weakly alkaline reflux is more effective to PPI treatment.

P1038 THE EFFECT OF ACID SUPPRESSION FOR CHRONIC COUGH: A PROSPECTIVE RANDOMIZED STUDY, PRELIMINARY RESULTS

Y. Park[1,*], J.-H. Kim[1], M. K. B. Byun[2], Y. J. Kim[3], J. J. Park[1], Y. H. Yoon[1], H. Park[1]. [1]*Gangnam Severance Hospital, Yonsei University College of Medicine, Gastroenterology,* [2]*Gangnam Severance Hospital, Yonsei University College of Medicine, Respiratory,* [3]*Gangnam Severance Hospital, Yonsei University College of Medicine, Clinical research, Seoul, Korea, Republic Of*

INTRODUCTION: Gastroesophageal reflux disease (GERD) is one of the causes of chronic cough. Some studies suggest an association between chronic cough and GERD, but the effectiveness of acid suppression with proton pump inhibitors (PPI) in chronic cough is controversy.
AIMS&METHODS: The aim of our study was to investigate prospectively the effect of PPI in the patients with chronic cough. Subjects with chronic cough for 8 weeks were evaluated. Subjects underwent a chest x-ray, PNS view, pulmonary function test, methacholine challenge test, and empiric trial of postnasal drip (PND) therapy. After excluding other causes of cough such as asthma, PND, or lung cancer, the remaining patients measured GERDQ questionnaire and underwent endoscopy with 24-h pH/impedance study to investigate the combination of typical GERD. Subjects were randomized to 3 groups; standard dose of PPI daily, high dose of PPI daily or placebo for 8 weeks. Therapeutic effect was measured by the Cough visual analogue scores (VAS) and Leicester cough questionnaire (LCQ) after 4 weeks and 8 weeks of treatment.
RESULTS: A total of 31 patients were enrolled and randomized. Seventeen patients (9 subjects with typical GERD and 8 without typical GERD) completed 8-week treatment. Nineteen patients (10 subjects with typical GERD and 9 without typical GERD) only completed 4-week treatment. Cough VAS and LCQ score improved in patients with typical GERD symptoms in 4-, 8-week treatment periods. This improvement was not statistically different between high dose and standard dose of PPIs. Patients without typical GERD also responded to PPI therapy for cough. Both Cough VAS and LCQ score improved in patients without typical GERD in 4-, 8-week treatment periods. This improvement was also not statistically different between high dose and standard dose of PPIs.
CONCLUSION: Acid suppression by PPI improved cough-related quality of life and symptoms in patients with chronic cough regardless of combined typical GERD or the dose of PPI. The final results of our study may be helpful for establishment of guidelines for PPI therapy in chronic cough.

P1039 CLINICAL STUDY OF ESOPHAGITIS INDUCED BY DABIGATRAN

S. Nyuzuki[1,*], R. Yamakawa[1], K. Kawauchi[1], M. Iwata[1], S. Oyama[1]. [1]*Gastroenterology, Kaetsu Hospital, Niigata, Japan*

INTRODUCTION: Dabigatran is an anticoagulant drug for atrial fibrillation. Compared with warfarin, dabigatran does not have interactions with many foods and does not require frequent laboratory monitoring, and has been shown to have at least the same efficacy in reducing stroke for patients with atrial fibrillation. It was reported that dyspepsia was the adverse effect that was more common with dabigatran (11.5%) than with warfarin (5.8%). There are some case reports of esophagitis induced by dabigatran, and we also have experienced many cases of esophagitis after administration of dabigatran.
AIMS&METHODS: The aim of this study was to determine the prevalence and clinical characteristics of esophagitis induced by dabigatran. First, a total of 112 patients prescribed dabigatran in 2012 were retrospectively analyzed. We investigated the prevalence of esophagitis symptoms (dysphagia, heartburn, regurgitation), and evaluated clinical characteristics such as age, sex, dose of dabigatran, and cotreatment with proton pump inhibitors (PPI). Second, a total of 35 patients prescribed dabigatran and 124 patients prescribed warfarin who underwent esophagogastroduodenoscopy (EGD) in 2012 were retrospectively analyzed. We have compared the prevalence, region and form of erosive esophagitis.
RESULTS: Esophagitis symptoms were observed in 25.9% (29/112), and medication was discontinued in 12.5% (14/112). Esophagitis symptoms were associated with the dose of dabigatran (4/5, 80% in 300mg/day, and 25/107, 23.4% in 220mg/day, p=0.015), but not with the other factors. The prevalence of erosive esophagitis at EGD was 20.0% (7/35) in the dabigatran group and 11.3% (14/124) in the warfarin group (p=0.144). Erosive esophagitis in the middle esophagus and in the lower esophagus were found in 5 and 4 cases in the dabigatoran

group, and 0 and 14 cases in the warfarin group, respectively. Linear erosions were found in 5/35 cases (14.3%) in the dabigatran group and in 14/124 cases (11.3%) in the warfarin group (p=0.851), and round erosions were found in 3/35 cases (8.6%) in the dabigatran group and in 0/124 cases (0%) in the warfarin group (p=0.009).
CONCLUSION: The prevalence of esophagitis symptoms after administration of dabigatran was 25.9%. We considered that round erosion in the middle esophagus is the characteristics of erosive esophagitis induced by dabigatran.

P1040 NON-CONJUGATED BILE ACIDS CAN MODIFY THE ACID-BASE TRANSPORTER FUNCTION OF THE METAPLASTIC HUMAN ESOPHAGEAL EPITHELIAL CELLS

D. Laczkó[1,*], V. Venglovecz[2], R. Róka[1], F. Izbéki[1], T. Wittmann[1], Z. Rakonczay[1], P. Hegyi[1], A. Rosztóczy[1]. [1]*First Department of Medicine,* [2]*Department of Pharmacology and Pharmacotherapy, UNIVERSITY OF SZEGED, Szeged, Hungary*

INTRODUCTION: Barrett's esophagus (BE) is the most severe complication of gastro-esophageal reflux disease (GERD). Exposure of gastric and/or bile acids during reflux episodes play a critical role in the pathogenesis of BE. The acid extruding mechanims of esophageal epithelial cells (EECs) are not completely understood, although the acid-base transporters may play an important role against these toxic agents.
AIMS&METHODS: The **aim** of our study was to investigate the effects of bile acids on human EECs.
Methods: CP-A esophageal epithelial cell line was derived from a region of non-dysplastic metaplasia of BE and grown to confluent monolayers. To monitor changes in intracellular pH (pH_i) cells were loaded with the fluorescent dye, BCECF-AM NH_4Cl pulse technique and RT-PCR were used to measure the activity and expression of the acid-base transporters.
RESULTS: Chenodeoxycholate (CDC; 0.1 mM, 0.5 mM and 1 mM) caused reversible and dose-dependent decrease in pH_i. CDC significantly increased the activity of Na^+/H^+ exchanger (NHE) while decreased the activity of Na^+/HCO_3^- cotransporter (NBC). It had no significant effect on Cl^-/HCO_3^- anion exchanger (AE). Twenty-four hour incubation of CP-A cells with 0.1 mM CDC significantly increased the expression of NHE-2 and decreased the expression of NBC, but had no effect on the expression of AE.
CONCLUSION: CDC reversibly decreased the pH_i and increased the activity and the expression of NHE indicating the activation of the defensive pH_i regulating mechanisms on the epithelial cells. The role of the decreased activity and expression of NBC in the development of gastroesophageal reflux related esophageal complications needs further investigation.

P1041 MONITORING OF BARRETT'S ESOPHAGUS IN ELDERLY PATIENTS: RESULTS OF FIVE-YEAR PROSPECTIVE STUDY

V.V. Tsukanov[1], E. Onuchina[2], A. Vasyutin[1,*], O. Amelchugova[1]. [1]*STATE SCIENTIFIC MEDICAL RESEARCH INSTITUTE FOR N, Krasnoyarsk,* [2]*Irkutsk state medical university, Irkutsk, Russian Federation*

INTRODUCTION: Barrett's esophagus (BE) is a disease, which increases significantly the probability of esophageal cancer [1]. In this regard great attention is paid to diagnostics and treatment of this pathology [2].
AIMS&METHODS: Aim. To study the frequency of transformation of GERD to BE in elderly patients based on the results of five-year prospective study.
Methods. We performed a prospective five-year observation of 891 elderly GERD patients (569 females, 322 males, median age 78,1 years). GERD was diagnosed on the basis of the Montreal Consensus (Vakil N et al., 2006). The presence of erosive esophagitis was defined based on the Los Angeles classification (Lundell LR et al., 1999). For endoscopic verification of Barrett's esophagus chromoendoscopy and five quadrant biopsy were used. During the five-year follow-up clinical examination and endoscopy of the esophagus were performed twice a year. Morphological examinations of the esophagus to determine BE were done in the beginning and the end of study.
RESULTS: A five-year prospective study in elderly patients showed an increase of frequency of BE and erosive esophagitis (Table 1). The risk factors for BE development in elderly patients were obesity (OR = 3,27, CI 1,53-4,90; p <0,001), smoking more than 20 cigarettes per day for more than 10 years (OR = 8,0, CI 3,65-9,66; p <0,001) and the lack of maintenance proton pomp inhibitors therapy (OR = 6,1, CI 4,0-9,2; p <0,001).

Table. Five-year dynamics of GERD structure.

	NERD		Erosive esophagitis		BE	
Pathology	Abs.	%	Abs.	%	Abs.	%
Beginning of the study	472	52,9	357	40,1	61	7,0
In 5 years	335	37,6	471	52,9	85	9,5
OR; CI; p	1,87; 1,56-2,26; <0,001		0,60; 0,49-0,72; <0,001		0,71; 0,51-1,0; 0,058	

CONCLUSION: GERD is a progressive disease in elderly patients, which is attended by increasing of BE frequency.

P1042 JUMBO BIOPSY FORCEPS IMPROVES ADEQUATE TISSUE SAMPLING IN PATIENTS WITH BARRETŕS ESOPHAGUS: FINAL RESULTS OF A RANDOMIZED STUDY

J. Martinek[1,*], J. Maluskova[2], M. Stefanova[3], Z. Vackova[4], M. Kollar[2], I. Tuckova[5], J. Spicak[1]. [1]*HEPATO-GASTROENTEROLOGY,* [2]*PATHOLOGY, INSTITUTE FOR CLINICAL AND EXPERIMENTAL MEDICINE, Praha 4,* [3]*INTERNAL MEDICINE, HOSPITAL NA FRANTISKU, Praha 1,* [4]*Internal Medicine,* [5]*PATHOLOGY, UNIVERSITY MILITARY HOSPITAL, Praha 6, Czech Republic*

INTRODUCTION: Good quality of biopsy specimen is required for reliable diagnosis of early neoplasia in patients with Barretís esophagus (BE). It remains controversial whether the use of jumbo forceps provides an advantage compared to large capacity forceps. The aim of this study was to assess sampling quality of 4 different forceps in patients with BE. We hypothesized that jumbo forceps if used with a standard diagnostic endoscope provides a better quality of biopsy specimen as compared to large capacity forceps.
AIMS&METHODS: A single center, randomized, prospective and single blind study. Thirty seven patients with BE (6 women, 31 men) were enrolled. The following forceps (with spike) were tested: **A:** disposable large capacity biopsy forceps FB-240K (Olympus), outer diameter 2.45 mm; **B.** disposable large capacity biopsy forceps BI01-D3-23 (Medwork), outer diameter 2.3 mm; **C.** single-use large capacity biopsy forceps (Medi-Globe), outer diameter 2.3 mm. **D.** single-use biopsy forceps Radial Jaw 4 (Boston Scientific), outer diameter 2.8 mm (jumbo). Targeted and random biopsies with all 4 forceps (in a random order) were obtained from every patient during a single endoscopy using a diagnostic endoscope (with a standard channel of 2.8 mm). The samples were analyzed by a blinded experienced pathologist. Main outcome measurement was specimen adequacy (defined as a well oriented biopsy sample 2 mm or greater with muscularis mucosa present).
RESULTS: A total of 436 biopsy samples were analyzed (**forceps A**: 121, **forceps B**: 115, **forceps C**: 108, **forceps D**: 92). Compared to all other forceps, a significantly higher proportion of biopsy samples with jumbo forceps (D) were adequate (A: 26%, B: 17%, C: 18%, D: 71%; p<0.001 D vs. other forceps). Biopsies with jumbo forceps (D) had the largest diameter (median 2.4 mm vs. 2 mm (A), 1.6 mm (B) and 2 mm (C); p<0.001 D vs. other forceps). Muscularis mucosae was detected in 45% of specimen with forceps A, in 23% with forceps B, in 82% with forceps C and in 52% with forceps D (p<0.001 C vs. other forceps). Excellent or good specimen orientation was present in 61% of samples with forceps A, in 44% with forceps B, in 66% with forceps C and in 77% with forceps D. There was a trend for a higher diagnostic yield with Jumbo biopsy forceps.
CONCLUSION: Jumbo biopsy forceps provides more adequate specimen as compared to three types of large capacity forceps. This might lead to an increased diagnostic yield regarding both the detection of intestinal metaplasia and early neoplasia.

P1043 LOW PREVALENCE OF BARRETT'S ESOPHAGUS AND ESOPHAGEAL ADENOCARCINOMA OVER A 10-YEAR PERIOD

J. Láng[1], B. Bittera[1], Z. M. Varga[1], B. László[1], M. Juhász[1], E. Mihály[1], P. Miheller[1], Z. Tulassay[1], L. Herszényi[1,*]. [1]*2nd Department of Medicine, SEMMELWEIS UNIVERSITY, Budapest, Hungary*

INTRODUCTION: Barrett's esophagus (BE) is prevalent in the Western world, however the majority of patients with BE will never develop esophageal adenocarcinoma (EAC). Few data are available on risk factors for progression to neoplasia. Identifying predictors of high-grade dysplasia (HGD) and EAC would be useful for risk stratification.

AIMS&METHODS: Clinical, endoscopic and histologic data were reviewed for patients with a new BE diagnosis between 2002 and 2011. Patients were classified as having specialized intestinal metaplasia, low grade dysplasia (LGD), HGD and EAC. Gender, age, presence of hiatal hernia, segment length of BE and Helicobacter pylori (H. pylori) status were evaluated for their association with dysplasia severity and presence of EAC.
RESULTS: Over a 10-year period 26.984 patients underwent upper gastrointestinal endoscopy. Erosive reflux esophagitis (ERD) was diagnosed in 53% (n=14322) of all patients. In all, 358 patients (61% men and 39% women, mean age: 58) were newly diagnosed with BE (1.33% of all patients and 2.5% of ERD patients). Among them 74 patients had LGD (0.52% of ERD and 20.7% of BE patients) and 17 patients HGD/EAC (0.06 of all investigated patients, 0.12% of ERD and 4.7% of BE patients). The presence of hiatal hernia was significantly more frequent in more severe ERD (Los Angeles classification C/D versus A/B, 55% and 37%, respectively, $p<0.05$). The presence of hiatal hernia ($P<0.001$), longer Barrett segment length ($P<0.001$), male gender ($P<0.05$) and absence of *H. pylori* infection ($P<0.05$) were significantly associated with higher pathological grade and presence of EAC.
CONCLUSION: We demonstrate a low prevalence of BE and EAC over a 10-year period. We confirm that only a minority of BE patients will develop EAC. Presence of hiatal hernia, segment length of Barrett, male gender and *H. pylori* negative status were strong predictors of risk for development of HGD and EAC.

P1044 DYSPLASIA IN BARRETŕS ESOPHAGUS. EXPERIENCE IN A TERTIARY CARE CENTER IN SOUTH EUROPE

P. L. Fernández Gil[1,*], M. A. Mieses Pun[2], D. Hernández Amunárriz[2], J. De la Peña Garcia[2], A. Terán Lantarón[2], M. Mayorga Fernández[3], J. Crespo Garcia[2].
[1]*Gastroenterology and Hepatology, Univerisity Hospital Marqués de Valdecilla,* [2]*Gastroenterology and Hepatology,* [3]*Pathology, Marques de Valdecilla University Hospital, Santander, Spain*

INTRODUCTION: Barretś esophagus (BE), as a premalignant condition, constitutes the principal risk factor for the development of esophageal adenocarcinoma (EAC).
AIMS&METHODS: To analyze prospectively patients with BE between 2009-2013. To analyze retrospectively the previous natural course of their disease. To evaluate epidemiological characteristics, development of dysplasia or EAC and natural course of BE.
We studied 179 patients, excluding 8 patients in whom BE was not confirmed. Thus, we included 171 patients (male 133, 77,8%). 38% of them presented a long BE and 62% a short BE. Median length of BE was 3 cm (1-20 cm). Median age of first BE detection: 54 years (23-84). Median time of follow up: 6 years (1-27). The endoscopic follow up was performed with a High Definition-NBI endoscope (H-180, Olympus). Patients were classified in four groups: intestinal metaplasia (IM), low-grade dysplasia (LGD), high-grade dysplasia (HGD), adenocarcinoma (EAC). Patients with confirmed HGD, were treated with HALO Radiofrequency.
RESULTS: According to the most severe histological grade presented during their course: 8 patients presented EAC (4,7%), 13 HGD (7,6 %), 54 LGD (31,6%) and 94 IM (56,1%). In relation to the follow up: 8 patients (4,7%), all of them men, presented EAC. 6 of them had a long BE. 50% at the same time of the diagnosis, and the other half during the follow up (median time 8,8 years). Six patients were treated surgically. 14 patients (8,2%) presented HGD at any time of their disease. 79% were male and 71% had long BE. 50% at the same time of diagnosis. Ten patients were treated with Radiofrequency. One patient rejected the endoscopic follow up, who developed a stenotic EAC after five years. Two patients, dysplasia resolved completely. 61 patients (35.6%) presented LGD at any time of their disease. 77% were male and 50% had a long BE. Almost half of the patients at the same time of diagnosis. (44,8%). In 49%, there has been a resolution of dysplasia. In the 11.5% there has been progression to HGD/ADC and in the rest of them (39.3%) LGD persisted. 133 patients (75.4%) presented IM. The 76% were male, with short BE predominatly. There has been a progression in 27,8% of them (24% to LGD, 3% to HGD and 0,8 to ADC).
CONCLUSION: Our patients with BE had similar epidemiological characteristics as published elsewhere. The HGD/ADC are more frequent in males with long BE. In our cohort, the presence of dysplasia in patients with BE is high, although LGD has a low rate progression. It is necessary a longer follow up in these patients.

P1045 OUTCOMES OF ENDOSCOPIC AND SURGICAL THERAPY FOR HIGH GRADE DYSPLASIA IN BARRETT'S OESOPHAGUS AND EARLY OESOPHAGEAL ADENOCARCINOMA: SINGLE CENTRE EXPERIENCE

Y. C. Lim[1,*], H. Laxaman[1], J. Allison[2], P. Safranek[3], R. Hardwick[3], R. Fitzgerald[2], M. Di Pietro[2]. [1]*Department of Gastroenterology, Addenbrooke's Hospital,* [2]*MRC Cancer Cell Unit,* [3]*Cambridge Oesophago-Gastric Centre, Cambridge, United Kingdom*

INTRODUCTION: Surgical therapy has long been considered standard of care for early Barrett's neoplasia. Recent evidence showed that endoscopic therapy is safer and equally effective compared to surgery. While neoplasia eradication in clinical trials can be as high as 95%, this is lower in routine clinical practice (1,2).
AIMS&METHODS: In this retrospective study, we report the outcomes of surgical and endoscopic treatment in a single tertiary referral centre. All patients with histological evidence of high grade dysplasia (HGD) or intramucosal carcinoma (IMC) on biopsies taken from the oesophagus or gastro-oesophageal junction were identified. Patients receiving photodynamic therapy were excluded. Patient with flat HGD received primary radiofrequency ablation (RFA), whereas patients with visible neoplasia underwent endoscopic resection (ER), followed by RFA. Surgical therapy consisted of minimally invasive oesophagectomy, results were assessed for complete remission of neoplasia (CR-N), disease recurrence and procedural complication. CR-N was defined as eradication of HGD or cancer based on follow up endoscopic biopsies.
RESULTS: Between January 2002 to March 2013, 72 patients were identified. Average age was 72.6, 53 patients had IMC and 19 patients had HGD. Median follow up was 23.8 months (range 1.4 - 134.5). 10 patients had primary oesophagectomy which led to 100% CR-N. 4 (40.0%) patients developed 5 post-operative complications (2 oesophageal strictures, 1 anastomotic leak, 1 dumping syndrome and 1 conduit dysfunction) which were all successfully managed. 62 patients underwent primary endoscopic treatment. 9 were excluded from analysis as they were upstaged to T1b following initial ER. Among the 53 patients with disease stage <T1b, 44 (83.1%) achieved CR-N. 5 (9.4%) went on to have successful rescue surgery. There were 5 (5.2%) complications following ER (3 perforation, 2 significant gastrointestinal bleed) and 8 (13.5%) complications following RFA (3 arrhythmias, 4 chest pain, 2 strictures). There were no disease related deaths.
CONCLUSION: Endoscopic therapy is safe and effective in high grade dysplasia and early oesophageal adenocarcinoma. Failure to achieve disease remission can be successfully managed with surgery. Endoscopic therapy alone achieved complete remission in 83.1%.

P1046 GASTRIC INTESTINAL METAPLASIA: A RETROSPECTIVE ANALYSIS IN A DISTRICT GENERAL HOSPITAL IN UNITED KINGDOM

A. Singanayagam[1,*], N. Chatrath[1], L. Pee[1], A. Loganayagam[1].
[1]*Gastroenterology, Queen Elizabeth Hospital Woolwich, London, United Kingdom*

INTRODUCTION: Gastric intestinal metaplasia (IM) is part of a carcinogenesis sequence leading to gastric cancer. Recent evidence-based European Society of Gastrointestinal Endoscopy (ESGE) guidelines have highlighted additional risk factors, such as the extensive intragastric distribution of IM and the presence of *Helicobacter pylori*. The former is identified with ≥2 antral and ≥2 corpus biopsies, involving the greater and lesser curvature, and warrants three-yearly surveillance endoscopies. The latter should be eradicated to slow the progression of carcinogenesis.
AIMS&METHODS: Using the keywords ''intestinal metaplasia'', the histology database for the Queen Elizabeth Hospital, South East London, was reviewed over 2000-11 to identify patients with IM on gastric biopsy. Gastro-oesophageal junctional IM was excluded. The number and site of biopsies taken and the presence of *H.pylori* was identified. The terminology used, with regards to ''extensive'' and ''focal'' IM, was compared with the suggestions from the ESGE guidelines. To investigate the development of cancer in patients with IM, histology and upper gastrointestinal cancer databases were compared.
RESULTS: 175 patients with gastric intestinal metaplasia were identified. Only one patient with gastric intestinal metaplasia developed gastric cancer. *Helicobacter pylori* was associated with 20/175 (11.4%) of gastric IM biopsies. After review of pathology reports, in 37/175 (21.1%) of cases with gastric IM, the pathologist did not receive sufficient clinical information specifying the site of the biopsies. Of those where the biopsy site was specified, only 10/138 (7.2%) had sufficient biopsies. The term ''extensive'' was used in 27/175 (15.4%) pathology reports despite either insufficient number or unspecified location of biopsies.
CONCLUSION: This study identified 175 patients with gastric intestinal metaplasia over 2000-2011. One patient developed gastric adenocarcinoma after 8 years. Since surveillance endoscopy is not routine practice in the Trust, all biopsies were incidental findings. This study suggests that, where biopsy site details were provided, only 7.2% of patients were adequately biopsied. Remaining cases should have a repeat endoscopy with ample biopsies to decide on surveillance. ''Extensive metaplasia'' refers to a wide intragastric distribution of IM to include the antrum and corpus. We identified discrepant use of nomenclature in pathology reporting in 15.4%. *Helicobacter pylori* was associated in 11.4%, where ESGE advocates its eradication. This study reveals further work is needed to risk stratify and survey this important pre-cancerous condition.

P1047 AGE DISTRIBUTION OF GASTRIC CANCER PATIENTS ACCORDING TO THE FAMILY HISTORY

H.-W. Kwak[1,*], I. J. Choi[1], C. G. Kim[1], J. Y. Lee[1], S.-J. Cho[1], Y.-W. Kim[1], K. W. Ryu[1]. *[1]Center for Gastric Cancer, National Cancer Center, Ilsandong-gu, Goyang-si, Korea, Republic Of*

INTRODUCTION: The risk of gastric cancer (GC) is higher in patients having family members with the disease.
AIMS&METHODS: The aim of our study was to evaluate whether gastric cancer patients having family history has young onset age. A total of 4282 patients diagnosed with GC in National Cancer Center Hospital from October 2002 to December 2012 were enrolled. Among them, 924 patients (21.6%) had the first- degree family member with GC. Information about the age of GC detection in the family members was obtained by questionnaire.
RESULTS: The mean onset age of patients with and without the first-degree family member diagnosed as GC were 58.0±10.7 and 58.1±12.0 years, respectively and showed no difference (p-value 0.897). Patient's age having GC family history in their father, mother and siblings were 54.4±10.4, 57.2±10.0 and 62.2±9.9 years, respectively. Patients having GC family history in their father showed 3.7 years earlier onset age than those without family history on average (p-value <0.001). Patients having GC family history in their mother showed no difference (p-value 0.222) and those having that in sibling showed 4.2 years later onset age than those without family history (p-value <0.001). Patient's age having father, mother or siblings with GC diagnosed before age of 50 years were 47.7±10.3, 48.6±10.4 or 57.4±11.5 years, respectively. Patients having father or mother with GC diagnosed before age of 50 years showed 10.4 or 9.5 years earlier onset age than those without family history (p-value both <0.001), respectively. But, patients having siblings with GC diagnosed before age of 50 years showed no difference than those without family history (p-value 0.603).
CONCLUSION: The patients having GC family history in their father or having parents with GC diagnosed before age of 50 years showed young onset age than those without family history.

P1048 THERAPEUTIC OUTCOMES OF ENDOSCOPIC PAPILLECTOMY FOR AMPULLARY NEOPLASMS: RETROSPECTIVE ANALYSIS OF A MULTICENTER STUDY

T. N. Kim[1], H. H. Chung[1,*], S. H. Kang[1], K. H. Kim[1], M. K. Jung[2], C. M. Cho[2], K. B. Cho[3], J. M. Han[4], H. G. Kim[4], H. S. Kim[5]. *[1]Internal medicine, Yeungnam University College of Medicine, [2]Internal medicine, Kyungpook National University School, [3]Internal medicine, Keimyung University School, [4]Internal medicine, Catholic University School, [5]Internal medicine, Fatima Hospital, Daegu, Korea, Republic Of*

INTRODUCTION: Endoscopic papillectomy (EP) is reported to be relatively safe and reliable procedure for complete resection of ampullary neoplasms. There were no large-scale studies concerning the effectiveness and complications related to EP.
AIMS&METHODS: This study was aimed to evaluate the therapeutic outcomes and complications of EP for ampullary neoplasms. A retrospective multicenter study was done with 5 participating centers from January 2007 to August 2012. A total of 84 patients who underwent EP for ampullary neoplasms were retrospectively reviewed. EP was performed by snare resection with or without saline lifting of the lesion.
RESULTS: The mean age of the84 patients was 60.2±12.5 years, and the male-to-female ratio was 2:1. A biliary and pancreatic stent was placed in 32 patients and in 44 patients, respectively. En bloc resection was possible in 75 patients (89.3%). Histology of resected specimen was as follows: low grade adenoma (42.7%), high grade adenoma (17.1%), adenocarcinoma (18.3%), hyperplastic polyp (9.8%), and others (12.1%). A pathologically incomplete resection was noted in 10 cases (11.9%). Of the 56 cases with low grade adenoma on biopsy specimen, 25% turned out to have high grade adenoma (12.5%) or adenocarcinoma (12.5%). After papillectomy, five patients with adenocarcinoma, one with high grade adenoma and one with carcinoid tumor underwent surgery due to positive resection margin. Procedure-related complications occurred in 28 patients (33.4%); bleeding (15 cases, 17.9%), pancreatitis (13 cases, 15.5%), and perforation (7 cases, 8.3%). Pancreatic duct stenting significantly increased the risk of pancreatitis by univariate and multivariate analysis. Pre EP endoscopic retrograde cholangiopancreatography (ERCP), saline lifting, sphincterotomy, biliary stenting, specimen size, and cauterization were not related with increased risk of complications. During follow-up endoscopy, remnant tumors were found in 7 patients, of whom one patient underwent surgery and the others six patients were treated with EP with and without argon plasma coagulation (APC).
CONCLUSION: EP seems to be a safe and effective treatment for ampullary neoplasms and can be considered as an alternative to surgery. However, risk of the procedure-related complications is a problem that must be considered.

P1049 THE ASSOCIATION OF ATROPHIC CHANGES OF BACKGROUND MUCOSA AND GHRELIN EXPRESSION WITH THE PREVALENCE AND ENLARGEMENT OF GASTROINTESTINAL STROMAL TUMORS OF THE STOMACH

K. Tominaga[1,*], S. Sugimori[1], M. Onishi[1], T. Tanigawa[1], T. Watanabe[1], Y. Fujiwara[1], T. Arakawa[1]. [1]*Department of Gastroenterology, Osaka City University Graduate School of Medicine, Osaka, Japan*

INTRODUCTION: The clinical predictor for enlargement potential of gastrointestinal stromal tumors (GISTs) of the stomach has not been identified. Ghrelin correlated with atrophic changes of the gastric mucosa is occasionally expressed and associated with the pathophysiology of tumor growth.
AIMS&METHODS: The aim of this study was to investigate background atrophy in patients with gastric GISTs (N = 74, 37 men and 37 women; mean age, 65.1 years) and their association with the enlargement of the tumors between April 2004 and April 2011. For age- and sex-matched analysis, we recruited 355 patients without gastric submucosal tumor (SMT) in our hospital between and 205 workers without gastric SMT in a health management center. *The tumor proliferation index*: the changes in tumor volume/follow-up days (mm^3/day).
RESULTS: After 1:3 matching for sex and age between patients with GISTs (n = 74) and patients without GISTs (n = 222), there was a significant difference in the prevalence of open-type atrophy (30.2% vs. 53.1%, $P = .009$, odds ratio (OR) = 2.62, 95% confidence interval (CI): 1.27-5.38). After 1:2 matching for sex and age for the GISTs (n = 44) and workers groups (n = 88), there were significant differences in the presence of gastric atrophy (53.8% vs. 86.0%, $P < .001$, OR = 5.29; 95% CI: 2.20-12.66) and prevalence of open-type atrophy (19.0% vs. 29.7%). The tumor proliferation index indicated the increased (n = 19, 20.2%) and unchanged growth groups (n = 75, 79.8%). The prevalence of severe atrophic changes of the gastric mucosa was lower in the increased growth group than in the other group (10.4% vs. 32.4%, $P = .061$). Histological ghrelin expression (found in approximately 50% of patients) was not associated with the tumor growth.
CONCLUSION: The severity of atrophic changes of the gastric mucosa may be partly associated with tumor enlargement of gastric GISTs.

P1050 OCCURRENCE OF TYPE 1 GASTRIC CARCINOID IN PATIENTS WITH AUTOIMMUNE CHRONIC ATROPHIC GASTRITIS

S. Massironi[1], R. E. Rossi[1,2], M. Spampatti[1,2,*], F. Cavalcoli[1,2], A. Zilli[1,2], C. Ciafardini[2], D. Conte[1,2]. [1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico,* [2]*Università degli Studi di Milano, Milano, Italy*

INTRODUCTION: The incidence of gastric carcinoids type 1 (GC1) has markedly increased over the last 50 years, although studies assessing long-term incidence of GC1 in patients with chronic autoimmune atrophic gastritis (CAAG) are scanty.
AIMS&METHODS: Aim of the study was to evaluate the incidence and prevalence of GC1 in a cohort of patients with CAAG.
From 2000 to 2012, 101 patients [83 women, median age 63 (21-80) years] were diagnosed as having CAAG, based on histological examination of gastric mucosa, presence of parietal cell antibodies, and elevated pH gastric levels. Active Helicobacter Pylori infection was excluded. They underwent regular clinical and endoscopic follow-up (median time of follow up 36 months, range 3-180). ECL cell status has been classified according to Solcia et al. in: no cell hyperplasia, simple, linear, micronodular hyperplasia, and GC1. Plasma chromogranin A (CgA) and gastrin levels were measured in all patients. During follow up the risk of developing GC1 was evaluated and expressed as person-time incidence rate.
RESULTS: At baseline, among 101 patients, 30 patients had no cell hyperplasia, 11 had simple, 5 linear, 32 micronodular hyperplasia, and in 23 patients GC1 were already present at the time of recruitment (single in 10 patients and multiple in 13, of variable sizes, diameter 0.2-3 cm), with a prevalence of 23%. Out of them, 13 were successfully endoscopically treated, whereas the remaining ten showed the persistence or recurrence of GC1 during the study period. After 321 person-years, one patient was newly diagnosed as having GC1, with a resulting annual incidence rate (person-year) of 0.3%. Patients with GC1 had significantly higher gastrin [median 1400 vs. 886 ng/L, $p < 0.001$] and chromogranin A [median 58 vs. 32 U/L, $p < 0.001$] levels compared with CAAG patients without GC1.
CONCLUSION: This cohort study confirms that GC1 is a possible complication in patients with CAAG due to the trophic effect of gastrin on the gastric wall mucosa. Despite an high prevalence observed in our study, the actual incidence is quite low and elevated level of CgA are strongly associated with the presence of GC1.

P1051 PREOPERATIVE PROGNOSTIC VALUE OF POSITRON EMISSION TOMOGRAPHY-COMPUTED TOMOGRAPHY(PET-CT) IN SURGICALLY RESECTED GASTRIC CANCER.

S. R. Choi[1,*]. [1]*DONG-A UNIVERSITY, BUSAN, Korea, Republic Of*

INTRODUCTION: Apart from the diagnostic value of Positron Emission Tomography-Computed Tomography(PET-CT), the prognostic value of pre-treatment PET-CT was not commonly evaluated in gastric cancer, so we investigated its preoperative prognostic value.
AIMS&METHODS: Retrospectively we collected 107 cases of gastric cancer patients who had underwent surgical treatment after being observed FDG uptake by preoperative PET-CT at a Dong-A University Medical Center from April 2007 to December 2010. Among firstly enrolled 107 patients, cases of follow up losses(13), palliative resection(5), neoadjuvant chemotherapy(1), unrelated death(1) were excluded and finally total 87 patients were evaluated. Follow up duration was defined as period from operation to date that patients were examined last imaging study such as PET-CT or CT, and the median follow up duration was 34.2 ± 14.8 months until June 2012. FDG uptake values were observed based on maximal standardized uptake value(SUVmax) varied by patients' weight. In order to find correlation of SUVmax with recurrence, Kaplan Meier's survival analysis with log rank test and cox proportional hazard model were performed with using SUVmax cutoff value defined from ROC curve.
RESULTS: Significant difference of T staging($p < 0.001$) and N staging($p < 0.001$) were observed between recurrence group and non-recurrence group in patients' baseline characteristics, but SUVmax was not showed strong difference between two groups(p-value 0.116). Significant statistical difference was observed in Kaplan Meier's survival analysis with log rank test(p-value:0.035) between high SUVmax group and low SUVmax group which separated by SUVmax cutoff value 5.6. However, in multivariate analysis with cox proportional hazard model revised for age, sex, T-staging, N-staging, the SUVmax did not showed statistical significance in correlation with recurrence(SUVmax : p-value 0.893, SUVmax classification by cutoff value : p-value 0.436).
CONCLUSION: High SUVmax on PET-CT is not independent risk factors to predict poor outcomes of surgically resected gastric cancer.

P1052 CHANGE OF THERAPEUTIC APPROACH FOR GASTRIC CANCERS PICKED UP BY X RAY SCREENING IN SAGA.

S. Yamaguchi[1,*], K. Nio[1], D. Yamaguchi[1], Y. Sakata[1], R. Shimoda[1], H. Sakata[1], R. Iwakiri[1], K. Fujimoto[1]. [1]*Internal medicine and gastrointerstinal medicine, Saga medical school, Saga, Japan*

INTRODUCTION: The medical treatment of the gastric cancer in Saga prefecture in Japan has changed dramatically in recent ten years.
AIMS&METHODS: We aim to report trends and therapeutic approaches in gastric cancers which were picked up X ray screening performed in the total number of 327,903 people in Saga prefecture from 2002 to 2010 in this study. Gastric cancers were detected in the 554 patients out of 327,903 series of X ray screening (detection rate: 0.17%) in Saga prefecture from 2002 to 2010. These cancers were categorized into three groups with the 3 year period; Period I: 2002-2004, Period II: 2005-2007, Period III: 2008-2010.
RESULTS: In Period I, stomach cancers were detected in 216 patients out of 130,286 screenings; Period II: 185 out of 108,261; Period III: 153 out of 89,396. The ratio of early gastric cancer/advanced gastric cancers in each period was Period I: 156/48 (undetected 12), Period II: 123/62, and Period III: 118/30 (undetected 5). We divided early gastric cancers into two groups of subjects who received and not received the X ray screening in every year. Period I: received 81, not received 75; Period II: received 83, not received 40; Period III: received 74, not received 44.
Locations of gastric cancer in each period were as follows (upper /middle/lower) Period I: 49/94/65; Period II: 37/85/ 61, Period III: 35/62/55. Pathological examination revealed as follows (differentiated type/ undifferentiated/ others/ unknown); Period I: 132/69/0/17; Period II: 123/54/2/6; Period III: 103/43/2/0. These data indicated the locations and pathological features of the stomach cancer in this survey were not changed in recent 10 years.
Regarding therapeutic approach to gastric cancer, open laparotomy was mainly applied to the gastric cancer in period I as 159 out of 216 patients. Endoscopic treatment was performed in 38 patients, whereas only 4 patients were treated under laparoscopy. In Period II, the ratio endoscopic treatment increased significantly (24.3%). The ratio of laparoscopic surgery increased form 1.9% to 13.0% (24/153), although the number of gastric cancer patients treated by open laparotomy was decreased (58.9%). In Period III, the ratio of laparoscopic surgery (32.0%) was markedly increased compared to Periods I & II, while increase in the ratio of endoscopic treatment was limited (34.0%).
CONCLUSION: This study showed that early gastric cancer was more often detected in the group which underwent repeated screening by X ray.

Therapeutic approach to the gastric cancer was replaced open laparotomy with endoscopic treatment and laparoscopic surgery in recent 10 years, although backgrounds of the gastric cancer were not changed.

P1053 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR EARLY GASTRIC CANCER WITH POST-ESD OR ENDOSCOPIC MUCOSAL RESECTION (EMR) SCAR

T. Ibuka[1,*], H. Araki[1], T. Nakanishi[1], J. Takada[1], M. Kubota[1], F. Onogi[1], M. Shiraki[1], M. Shimizu[1], T. Kato[1], H. Moriwaki[1]. [1]*Gastroenterology, GIFU UNIVERSITY SCHOOL OF MEDICINE, Gifu, Japan*

INTRODUCTION: Fibrotic changes are one of factors correlating with the technical difficulty of endoscopic submucosal dissection (ESD). We conducted a clinicopathological analysis on ESD for lesions with scar of post-ESD or post-endoscopic mucosal resection (EMR).
AIMS&METHODS: Between June 2002 and November 2012, we carried out ESD in 803 cases in our department, including 34 cases with post-ESD or post-EMR scar. We defined the case with fibrosis in a part of submucosal layer as Grade1 (G1), and that with fibrosis in all submucosal layer as Grade2 (G2). We examined the degree of fibrosis about site, post-ESD or post-EMR, and the period since the last ESD procedure in the post-ESD group with scar.
RESULTS: We recognized 10 cases with post-EMR scar and 24 cases with post-ESD scar. We combined with snare in 8.8% (3/34). The en bloc resection rate was 97.1% (33/34). The mean tumor size was 18 (4-75) mm. The procedure time was 84.8 (20-233) minute. The delayed bleeding rate of ESD was 11.8% (4/34). Perforation did not occur. The rate of G2 was 57.1% (4/7) in upper portion location, 63.2% (12/19) in middle portion location, and 25% (2/8) in lower portion location. The rate of G2 in lesser curvature lesions was 65% (13/20), and the other site was 35.7% (5/14). The G2 rate of post-ESD and post-EMR was 30% (3/10) and 62.5% (15/24). They did not produce significant difference. But in lower portion location, in the site other than lesser curvature and in post-EMR, the tendency with lower rates of G2 was recognized. After the last ESD procedure, the average period to re-ESD was 527.2 (4-1932) days. The time to re-ESD procedure of the G2 group was significantly shorter compared to the G1 group ($P < 0.05$). The rate of G2 on less than the 527days after the last ESD procedure and on 527 day or later was 80% (12/15) and 33.3% (3/9), respectively ($P < 0.05$).
CONCLUSION: The cases with strong fibrosis increases, if the time period from the last ESD is short. When performing ESD at the first time, it is necessary to observe the circumference carefully. ESD was possible safely by appropriate procedure and device even for lesions with post-EMR or post-ESD scar.

P1054 CLINICOPATHOLOGICAL AND MOLECULAR ANALYSIS OF EPSTEIN–BARR VIRUS POSITIVE GASTRIC CARCINOMA

T. Tahara[1,*], T. Shibata[1], M. Okubo[1], T. Ishizuka[1], Y. Ichikawa[1], M. Miyata[1], K. Sumi[2], T. Kawamura[2], M. Nakamura[3], M. Nagasaka[1], Y. Nakagawa[1], N. Ohmiya[1], T. Arisawa[3], I. Hirata[1]. [1]*Gastroenterology,* [2]*Fujita Health University School of Medicine, Toyoake,* [3]*Gastroenterology, Kanazawa Medical University, Ishikawa, Japan*

INTRODUCTION: Epstein–Barr virus (EBV) infection is involved in a subset of gastric carcinomas (GCs), providing distinct clinical and molecular features.
AIMS&METHODS: We performed prevalence screening of EBV using surgically or endoscopically resected GC specimens in our hospital and correlated the result with clinical and molecular characteristics. In total of 217 GC cases were examined for the presence of EBV genome. The specimens were first screened for the presence of the EBV genome by PCR with primers specific the EBV BamHI W region. Then, the result was confirmed by real-time quantitative PCRs with dual-labeled fluorogenic hybridization probes (one toward the BamHI-W region; and the other toward the EBNA-1 region). For EBV positive (EBV+) cases, mutations of *TP53*, *KRAS*, *PIK3CA* were examined. The status of CpG island methylator phenotype (CIMP) was also examined using 13 panels of genes (*MINT1, 2, 12, 25* and *31, RORA, GDNF, ADAM23, MLF1, PRDM5, RASSF1A, ATP2B4* and *MLH1*).
RESULTS: Among the 217 GC cases, presence of EBV was confirmed in ten cases (4.6%). These ten cases consisted of nine males and one female and the mean age was 57 years old. Histologically, the cases consisted of 3 well, 2 moderate, 3 poorly differentiated and 2 mixed type adenocarcinomas. Four cases of superficial cancer (pM and pSM1) were diagnosed as either well or moderate differentiated type adenocarcinomas. Nine out of ten lesions located in middle and upper body having multiple lesions in three cases. All lesions presented depressed type (or with ulceration) morphology. Eight out of ten cases were CIMP showing dense methylation in all markers examined, except for *MLH1*. Two CIMP-positive cases presented missense mutation in *TP53*, one was within hot-spot lesion in DNA-binding domain (R175H) and the other was in the novel position in DNA-binding domain (D259Y), resulting in truncating protein predicted by SHIFT. One CIMP-positive case also presented *PIK3CA* missense mutation affecting helical domain (E545A).
CONCLUSION: Prevalence, clinical and molecular features of EBV-positive GCs (male dominance, multiple lesions in middle and upper body, CIMP positivity) were in line with previous report, while it was also revealed that subset of EBV+ cases show inactivating mutations in *TP53* and oncogenic mutation in *PIK3CA*. Moreover, the fact that pathologically superficial cancer presented differentiated histologic type suggests that majority of the EBV+ cases may have originally developed as differentiated type histopathology.

P1055 CLINICOPATHOLOGICAL FEATURES RELATING TO LYMPH NODES METASTASIS AND IMPACT OF THE EXTENT OF LYMPHADENECTOMY ON PROGNOSIS IN EARLY GASTRIC CANCER

W. Hui[1,*], H. Yu-long[1]. [1]*Surgical Department of Gastroenterology, the First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

INTRODUCTION: Despite current treatment guidelines recommend endoscopic resection or D1 / D1+ lymphadenectomy for cases of early gastric cancer without lymph nodes metastasis, and D2 lymphadenectomy for cases with lymph nodes metastasis. Currently, information of lymph nodes metastasis in early gastric cancer mainly relies on ultrasonography, however, it's accuracy is not satisfied. Therefore, it is difficult to select a reasonable extent of lymphadenectomy for the case of early gastric cancer with unclear lymph nodes metastasis.
AIMS&METHODS: To explore the clinicopathological features relating to lymph nodes(LN) metastasis and the impact of the extent of lymphadenectomy on prognosis in early gastric cancer. A total of 142 cases of early gastric cancer undergoing radical dissection screened from data base of Gastric Cancer Center of Sun Yat-sen University, from Aug. 1994 to Jan. 2008, were divided into negative and positive group according to LN metastasis. The clinicopathological features and impact of extent of lymphadenectomy on prognosis were compared between two groups.
RESULTS: There had no significant differences in age, gender, tumor size and location, Borrmann type, WHO type, histological type, CEA level between two groups($P > 0.05$). In negative and positive group, the ratio of TNM stage IA, IB, II were 100% vs. 0.0%, 0.0% vs. 88.5%, 0.0% vs. 11.5% respectively ($P < 0.001$). No significant difference existed in postoperative hospital day(d), blood transfusion volume(ml), operation time(min), postoperative complication between cases received D1 and D2 dissection ($P > 0.05$). The number of LN dissected was significant higher in case received D2 than that in D1(P=0.000), but no significant difference existed in the number of positive LN between 2 groups (P=0.502). COX regression analysis showed LN metastasis and the extent of lymphadectomy were independent prognostic factors for total cases. The prognosis of negative group was better than that of positive group (P=0.010), and D2 dissection prolonged survival time significantly as compared with D1 dissection(P=0.0022). In negative group, no significant difference in the prognosis was found between cases received D1 and D2 dissection (P=0.502), whereas D2 dissection prolonged survival time significantly when compared with D1 dissection in positive group(27 vs. 96 months)(P=0.001).
CONCLUSION: The status of LN metastasis could not be assessed accurately preoperatively based on patients' clinicopathological features. For the cases with unclear LN metastasis, D2 dissection should be carried out due to similar mortality and complication rates but prolonged survival time when compared with D1 dissection.

P1056 CHARACTERISTICS OF SECOND PRIMARY CANCER IN PATIENTS WITH EARLY GASTRIC CANCER AFTER ENDOSCOPIC RESECTION

Y. W. Chang[1,*], J. Y. Jang[1], J.-W. Kim[1], W.-J. Ko[1]. [1]*gastroenterology, Kyung Hee University Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Second primary cancer influences the prognosis of gastric cancer patients. Increment in diagnosis of early gastric cancer (EGC) and improvement of the prognosis for gastric cancer has led to increased incidence of second primary cancer. Endoscopic resection (ER) of EGC is widely performed in Korea. The aim of this study is to analyze the incidence rate, clinico-pathologic features and risk factors of second primary cancer in patients with EGC having history of ER and those with AGC, and compare the results between the two groups.

AIMS&METHODS: We retrospectively reviewed medical information of 716 adult patients with gastric cancer, between January 2006 and December 2010 at a single center, Kyung Hee University Hospital, Seoul, South Korea. The patients who underwent operation for EGC, those with history of previous malignancy and those lost to follow up within 12 months were excluded, and 461 patients were enrolled for the study. We defined synchronous cancers as those occurring within 6 months after diagnosis of the first primary cancer, and metachronous cancers as those occurring more than 6 months later. We collected the demographic data of patients, the incidence rates of synchronous and metachronous cancers and the clinico-pathologic features in EGC with ER and AGC, respectively.

RESULTS: Out of 461 patients, 232 patients (232/461, 50.3%) underwent ER for EGC, and 229 patients (229/461, 49.7%) were diagnosed with AGC. There were no significant differences between the two groups with regard to mean follow-up period (32.9±14.9 months vs. 33.4±16.7 months, P=0.679) and mean age (<60 vs. >60, P= 0.850). Synchronous cancers were diagnosed in 9(3.9%) patients of EGC with ER group and in 10 (4.4%) patients of AGC group. Metachronous cancers were diagnosed in 10(4.3%) patients of EGC with ER group and in 11(4.8%) patients of AGC group. There was no difference in overall incidence of synchronous and metachronous cancers between the two groups (3.9% and 4.3% vs 4.4% and 4.8%, P=0.819 and P=0.828). The most common site of second primary cancer occurrence in EGC with ESD group was the lung (21%), followed by colorectum (16%) and esophagus (16%). The most frequent site of second primary cancer occurrence in AGC group was the colorectum (14%), lung (14%) and esophagus (14%). Logistic regression analyses showed no meaningful risk factors in either group.

CONCLUSION: There was no significant differences in the incidence rate of synchronous and metachronous cancers between EGC with ER and AGC group. Therefore, careful evaluation and close surveillance for detecting synchronous and metachronous cancer is strongly recommended in patients who underwent ESD for ER.

P1057 CLINICAL BEHAVIORS OF GASTRIC CARCINOID TUMORS ACCORDING TO THE WHO 2010 CLASSIFICATION

Y. Kinjo[1,*], H. Suzuki[1], I. Oda[1], C. Sato[1], M. Makazu[1], M. Sekiguchi[1], S. Abe[1], S. Nonaka[1], S. Yoshinaga[1], Y. Saito[1], R. Kushima[2]. [1]*Endoscopy Division,* [2]*Pathology Division, National Cancer Center Hospital, Tokyo, Japan*

INTRODUCTION: There have been several classifications defining the clinical characteristics of gastric neuroendocrine tumors (NETs) including gastric carcinoid tumors (GCTs). The World Health Organization (WHO) updated its previous classifications in 2010 and classified GCTs as NET G1 and NET G2. However, the clinical behaviors of these newly classified tumors has not been fully evaluated.

AIMS&METHODS: The aim of this study was to clarify the clinical behaviors of GCTs according to the WHO 2010 classification so we reviewed cases involving 23 GCTs at our institution between 1997 and 2012 and retrospectively assessed their clinical behaviors according to the WHO 2010 and the TNM classifications (UICC 7th).

RESULTS: GCTs were treated based on Rindi's classification with surgical resections performed in six cases, endoscopic resections performed in 12 cases and observation without treatment conducted in five cases. Among the 23 GCTs, 15 were classified as NET G1 and eight as NET G2 according to the WHO 2010 classification. Based on the TNM classification, 19 GCTs were classified as T1N0M0 Stage I, three as T2N0M0 Stage IIA and one as T2N1M0 Stage IIIB. There were no cases involving local recurrence, lymph-node (LN) metastasis, distant metastasis or tumor-related death during the median follow-up period of 57 months (range, 2-180 months) except for one patient who died of liver metastasis 78 months after surgical resection whose GCT was classified as NET G2 (Ki-67 index of 12%) and T1. There were four cases involving lymphovascular invasion including one NET G2/T1 case, one NET G2/T2 case and two NET G1/T2 cases as well as two cases involving metastasis including one NET G1/T2 case of regional LN metastasis and the previously mentioned NET G2/T1 case in which the patient died of liver metastasis. Cases involving lymphovascular invasion or metastasis occurred in three of the eight (37.5 %) NET G2 cases and three of the 15 (20%) NET G1 cases (p=0.63). Lymphovascular invasion or metastasis in six of 11 (55%) NET G2 or T2 cases was significantly higher than the total absence of such characteristics in 12 (0%) NET G1/T1 cases ($p<0.05$).

CONCLUSION: The results of this study suggest a comprehensive evaluation using both the WHO 2010 classifications and the T category of the TNM classifications may be useful in predicting the risks of lymphovascular invasion and metastasis in cases involving GCTs.

P1058 THE THERAPEUTIC POTENTIAL OF IRREVERSIBLE ELECTROPORATION IN GASTRIC CANCER: EXPERIMENTAL STUDY IN RAT STOMACH

H. S. Choi[1,*], E. S. Kim[1], B. Keum[1], Y. Seo[1], Y. T. Jeen[1], H. S. Lee[1], H. J. Chun[1], S. H. Um[1], C. D. Kim[1], H. S. Ryu[1]. [1]*Internal Medicine, KOREA UNIVERSITY COLLEGE OF MEDICINE, Seoul, Korea, Republic Of*

INTRODUCTION: Irreversible electroporation (IRE) is a novel, non-thermal method of tissue ablation using short pulses of high-voltage pulse current. IRE induces the breakdown of cell homeostasis and thereby cell death. Studies regarding the clinical application of IRE have been performed in humans, as well as in animals, for organs such as the liver, kidney, pancreas, prostate, brain, etc. and IRE has been tried as a novel anti-cancer ablation modality. This is the first study about the effect of IRE on stomach. The aim of this study was to evaluate the therapeutic potential of IRE in rat gastric tissue according to different electric energy.

AIMS&METHODS: Twenty-six 8-weeks-old Sprague-Dawley rats were used throughout this study. A 3-cm midline abdominal incision was made, exposing the stomach. Small incision was done on greater curvature of stomach, a set of needle electrodes were gently applies on both side of the stomach. From 50 to 160 pulses of 1000, 1500, 2000, 2500, 3000V/cm were delivered for each ablation. All samples for histologic analysis and tunnel assay were got at 0hours, 10 hours, 24 hours and 48 hours after IRE application. The aim of this study was to evaluate the therapeutic potential of IRE in rat gastric tissue according to different electric energy.

RESULTS: All animals survived for their designated times of 10 hrs, 24 hrs and 48 hrs respectively. H-E staining showed extensive areas and severe cell death, which were proved by a pyknotic nucleus and eosinophilic cytoplasm near absence of cell at 10 hours after IRE ablation. Positive results of TUNEL assay were found in the ablated zone at gross assessment, indicating involvement of apoptotic cell death. After 24 and 48 hours, mucosa becomes much thinner by shedding of dead cells in the mucosa. Similar to 10 hours finding, viable cells were rarely observed. Instead, neutrophil infiltration was much increased. And this result shows a morphologically intact endothelium of vessel on submucosal layer after IRE irrespective of time, indicating sparing of connective tissue. The apoptotic area and signals were increased according to applied voltages and pulse in H & E stain and tunnel assay.

CONCLUSION: This study showed that IRE ablated stomach tissue very effectively through the induction of cellular apoptosis. And apoptotic area was increased according to amplified IRE electric energy to 3000V/cm without damage to adjacent structure. This study suggests the potentiality of IRE application in the treatment of gastric cancer without metastasis.

P1059 THE ROLE OF NDP KINASE–A IN GASTRIC LYMPHOMA: AS A METASTATIC SUPPRESSOR

H. J. Cho[1,*], J. I. Kim[1], D. Y. Cheung[1], J. K. Kim[1], S. H. Park[2]. [1]*Gastroenterology,* [2]*Gastroenterology,, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of*

INTRODUCTION: The *nm23-H1* gene encodes the NDPK-A (nucleoside diphosphate kinase A) that contributes variably to the migration of cancer cell.

AIMS&METHODS: Aim: To investigate the role of the NDPK-A in gastric lymphoma, we examined the expression of NDPK-A in two different cancer cell lines of the same gastric lymphoma patient.

Methods: The primary cell line of gastric lymphoma, RF-1, was cultured from the primary gastric lymphoma site, and the other cell line RF-48 was metastasized to the peritoneum of the same patient after 6 months. We have generated stable gastric lymphoma transfectants, pIRES-NDPKA-GFP-neo, that constitutively over-express transfected and vector form of NDPK-A, in addition to a reporter, green fluorescent protein(GFP). The transfected gastric lymphoma cell migration

assay was performed 24-well modified chemotaxis chambers with FluroBloc membrane.
RESULTS: In regard to the migration rate of the gastric lymphoma cell lines, RF-1 vector was 75.8±7.5%, RF-1 transfected was 54.4±12.3%, RF-48 vector was 84.7±15.4%, RF-48 transfected type was 62.3±9.2%, RF-48 migrated better than RF-1, and the vector type migrated better than the transfected type. NDPK-A was presented more in RF-1 than RF-48, and presented more in the transfected type than the vector type, and concerning the migration rate, RF-48 migrated better than RF-1, and the vector type migrated better than the transfected type.
CONCLUSION: Concerning NDPK-A in gastric lymphomas, more abundant was NDPK-A, poorer was migration, and thus it played a role of the suppressor of migration. We concluded that NDPK-A acts as a migration suppressor in gastric lymphoma

P1060 GENE-EXPRESSION OF THE WNT-MODULATOR RACGAP1 CORRELATES INVERSELY WITH CDKN1A (P21) IN PATIENTS WITH GASTRIC CANCER.

J. Bornschein[1,2,*], J. Nielitz[2], M. Selgrad[2], K. Toth[3], D. Kuester[4], T. Wex[2], A. Link[2], P. Malfertheiner[2]. [1]*MRC Cancer Cell Unit, Hutchison MRC, Cambridge, United Kingdom,* [2]*Gastroenterology, Hepatology & Infectious Dis., Otto-v.-Guericke University Magdeburg, Magdeburg, Germany,* [3]*2nd Department of Internal Medicine, Semmelweis University, Budapest, Hungary,* [4]*Institute of Pathology, Otto-v.-Guericke University Magdeburg, Magdeburg, Germany*

INTRODUCTION: RACGAP1 has been recently identified as regulatory gene involved in gastric carcinogenesis by in silico gene-gene co-expression network analysis. RACGAP1 is suggested as downstream modulator of the Wnt-signalling pathway. Up to date, there are no data on RACGAP1 expression in human gastric cancer.
AIMS&METHODS: Here, we investigated the interaction of RACGAP1 with the p21 gene (CDKN1A) and Wnt-dependent signalling (DKK2, β-catenin) pathways in gastric cancer.
Biopsy samples of gastric cancer tissue and adjacent non-malignant gastric mucosa were prospectively collected (n=48; intestinal type n=28; diffuse type n=20). Antrum and corpus biopsies from subjects without any pathology of the upper gastrointestinal tract have been used as a control (n=30). Transcript levels of RACGAP1, CDKN1A, DKK2 and β-catenin were quantified by quantitative real-time PCR. For statistical analysis, non-parametric tests were applied with $p<0.05$ regarded as significant.
RESULTS: The expression of RACGAP1 in the tumour correlated inversely with CDKN1A expression (r=-0.359, p=0.011), but showed a positive association to both β-catenin and DKK2 in tumour tissue (β-catenin: r=0,300; p=0,036; DKK2: r=0,373; p=0,008). Pairwise comparison revealed no difference in the RACGAP1 or CDKN1A gene expression between samples from tumour, tumour-adjacent and tumour-distant mucosa.
However, the expression of RACGAP1 was significantly lower in samples (tumour and non-tumorous tissue) from gastric cancer patients compared to controls (2.8e-03 vs 8.3e-03, $p<0.001$), whereas CDKN1A expression was higher in tumour patients (1.4e-04 vs 7.3e-05, p=0.003). Interestingly, differential expression of RACGAP1 in tumours could be confirmed for both antrum and corpus (p=0.008, $p<0.001$, resp.). CDKN1A expression difference was observed only for corpus mucosa of the controls, but not antrum (p=0.008).
Subgroup comparison revealed no significant difference of the gene expression of neither RACGAP1 nor CDKN1A if stratified by Laurén type (58% intestinal), localisation of the main tumour mass (20% proximal GC), as well as *H. pylori* status (74% positive).
CONCLUSION: RACGAP1 expression is downregulated in gastric cancer and is associated with the expression of target genes of Wnt-dependent signalling. RACGAP1 correlates inversely with CDKN1A gene expression, therefore its role as prognostic indicator needs further assessment.

P1061 THE EFFECTS OF DNA METHYLTRANSFERASE INHIBITOR DECITABINE ON HOXD10-CASPASE3-MEDIATED APOPTOSIS AND PROLIFERATION OF GASTRIC CANCER CELL LINE MKN45

Z. Yuan[1], L. Yu[2,*], F. Xu[2], C. Sun[2], C. Yin[2], Y. Zhu[2], X. Pan[2], S. Yang[2], R. Shi[2]. [1]*Department of Gastroenterology, Changzhou Wujin Hospital Affiliated to Jiangsu University, Changzhou,* [2]*Department of Gastroenterology, the First Affiliated Hospital with Nanjing Medical University, Nanjing, China*

INTRODUCTION: Gastric cancer is the second most common cancer with the incidence of 69 cases per 100,000 people per year in China. Epigenetic alterations such as promoter hypermethylation of tumor suppressor genes (TSGs), which lead to the silence of TSGs, has been demonstrated to contribute to gastric cancer progression.
DNA methylation is controlled by DNA methyltransferases (DNMTs). DNMTs inhibitor decitabine is a kind of cytidine nucleoside analogues. It depletes cells of functional methyltransferase activity through forming a irreversible covalent bond with DNMTs. Inhibition of DNA methylation with decitabine has been shown to reactivate the expression of genes silenced by hypermethylation in tumor cells in vitro or in vivo. In 2006, decitabine was approved by the US FDA for the treatment of patients with myelodysplastic syndrome (MDS).
AIMS&METHODS: This study was designed to investigate the relationship between the dose-time and anti-tumor effect of DNA methyltransferases (DNMTs) inhibitor decitabine in human gastric cancer cell line MKN45. Human gastric cancer cell line MKN45 was treated with a dose range (0-20 μmol/L) of decitabine for 48,72 and 96 hours, respectively. Flow cytometric analysis of Annexin V-FITC/PI staining and CCK8 assays were used to study apoptosis and proliferation in MKN45 cells. RT-PCR and Real-Time PCR were used to examine the expression of Homeobox D10(HoxD10) at the mRNA levels. Cleaved-caspase3 expression was determined by Western blot.
RESULTS: (1) Annexin V-FITC/PI staining showed that decitabine induced apoptosis of MKN45 in a time-dependent manner. The maximal amount of proapoptosis effect 17.37±1.10% was detected at 96h with 20μmol/L decitabine. (2) Decitabine was an effective inhibitor of MKN45 proliferation and the effect was time-dependent. A decitabine concentration of 20μmol/L accounted for the inhibition of cell proliferation of 59.96±4.28% at 96 hours.(3)The mRNA expression of HoxD10 in gastric cell line MKN45 was markedly downregulated than that in normal gastric epithelial cell line GES1. Decitabine could induce HoxD10 reexpression in a time-dependent manner through demethylation effect in MKN45 cells.(4)Cleaved-caspase3 was activated significantly with decitabine treatment comparing to the controls.
CONCLUSION: Our results demonstrated that decitabine exert proapoptotic and growth inhibition effects in human gastric cancer cell line MKN45 in a time-dependent manner. Reexpression of tumor suppressor gene HoxD10 and cleaved-caspase3 activation contributed to the apoptosis of MKN45 cells. DNA methylation plays an important role in gastric cancer progression.

P1062 COMMON FUNCTIONAL GENETIC POLYMORPHISMS ASSOCIATED WITH SURVIVAL OF GASTRIC CANCER PATIENTS

T. Tahara[1,1], M. Okubo[1,*], T. Shibata[1], T. Ishizuka[1], Y. Ichikawa[1], M. Miyata[1], K. Sumi[2], T. Kawamura[2], M. Nakamura[3], M. Nagasaka[1], Y. Nakagawa[1], N. Ohmiya[1], T. Arisawa[3], I. Hirata[1]. [1]*Gastroenterology,* [2]*Fujita Health University School of Medicine, Toyoake,* [3]*Gastroenterology, Kanazawa Medical University, Ishikawa, Japan*

INTRODUCTION: So far, a number of association studies have focused on the effect of common functional SNPs on the susceptibility to gastric cancer (GC).
AIMS&METHODS: Here, we evaluated the possible association between common functional SNPs in pro-inflammatory cytokines, DNA repair and xenobiotic molecules, and pre-miRNAs with the overall survival in GC patients. 12 candidate SNPs (IL-1β gene -31T>C and -511C>T, TNF-α-857C>T, XRCC1 Arg399Gln and Arg194Trp, GSTP1 Ile104Val, GSTT1, GSTM1, Cyclin D1 G870A, miR-196a2, miR-146a and miR-499) were determined in 130 GC patients in relation to the overall survival, defined as the time from the date of surgery for respectable cases and the date of initial chemotherapy for unrespectable cases. Survival among different genotypes was assessed using the Kaplan–Meier method and compared using the log-rank test.
RESULTS: The median follow-up period of patients was 30.0 months. TNF-α-857T carrier showed significantly better overall survival than patients with CC genotype (p=0.01). GC patients who have either of IL-1β-31 CC or IL-1β-511 TT or TNF-α-857 T carrier genotypes showed also better survival than the other genotypes (p=0.02). The patients with the GSTT1 null genotype also presented better overall survival than the GSTT1 present genotype (p=0.019). When the subjects were divided according to age group, the miR-196a2 rs11614913 T carrier tended to be associated with worse overall survival than the CC genotype in patients younger than 65 years of age (p=0.05).
CONCLUSION: TNF-α-857T carrier and GSTT1 null genotype seems to be associated with better overall survival of GC patients. miR-196a2 rs11614913 T carrier might be associated with worse overall survival in younger cases.

INTRODUCTION: Pepsinogen (PgI) and the ratio between PgI and pepsinogen II (PgI/PgII) detection is used as an indirect marker for atrophy in the corpus of the stomach mucosa.
AIMS&METHODS: The aim of the study was to evaluate the dynamics of pepsinogen test results within a 3-year period in a Caucasian population.
Patients that were reported to have decreased Pg levels at the time of initial sampling, were invited to undergo repeated plasma sampling and upper endoscopy with biopsy work-up according to updated Sydney system in average 3 years after the initial blood sample. PgI and PgII were measured in plasma simultaneously in the initial sample and the follow-up sample (Eiken Chemical Co., Tokyo, Japan). The initial selection of the cases was made based on a cross-sectional population-based study in Latvia.
RESULTS: Plasma samples from 107 cases were available for the analysis (45 men; the mean age was 62).

The mean PgI level was 33.1 in the initial sample and 32.2 in the follow -up sample, no statistical difference was revealed (p=0.61). The mean PgI/PgII was 2.0 and 2.2, respectively (p=0.06).
In the group of patients with moderate to severe corpus atrophy and/or intestinal metaplasia (according to histology; 11 patients altogether) the mean PgI was 19.4 initially and 16.8 at the control (p=0.28); mean PgI/II was 1.0 initially, and 0.99 at the control (p=0.85)
Altogether 11 patients had undergone *H.pylori* eradication therapy during the study period. In those having undergone eradication the mean PgI was 35.0 initially and 35.1 at the control (p=0.97); mean PgI/II was 2.1 and 2.7, respectively (p=0.11).
In the group of 45 men the mean PgI level was 33.1 in the initial sample and 32.7 in the follow - up sample (p=0.86); mean PgI/II was 1.9 initially, and 2.1 - in the follow -up sample (p=0.04).
CONCLUSION: Our data show that initially PgI or PgI/PgII levels are relatively stable and do not change substantially during a three year period neither in the entire patient sample nor in patients with *H.pylori* eradication therapy as well as in patients with moderate to severe corpus atrophy and/or intestinal metaplasia. Slight increase of PgI/II in men during a 3-year period was observed.

P1064 ALPHA1 ACID GLYCOPROTEIN BINDS TO PACLITAXEL AND SUBSTANTIALLY ALTERS ITS ANTICANCER EFFECTS WHICH COULD BE RESTORED BY ERYTHROMYCIN

S. Fushida[1,*], Y. Obatake[1], T. Tsukada[1], J. Kinoshita[1], K. Oyama[1], I. Ninomiya[1], T. Fujimura[1], T. Ohta[1]. [1]*Gastroenterological Surgery, KANAZAWA UNIVAERSITY HOSPITAL, Kanazawa, Japan*

INTRODUCTION: Paclitaxel (PTX) is widely used for gastric cancer treatment, especially as low dose weekly administration. Intravenously administrated PTX elutes into ascites, which concentration is about 10 nM, and shows anticancer effects directly in peritoneal cavity. It is well known that according to cancer progression, the level of Alpha1 acid glycoprotein (AGP) in serum and ascites often increase.
AIMS&METHODS: The aim of the present study was to clarify whether AGP binds to PTX and alters its anticancer effects. For the establishment of experimental dosage, the concentration of AGP in serum and ascites of gastric cancer patients with peritoneal carcinomatosis (PC) was measured by radial immunodiffusion assay. The inhibitory effects of AGP to PTX *in vitro* were evaluated by MTT assay using gastric cancer cell line; OCUM-2MD3. We also examined the combined effects of erythromycin (EM) with AGP *in vitro* and *in vivo*.
RESULTS: The mean levels of AGP were 1.524 mg/ml in serum and 0.834 mg/ml in ascites. Addition of AGP disturbed cell growth inhibition of PTX on dose dependent manner (0.2 to 1.2 mg/ml). However, combination with EM restored anticancer effects of PTX. The elevated level of AGP was detected in ascites of mice PC model inoculated OCUM2MD3 and reached a plateau on Day 17. PTX (5mg/kg/iv) alone did not diminished PC remarkably when PTX was administrated Day 7 and 14, whereas co-administration of PTX and EM (5 mg/kg/D7-17) significantly reduced PC *in vivo* (p=0.011).
CONCLUSION: AGP is an important regulatory factor modulating the ability of intravenous PTX, and combined therapy with PTX and EM might be useful for treatment of PC in gastric cancer.

P1065 ENDOSONOGRAPHY-GUIDED FINE-NEEDLE ASPIRATION VERSUS KEY-HOLE BIOPSY IN DIAGNOSTICS OF GASTRIC SUBMUCOSAL TUMORS – A RANDOMIZED STUDY

V. Zoundjiekpon[1,*], K Zezulková[1], **:** , M Kliment[1], P Falt[1], P Fojtík[1], E Kundrátová[1], O Mikolajek[1], M Hanousek[1], K Reiterová[2], O Urban[1], 1 Digestive Diseases Center, Vitkovice Hospital, Ostrava, Czech Republic. [1]*Digestive Diseases Center, Vitkovice Hospital, Ostrava, Czech Republic*[2]*Biopsy and cytology Department, Agel Laboratories, Nový Jičín, Cze*

INTRODUCTION: Gastric submucosal tumors (g-SMTs) are tumors arising from subepithelial layers of the gastric wall, mostly from submucosa and muscular layer. They usually have an intact mucosa lining on the inner surface. Prognosis and treatment of g-SMTs depend on its correct diagnosis which consists in the cytohistological and immunohistochemical examination. A standard forceps biopsy of mucosa is usually not helpful due to their location. Therefore, biopsy techniques capable of reaching deeper layer of gastric wall are needed.
AIMS&METHODS: Compare the yield and success of Endosonography-Guided Fine-Needle Aspiration (EUS-FNA) and Key- Hole Biopsy (KHB) in cytohistological and immunohistochemical diagnostics of g-SMTs.
Patients with endoscopically detected g-SMTs with diameter $\geq$ 2cm were randomly allocated to undergo either EUS-FNA by 22G needle or KHB (consisting of forceps biopsy through mucosal incision by a needle knife), both with subsequent histological/cytological and imunohistochemical evaluation of the specimen. In case of failure of the initial method, the other method was performed (cross-over).
RESULTS: Up to now, a total of 24 subjects (37,5% men, mean age 65,7 years), twelve in each group, with g- SMTs were enrolled in the study .
Primary tissue diagnosis was obtained in 83,3% (10/12) of patients in each group. The final diagnosis was established by the initial sampling in 20 (80%) and in 3 patients after cross-over. In the whole study population the final tissue diagnosis was: GIST (n = 15, 62,5%), leiomyoma (n = 4, 16,7%), lipoma (n = 2, 8,3%), MALT lymphoma (n = 1, 4,16%), adenocarcinoma (n = 1, 4,16%). In one case (4,16%) no diagnosis was obtained. In the population with final diagnosis GIST, ten patients were in the EUS-FNA group. Of 15 patients with a diagnosis of GIST, some MA could be evaluated only in 5 patients (2 in the EUS-FNA group). A number of mitoses in the required 50 high power fields was approximately specified only in 3 patients . In the trial population, twelve patients (five in tke KHB group, ten with diagnosis GIST and two with diagnosis Leiomyoma) were operated. The post-operative tissue diagnosis corresponded in 4/5 (80%) patients in the KHB group and 7/7 (100%) in FNA group.
CONCLUSION: 1) According to our study Gastrointestinal Stromal Tumors are the most common Gastric Submucosal Tumors (in 62,5%).
2) Endosonography-Guided Fine-Needle Aspiration and Key-Hole biopsy enable diagnosis Gastrointestinal Stromal Tumors.
3) Neither Endosonography-guided Fine-Needle Aspiration nor Key-Hole Biposy is able to provide adequate tissue sample to determine prognostic mitotic activity.

P1066 CHANGES OF ESOPHAGUS IN PATIENTS INFECTED WITH CAGA(-) AND CAGA(+) STRAINS OF HELICOBACTER PYLORI

N. V. Baryshnikova[1], Y. P. Uspenskiy[1,*], I. G. Pakhomova[2]. [1]*surgical gepatology with a gastroenterology course, St-Petersburg State Medical University n.a. I.P. Pavlov,* [2]*Introdiction into internal diseases, North-West State Medical University n.a. I.I. Mechnikov, St-Petersburg, Russian Federation*

INTRODUCTION: Data about association between *Helicobacter pylori* infection and gastro-esophageal reflux disease (GERD) are controversial. Some studies have shown that *H. pylori* may protect against GERD and *H. pylori* eradication may be a risk factor of development of inflammation and erosive changes in esophagus. But other studies did not confirm it.
AIMS&METHODS: Aim: To estimate changes of esophagus in patient infected with *cagA(+)* and *cagA(-)* strains of *H. pylori.*
Materials and methods: 41 persons infected with *H. pylori* were under supervision. For all the surveyed patients analysis of complains and esophagogastroduodenoscopy were performed to estimate clinical and endoscopic signs of changes in esophagus. Also for all patients a biopsy from a stomach antrum was performed for verification of *H. pylori* infection by means of rapid urease test and polymerase chain reaction (PCR) with detection of genes of *H. pylori* pathogenicity island: *ureC, cagA, cagC, cagE, cagH* (Research laboratory "Diagnostics"). The choice of the genes selected for the analysis was based on the fact that these genes encode for several cytotoxins - the most important pathogenecity factors of *H. pylori.* All the surveyed patients have been divided into two groups: Patients from the 1st group (12 patients) were infected with *cagA(-)* strains. Patients from the 2nd group (29 patients) were infected with *cagA(+).* Statistical estimation was performed in programs Excel and Statistica 6.0 for Windows XP.
RESULTS: heartburn was in 75% in patients from 1st group and 79.3% in 2nd group. Hyperemia of esophagus (distal esophagitis) was in 41.7% of patients in 1st group and in 24.1% of patients in 2nd group ($p<0.05$). Erosions of esophagus were no in 1st group patients and were in 3.4% of patients in 2nd group ($p<0.05$). At the analysis of features of *cag*-status of *H. pylori* in these groups of patients it has been revealed that in patients from 1st group a frequency of occurrence of other investigated genes of *cag*-group (except *cagA*) of *H. pylori* pathogenicity islands was significantly lower than in patients from 2nd group: *cagC* gene – 8.3% and 55% ($p<0.05$), *cagE* gene – 22.2% and 33.3%, *cagH* gene – 25% and 80% ($p<0.05$) correspondingly.
CONCLUSION: Changes of esophagus are common in patients infected with as highly and lower virulence strains of *H. pylori. CagA(+)* status is associated with erosive changes of esophagus. Heartburn without hyperemia or erosions of esophagus can be sign of functional dyspepsia or endoscopic negative GERD.

P1067 VARIATION IN HELICOBACTER PYLORI CAGA PROMOTER REGION IS ASSOCIATED WITH CAGA EXPRESSION AND INFLUENCES INTERLEUKIN-8 SECRETION

R. M. Ferreira[1,*], I. Pinto-Ribeiro[1], J. C. Machado[1,2], C. Figueiredo[1,2].
[1]*IPATIMUP - Institute of Molecular Pathology and Immunology of the University of Porto,* [2]*Dept. Pathology and Oncology, Faculty of Medicine of the University of Porto, Porto, Portugal*

INTRODUCTION: *Helicobacter pylori* CagA is a main virulence factor that is present in about 70% of the strains from Western countries, and is a major contributor for peptic ulcer disease and gastric carcinoma. Recently, four motifs have been identified that exhibit sequence heterogeneity in the promoter region of *cagA*, located at positions -344, -53, -10 and +59 bp from the transcription start site. The presence of the +59 motif has been defined as determinant of enhanced CagA protein expression, and both the presence of the +59 motif and high CagA expression have been associated with worse histopathological scores in a population of Colombia at high risk for gastric carcinoma (1).
AIMS&METHODS: The aim of this study was to characterize the *H. pylori cagA* promoter region, to assess the relationship between variation in this region and CagA expression, and to investigate the influence of *cagA* promoter variation and CagA expression on IL-8 secretion.
The *cagA* promoter region was sequenced in 46 *cagA*-positive clinical isolates and two reference strains (26695 and 60190). The CagA expression levels were assessed by western blot, and IL-8 secretion was evaluated by ELISA in culture supernatants of the gastric cell line AGS infected with *H. pylori*.
RESULTS: Nucleotide sequences of the *cagA* promoter region showed high heterogeneity among *H. pylori* strains. The differences included variation in sequence and copy number of the -344 and -54 motifs. The -10 motif only showed sequence variation, being TATAATGA the most common sequence found (54.6%). The +59 motif was either absent (23.9%), or present as one (73.9%) or two (2.2%) copies in the clinical *H. pylori* strains analysed.
CagA protein expression was associated with the -10 TATAATGA sequence ($p = 0.012$) and with the presence of the +59 motif ($p = 0.003$). Moreover, the levels of IL-8 secreted by AGS cells were correlated with the levels of CagA expression ($r_p = 0.391$; $p = 0.009$), as well as with the presence of the +59 motif in the *cagA* promoter ($p < 0.001$). No relationships were found between CagA expression ($p = 0.237$) or IL-8 secretion ($p = 0.403$) and the number of CagA EPIYA C motifs present in the *H. pylori* strains.
CONCLUSION: Variation in the *cagA* promoter region is associated with CagA expression and influences IL-8 secretion by gastric cells. Further studies are needed to confirm the usefulness of specific regions on the *cagA* promoter as markers to predict disease risk.

P1068 PRIMARY CLARITHROMYCIN RESISTANCE IN H. PYLORI ISOLATES IN ITALY IS ASSOCIATED WITH NEW POINT MUTATIONS IN THE RRNA.

V. De Francesco[1,*], A. Zullo[2], F. Giorgio[3], I. Saracino[4], C. Zaccaro[4], C. Hassan[2], E. ierardi[3], A. Di Leo[3], V. Castelli[4], G. Fiorini[4], D. Vaira[4]. [1]*Section of Gastroenterology Department of Medical Sciences, University of Foggia,, Foggia,* [2]*Gastroenterology and Digestive Endoscopy, ''Nuovo Regina Margherita'' Hospital,, Rome,* [3]*Section of Gastroenterology, Department of Emergency and Organ Transplantation, University of Bari, Bari,* [4]*Department of Clinical Medicine, University of Bologna, Italy, Bologna, Italy*

INTRODUCTION: Phenotypic clarithromycin resistance in *H. pylori* strains is associated with different genotypic point mutations in the bacterial rRNA. The A2143G, A2142G, A2142C are the point mutations involved in more than 90% of clarithromycin resistant in Western countries.
AIMS&METHODS: Aim: To assess the prevalence of different genotypic mutations in *H. pylori* strains with phenotypic clarithromycin resistance isolated in Italy.
Methods: Paraffin-embedded biopsies of consecutive patients with *H. pylori* strains harbouring primary clarithromycin resistance assessed by culture (MIC $\geq$0.5 mg/L) were retrieved. A TaqMan-PCR was performed to search for different point mutations.
RESULTS: A total of 42 isolates were evaluated, and a genotypic mutation in the rRNA was identified in 37 (88%). In detail, the presence of at least 1 of the most frequent point mutation was detected in only 23 (54.8%) cases, including 13 A2143G, 8 A2142G, and 2 A2143G plus A2142G. A different point mutation was detected in further 14 (33.3%) of phenotypic resistant isolates, including 6 G2141G, 4 A2144T, 3 A2115; G, and 1 A2115G plus A2144G. None of tested mutations was present in the remaining 5 isolates.
CONCLUSION: The prevalence of the 3 most frequently detected point mutations of clarithromycin resistance is declining, whilst other point mutations are emerging in *H. pylori* isolates in Italy. This observation should be considered when assessing clarithromycin resistance by using only a PCR-based tool.

P1069 RECOVERY OF GASTRIC FUNCTION AFTER HELICOBACTER PYLORI ERADICATION AND ACETIUM ADMINISTRATION: A 6 YEARS STUDY IN ATROPHIC GASTRITIS SUBJECTS.

F. Di Mario[1,*], M. Rugge[2], F. Ferrara[1], T. Slongo[1], N. Dal Bo'[1], G. Guarnieri[1], R. Marcello[1], A. Caroli[1], H. Heras Salvat[1], R. Rigoli[3], A. P. Dei Tos[4], C. Scarpignato[5]. [1]*Department of Specialist Medicine, Gastroenterology Unit, Treviso General Hospital, Treviso,* [2]*Department of Diagnostic Medical Sciences and Special Therapies, Surgical Pathology and Cytopathology Unit, University of Padova, Padova,* [3]*Department of Clinical Pathology,* [4]*Department of Clinical Pathology, Pathology Unit, Treviso General Hospital, Treviso,* [5]*Department of Clinical Sciences, Laboratory of Clinical Pharmacology, University of Parma, Parma, Italy*

INTRODUCTION: The relationship between *H.pylori* eradication and atrophic changes in the gastric mucosa has not yet been fully defined. Athough studies report a partial restoration of serum pepsinogenI(sPGI)after eradication, it is not clear if this finding reflects gastric mucosal ealing on a morphological level. Recently a new compound(L-cystein Acetium, Biohit, Fin) has been proposed for prevention of gastric carcinogenesis in patients with atrophic gastritis, by reducing acetaldehyde production after food intake.
AIMS&METHODS: To assess alteration in gastric function after *H.pylori* eradication on moderate-severe body atrophiv gastritis by determination of sPGI levels and Gastrin 17 (sG-17). 74 dyspeptic pts, selected from 738 consecutive *H.pylori* + patients, with histological features of moderate-severe body atrophic gastritis and sPGI <25microg/L (34men, mean age 58, range 26-83yrs), underwent an upper gastrointestinal endoscopy with gastric biopsies and sPGI and sG-17determination at baseline. All patients underwent eradication therapy. Serum sPGI and sG-17 were measured again after 6 months, and at 1,2,3,5 and 6yrs after eradication.
RESULTS: Mean sPGI levels prior to eradication were 13,4microgr/L(range:1,5-24microgr/L). 6 months after eradication therapy, mean sPGI levels significantly increase to 16,6 microgr/L (p=0.05). At the completion of the study, 6yrs after eradication, sPGI levels increased to 27,3microgr/L (p=0.01). Conversely, the sG 17 dropped out from 84,8 at baseline to 67,6pmol/L after the 6 yrs follow up period($p<0.01$).21 patients(16 fem, mean age 44, range 27-61 yrs) out of the 74 sample atrophic gastritis subjects experienced a 3 month period of treatment with Acetium 100 mg at dosage of 3 capsules daily before eating. In all, both sPGI and sG 17 were reduced at baseline and after 3 months period of treatment. The mean levels of sPGI increases from 7,9microgr/L at baseline to 11,4 after 90 days of Acetium intake as well as sG-17 drop out from30,3 to 25,5pmol/L.
CONCLUSION: After H. Pylori eradication subjects with body atrophic gastritis showed long-lasting improvement of physiological gastric function, reflected by significantly and stabile increasing of sPGi levels and a parallel decreased of sG 17 over a 6-year period of follow up. L-cysteine seem to be usefull in restoring gastric secretion in subjects with chronic atrophic gastritis, but other studies are required to confirm and clarify this finding.

P1070 DIFFERENT BIOLOGICAL IMPLICATION OF INHIBITORY TGF-β SIGNALING, SMAD7, IN GASTRIC MUCOSAL DAMAGES ACCORDING TO HELICOBACTER PYLORI INFECTION AND NSAID ADMINISTRATION

K. B. Hahm[1,*], E. H. Kim[1], S. P. Hong[1], J. M. Park[1]. [1]*Gastroenterology, CHA UNIVERSITY OF MEDICINE AND SCIENCE, Seongnam, Korea, Republic Of*

INTRODUCTION: *Smad7* has been known as inhibitory signaling molecule of transforming growth factor (TGF)-β superfamily, leading to block TGF-β–induced cell apoptosis and immune suppression. Since inflammation, apoptosis, endoplasmic reticulum-stress, and autophagic cell death have been identified as key cytotoxic mechanisms implicated in either *H. pylori*- or NSAIDs-induced gastric damages, we have the curiosity how *smad7* can influence *H. pylori*- and NSAID-induced gastritis.
AIMS&METHODS: To investigate the biological role of TGF-β1 or its antagonist, *Smad7*, in *H pylori*- and NSAIDs-induced gastric damages, respectively, we generated *Smad7* overexpressed RGM1 cells. Using these cells, we compared the different gene expression between MOCK transfected cells and overexpressed-*Smad7* cells after *H. pylori* and NSAIDs by high throughput analysis of cDNA microarray. We validated the findings by detecting the protein expression of inflammation-, proliferation-, apoptosis-, and autophagy- related mediators.
RESULTS: *Smad7* overexpression significantly increased *H. pylori*-induced inflammation and apoptotic actions, whereas *Smad7* overexpression suppressed indomethacin-induced apoptosis and autophagic cell death, quite contrary implications of *Smad7* according to kind of irritant. Furthermore, indomethacin treatment significantly decreased the expression of *Smad7* and induced gastric damage by *Smad7* degradation as confirmed by *Smad7* knockdown. cDNA microarray revealed these contrary implications of *smad7* in gastric epithelial damages were based on different transcriptional regulation of inflammatory and cytotoxic mediators as well as autophagy.
CONCLUSION: Our novel findings suggest that the maintenance of *Smad7* expression may have different possible therapeutic actions in *H. pylori*- and NSAIDs-induced gastric injury, rendering dual sword implication of *Smad7* in gastric damages.

P1071 ACTIVATION-INDUCED CYTIDINE DEAMINASE (AID) EXPRESSION IS CORRELATED WITH OLGA AND OLGIM STAGING IN HELICOBACTER PYLORI-INFECTED MUCOSA

N. Nagata[1,*], J. Akiyama[1], K. Watanabe[1], T. Sakurai[1], C. Yokoi[1], M. Kobayakawa[1], M. Mizokami[2], N. Uemura[3]. [1]*Department of Gastroenterology and Hepatology, National Center for Global Health and Medicine, Tokyo,* [2]*The Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine,* [3]*Department of Gastroenterology and Hepatology, National Center for Global Health and Medicine, Kohnodai hospital, Chiba, Japan*

INTRODUCTION: Recent studies have shown the important roles played by activation-induced cytidine deaminase (AID), an intrinsic genome mutator, in *Helicobacter pylori*-associated gastric cancer development.
AIMS&METHODS: Our aim was to evaluate the relationship between OLGA/OLGIM (Operative Link on Gastritis/Intestinal Metaplasia Assessment) staging and AID expression. A total of 109 patients with functional dyspepsia who had undergone endoscopy were selected. Histological staging of OLGA and OLGIM was assessed according to the updated Sydney system (USS). *H. pylori* infection was diagnosed by serological testing, the ^{13}C urea breath test, and histological examination. Immunohistochemical AID and p53 expression in the biopsy specimens was scored.
RESULTS: Of the 109 patients, 60 (55%) were *H. pylori*-positive and 49 (45%) were *H. pylori*-negative. AID expression was significantly higher in *H. pylori*-positive patients than in *H. pylori*-negative patients (median AID score, 14 vs 3, $p<0.01$). AID expression correlated significantly with OLGA staging (Spearman's rho, 0.51, $p<0.01$), and OLGIM staging (Spearman's rho, 0.55, $p<0.01$). In addition, AID expression correlated strongly with p53 expression (Spearman's rho, 0.71, $p<0.01$).
CONCLUSION: AID was found in the gastric epithelium of biopsy specimens, especially in association with *H. pylori* infection. Both OLGA and OLGIM staging correlated with AID and p53 expression, suggesting a significant role in atrophic change with intestinalization accompanying the development of gastric cancer.

P1072 THE EFFECT OF H. PYLORI ON THE EGFR-INDUCED SIGNAL TRANSDUCTION AND PREVENTIVE EFFECT OF CELECOXIB IN THE GASTRIC CANCER CELLS

N. Kim[1,*], J. Kim[2], D. H. Lee[1], S. M. Park[3]. [1]*Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam,* [2]*Department of Internal Medicine, Seoul National University College of Medicine, Seoul,* [3]*Department of Internal Medicine, Chungbuk National University College of Medicine, Cheongju, Korea, Republic Of*

INTRODUCTION: Epithelial growth factor receptor (EGFR) downstream targets phosphatidyl inositol 3-OH kinase (PI3K)-Akt-glycogen synthase kinase-3 (GSK3) pathways, thus regulates cell survival and migration. *Helicobacter pylori* (*H. pylori*) infection induces cyclooxygenase-2 (COX-2) over-expression, and previous study showed that selective COX-2 inhibitor, celecoxib, blocked Akt signaling pathway. COX-2 and EGFR may cross talk through Akt-signaling pathways.
AIMS&METHODS: Aim: To evaluate the effect of *H. pylori* on EGFR signaling pathways and to find out whether celecoxib has inhibitory effect on the EGFR signaling pathway or not.
Methods: AGS gastric epithelial cell lines were co-cultured with *H. pylori cagA+*, *vacA+* G27 and the *cagE-* mutant of G27. The expressions of COX-2, EGFR and TGF-ß were measured by real-time PCR. In the next, Western blot analyses of COX-2, EGFR, total Akt (tAkt), phosphorylated Akt (pAkt) and pGSK3ß were carried out at various concentrations of celecoxib (0, 10, 20, 30 μmol/L) for 24 hours in *H. pylori* treated AGS cell lines.
RESULTS: *H. pylori* infection significantly up-regulated the mRNA levels of COX-2, EGFR, HB-EGF and TGF-ß by RT-PCR. However, AGS cells treated with *cagE-* mutants, which have a defective type IV secretion system, did not show EGFR up-regulation. Celecoxib had inhibitory effects on *H. pylori*-induced over-expression of COX-2 (p=0.015), EGFR (p=0.025), pAkt (p=0.025) and pGSK3ß (p=0.029) in AGS cell lines by Western blot analysis.
CONCLUSION: *H. pylori* activated COX-2-Akt-GSK pathway, and EGFR signal pathways in AGS cell lines, which was dependent on type IV secretion system. As celecoxib showed inhibitory effects not only on COX-2-Akt-GSK pathway but also on EGFR signal pathway, it looks like that COX-2 and EGFR cross talk, mediating the *H. pylori*-induced gastric cancer.

P1073 ENHANCED EXPRESSION OF INDOLEAMINE 2,3-DIOXYGENASE (IDO) IN HELICOBACTER PYLORI-INFECTED HUMAN GASTRIC MUCOSA DOWNREGULATES INTERLEUKIN (IL)-17 AND UPREGULATES IL-4 PRODUCTION

T. Larussa[1,*], I. Leone[1], E. Suraci[1], T. Procopio[2], F. Conforti[1], L. Abenavoli[1], M. L. Hribal[2], M. Imeneo[1], F. Luzza[1]. [1]*Department of Health Science,* [2]*Department of Medical and Surgical Science, University of Catanzaro ''Magna Graecia'', Catanzaro, Italy*

INTRODUCTION: The activation of IDO results in depletion of tryptophan (Trp) and production of its catabolites from kynurenine-metabolism pathway which are directely toxic to effector T-cells and promote the differentiation of regulatory T cells. Data from animal models propose that IDO may play a role in self-limiting Th1 response and promoting Th2 cytokine profile. IL-17, a Th17-derived cytokine up-regulated in *H. pylori*-infected human gastric mucosa, plays a role in the host response against the bacterium and, possibly, in its clearance/persistence.
AIMS&METHODS: Five antral biopsies were taken from 20 patients (10 M, median age 41 yrs, range 25-70) who underwent upper gastrointestinal endoscopy for dyspeptic symptoms: 1 for urease quick test (Yamanouchi Pharma, Milan, Italy), 2 for histology (Giemsa staining for *H. pylori* and modified Sydney System for gastritis score), and 2 for protein extraction. A C13-urea breath test was also performed (at least two tests positive and all the three tests negative to be considered *H. pylori*-infected or uninfected). In a subgroup of patients, further antral biopsies were taken, immediately placed in an organ culture chamber, and treated for 24 hours with and without IDO inhibitor 1-methyl-L-Trp (Sigma, St. Louis, MO). The expression of IDO protein and that of IL-17 and IL-4 was determined by Western blotting in total proteins extracted from freshly obtained gastric biopsies and gastric biopsy cultures, respectively. The ratio of IDO, IL-17, and IL-4 with beta-actin was calculated by densitometry and values expressed as means ± SD arbitrary units (a.u.).
RESULTS: IDO expression was found enhanced in gastric biopsies from *H. pylori*-infected (n=10) compared to uninfected (n=10) patients (1.28±0.20 a.u. *vs* 0.98±0.35 a.u., P=0.037, respectively). Higher levels of IDO were fairly associated with higher grade of gastritis score in all patients (r=0.409, P=0.07) but not in the *H. pylori*-infected subgroup (r=-0.262, P=0.46). In gastric biopsy cultures, IDO inhibition significantly ($P<0.05$) increased IL-17 while decreased IL-4 expression, particularly in *H. pylori*-infected compared to uninfected samples.
CONCLUSION: This study demonstrates, for the first time, that an enhanced expression of IDO takes place in *H. pylori*-infected human gastric mucosa. This is capable of downregulating IL-17 and upregulating IL-4 production and, possibly, of favouring the persistence of *H. pylori*. Targeting IDO pathway may be a new strategy for modulating *H. pylori*-induced mucosal immune response.

P1074 EFFECT OF COMMON FUNCTIONAL GENETIC POLYMORPHISMS ON CPG ISLAND METHYLATION IN NON-NEOPLASTIC GASTRIC MUCOSA

T. Tahara[1,*], T. Shibata[1], M. Okubo[1], T. Ishizuka[1], Y. Ichikawa[1], M. Miyata[1], K. Sumi[2], T. Kawamura[2], M. Nakamura[3], M. Nagasaka[1], Y. Nakagawa[1], N. Ohmiya[1], T. Arisawa[3], I. Hirata[1]. [1]*Gastroenterology,* [2]*Fujita Health University School of Medicine, Toyoake,* [3]*Gastroenterology, Kanazawa Medical University, Ishikawa, Japan*

INTRODUCTION: CpG island hyper methylation (CIHM) is also closely associated with *H. pylori* infection, degree of gastritis, suggesting that this epigenetic change seems to be an early step in carcinogenesis in the stomach.
AIMS&METHODS: To evaluate the influence of host genetic factors on methylation related carcinogenesis, we investigated the association between common functional SNPs in pro-inflammatory cytokines, DNA repair and xenobiotic molecules, and pre-miRNAs with DNA methylation status in non-neoplastic gastric mucosa. Eleven candidatete SNPs (IL-1β gene -31T>C and -511C>T, TNF-α-857C>T, XRCC1 Arg399Gln and Arg194Trp, GSTP1 Ile104Val, GSTT1, GSTM1, miR-196a2, miR-146a and miR-499) were determined in 415 cancer free subjects, in relation to four candidate CpG (p14, p16, DAP-kinase and CDH1) loci, assessed by Methylation-Specific-Polymerase Chain Reaction (MSP). CIHM high was defined as two or more CpG islands methylated.
RESULTS: Methylation of all four genes and CIHM high were significantly associated with *Helicobacter pylori* infection. In over all, significant association was found between IL-1β-511 TT, XRCC1 codon 399 Gln/Gln genotypes and DAP-kinase methylation (adjusted OR=0.48, 95%CI=0.29-0.78 and OR=0.30, 95%CI=0.13-0.71, respectively) and CIHM high (OR=0.53, 95%CI=0.32-0.86, and OR=0.42, 95%CI=0.19-0.97, respectively). Also, significant associations were found between miR-196a2 and miR-146a SNPs and methylation of p16 (miR-196a2 rs11614913 CT vs. CC, OR=0.52, 95%CI=0.28-0.99, miR-146a rs2910164 CC vs. GG, OR=0.42, 95%CI=0.22-0.82 and CC vs. GG+GC, OR=0.54, 95%CI=0.33-0.89). When subjects were divided according to age, an association was also found between GSTM1 null genotype and to CIHM high in the 50 years and older generations (OR=1.63, 95%CI=1.01-2.62, p=0.045).
CONCLUSION: Host genetic factors, related to pro-inflammatory cytokines, DNA repair and xenobiotic molecules, and pre-miRNAs may have a role in methylation related gastric carcinogenesis.

P1075 SEQUENTIAL VS. CONCOMITANT THERAPY FOR THE FIRST-LINE HELICOBACTER PYLORI ERADICATION TREATMENT.

P. Apostolopoulos[1], I. Koumoutsos[1], P. Tsibouris[1], P. Dogantzis[1], E. Vlachou[1,*], C. Beltsidou[1], A. Koumi[1], A. Karamoutzos[1], C. Kalantzis[1], P. Mavrogianni[1], G. Alexandrakis[1]. [1]*GASTROENTEROLOGY, NIMTS GENERAL HOSPITAL, Athens, Greece*

INTRODUCTION: Whenever resistance to metronidazole and clarithromycin surpasses 20% triple eradication regimens have a poor effectiveness.
AIMS&METHODS: Aim: A prospective study to compare the efficacy of the first-line pantoprazole-based sequential therapy and concomitant therapy (pantoprazole, amoxicillin, clarithromycin and metronidazole) to eradicate Helicobacter pylori (H. pylori) infection.
METHODS: A total of 63 patients with *H. pylori* positive patients were randomly assigned to either concomitant therapy group (pantoprazole 40mg b.i.d, amoxicillin 1000mg b.i.d, clarithromycin 500mg b.i.d, metronidazole 500mg b.i.d for 10 days, 33 patients, mean age 60±13 years, 19 men, 8 smokers) and sequential therapy group (5-day course with pantoprazole 40mg b.i.d and amoxicillin 1000 mg b.i.d., followed by 5-day course with pantoprazole 40mg b.i.d, clarithromycin 500 mg b.i.d. and metronidazole 500 mg b.i.d, 30 patients, mean age 58±9 years, 18 men, 8 smokers). *H. pylori* eradication was evaluated 4 weeks later by either histology whenever endoscopy was necessary or urea breath test. Stat:X2, t-test.
RESULTS: Intention to teat analysis: 29 (88%) patients successfully eradicated *H. pylori* with concomitant therapy, but only 19 (63%) with sequential therapy (p=0.02). Per protocol analysis: 29 (97%) patients successfully eradicated *H. pylori* with concomitant therapy and 19 (73%) with sequential therapy (p=0.01). 5 (45%) failures in sequential group were due to double antibiotic resistance (metronidazole and clarythromycin) but none in concominant treatment group (p=0.11).
20 (61%) patients in concomitant group and 22 (73%) in sequential group reported any side effect (p=0.28), while 3 (9%) in concomitant group and 2 (7%) in sequential group discontinued treatment due to side effects (p=0.72).
CONCLUSION: First-line pantoprazole-based concomitant therapy seems to be equally well-tolerated but significantly more effective than sequential therapy in terms of *H. pylori* eradication rate.
Disclosure of Interest: None Declared
Keywords: Concomitant therapy, Helicobacter pylori eradication, Sequential therapy

P1076 EFFECT OF THE SUPPLEMENTATION OF A HIGH-DOSE AMOXICILLIN BASED TRIPLE THERAPY WITH FRUCTOOLIGOSACCHARIDES LACOTFERRIN AND BACILLUS COAGULANS IN PATIENTS UNDERGOING H. PYLORI ERADICATION

F. FRANCESCHI[1], A. Tortora[1,*], T. DI RIENZO[1], G. D'ANGELO[1], G. ZUCCALA''[1], G. GASBARRINI[2], A. GASBARRINI[1]. [1]*CATHOLIC UNIVERSITY OF SACRED HEART, Rome,* [2]*FONDAZIONE RICERCA IN MEDICINA, BOLOGNA, Italy*

INTRODUCTION: We have previously demonstrated that increasing the dosage of amoxicillin results in an increased performance of a standard first-line *H. pylori* eradicating triple therapy. Whether the supplementation of a high-dose amoxicillin eradicating regimen with a mix of fructooligosaccharides, lactoferrin and Bacillus coagulans may increase the eradication rate or reduce antibiotic-related side effects has never been studies
AIMS&METHODS: AIM: To compare the efficacy and the occurrence of side effects of a standard first line triple therapy with a high-dose amoxicillin based therapy with or without a mix of fructooligosaccharides, lactoferrin and Bacillus coagulans. METHODS: 90 sex and age matched patients were randomized into 3 different therapeutic schemes (30 patients each): (1) standard LCA, lansoprazole 15 mg bid, clarithromycin 500 mg bid and amoxicillin 1000 mg bid for 7 days; (2) high dose LCA (HD-LCA), lansoprazole 15 mg bid, clarithromycin 500 mg bid and amoxicillin 1000 mg tid for 7 days; (3) high dose LCA plus a mix of fructooligosaccharides, lactoferrin and Bacillus coagulans for 7 days (HD-LCA-mix). Eradication was confirmed by ^{13}C-urea breath test. Occurrence of adverse effects was assessed by a validated questionnaire
RESULTS: Eradication rates were: LCA (53% PP, 50% ITT), HD-LCA (73% PP, 70% ITT), HD-LCA+mix (73% PP; 70% ITT). Eradication rates were significantly higher in HD-LCA and HD-LCA+mix group compared to LCA ($p<0.01$), while no significant differences were observed between HD-LCA and HD-LCA+mix group. Diarrhea, dysgeusia, headache and nausea were the most common side effects recorded by patients. Adding a mix of fructooligosaccharides, lactoferrin and Bacillus coagulans to a HD-LCA therapy resulted in a reduced occurrence of diarrhea (9 of 30 vs 2 of 30; $p<0.019$), and nausea (8 of 30 vs 2 of 30; $p<0.038$)
CONCLUSION: High dose amoxicillin based eradicating treatment is superior to standard triple therapy. The supplementation with a mix of fructooligosaccharides, lactoferrin and Bacillus coagulans does not increase the eradication rate but significantly improves some antibiotic-related side effects

P1077 GELATINE TANNATE SUPPLEMENTATION REDUCES ANTIBIOTICS ASSOCIATED SIDE-EFFECTS OF ANTI-HELICOBACTER PYLORI FIRST-LINE THERAPY

G. Gigante[1,*], G. Caracciolo[1], M. Campanale[1], V. Cesario[1], V. Bove[1], G. Ianiro[1], V. Ojetti[1], G. Cammarota[1], G. Gasbarrini[2], A. Gasbarrini[1]. [1]*Internal Medicine and Gastroenterology, Catholic University - Gemelli Hospital, Rome,* [2]*Fondazione Italiana Ricerca in Medicina, Bologna, Italy*

INTRODUCTION: Therapeutic schemes to eradicate Helicobacter pylori infection are based on the association of antibiotics and a proton pump inhibitor. Gastrointestinal side-effects during antibiotic therapy include diarrhea, nausea, taste distortion, stomatitis and bloating, and are major determinants for a lack of compliance, so to determine a failure to eradicate *H. pylori*. Gelatine tannate is a powder composed by a proteic portion, the gelatin, and a sequestrant, the tannic acid. It provides a mechanical protection to intestinal mucosa when becomes jelly-form in the small intestine, forming a protective film. It has been shown to be efficacious in treating acute diarrhea in infant. No information exists about its role in cure or prevent diarrhea in adults.
AIMS&METHODS: Aim: To explore whether Gelatine Tannate 500mg t.d supplementation is efficacious in preventing diarrhea and GI side effects related to anti-H. pylori standard first line eradication therapy with esomeprazole 20 mg b.d., clarithromycin 500 mg b.d. and amoxicillin 1 g b.d.
Methods: Forty (23F/17M, mean age 40±15) *H. pylori*-positive consecutive patients were enrolled to receive standard triple therapy with Gelatine Tannate for 14 days (Gelatine Tannate group, GTg). Each patient was required to complete a validated daily diary for 4 weeks, starting from the first day of the eradicating treatment. The diary was assessing onset, intensity and frequency of gastrointestinal side-effects. *H. pylori* status and side effects were assessed 6 weeks after treatment. We referred to our previous published study (Nista, 2004), as a control population (CT).
RESULTS: All patients completed Hp eradication therapy. Occurrence of nausea was 10 % in GTg at 1 week, way lower compared to 50 % of CT. At 2 weeks, incidence of nausea was respectively 5% in GTg and 30% in CT. Patients experienced diarrhea only in 5% at 1 week and 2,5% at 2 weeks in GTg compared to 30% and 10 % of CT. The incidence of epigastric pain, vomiting, constipation and skin rash were absent in GTg, as well as in CT. *H. pylori* eradication rate was similar (75 % eradication rate) between GTg and CP.
CONCLUSION: We report the efficacy of Gelatine Tannate in preventing *H. pylori* eradication therapy induced GI side effects. Although it is a non controlled and open label trial it can be argued that effects of gelatin tannate in preventing nausea and diarrhea are real. Data suggest that the efficacy of gelatin tannete is particularly visible in the first week of treatment while antibiotics are co-administered and the higher incidence of side-effects is usually registered.

Orsola-Malpighi Hospital, University of Bologna, Italy,* [4]*1Dept. of Internal Medicine and Gastroenterology, S. Orsola-Malpighi Hospital, University of Bologna, Bologna,* [5]*3Gastroenterology Unit, University of Brescia, Brescia,* [6]*Gastroenterology and Digestive Endoscopy Unit, Versilia Hospital, Lido di Camaiore,* [7]*Department of Gastroenterology and Digestive Endoscopy, ''Nuovo Regina Margherita'' Hospital, Rome,* [8]*Dept. of Internal Medicine and Gastroenterology, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy*

INTRODUCTION: Background: Sequential therapy was able to achieve remarkable results also in patients harbouring strains resistant to clarithromycin.
AIMS&METHODS: Objective: To assess the efficacy of Sequential therapy in eradicating never been treated *Helicobacter pylori* patients with multi-resistant strains, prospectively. **Methods:** Between 2010 and 2013, consecutive patients undergoing upper endoscopy were evaluated. Each patient had a ^{13}C-UBT, and during endoscopy 2 biopsies each from the antrum, angulus, and corpus were obtained to perform histology. Further biopsies from antrum were also taken for ultrafast urease test and to carry out culture and antimicrobial sensitivity performed by Epsilometer test (Etest). According to new EUCAST 2012 the following MIC breakpoints were used to evaluate resistance :> 0.5,>8 and 1 microgram/ml for clarithromycin, metronidazole and levofloxacin, respectively. Patients were considered infected if culture alone or histology and ultrafast urease test were positive. All received standard Sequential therapy. Four to 6 weeks after the end of the treatment, eradication was assessed by ^{13}C-UBT.
RESULTS: Results: Up to date, 717 naïve consecutive *Helicobacter pylori* infected patients were enrolled. Follow up are now available in 696 out of 717; eradication rate was achieved in 664 out of 696 (95.4%; 95% CI: 93.8-97). Eradication rates according to antibiotic resistance pattern were provided in the Table.

Resistance	Total cases	Cases controlled	Eradication rate (%)
Cla	196	189	89.5
Metro	207	199	93
Levo	149	145	94
Cla + Metro	109	105	86.6
Cla + Levo	79	75	89.3
Metro + Levo	93	90	93.3
Cla + Metro + Levo	60	57	89

CONCLUSION: Conclusions: Sequential therapy is able to overcome the problem of multi-resistant strains in a large proportion of patients. Sequential therapy may be the optimal treatment for patients suspected of having multi-drug resistant strains.

P1079 ERADICATION RATES OF HELICOBACTER PYLORI INFECTION FOR STOMACH CANCER PATIENTS WHO UNDERGO SUBTOTAL GASTRECTOMY

K. K. Kang[1,*], D. H. Lee[1], D. H. Oh[1], N. Kim[1], Y. S. Park[1], C. M. Shin[1], H. Yoon[1]. [1]*Internal medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

INTRODUCTION: The eradication rate of *Helicobacter pylori* with standard triple treatment showed to decrease worldwide. So, many authors are introducing various regimens. We investigated the eradication rate and trend of it using standard triple regimen as first-line anti-*Helicobacter pylori* treatment on patients who were experienced subtotal gastrectomy for adenocarcinoma. Also, we looked into efficacy of bismuth containing quadruple regimen as rescue therapy.
AIMS&METHODS: From January 2004 to December 2010, a total of 430 patients with *H. pylori* infection after receiving subtotal gastrectomy for adenocarcinoma were treated with 7days-standard triple therapy (amoxicillin 1000mg b.i.d, clarithromycin 500mg b.i.d, esomeprazole 20mg b.i.d). We retrospectively analyzed overall eradication rate and trend of it using ITT(Intention To Treatment) and PP(Per-Protocol). As same way, we assayed efficacy of 10days-bismuth containing quadruple treatment(tripotassium dicitrato bismuth 300mg q.i.d, tetracyclin 500mg q.i.d, metronidazole 500mg t.i.d, esomeprazole 20mg b.i.d) as rescue therapy.
RESULTS: The overall eradication rates were 81.0%(95% CI, 77.2-84.3) and 88.3%(95% CI, 85.0-91.0) by ITT and PP. The annual eradication rate from year 2004 to 2010 were 89.4%, 95.4%, 85.2%, 89.7%, 85.5%, 86.5% and 87.3% by PP. There was no decreasing tendency and no statistical significant of the eradication rate(p=0.588). Twenty-eight patients treated with bismuth containing quadruple therapy as rescue regimen, only two of them were failed. PP was 92.8%(95% CI 77.3-98.0).
CONCLUSION: The postoperative eradication rate of *H.pylori* infection using standard triple therapy did not show satisfied result. But it had higher rate than it of other eradicated indications not having operation in Korea. And bismuth containing quadruple treatment after failure of first line therapy had high efficacy.

P1080 COMPARISON WITH ERADICATION RATES OF MOXIFLOXACIN CONTAINING TRIPLE THERAPY AS SECOND LINE TREATMENT FOR HELICOBACTER PYLORI INFECTION ACCORDING TO FIRST LINE REGIMEN

K. K. Kang[1,*], D. H. Lee[1], D. H. Oh[1], N. Kim[1], Y. S. Park[1], C. M. Shin[1], H. Yoon[1]. [1]*Internal medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

INTRODUCTION: There was a controversy the efficacy of eradication with moxifloxacin based triple therapy as second line treatment for *Helicobacter pylori* infection. And most of published papers focused on patients failed to treat with standard triple therapy. So, we investigated the efficacy of moxifloxacin as second line therapy and the eradication rates of that according to previous first-line regimen.
AIMS&METHODS: A total of 298 patients who were failed to eradicate with first line treatment received 14 days moxifloxacin containing triple therapy (moxifloxacin 400mg q.d, amoxicillin 1000mg b.i.d, rabeprazole 20mg b.i.d). As first line treatment, they were prescribed 7day-standard triple therapy (n=184), 7day-bisthmus containing quadruple therapy (n=29), 7day-concomitant therapy (n=39) and 14day-sequential therapy (n=46). Primary outcome was the eradication rate by intention-to treat (ITT) and per-protocol (PP) analysis
RESULTS: The eradication rate of moxifloxacin based triple therapy was 61.7%(95% CI 56.1-67.0) by ITT, and 73.6%(95% CI 67.8-78.6) by PP. ITT and PT according to first regimen were 63.5/77.0%(95% CI 56.4-70.2/69.6-82.9) in standard triple group, 62/69.2%(95% CI 44.0-77.3/50.0-83.5) in bisthmus containing quadruple group, 56.4/66.7%(95% CI 40.9-70.7/49.6-80.2) in concomitant group and 58.6/69.2%(95% CI 44.3-71.7/53.5-81.4) in sequential group. There was no significant difference between groups (p=0.504).
CONCLUSION: Two-week moxifloxacin based triple therapy as second line did not show expected level for the primary outcome. The group treated with moxifloxacin after failure of standard triple therapy had highest rate of eradication, but there was no statistical significance in the efficacy among the first line regimens.

P1081 THE TREND OF ERADICATION RATE OF FIRST-LINE THE TREND IN THE ERADICATION RATES OF FIRST-LINE THERAPY FOR HELICOBACTER PYLORI INFECTION AND RISK FACTORS OF ERADICATION THERAPY

S. E. Kim[1,*], M. I. Park[1], S. J. Park[1], W. Moon[1], Y. J. Choi[1], J. H. Cheon[1], H. J. Kwon[1], K. H. Ku[1], C. H. Yoo[1]. [1]*Internal Medicine, Kosin University College of Medicine, Busan, Korea, Republic Of*

INTRODUCTION: The standard triple therapy which was combined with proton pump inhibitor (PPI), amoxicillin and clarithromycin was widely used for *Helicobacter pylori* (*H. pylori*) infection in Korea. However, the recent trend of the eradication rates in *H. pylori* using first-line triple therapy has been infrequently reported.
AIMS&METHODS: The aims of this study were to evaluate the trend of the *H. pylori* eradication rates in single center during recent six years and to identify the risk factors relating the failure of eradication therapy. From January 2007 to December 2012, *H. pylori* eradication rates in 1168 patients who diagnosed with *H. pylori* infection and received 7 days triple therapy were investigated according to years, demographic and clinical factors retrospectively. *H. pylori* eradication was confirmed by ^{13}C-urea breath test, rapid urease test or histopathological examination at least 4 weeks after the completion of triple therapy.
RESULTS: The overall *H. pylori* eradication rate was 84.5%. The annual eradication rates from the year 2007 to 2012 were 91.9%, 89.1%, 85.5%, 84.3%, 84.5% and 79.0% consecutively by per-protocol analysis. The eradication rate in first-line triple therapy was decreased during the recent six years ($p = 0.024$). Multivariate analysis showed that female (OR 1.55; 95% CI 1.02-2.36) and smoking (OR 1.60; 95% CI 1.03-2.48) were associated with the failure of *H. pylori* eradication therapy.
CONCLUSION: The effect of first-line triple therapy for *H. pylori* infection has decreased during recent six years, which suggests that the antibiotic resistant *H. pylori* has increased against the therapy based on the combination of PPI, amoxicillin and clarithromycin. Therefore, other variable first-line therapies might be considered for *H. pylori* eradication in the near future.

P1082 HIGH RATES OF MULTI-DRUG RESISTANT STRAINS IN PATIENTS WHO HAVE NEVER BEEN TREATED FOR H PYLORI

V. Castelli[1,*], N. Vakil[2], G. Fiorini[1], I. Saracino[1], C. Zaccaro[1], C. Ricci[3], A. Zullo[4], V. Dino[1]. [1]*Department of Clinical Medicine, University of Bologna, Italy, Bologna, Italy,* [2]*University of Wisconsin, School of Medicine & Public Health, Madison, USA, University of Wisconsin, School of Medicine & Public Health, Madison, USA, Madison, United States,* [3]*Gastroenterology Unit, University of Brescia, Brescia,* [4]*Department of Gastroenterology and Digestive Endoscopy, "Nuovo Regina Margherita" Hospital, Rome, Italy., Rome, Italy*

INTRODUCTION: Antibiotic resistant strains of *H. pylori* have been increasing worldwide, and it has been speculated that this may account for progressive decrease in eradication rates reported in the literature.
AIMS&METHODS: Aim: to assess the prevalence of resistant strains to metronidazole, clarithromycin, and levofloxacin in a cohort of naïve patients performing an EGDS for dyspeptic symptoms in Italy.
Methods: 915 *H.pylori* infected patients who had never been treated for H pylori (Male: 39%; median age: 51 years; IQR: 40 and 62 years) underwent upper endoscopy and a biopsy sample was also obtained to perform culture and an *in vitro* antimicrobial susceptibility testing. According to new EUCAST 2012, susceptibility testing was performed by epsilometer test (Etest) and the following MIC breakpoints were used: resistance to clarithromycin (>0.5 microgram/ml); resistance to metronidazole (>8 microgram/ml), and resistance to levofloxacin (> 1 microgram/ml).
RESULTS: Data on resistance were available for 855 out of 915 (93%) patients. Resistance to metronidazole was found in 33%; to clarithromycin in 30%; and to levofloxacin in 21% of the strains. Double resistance to clarithromycin + metronidazole was found in 18%; to clarithromycin + levofloxacin in 11%; and to metronidazole + levofloxacin in 13% whilst 9% of the strains were resistant to metronidazole + clarithromycin + levofloxacin. Considering resistance to a single antibiotic, resistance to metronidazole was more likely to occur in women than men (OR: 2.8; 95% CI: 2.1 to 3.9); considering the double resistance, women were also more likely to have

resistance to both clarithromycin + metronidazole than men (OR: 2.6; 95% CI: 1.7 to 4.0).

Resistance	%
ClaR	30
MetroR	33
LevoR	21
ClaR + MetroR	18
ClaR + LevoR	11
MetroR + LevoR	13
ClaR + MetroR + LevoR	9

CONCLUSION: 1. Single and multiple-drug resistant strains are becoming widely prevalent in patients who have never been treated for H pylori. 2. Initial treatment for H pylori needs to account for these changes- failure rates for clarithromycin triple therapy will increase further 3. Levofloxacin based triple therapies are unlikely to represent an alternative front-line therapy as the resistance rates are already quite high.

P1083 RISK OF ADVERSE PREGNANCY OUTCOMES AMONG WOMEN WITH COELIAC DISEASE OR DERMATITIS HERPETIFORMIS COMPARED TO THE GENERAL POPULATION: A POPULATION BASED CASE-CONTROL STUDY

A. Abdul Sultan[1,*], L. J. Tata[1], K. Fleming[1], C. Crooks[1], T. Card[1], J. West[1].
[1]*Division of epidemiology and public health, University of Nottingham, Nottingham, United Kingdom*

INTRODUCTION: Knowledge about the adverse birth outcome and pregnancy related complications are crucial when counselling pregnant women with coeliac disease (CD) and dermatitis herpetiformis (DH). Limited population based data exist that have determined the association between CD, DH, pregnancy related complications and birth outcomes.
AIMS&METHODS: We calculated the proportion of pregnancies in women with and without CD or DH between 1997 and 2010 throughout England using linked primary care data from the Clinical Practice Research Datalink (CPRD) and secondary care Hospital Episode Statistics (HES) data. Risk of pregnancy related complications (postpartum haemorrhage, pre-eclampsia and emergency caesarean section) and adverse birth outcomes (pre-term birth, stillbirth and low birth weight) in pregnancies in women with CD or DH were compared to risks in pregnancies in women without either condition in terms of odds ratios (OR) using logistic regression model.
RESULTS: Of 245,969 singleton pregnancies resulting in live or stillbirths, 388 (0.16%) were among women with CD/DH. Overall all pregnant women with CD/DH were 31% (Table 1; OR=1.3 95%CI 1.03-1.67) more likely to develop pregnancy related complications (eclampsia/pre-eclampsia, postpartum haemorrhage or undergone emergency caesarean section). Finally women with CD/DH appeared to be at 14% higher risk of developing adverse birth outcome (stillbirth, low birth weight or preterm birth) however our result was not statistically significant (OR=1.14 95%CI 0.81-1.61) at the 5% level.
Table 1: Pregnancy related complication and adverse birth outcome in women with CD/DH

Variable	Controls (Total=246,581)		Cases (Total=388)		OR (95%CI) (Adjusted)*
	No.	%	No.	%	
Any one pregnancy related complication	55,087	22.5	106	27.5	1.31 (1.03-1.67)
Emergency Caesarean	35,108	14.2	67	17.3	1.38 (1.02-1.87)
Postpartum haemorrhage	22,858	9.3	48	12.4	1.36 (1.00-1.86)
Pre-eclampsia/eclampsia	5,735	2.3	12	3.1	1.43 (0.76-2.67)
Any one adverse birth outcome[1]	23,521	9.5	42	10.8	1.14 (0.81-1.61)

*Adjusted for age, body mass index and cigarette smoking
[1]Includes pregnancy of women resulting in low birth weight, stillbirth or pre-term birth

CONCLUSION: We have shown significantly increased relative risk of pregnancy related complications but not adverse birth outcome. The absolute differences are however small indicating that most women with CD/DH do not have a big excess risk. Though this association may well not be causal we believe that our study provides new evidence that will aid clinicians to better counsel pregnant women with CD/DH.

P1084 CAN NARROW BAND IMAGING PREDICTDUODENAL HISTOLOGY IN CELIAC DISEASE? A PROSPECTIVE DOUBLE BLIND PILOT STUDY

S. K. Sinha[1,*], J. Basha[1], S. Appasani[1], K. Vaiphei[2], K. Singh[1], R. Kochhar[1].
[1]*Gastroenterology,* [2]*Pathology, PGIMER, Chandigarh, India*

INTRODUCTION: Celiac disease(CD) is characterized by varying degrees of villous atrophy. Image enhancement with narrow band imaging(NBI) delineates villous patterns better than routine endoscopy. Role of NBI in delineating villous morphology ofCD is sparsely reported.
AIMS&METHODS: Aim: To compare the diagnostic accuracy of NBIwith histopathologyin predicting the duodenal villous morphology in CD.
Methods: Amongst the 50subjects(mean age-28.17±12.7 years, 29-females)included in the study, 34 were suspectedto have CD(serology positive), 4 were follow up patients ofCDon gluten free diet and 12had dyspepsia with no evidence of CDon complete evaluation. CD was diagnosed on the basis of modified ESPGHAN criteria. They underwentesophagogastroduodenoscopy(EGD) along with NBI using an Olympus GIF-180 gastroscope to evaluate the villous pattern of duodenal mucosa. These images were digitally recorded for further characterization. Four duodenal biopsies were taken from second part of duodenum for histopathology. Digitally recorded images were analyzed by twoexperienced endoscopists and biopsy specimen by an experienced pathologist all of whom were blinded to clinical details and serological investigations. Villous patterns on NBI were classified into Normal-villous pattern(NVP), Distorted&blunted-villous pattern(DVP)and Absent-villous pattern(AVP). NBI findings were correlated with histopathology.
RESULTS: NBI in total study population revealed AVP in 14, DVP in 13 and NVP in 23 patients. In CD, EGD revealed grooving pattern in 94.1% patients, scalloping in 82.3% and decreased fold height in 52.9%. In this study group(CD, n=34) 14 had AVP,13 had DVP and 7 had NVP on NBI, while on histopathology 11 had total villous atrophy, 11 had partial villous atrophy and 12 had no villous atrophy. CD patients on gluten free diet(n=4) and the 12 dyspepsia patients(control group) had normal villous pattern on both NBI and histopathology. Significant correlation was observed between NBI and histopathological examination($p<0.001$). The overall sensitivity and specificity of NBI for delineating villous pattern were 100% and 82.1% and the positive and negative predictive values were 81.4% &100% respectively.
CONCLUSION: NBI can predict villous atrophy with high sensitivity and negative predictive value in CD.

P1085 SCREENING FOR COELIAC DISEASE IN WOMEN WITH PRETERM CHILDBIRTH.

L. Petrarca[1,*], R. Nenna[1], R. Ferro[1], P. Favata[1], F. Lucantoni[1], M. Mennini[1], S. Ciccarelli[1], M. Florio[1], M. G. Pattumelli[1], G. Mastrogiorgio[1], M. Bavastrelli[1], M. Bonamico[1]. [1]*Department of Paediatrics,* "*SAPIENZA*" *UNIVERSITY OF ROME, Rome, Italy*

INTRODUCTION: Coeliac disease (CD) is a chronic, immuno-mediated entheropathy caused by ingestion of gluten in genetically predisposed individuals. It may present with a variety of symptoms (such as diarrhea, weight loss, iron deficient anemia, etc…) or completely silent. The association between CD and pregnancy outcome has been investigated, with contrasting results.
AIMS&METHODS: Our aim was to screen for CD women with preterm childbirth or low birth weight. In our prospective study, we performed a CD screening in a group of women with preterm childbirth (defined as <37 weeks of gestational age) or with low birth weight (< 2500 gr), using RIA IgA anti-transglutaminase antibodies (tTGAb). Positive patients were referred to our Operative Unit on Coeliac disease, where they were submitted to a further serological evaluation. Confirmed positive patients were submitted to upper gastrointestinal endoscopy with multiple duodenal biopsies, and if diagnosed to be celiac, started the gluten-free diet (GFD).
RESULTS: A total of 75 women (age range: 19-49 years) participated in the study. Four (5.3%) women resulted tTGAb positive (age range: 20-31 years, gestational age range: 31weeks+6 days- 35weeks+ 6 days, birth weight range: 1650-2720 gr). The four women were all primiparae but one, who already had a preterm child. All the patients were confirmed at the second serum sample. One of these women performed upper endoscopy with duodenal biopsies, showing subtotal villous atrophy (3b sec. Marsh modified by Oberhuber) and started the GFD. The other three women are still under evaluation, waiting to perform the upper endoscopy.
CONCLUSION: Our study demonstrates that CD prevalence is higher in women with preterm childbirth or low birth weight rather than in the Italian population. Screening for CD could be advisable as part of the diagnostic flow-chart in these patients. In fact, a timely diagnosis and the prompt GFD, in otherwise asymptomatic patients, could improve the pregnancy outcome.

P1086 INCREASED OSTEOPROTEGERIN AND DECREASED COOH-TERMINAL PROPEPTIDE OF TYPE I PROCOLLAGEN SELECT CELIAC DISEASE PATIENTS ON LONG-TERM GLUTEN-FREE DIET WITH PERSISTING LOW BONE MASS

M. DI STEFANO[1], C. MENGOLI[1], O. TOMARCHIO[2], M. BERGONZI[1,*], E. PAGANI[1], M. DE AMICI[3], D. ILARDO[2], C. VATTIATO[1], F. BIAGI[1], A. ZANABONI[1], G. R. CORAZZA[1]. [1]*1st Medical Department, IRCCS S Matteo Hospital Foundation,* [2]*Department of Radiology, "S. Maugeri" Foundation,* [3]*Department of Paediatrics, IRCCS S Matteo Hospital Foundation, Pavia, Italy*

INTRODUCTION: Bone mass and mineral metabolism alterations are very frequent in untreated celiac disease (CD) but also the persistence of bone loss after long-term gluten-free. It was demonstrated that a high rate of osteosynthetic activity before treatment is predictive of the recovery of bone mass after two years of dietary treatment (1), but we have no information about the long-term predictivity of pretreatment bone metabolism indices. It was recently shown that mucosal immunity activation causes the production of circulating factors which stimulate osteoclastogenesis, through the RANKL/RANK/osteoprotegerin (OPG) pathway (2).
AIMS&METHODS: The aim of this study was to evaluate the role of inflammatory, hormonal and lifestyle factors in the pathogenesis of the persisting bone derangement in CD patients on long-term GFD.
Sixteen asymptomatic CD female patients (range 27-43 yrs) diagnosed in adult life, with a long period of GFD (> 8yrs) were enrolled. All patients showed a strict adherence to GFD and no-one was in menopausal or perimenopausal period. In all patients, lumbar and femoral BMD was measured by DEXXA and BMI was calculated. Circulating serum calcium, phosphate, PTH, OPG, RANKL, 1,25 OH vitamin D, 25 OH vitamin D, Il-1, IL-6, and TNF-alfa, COOH-terminal telopeptide of type I collagen (ICTP), COOH-terminal propeptide of type I procollagen (PICP) level were evaluated. Validated questionnaires for sunlight exposure and physical exercise were administered.
RESULTS: Eight out of 16 patients showed a pathological reduction in bone density. In comparison with the subgroup of patients with normal BMD, patients with low bone mass showed a lower BMI (19.9 ± 1.14vs22.8 ± 2.95 kg/m^2, $P<0.05$); no difference in age, age at diagnosis, duration of GFD, serum levels of cytokines and hormonal factors was found. On the contrary, femoral T score was significantly and indirectly correlated with OPG and significantly and directly correlated with PICP ($P<0.05$ for both). Finally, no difference was evident in physical activity or sunlight exposure score.
CONCLUSION: High levels of OPG and low levels of PICP select the subgroup of CD patients with a persistent reduction of bone mass, despite strict adherence to GFD and architectural villi reconstitution. These markers might be used to identify those patients who need a a mineralo-active treatment associated to gluten-free diet.

P1087 FRAX SCORE CORRELATES WITH THE ACTIVATION OF LOCAL FACTORS IN ADULT PATIENTS WITH CELIAC DISEASE IN GLUTEN-FREE DIET

M. DI STEFANO[1], M. BERGONZI[1,*], O. TOMARCHIO[2], C. MENGOLI[1], E. PAGANI[1], M. DE AMICI[3], D. ILARDO[2], C. VATTIATO[1], F. BIAGI[1], E. MICELI[1], A. ZANABONI[1], G. R. CORAZZA[1]. [1]*1st Medical Department, IRCCS S Matteo Hospital Foundation,* [2]*Department of Radiology, "S. Maugeri" Foundation,* [3]*Department of Paediatrics, IRCCS S Matteo Hospital Foundation, Pavia, Italy*

INTRODUCTION: Celiac disease (CD) is frequently associated with bone mass and mineral metabolism alterations, often persisting besides a strict adherence to long term GFD. The incidence of fractures in CD is an incompletely clarified issue. FRAX score is a validated tool to estimate the risk of fracture in the general population.
AIMS&METHODS: Accordingly, in a group of celiac patients we calculated the FRAX score and correlated it to circulating levels of indices of bone and mineral metabolism.
28 asymptomatic CD female patients (range 18-43 yrs) with a long history of GFD (> 8yrs) were enrolled. Diagnosis was made in adult life, none of the patiens was in menopausal and perimenopausal period. All patients showed strict adherence to GFD. Lumbar and femoral BMD was measured by DEXXA. Circulating serum calcium, phosphate, PTH, OPG, RANKL, 1,25 OH vitamin D, 25 OH vitamin D, IL-1, IL-6, and TNF-alfa level were evaluated. The OPG/RANKL ratio was computed, as a marker of bone turnover. The FRAX score, a web-based clinical scale (http://www.shef.ac.uk/FRAX/) assessing the 10-year fracture risk, was evaluated.
RESULTS: All patients but one, showing a moderate risk, were classified by FRAX score as a low risk of fracture at 10 yrs. Nine out of 28 patients showed a pathological reduction in bone density. The FRAX score proved to be significantly correlated with OPG/RANKL ratio ($r=0.7$, $p<0.01$) and with serum TNFalfa levels ($r=0.6$, $p<0.05$).
CONCLUSION: OPG/RANKL ratio could be considered an accurate biomarker of fracture risk and could be used in the follow up of CD patient.

P1088 HIGHER NUMBER OF ENTEROCHROMAFFIN CELLS IN REFRACTORY COELIAC DISEASE

A. Di Sabatino[1,*], P. Giuffrida[1], P. Biancheri[1], A. Vanoli[2], O. Luinetti[2], R. Manca[2], G. Bergamaschi[1], C. Alvisi[1], A. Pasini[1], C. Salvatore[1], F. Biagi[1], E. Solcia[2], G. R. Corazza[1]. [1]*Department of Internal Medicine,* [2]*Department of Molecular Medicine, Fondazione IRCCS Policlinico S. Matteo, University of Pavia, Pavia, Italy*

INTRODUCTION: In the gut serotonin-producing enterochromaffin (EC) cells are the prevalent neuroendocrine cell type, almost of all of which are characterised by the expression of the pan-neuroendocrine marker chromogranin A (CgA). Several immune-mediated gastrointestinal disorders, including coeliac disease (CD), are associated with EC cell hyperplasia. However, neither number nor function of EC cells have been ever explored in refractory CD type 1 (RCD1) and type 2 (RCD2).
AIMS&METHODS: Seriate duodenal sections from 17 refractory CD patients (6 RCD1, 11 RCD2), 16 uncomplicated CD patients before and after gluten-free diet (GFD), and 16 control subjects (CS) were processed for the immunohistochemical detection of neuroendocrine markers CgA, serotonin and somatostatin. Mucosal tryptophan hydroxylase (TpH)-1 and serotonin-selective reuptake transporter (SERT) transcripts were measured by quantitative RT-PCR. Serum CgA and 24-h urine 5-hydroxyindoleacetic acid (5-HIAA) were also measured. Uncomplicated treated CD biopsies were cultured with serotonin or peptic tryptic digest of gliadin (PT-gliadin), and interferon (IFN)-γ was detected by ELISA in culture supernatants.
RESULTS: Both CgA-positive cells and EC cells, counted per 100 crypt cells, were significantly increased in RCD1 and RCD2 patients compared to uncomplicated CD patients before and after GFD and CS, with no difference between RCD1 and RCD2, whereas no change was found for somatostatin-positive cells amongst all groups. Raised transcripts of mucosal TpH-1, but not SERT, were found in RCD1 and RCD2 patients. Serotonin up-regulated the *ex vivo* production of IFN-γ at levels comparable to those of PT-gliadin. Serum CgA, but not urine 5-HIAA, was increased in RCD1 and RCD2 patients.
CONCLUSION: EC cells are increased in refractory CD mucosa. The up-regulation of IFN-γ induced *ex vivo* by serotonin suggests that this monoamine may have a role in sustaining the local inflammatory response in CD.

P1089 PREDICTIVE VALUE OF "MARSH 1" TYPE HISTOLOGY IN SUBJECTS WITH SUSPECTED COEALIC DISEASE

R. Tortora[1,*], P. Capone[1], G. D. De Palma[1], N. Imperatore[1], G. De Stefano[1], S. Tafuto[1], N. Gerbino[1], M. Leo[1], N. Caporaso[1], A. Rispo[1]. [1]*Clinical Medicine and Surgery, University Federico II of Naples, Naples, Italy*

INTRODUCTION: The diagnosis of celiac disease (CD) is based on duodenal histology in combination with anti-tissue transglutaminase (aTG) and anti-endomysial antibodies (EMA). The sole increase of intraepithelial lymphocytes (IELs) defines the Marsh 1 type on histology. However, even if it is thought that Marsh 1 characterises the early phase of CD, it appears to be not specific for CD.
AIMS&METHODS: to explore the positive predictive value (PPV) and the clinical relevance of Marsh 1 type histology in subjects with suspected CD.
METHODS: From September 2011 to March 2013 we performed a prospective study evaluating the predictive value of Marsh 1 (IELs > 40) in diagnosing potential CD in all consecutive subjects referred to our third-level centre. All participants were tested for aTG, EMA and HLA DQ2/DQ8. Diagnosis of potential CD was defined in presence Marsh 1 histology associated with both aTG IgA > 7 U/ml and positive EMA. Furthermore, all patients were investigated for abdominal symptoms, CD familial aggregation, thyroid/intestinal/rheumatological diseases and drug assumption. Statistical analysis was performed by using X^2 and Mann-Whitney U test when indicated.
RESULTS: The study included 42 patients with Marsh 1. Final diagnosis of potential CD was made in 14 subjects (33%), so that Marsh 1 showed a PPV of 33%; all these patients were HLA DQ2/DQ8 positive. The remaining 28 patients (67%) were negative for celiac serology; 12 subjects (42,8%) were DQ2/DQ8 positive. About familial aggregation, patients with potential CD showed a higher frequency of familiarity (71,4% *vs* 14,8% ; $p< 0.01$). When comparing the CD patients to the other group, no significant difference was seen about symptoms (anaemia 14,2% *vs* 14,8% ; p=ns; abdominal pain 28,5% *vs* 25,9% ; p=ns; weight loss 14,3% *vs* 11,1% ; p=ns; bloating 21,42% *vs* 18,52% ; p=ns). Moreover, we defined the presence of diagnoses other than CD in the remaining population: 5 patients (17,86%) showed immune-mediated diseases including Hashimoto's thyroiditis (n=4 ; 14,28%) and ankylosing spondylitis (n=1 ; 3,6%); 4 patients (14,28%) were infected by Helicobacter pylori. About drug assumption, 2 patients (7,14%) were on NSAIDs while other 3 (10,71%) were treated with antihypertensive, anti-hyperglycemic and anti-arrhythmic drugs, respectively.
CONCLUSION: The Marsh 1 type at histology is not specific for CD, especially when not correlated with serologic panel and familial aggregation. Increased IELs can also be associated with the presence of autoimmune disorders, Helicobacter pylori infection and NSAIDs assumption.

P1090 METABOLIC SYNDROME IN COELIAC DISEASE: EFFECT OF THE GLUTEN-FREE DIET

R. Tortora[1,*], P. Capone[1], G. De Stefano[1], N. Imperatore[1], G. D. De Palma[1], N. Gerbino[1], M. Leo[1], S. Tafuto[1], N. Caporaso[1], A. Rispo[1]. [1]*Clinical Medicine and Surgery, University Federico II of Naples, Naples, Italy*

INTRODUCTION: Several studies have shown that weight changes are common in coeliac patients after the adoption of a gluten-free diet (GFD). However data on the prevalence of metabolic syndrome (MS) in patients with coeliac disease (CD) on free diet and after GFD are still scarce.
AIMS&METHODS: Aim of our study was to evaluate the prevalence of MS in patients with CD at time of diagnosis and 1 year after starting GFD. Between January 2012 and April 2013, we enrolled all consecutive patients with newly diagnosed CD who were referred to our third-level CD Unit. All patients were investigated about waist circumference with BMI, blood pressure, lipid profile (HDL cholesterol, triglycerides) and levels of glucose. MS diagnosis was made according to International Diabetes Federation criteria for European countries. The prevalence of MS and the features of its sub-categories were revaluated after 12 months of GFD. Statistical analysis was performed by using X^2, Mann-Whitney U test and Wilcoxon signed-rank test for SPSS when indicated. The differences were considered significant with a $p < 0.05$.
RESULTS: Finally, 70 CD patients (22 men, 48 women; mean age: 36.5 years) were analysed at diagnosis and after 1 year of GFD. At diagnosis, only 1 CD patient (1.4%) fulfilled the criteria for MS while 22 patients (31.4%) met the diagnostic criteria of MS after 12 months of GFD ($p < 0.01$). According to MS criteria, 18 patients had an increase of BMI class (25.7%), 19 patients exceeded waist circumference cut-off (27.1%), 11 patients showed high values of blood pressure (15.7%), 13 patients had reduced levels of HDL cholesterol (18.6%), 15 patients exceeded glycemic threshold (21.4%), and 8 patients had high levels of triglycerides (11.4%); all these differences were statistically significant ($p < 0.01$) when compared to the pre-GFD status.
CONCLUSION: CD patients on gluten-free diet are at risk of metabolic syndrome. We suggest a deep nutritional assessment at diagnosis and during the follow-up of patients affect by coeliac disease.

P1091 THERAPEUTIC RESPONSE IN BILE ACID DIARRHOEA – A TWO CENTRE EXPERIENCE IN THE UK

A. Dhaliwal[1,*], S. Chambers[1], C. Nwokolo[1], N. Williams[1], J. Cullis[1], M. Smith[2], P. Basumani[2], K. D. Bardhan[2], R. Arasaradnam[1]. [1]*UNIVERSITY HOSPITALS OF COVENTRY AND WARWICKSHIRE NHS TRUST, Coventry,* [2]*Rotherham General Hospital NHS Trust, Rotherham, United Kingdom*

INTRODUCTION: Bile acid diarrhoea (BAD) is a common cause of chronic diarrhoea, currently diagnosed using Se^{75}-homo-chloro-tauric-acid (Se^{75}HCAT) testing, the ''gold standard'' in the UK and available to centres which support a gamma camera. Although the test has been available for over two decades, uptake has been slow despite its diagnostic value and evidence that treatment with sequestrants can be effective. This stems from a lack of formal clinical trials, which encourages a belief the good results reported may reflect patient selection, resulting in therapeutic nihilism. Thus the aim of this study was to compare treatment results between two centres: experienced (α), using data reported earlier, and novice (β), with current data.
AIMS&METHODS: The patients recruited comprised those with structural disease (e.g. ileal resection, cholecystectomy), and non-structural, the majority with diarrhoea-predominant irritable bowel syndrome (D-IBS). Abnormal Se^{75}HCAT results were defined as $<10\%$ retention on Day-7. Response to treatment: 1st line (cholestyramine, colestid, colesitpol) or 2nd line (colesevelam) was recorded in three categories: good, partial or poor.
RESULTS: Centre α: 2001-2006; recruited n=162; treatment assessed n=129.
Centre β: 2008-2012; recruited n=126; treatment assessed n=99.
Response to treatment

Response	Centre α	Centre β
Good	60 (47%)	40 (40%)
Partial	30 (23%)	23 (23%)
Poor	15 (12%)	10 (10%)

D-IBS - Abnormal Se^{75}HCAT: centre α 33%, Centre β 31%.
CONCLUSION:
1. Both centres had similar proportions with abnormal Se^{75}HCAT values, suggesting gastroenterologists are able to select appropriate patients who are likely to benefit from the test.
2. Treatment response in both centres was similar, ~70% responding. This suggests treatment is genuinely effective and not limited only to centres with a special interest.

P1092 EXPRESSION OF FRUCTOSE TRANSPORTERS, GLUT5 AND GLUT2, MRNA IN PATIENTS WITH IRRITABLE BOWEL SYNDROME AND FRUCTOSE INTOLERANCE

C. H. Wilder-Smith[1,2,*], X. Li[2], R. Wong[2], S. SY Ho[3], H. Lee[3], E. Koay[3], R. P. Ferraris[4]. [1]*Gastroenterology Group Practice, Brain-Gut Research Group, Bern, Switzerland,* [2]*Neurogastroenterology Unit, Dep Medicine, National University Singapore,* [3]*Dep Laboratory Medicine, National University Hospital, Singapore, Singapore,* [4]*Dep Pharmacology & Physiology, New Jersey Medical School, Newark, United States*

INTRODUCTION: Intolerances to food are a major complaint of patients with functional gastrointestinal disorders (FGID) and may underlie many of the symptoms. The prevalence of fructose intolerance in FGID is up to 70%, but in contrast to lactose intolerance, the causative mechanism is unknown[1]. The monosaccharide, fructose, is transported across the intestinal epithelia by glucose transporters 5 (GLUT5, Slc2a5) and 2 (GLUT2, Slc2a2) in the apical and basolateral membranes, respectively[2]. In mice, deletion of GLUT5 caused malabsorption of dietary fructose and typical signs of intolerance[3]. Several of the postulated underlying mechanisms in FGID, such as inflammation and stress, have been shown to reduce GLUT5 expression[2]. The aim of this study was to assess for the first time the hypothesis that reduced intestinal GLUT5 and/or GLUT2 expression is associated with fructose intolerance in humans with FGID.
AIMS&METHODS: Duodenal biopsies were obtained in 12 male or female Irritable Bowel Syndrome patients (IBS, Rome III criteria) with fructose intolerance diagnosed by breath testing (8 hours fasting, 35g fructose, symptom index, $H_2 > 20$ppm or $CH_4 > 10$ppm) and 15 matched healthy controls aged between 18 and 60 years. Coeliac's disease and IBD were excluded. mRNA for GLUT5 and GLUT2 was quantified by multiplex RT-qPCR, with β-actin as reference. Group comparisons were performed using the Mann-Whitney test.
RESULTS: The median (interquartile range) relative GLUT5 mRNA levels in the duodenal biopsies were 0.195 (0.132-0.251) in patients with fructose intolerance and 0.165 (0.123-0.194) in healthy controls (no significant difference). Relative GLUT2 mRNA expression was also not significantly different between the fructose intolerant, 0.262 (0.206-0.344), and the controls, 0.255 (0.186-0.312).
CONCLUSION: Duodenal GLUT5 and GLUT2 mRNA expression did not differ significantly between fructose-intolerant patients with FGID and healthy controls. Our results suggest that human fructose intolerance may not be associated with marked changes in GLUT5 and GLUT2 mRNA expression. However, efforts are underway to quantify GLUT5 and GLUT2 protein levels in these samples.

P1093 CLINICAL VALUE OF SEHCAT SCAN IN PATIENTS WITH CHRONIC DIARRHOEA

M. M. Widlak[1,*], E. Atallah[1], P. Strouhal[2], A. Johnson[3], M. Brookes[1]. [1]*Gastroenterology,* [2]*Radiology,* [3]*Nuclear Medicine, The Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom*

INTRODUCTION: Chronic diarrhoea accounts for vast majority of referrals to secondary care where patients are often given a diagnosis of irritable bowel syndrome with diarrhoea (IBS-D). Studies show that a significant proportion of these patients may have bile acid malabsorption (BAM). SeHCAT (75 Selenium HomotauroCholic Acid Taurine) is increasingly used to identify BAM which can be divided into 3 types depending on aetiology: Type 1 following ileal resection or inflammation of the terminal ileum; Type 2 idiopathic BAM and Type 3 associated with cholecystectomy, peptic ulcer surgery, chronic pancreatitis, coeliac disease or diabetes mellitus. The purpose of this study was to evaluate usefulness of SeHCAT scan at investigation patients with chronic diarrhoea.
AIMS&METHODS: Consecutive patients with chronic diarrhoea who underwent SeHCAT scan at our centre over a 3-year period (2009-2011) were identified retrospectively. BAM was defined as present at a 7 day SeHCAT retention of $<12\%$. Patients' medical records were reviewed to obtain information regarding demographics, previous medical and surgical history as well as investigations.
RESULTS: Of 147 who had SeHCAT scan during the study period, 91 patients (62%) were diagnosed with BAM. A diagnosis of Type 1 was established in 22 patients (24%), including 2 patients who received pelvic/abdominal radiation, whereas 18 patients (20%) had Type 3 and all of them underwent cholecystectomy. 51 patients (56%) were diagnosed with idiopathic BAM (Type 2) and half of these had previous diagnosis of IBS-D. In the group with normal SeHCAT retention only 2 underwent cholecystectomy and there were no patients with small bowel resections or terminal ileum inflammation. 21 out of 147 patients had borderline results, defined as bile acid retention between 12% and 19%, and 71% were diagnosed with IBS-D.
CONCLUSION: In the investigation of patients presenting with chronic diarrhoea, SeHCAT scan should be considered to assist in the diagnosis of idiopathic BAM. Patients with Type 1 and 3 BAM however should be easily detected by taking an adequate clinical history and SeHCAT testing in these groups should perhaps be restricted.

P1094 CLINICAL ACCURACY AND USEFULNESS OF THE LACTOSE INTOLERANCE QUICK TEST FOR THE DIAGNOSIS OF LACTOSE MALABSORPTION

T. Tsadok Perets[1], E. Shporn[1], S. Levy[2], E. Kelner[1], S. Aizic[1], L. Pakanaev[1], Y. Niv[1], R. Dickman[1,*]. [1]*Gastroenterology,* [2]*The Academic College of Tel Aviv-Jaffa, Rabin Medical Center, Petach Tikva, Israel*

INTRODUCTION: The lactose breath test (LBT) is considered the gold standard technique for diagnosing lactose malabsorption. The Lactose Intolerance Quick Test (LIQT) measures lactase activity and may offer an alternative to the LBT.
AIMS&METHODS: To assess the efficacy of LIQT to correctly diagnose lactose malabsorption.
The study group included 69 dyspeptic patients that were evaluated by upper gastrointestinal endoscopy. Duodenal biopsies were used to rule out celiac disease (CD) and for the assessment of the LIQT (Biohit, Helsinki, Finland). In addition, all participants were evaluated for lactose malabsorption by the LBT. The results of LIQT were compared to LBT in order to define sensitivity, specificity, and predictive values of LIQT.
RESULTS: Groups were matched by mean age 54.4 yrs; M/F ratio 1/3; mean BMI 25.2 and none had celiac disease. The LIQT indicated hypolactasia in 55 participants (80%) and of those: 14 (25%) had mild hypolactasia and 41(75%) severe hypolactasia. The LBT indicated lactose malabsorption in 32 participants (46%). Of those with a normal LBT: 13 (35%) had normal lactase activity, 11 (30%) mild hypolactasia, and 13 (35%) severe hypolactasia by the LIQT. The sensitivity, specificity, positive predictive value and negative predictive value of the LIQT were: 97%, 35%, 56%, and 93%, respectively.
CONCLUSION: A finding of normal lactase activity with the LIQT rules out lactose malabsorption in almost all participants. However, the LIQT is associated with a high rate of overdiagnosis, with low specificity and a low positive predictive value relative to the LBT.

P1095 SEHCAT TESTING IN A LONDON DGH - IS BILE ACID MALAPSORPTION OVERLOOKED?

R. Saleem[1,*], J. Bashford[1], A. Paolino[1], J. Bugler[2], V. Saxena[1]. [1]*Gastroenterology,* [2]*Nuclear Medicine, Queen Elizabeth Hospital, South London Healthcare NHS, London, United Kingdom*

INTRODUCTION: Bile acid malabsorption (BAM) is a common cause of chronic diarrhoea and is an easily treatable condition. A therapeutic trial of bile acid sequestrants is commonly used to diagnose BAM but this approach lacks diagnostic accuracy. A recent systematic review confirmed that idiopathic BAM was diagnosed in one third of patients otherwise labelled as functional diarrhoea or diarrhoea predominant irritable bowel syndrome (D-IBS)[1]. British Society of Gastroenterology guidance for investigation of chronic diarrhoea places the use of 75Se-homocholyltaurine (SeHCAT) test at a late stage in the investigation algorithm[2]. SeHCAT test is a simple non-invasive method of diagnosing BAM, and perhaps not fully utilised. Our study reviewed the use of SeHCAT testing in a London District General Hospital (DGH).
AIMS&METHODS: A retrospective analysis of our local database was undertaken to identify all patients who have had SeHCAT testing performed between January 2010 and December 2011. Clinic letters, hospital notes, biochemical, endoscopic and radiological data were recorded. BAM was defined as SeHCAT retention of $<15\%$ (mild 10-15%; moderate 5-10%; and severe $<5\%$).
RESULTS: A total of 92 patients had SeHCAT testing during this period for chronic diarrhoea. Notes were not available in five cases, so 87 were included in the study. Mean age was 50 (range 26-85). BAM was found to be the cause of chronic diarrhoea in 44/87 (50.1%) patients. Of these, 28 (63.6%) had severe BAM, 10 (22.7%) had moderate and 6 (13.6%) had mild BAM. 24 (54.5%) had type 1 BAM (secondary to terminal ileal disease or resection), 15 (34.1%) had type 2 (idiopathic) and 5 (11.4%) had type 3 BAM (post cholecystectomy, celiac disease). Out of the 44 patients with an abnormal SeHCAT result, 34 (78%) were treated with bile acid sequestrants, either with colesevelam (n=23) or with cholestyramine (n=11) as 1st line therapy. 24/34 (70%) patients had either partial or good treatment response, 4 patients discontinued cholestyramine due to intolerance while no documentation of treatment response was available in 6 patients. Overall, colesevelam was found to be more effective and well tolerated. The remaining 10/44 patients had either no documented follow-up or their symptoms resolved spontaneously.
CONCLUSION: BAM appears to be common, easily treatable and probably an under-recognised cause of chronic diarrhoea. Despite the utility, safety and relatively low cost of the SeHCAT test, it is not commonly performed in patients with D-IBS type symptoms. Our study suggests that SeHCAT testing is useful in this group of patients and should be considered perhaps earlier in the investigation of unexplained chronic diarrhoea.

P1096 DETERMINANTS OF LONG-TERM OUTCOME IN PATIENTS WITH CHRONIC INTESTINAL FAILURE DUE TO SHORT BOWEL SYNDROME

T. Krafft[1,*], B. Knape-Drzikova[1], U. Gerlach[2], S. Maasberg[1], M. Kuhberg[3], A. Sturm[4], B. Wiedenmann[1], J. Sehouli[3], A. Pascher[2], U.-F. Pape[1], Interdisciplinary Intestinal Failure Team Charité Campus Virchow Clinic. [1]*Hepatology and Gastroenterology,* [2]*General, Visceral and Transplantation Surgery,* [3]*Gynecology and Obstetrics, CHARITÉ, UNIVERSITY MEDICINE BERLIN,* [4]*Internal Medicine, Krankenhaus Waldfriede, Berlin, Germany*

INTRODUCTION: Intestinal failure (IF) occurs in patients (pts) who are insufficiently nourished mostly due to post-surgical short bowel syndrome (SBS). IF leads to severe malnutrition due to decreased absorption of macro- and micronutrients as well as fluid imbalances. However, only limited data on complications and outcome of long-term parenteral nutrition (PN) are available. We therefore aimed to evaluate long-term outcome and prognostic factors in IF.
AIMS&METHODS: A retrospective analysis was performed in a single center cohort from a tertiary referral center. All pts were treated by a specialized interdisciplinary team between 2004-2012. Documented features of IF and complications were characterized and survival analysis for overall survival and specific risk factors was performed.
RESULTS: 144 pts with clinically diagnosed IF (143 due to SBS) were studied with a mean follow-up of 45.7 months. Overall survival was significantly shorter by log-rank-testing in pts with malignant vs. non-malignant cause of IF. The 5-year survival rate (YSR) byKaplan-Meier analysis was lower in pts with stoma (types I and II-SBS)vs. no stoma (type IIISBS; p=0.027), on PN vs. no PN (p=0.069) and remaining small bowel length of <100cm vs. >100cm (p=0.065). Longterm complications of PN with occurrence of catheter-related blood infections (CRBI, 28% of pts) vs. no CRBI (p=0.019) and with PN-associated liver disease as defined by pathological liver tests (PNALD, 50% of pts) vs. no PNALD (p=0.002) also indicated a poorer prognosis.
CONCLUSION: This analysis of a large cohort of IF/SBS-pts demonstrates the prognostic relevance of the underlying disease, post-surgical small bowel anatomy and remaining small bowel length as well as complications of long-term PN. Both, careful monitoring of these risk factors as well as meticulous management of complications are thus mandatory for improvement of long-term outcome in these challenging pts.

P1097 PREVALENCE OF BILE ACID MALABSORPTION AS A CAUSE OF DIARRHOEA IN CONSECUTIVE NEW PATIENT REFERRALS TO A GASTROENTEROLOGY CLINIC

U. Shivaji[1,*], F. U. Chowdhury[2], A. C. Ford[1]. [1]*Gastroenterology,* [2]*Nuclear Radiology, Leeds Teaching Hospitals NHS Trust,Leeds, Leeds, United Kingdom*

INTRODUCTION: Diarrhoea is a common presenting complaint in the Gastroenterology outpatient department. The potential causes are numerous, but include irritable bowel syndrome (IBS), inflammatory bowel disease (IBD), coeliac disease, and colorectal cancer. Interest in bile acid malabsorption (BAM) as a cause of diarrhoea has increased recently. However, guidelines from the British Society of Gastroenterology do not recommend routine exclusion of this condition using 23-seleno-25-homo-tauro-cholic acid (SeHCAT) scanning.
AIMS&METHODS: Review of consecutive unselected new patient referrals to a single Gastroenterologists' outpatient clinic during a 3-year period, from January 2010 to December 2012. All clinic letters were reviewed retrospectively, and symptoms reported by the patient at the initial consultation were recorded. Radiology, endoscopy, chemical pathology, and histopathology databases were then cross-examined in order to ascertain the final diagnosis following full investigation, to the level deemed appropriate by the consulting physician. We defined BAM using a SeHCAT retention value of $<15\%$ at 7 days.
RESULTS: Of 613 consecutive unselected new patient referrals to a single Gastroenterologist between January 2010 and December 2012, 151 (24.6%) reported diarrhoea. After investigation the final diagnoses are listed in Table 1. The second commonest cause of diarrhoea, after IBS, was BAM. Nine (45.0%) of 20 patients with BAM reported lower abdominal pain or discomfort. In 13 (65.0%) patients there was no obvious cause of BAM, and these were classified as idiopathic, or type II, BAM.

	Number (n = 151)	Percentage
IBS	32	21.2
BAM	20	13.2
IBD	16	10.6
Functional diarrhoea	7	4.6
Coeliac	7	4.6
Microscopic colitis	6	4.0
PPI-related	5	3.3
Pancreatic insufficiency	2	1.3
Colorectal cancer	1	0.7

CONCLUSION: BAM was the commonest underlying cause of diarrhoea after IBS. Idiopathic BAM was commoner than coeliac disease. Almost 50% of patients with BAM reported lower abdominal pain or discomfort, which may

lead to misdiagnosis as IBS unless further investigations are performed. BAM should be considered as a likely diagnosis in all patients with diarrhoea, and SeHCAT scanning should be moved up the hierarchy of diagnostic tests in such patients.

P1098 CORRECTION OF THE MITOCHONDRIAL DYSFUNCTION IN THE EXPERIMENTAL MODEL OF PROTEIN-ENERGY INSUFFICIENCY IN THE GROWING RATS

A. T. Kamilova[1,*], D. H. Dustmuhamedova[1], J. V. Levitskaya[1], O. S. Charishnikova[1]. [1]*Gastroenterology, Republican Specialized Research-Practical Medical Center of Pediatrics, Tashkent, Uzbekistan*

INTRODUCTION: The investigations of the activity of mitochondria in protein-energy insufficiency and medicamentous correction of the disorders revealed have been studied insufficiently.
AIMS&METHODS: The purpose of our investigation was to study in experiment the effect of phytoecdisteroid ecdisten on the correction of mitochondrial dysfunction in the growing rats with protein-energy insufficiency.
Material and methods. The protein-energy insufficiency was induced in the laboratory white rats (16) by method of chronic malnutrition (quantitative decrease of the diet of the vivarium by 50% from norm). On the 30^{th} day the animals were divided into 2 groups (n=8). One group was given phytoecdisteroid ecdisten in dose 2,5 mg/kg during 10 days (from the 30^{th} to 40^{th} day of life) (studied group), group 2 received physiological solution. Control group included healthy young rats (8). Mitochondria were isolated from the liver of the 40-day rats, measurement of the parameters of oxidative phosphorylation and respiration velocity of mitochondria were performed with use of polarogroaphy LP-7. The velocity of isolated mitochondria breathing in the metabolic state V4 and V3, as well as values of the respiratory control and ADP/O was determined by method of Chans (Leninger, 1986).
RESULTS: The velocity of oxygen consumption at the state V4 was also reduced and accounted for 13,27 ± 0,7 ng at M/min/mg of protein in group of the ill animals, while in the control group the velocity was 19,7± 0,9 ng at O/min/mg of protein ($P<0,02$). In addition of the disconnector of the oxidative phosphorylation 2,4-dinitrophenol (Vdnf) there was also obtained confirmation of the mitochondria uncoupling - in the control group this indicator was 123,9 ± 3,7, and in the group of ill animals – only 56,07 ± 1,7 ng at O/min/mg of protein ($P<0.001$). Respiratory control being indicator of the intact functionality of mitochondria in group of control animals accounted for 6,15 ± 0,38, at the same time in group of control animals this indicator was reduced by 20% and was 4,8 ± 0,36. The proportion ADP/O was also decreased and accounted for 2,5 ± 0,12 against 2,8 ± 0,15 in control group. In cases of the use of ecdisten as correcting agent there was found that the state V3 had value 93,72±1,9; V4 – 15,62 ± 0,8; V dnf – 109,34 ± 3,3 ng at O/min/mg of protein ($P<0.01$).
CONCLUSION: The data obtained indicated about obvious disconnection of the respiratory chain in the suspension of mitochondria in diet of animals poor with protein contents as well as about presence of significant correcting effect of preparation ecdisten.

P1099 PREGNANT WOMEN INTRACERVICAL MICROFLORA INFLUENCE ON FORMATION OF INTESTINAL MICROFLORA AT NEWBORN CHILDREN IN EARLY NEONATAL THE PERIOD. A CONTROLLED, RANDOMISED STUDY

L. Kunovska[1,*], V. Kunovsky[1]. [1]*Danylo Galitsky Lviv National Medical University, Lviv, Ukraine*

INTRODUCTION: The role of mother's intracervical microflora in the microbe colonization of newborns intestines is unequivocal and determining.
AIMS&METHODS: The comparison of bacteriological researches results of the crop from vagina and newborns gastric allocation. Prospective research covered a group of 300 newborns with clinical signs of newborns prenatal infection (NPI) and their mothers. There were 145 newborn boys and 155 girls. Pursuant to newborn's development terms 168 children (56 %) were born in 30 - 36 weeks, 132 (44 %) - in terms of 37 - 40 weeks. The weight of children at a birth varied from 1000 to 4500 g. However among newborns prevailed 73 % babies with weight of a body from 1500±124 up to 2989±243 g. The newborn's majority 91 % were born with an estimation of vital parameters behind scale Apgar of 5-7 points.
RESULTS: In structure of pregnant women vaginal microflora were determined Staphylococcus epidermidis (31,9 %), Staphylococcus aureus (28,7 %), Escherichia coli (27,7 %), Klebsiella spp. (6,5 %), Enterobacter spp. (2,1 %), Proteus spp. (1,9 %), Citrobacter spp. (1,2 %). In the majority of researches (72 %) there were polymicrobic associations Staphylococcus epidermidis and Staphylococcus aureus with Candida, Escherichia coli, Chlamydia spp. According to the bacteriological researches in newborn's gastric allocation fluid prevailed Staphylococcus epidermidis (32,2 %), Staphylococcus aureus (23,3 %), Escherichia coli (87,1 %), Klebsiella spp (8,2 %). In 40 cases the anaerobic colonies growth was confirmed (Clostridium Pneumoniae (5,3 %) and Clostridium difficile (8 %)). With the aim of newborn's with NPI intestinal microflora renewal by used in the complex of medicamentous therapy the Saccharomyces boulardii during ten days according to the scheme - 1-3 day - 250 mg twice a day, 4-6 - 125 mg 3-times a day, next 4 days - 125 mg twice a day. Bacteriological per rectum researches of newborn's intestinal microflora structure, made on the 5-th day of neonatal period, confirmed in 267 (89 %) children authentically ($p<0,05$) the reduction of Escherichia coli, Staphylococcus epidermidis, Staphylococcus aureus and Candida krusei colonies and the growth of Bifidobacterium spp. colonies 10^{-9}-10^{-11} CFU/ml and Lactobacillus spp. 10^{-6}-10^{-8} CFU/ml.
CONCLUSION: In the newborn's majority microflora observation (87,7 %), as well as at their mothers, has been submitted polymicrobic associations Staphylococcus epidermidis, Staphylococcus aureus with Candida and Escherichia coli.

P1100 STOOL SHORT CHAIN FATTY ACID CONCENTRATIONS IN A COHORT OF PRETERM VERY LOW BIRTH WEIGHT INFANTS WITH AND WITHOUT NECROTISING ENTEROCOLITIS

L. Beattie[1,1,*], D. J. Morrison[2], C. A. Edwards[2], A. R. Barclay[2], J. H. Simpson[1]. [1]*Neonatal Unit, Royal Hospital for Sick Children, Glasgow,* [2]*Department of Human Nutrition, University of Glasgow, Glasgow, United Kingdom*

INTRODUCTION: Diagnostic markers of necrotising enterocolitis (NEC) remain evasive. Stool short chain fatty acids (sSCFAs) are a product of bacterial fermentation of undigested carbohydrate and protein noted to alter in preterm infants with necrotising enterocolitis. According to the Lawrence Hypothesis, they may be implicated in the aetiology of NEC. We sought to correlate changes in sSCFAs over the first month of life in a cohort of preterm, very low birth weight infants with and without NEC.
AIMS&METHODS: 56 sequentially recruited infants <32 weeks and <1.5Kg birth weight within week 1 of life. Stool samples taken once weekly for the first 4 weeks, analysed by gas chromatography-mass spectrometry (mcg/g wet weight). 11 individual acids were measured: acetate, lactate, isobutyrate, butyrate, isocaproate, caproate, isovalerate, valerate, octanoate, heptanoate and lactate. NEC was diagnosed by consultant, external collaborator, radiologist, and classified by Bell's Criteria.
RESULTS: n=56. 32 developed NEC, 20 ≥Bell's 2a. 8 required surgery (5 ileostomy). NEC strongly correlated with low gestation and extremely low birth weight. There were no correlations between gestation, feed type, or NEC and sSCFA concentration. No significant differences were observed in weekly totals, and wide interquartile ranges were noted throughout. Acetate and lactate dominated each sample, regardless of gestation, feed type or NEC. Subgroup analysis revealed significant differences in stage 2a and 3b NEC. Stage 2a NEC showed higher concentrations of propionate in week 4 than week 3, and lower valerate in week 4 than 2. Stage 3b levels of isobutyrate and heptanoate were significantly lower in week 4 than 3. All analytes were non-normally distributed thus further multivariate regression analysis was deemed inappropriate. None of the analytes were significantly correlated according to Pearson's correlation.
CONCLUSION: Despite a wide variation in clinical status, the levels of sSCFAs remained remarkably consistent. Small yet significant differences in minor sSCFAs were seen in subgroup analysis in those with stage 2a and 3b NEC. Reasons for the high incidence of NEC require further investigation.

P1101 ADULT AUTOIMMUNE ENTEROPATHY : A RARE CAUSE OF NON CELIAC VILLOUS ATROPHY

S. Scialom[1], G. Malamut[1,*], B. Meresse[2], C. Derrieux[3], V. Verkarre[3], E. Macintyre[3], N. Brousse[3], F. Carbonnel[4], N. Cerf-Bensussan[2], C. Cellier[1]. [1]*HOPITAL EUROPEEN GEORGES POMPIDOU - APHP,* [2]*Inserm U989, Université Paris Descartes,* [3]*Hôpital Necker Enfants Malades, Paris,* [4]*Hôpital Bicêtre, Kremlin-Bicêtre, France*

INTRODUCTION: Adult autoimmune enteropathy (AIE) is an uncommon intestinal disease. Clinical presentation, serological markers, phenotype and efficient treatments remain undefined.
AIMS&METHODS: Aim: to precise diagnostic criteria and outcome in a well defined series of patients with adult AIE.
Patients and Methods: medical files of 11 patients (8F/3M) with diagnosis of AIE or AIE-like were studied retrospectively. All the patients presented villous atrophy without diagnostic criteria of celiac disease (lacking serological markers, and/or celiac susceptibility HLA type II and no response to a gluten free diet (GFD)) or common variable immunodeficiency (normal dosage of IgA, IgG and IgM). The work included centralized histological review, molecular and phenotype analyses of intestinal specimens.
RESULTS: Results: Mean age at diagnosis was 47 years [21-79]. Mean body mass index was 19. The most frequent symptoms were chronic diarrhea (100%), abdominal pain (55%) and vomiting (45%). Personal and family histories of autoimmune diseases were noted in 45% and 36% of patients, respectively. Histological damages were intestinal villous atrophy, mainly of severe type, with glandular lesions. One third of patients presented associated lymphocytic colitis. More than half patients had positive serum anti-AIE 75KD antibodies at diagnosis and less frequently anti-enterocytes antibodies. Patients seronegative for AIE had no celiac antibodies and, except in one patient resisting to a GFD, no celiac susceptibility HLA. Phenotype of isolated lymphocytes showed increased expression of Natural Killer (NK) markers (CD57, NKG2C) in intestine and normal count of CD4+CD25+FoxP3+ peripheral blood lymphocytes, both in seropositive and seronegative (for AIE-75KD) patients. Majority of patients had clinical and histological response to immunosuppressive

drugs targeting T cell responses (Thiopurines, anti-TNF-alpha, cyclosporine, mTor inhibitors) but none with anti-B cells therapy. Regular endoscopic follow-up detected emergence of intestinal TCR gamma chain rearrangement in three patients treated by suppressive therapy. In one of them it raised in intestinal T cell lymphoma.
CONCLUSION: Adult AIE is characterized by severe villous atrophy, glandular destruction and intestinal infiltration by T lymphocytes expressing highly NK markers. AIE is commonly responsive to immunosuppressors but regular follow-up is necessary to screen emergence of clonal T cell proliferations.
Disclosure of Interest: None Declared
Keywords: Anti-AIE 75KD antibodies, Autoimmune enteropathy

P1102 DETECTION OF SMALL BOWEL TUMORS: GROWING TREND TOWARDS WELL-TIMED PREOPERATIVE RECOGNITION AND ENDOSCOPIC TREATMENT

E. Ivanova[1,*], E. Fedorov[1], D. Seleznev[1], O. Yudin[1], L. Mikhaleva[1], E. Polukhina[1]. [1]*endoscopy, MOSCOW UNIVERSITY HOSPITAL NO 31, Moscow, Russian Federation*

INTRODUCTION: For many years majority of small bowel tumors (SBT) have been diagnosed and treated untimely.
AIMS&METHODS: The aim of the study is to evaluate the detectability of SBT and changes in the management of patients after capsule (CE) and balloon-assisted enteroscopy (BAE) implementation. From I.2007 to IV.2013 we observed 61 pts. (m-27, f-34), ranged from 17 to 85 years, (mean age 50,8±17,6 years) with SBT. The main complaints in 26 (42,6%) pts. was recurrent obscure GI bleeding; a clinical picture of intestinal obstruction was in 7 (11,5%) pts.; nonspecific symptoms - in 22 (36,1%) pts.; the other 6 (9,8%) pts. were asymptomatic. Surgical interventions due to intestinal tumors underwent 10 (16,4%) pts in the past history. The duration of the disease lasted at least 6 months in 26 (42,6%) pts., up to 3 years - in 18 (29,5%) and more than 3 years in 17 (27,9%) pts. For the small bowel examination we have used CE in 22 (36,1%) pts. and BAE in 47 (77,0%) pts., including 20 cases after CE. In 10 (16,4%) pts. SBT were detected during urgent surgery, without prior endoscopy.
RESULTS: According to CE data SBT were revealed in 20 (39,2%) cases. BAE detected tumors in 43 (70,5%) cases. Endoscopic ultrasonography during BAE was performed in 9 (14,8%) pts. In 6 (9,8%) pts. SBT were revealed by laparoscopy. Histologically, in 29 (47,5%) cases that was malignant tumors: adenocarcinoma – 5, neuroendocrine tumors – 8 (incl. carcinoid - 5), GIST – 8, metastatic lesions – 2, undifferentiated carcinoma – 1, lymphoma – 5), and in 30 (49,2%) cases - benign tumors: Peutz-Jegher's hamartomas – 11, hyperplastic polyp - 8, tubular adenoma - 3, fibroid polyps – 2, lymphangioma – 2, angiofibrolipoma – 1, cavernous hemangioma – 1, leiomyoma -1, lipoma - 1. Two patients after CE with submucosal tumors abandoned the following treatment. There were 51 (83,6%) cases with intraluminal growth of the tumor, 2 (3,3%) cases with extraluminal growth and 8 (13,1%) cases had mixed variant. Conservative treatment have been applied in 11 (18,0%) pts. Endoscopic interventions were performed in 17 (27,9%) pts.: polypectomy - in 13 pts. (124 tumors were removed in course of 25 interventions), EMR - in 4 pts. A complication – bleeding after polypectomy in the ileum, was stopped endoscopically. Surgery was performed in 33 (54,1%) pts.
CONCLUSION: SBT can be estimated timely, before urgent surgery because of complications, in 83,6% of pts. BAE allows to perform endoscopic treatment in 27,9% and to avoid surgery in 45,9% of pts.
Disclosure of Interest: None Declared

P1103 CAPSULE ENDOSCOPY FINDINGS IN INTESTINAL FOLLICULAR LYMPHOMA

E. Washio[1,*], M. Esaki[1], K. Ikegami[1], K. Kawasaki[2], K. Kurahara[2], Y. Kumagae[3], M. Hirahashi[3], S. Nakamura[4], T. Kitazono[1], T. Matsumoto[5]. [1]*Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka,* [2]*Division of Gastroenterology, Matsuyama Red Cross Hospital, Matsuyama,* [3]*Department of Anatomic Pathology, Graduate School of Medical Sciences, Kyushu University,* [4]*Center for Advanced Medical Innovation,* [5]*Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan*

INTRODUCTION: Cases of gastrointestinal follicular lymphoma (FL) has been increasingly reported in Japan. The duodenum, the jejunum and the ileum are the predominant sites involved by FL.[1] However, endoscopic characteristics of small bowel FL (SB-FL) have not been well documented.
AIMS&METHODS: We aimed to investigate endoscopic characteristics of SB-FL using capsule endoscopy (CE) and to assess a possible relevance between the findings of the duodenum and the small bowl. 26 patients with newly diagnosed gastrointestinal FL, who underwent CE and double-balloon endoscopy (DBE) together with biopsy were enrolled. Based on CE findings, SB-FL was divided into either whitish lesions (localized dense villi, multiple nodules, and flat protrusions) or non-whitish lesions (lymphoid hyperplasia like nodules and mass lesions). As for whitish lesions, the severity was graded according to the number of the segments involved by the lesions. Duodenal FL was classified into localized type (less than one-fourth circumferential spread) and circular type (greater than one-fourth) based on the findings in the descending duodenum under esophagogastroduodenoscopy (EGD). The prevalence of each type of SB-FL was analyzed in the jejunum and the ileum, and the severity of whitish lesions was compared with the severity of duodenal FL.
RESULTS: Under CE, jejunal involvement was found in 21 patients, and ileal involvement in 10 patients. CE identified whitish lesions in 21, and non-whitish lesions in 5, respectively. Among whitish lesions, multiple nodules and localized dense villi were frequently observed under CE (21patients and 19 patients, respectively), and such lesions were predominantly located in the jejunum (both in 19 patients). Whitish lesions were also found in the ileum in 7 of 21 patients, all of whom had jejunal involvement. When compared whitish lesions of SB- FL with the severity of duodenal FL, patients with circular type of duodenal involvement had more severe whitish lesions of SB-FL under CE than patients with localized duodenal involvement did ($p < 0.05$).
CONCLUSION: Multiple whitish nodules and localized dense villi in the jejunum are characteristic CE findings in SB- FL. There is a close association between the severity of SB-FL under CE and that of the descending duodenum under EGD.

P1104 CD4 LYMPHOPROLIFERATIVE DISORDER OF THE INTESTINE: FEATURES AND OUTCOME

G. Malamut[1,*], B. Meresse[2], S. Kaltenbach[3], C. Derrieux[3], V. Verkarre[3], E. Macintyre[3], A. Fourmestraux[4], B. Fabiani[4], J.-F. Colombel[5], I. Radford-Weiss[3], N. Brousse[3], O. Hermine[3], N. Cerf-Bensussan[2], C. Cellier[1]. [1]*HOPITAL EUROPEEN GEORGES POMPIDOU - APHP,* [2]*Inserm U989, Université Paris Descartes,* [3]*Hôpital Necker Enfants Malades,* [4]*Hôpital Saint Antoine, Paris,* [5]*Hôpital Huriez, Lille, France*

INTRODUCTION: CD4 T cell lymphoproliferative disorder of the intestine is very rare, mainly diagnosed during investigations for suspicion of refractory celiac disease.
AIMS&METHODS: Aims: We aimed to better characterize pathological and molecular features and outcome was evaluated of intestinal CD4 T cell proliferation in a series of thoroughly characterized patients.
Patients and Methods: The medical files of 114 consecutive patients, investigated for suspicion of refractory celiac diseases in three Gastroenterology Departments in France, were studied retrospectively. The study focused on 9 of them who presented histological features of intestinal CD4 T cell lymphoproliferations and included centralized with histolopathological, phenotypical and molecular analysis.
RESULTS: The nine patients (4F/5M; mean age at diagnosis: 54 years) presented with chronic diarrhea and malnutrition. Aspect of intestinal villous atrophy was observed in six patients, mainly severe (total or subtotal) whereas the three other patients did not present architectural change. The common pathological feature was the dense infiltration of the lamina propria by a polymorphous population of monomorphic small lymphoid cells expressing CD3, CD4, betaF1 and specific Vbeta detected by immunohistochemistry or T Cell Receptor (TCR) beta chain sequencing. Clonal rearrangement of the TCR gamma was found in all patients with rearrangement of the beta chain in most cases. Phenotyping analysis of isolated intraepithelial and lamina propria lymphocytes confirmed histological aspect, showing huge infiltration of epithelium and lamina propria by CD4+ T cells. CGH array analysis showed a heterogeneous profile of chromosomal abnormalities. Gastric and colonic involvements were observed in one third of patients and extension outside the gut (liver, bone marrow) in 20% of patients. Regarding all the treatments tested (steroids, chemotherapy, purine analogs, anti-CD52), anti-CD52 antibodies appear the most efficient inducing clinical and histological responses with reversion of abnormal phenotype in the two treated patients. At latest news, all the patients were still alive.
CONCLUSION: CD4 T cell lymphoproliferative disorder of the intestine is an uncommon intestinal T cell lymphoma with various Vbeta repertoires. Except anti-CD52 antibodies efficient but responsible of strong immune depletion, there is no evident therapy for this indolent intestinal T cell lymphoma.
Disclosure of Interest: None Declared
Keywords: intestinal CD4 T cell lymphoproliferative disorder, intestinal T cell lymphoma

P1105 PREDICTION OF TUMOR RECURRENCE IN PATIENTS WITH GASTROINTESTINAL STROMAL TUMORS FOLLOWING RESECTION BY THE MODIFIED NIH CRITERIA

J. E. Kwon[1], J. P. Im[1,*], S. G. Kim[1]. [1]*Department of Internal Medicine and Liver Research Institute, Seoul National University Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: The modified National Institutes of Health (NIH) criteria is currently widely accepted to assess the risk of recurrence of gastrointestinal stromal tumors (GISTs). This criteria includes both tumor site and tumor rupture as additional prognostic factors. The aims of this study were to clarify the clinical usefulness of the modified NIH criteria for risk stratification in Korea and to determine the association of the prognostic factors for GIST recurrence.
AIMS&METHODS: From January 2000 through September 2012, 261 patients who underwent curative resection for primary GIST were included and those who received adjuvant chemotherapy after surgery were excluded. The enrolled patients were divided into two groups according to primary tumor site; each group was stratified to predict recurrence by the original NIH criteria and modified NIH criteria. Clinical and pathologic data were collected and analyzed retrospectively.
RESULTS: A total of 172 patients had gastric GISTs; 89 patients had non-gastric GISTs. The mean age was 58.9 years (range: 22-89 years) and the

median follow-up duration was 4.26 years (range: 0.04-12.75 years). In the gastric GIST group, both risk stratification systems yielded the identical classification. Only 1 patient (1.9%) in the intermediate category and 8 patients (19%) in the high risk category experienced tumor recurrence. In the non-gastric GIST group, all patients who were placed in the intermediate risk category by the original NIH criteria were reclassified into the high risk category according to the modified NIH criteria. Among the 22 reclassified patients, 6 patients suffered a recurrence during the observational period. The primary tumor site, tumor size, mitotic count, presence of microscopic tumor necrosis and presence of tumor hemorrhage were significantly associated with the risk of tumor recurrence with univariate analysis. With multivariate analysis, the primary tumor site, tumor size, mitotic count, and presence of tumor hemorrhage were statistically significant variables.

CONCLUSION: The high risk category by the modified NIH criteria was found to have a high recurrence rate of GIST; furthermore, the non-gastric GIST group had a worse prognosis than gastric GIST group. Therefore, the modified NIH criteria accurately predicted the recurrence of GISTs after curative resection. In addition, the presence of bleeding might be considered to be an additional prognostic factor for GIST.

NUTRITION II – Poster Area

P1106 NATURAL DIETARY OLIVE OIL POLYPHENOLS, DOWNREGULATE MACROPHAGE LPS-INDUCED INFLAMMATORY RESPONSE THROUGH MAPKS AND NFKAPPAB SIGNAL PATHWAYS

A. Cardeno[1,*], M. Sanchez-Hidalgo[1], M. Aparicio-Soto[1], S. Sanchez-Fidalgo[1], C. Alarcon de la Lastra[1]. [1]*Pharmacology, University of Seville, Seville, Spain*

INTRODUCTION: Traditional Mediterranean diet is characterized by the usual high intake of extra virgin olive oil (EVOO), from olive tree, *Olea europaea*. Phenolic compounds present in EVOO (PE) are recognized as a group of highly bioactive components, with antioxidant and anti-inflammatory properties among others. Current epidemiological and experimental studies support a beneficial role of dietary polyphenols in several gastrointestinal diseases, including inflammatory bowel disease (IBD). Recent reports have demonstrated that dietary PE supplementation attenuated chronic ulcerative colitis in mice (Sánchez-*Fidalgo et al, 2013*). On the other hand, macrophages are dramatically involved in the pathogenesis of inmuno-inflammatory disorders. Regarding IBD, macrophages are pivotal mediators of innate immunity and appear to play a key role stimulating the subsequent adaptive immunity.

AIMS&METHODS: The present study was designed to evaluate potential anti-inflammatory effects of PE in lipopolysaccharide (LPS)-stimulated peritoneal murine macrophages and deep insight into the molecular action mechanisms. Nitric oxide (NO) production was analyzed by Griess method and intracellular reactive oxygen species (ROS) by fluorescence analysis. Moreover, changes in the protein expression of the proinflammatory enzymes cyclooxygenase (COX)-2, the inducible nitric oxide synthase (iNOS) and microsomal prostaglandin E synthase-1 (mPGES-1), as well as the role of mitogen-activated protein kinases (MAPKs) and the nuclear transcription factor kappa B (NFKappaB) signaling pathways were analyzed by western blot.

RESULTS: PE exerted significant anti-inflammatory and anti-oxidant effects inhibiting LPS-induced intracellular NO and ROS production. Additionally, PE induced a significant downregulation of iNOS, COX-2 and mPGES-1 proteins expression. Moreover, PE treatment reduced MAPKs activation and prevented the nuclear NFKappaB translocation in murine macrophages, which were increased in LPS-stimulated cells.

CONCLUSION: PE compounds could play an important role in the anti-inflammatory effect of virgin olive oils and probably might yield novel preventive or palliative nutritional treatments in the management of IBD.

P1107 FOOD INTAKE IN HUMANS WAS NOT AFFECTED BY GLUCAGON-LIKE PEPTIDE-1 RECEPTOR BLOCKADE THROUGH EXENDIN9-39

A. C. Meyer-Gerspach[1,*], R. E. Steinert[1], J. Schirra[2], B. Göcke[2], C. Beglinger[1]. [1]*Department of Biomedicine and Division of Gastroenterology, University Hospital Basel, Basel, Switzerland,* [2]*Department of Internal Medicine II, Clinical Research Unit, Clinical Center of the Ludwig Maximilians University, Munich, Germany*

INTRODUCTION: Exogenous administration of glucagon-like peptide-1 (GLP-1), or of its potent, long-acting analogs, inhibits eating and improves postprandial glycemia in many species, including humans. In addition, chronic administrations of GLP-1 or its analogs effectively reduces body weight and improves glucose metabolism in overweight individuals and type 2 diabetics. In animals, GLP-1 receptor (GLP-1R) blockade by the specific GLP-1R antagonist exendin9-39NH2 (ex9-39) stimulates eating under some conditions indicating that satiation can be delayed when endogenous GLP-1 signalling is blocked. In other studies, however, ex9-39 administration fails to stimulate eating suggesting that endogenous GLP-1 is not involved in the control of eating.

The role of GLP-1 receptor antagonism in modulating eating in humans has not been investigated yet. The objectives were therefore to use the antagonist as a probe of the physiologic actions of glucose or fat stimulated endogenous GLP-1 by assessing the effects on a) food intake, b) plasma GLP-1 concentrations, and c) endocrine pancreatic functions.

AIMS&METHODS: Two double-blind, 4-way cross-over studies were performed, each with 10 healthy men. In part A, subjects received either an intravenous (iv) infusion of ex9-39 or saline (control) plus an glucose preload and an intraduodenal (ID) infusion of glucose or saline; in part B, iv infusions were identical, but an mixed liquid meal preload and an ID infusion of oleic acid or saline were administered. After 30 min, an ad libitum test meal was served and subjects were invited to eat and drink as much as they wished. The amount of food eaten and fluid drunk, the time to complete the meal as well as appetite sensations were quantified; Plasma GLP-1, insulin, glucose and glucagon were measured.

RESULTS: In both parts, iv exendin9-39 induced a significantly higher increase in plasma GLP-1 and glucagon levels compared to iv saline ($P \leq 0.001$). Insulin was lower with iv exendin9-39 in response to ID glucose ($P \leq 0.05$). Appetite sensations, energy intake, fluid intake, or eating duration were not affected by iv exendin9-39 in either parts.

CONCLUSION: We confirm the usefulness of the GLP-1R antagonist ex9-39 as a probe of the physiologic activity of endogenous GLP-1, revealing in healthy men 1) a central role of GLP-1 in postprandial control of insulin and glucagon secretion, and 2) a limited role of GLP-1 in controlling appetite and eating.

P1108 PYRROLOQUINOLINE QUINONE SECRETING GENETICALLY MODIFIED ESCHERICHIA COLI NISSLE 1917 MINIMIZES OXIDATIVE STRESS AND REDUCES BLOOD LIPID LEVELS IN AGING RATS

A. K. Singh[1,*], S. K. pandey[1], N. K. G[1]. [1]*Department of Biochemistry, The Maharaja Sayajirao University of Baroda, vadodara, India*

INTRODUCTION: Aging is a degrading mechanism accompanied by progressive increase in free radicals and decrease in antioxidant defense leading to functional decline of various cellular processes in the body. Mitochondrial dysfunction and decrease in mitochondrial content is observed with progressive age. Pyrroloquinoline quinine (PQQ) acts as potent antioxidant and helps in mitochondrial biogenesis through its interaction with cell signaling network.

AIMS&METHODS: This work aims to evaluate the effect of PQQ secreting genetically modified probiotic *Escherichia coli* Nissle 1917 (EcN-*pqq*) on colonic and hepatic antioxidant status, and blood lipid profile in aging rats. Since mitochondrial generation of reactive oxygen species in major cause of its damage, we analyzed protective efficacy of PQQ against rotenone (complex I inhibitor) induced oxidative damage *in vivo*. Adult male Charles Foster rats, 8 months of age were weekly treated with probiotics for 6 months. Rotenone (2mg/kg body weight) was given for 30 days with and without PQQ (10 μg/kg body weight) daily.

RESULTS: Native EcN treatment could minimize colonic lipid peroxidation as compared to untreated but did not have any effect on colonic antioxidant enzyme activities as well as hepatic parameters. However, EcN-*pqq* treatment reduced colonic lipid peroxidation more efficiently than native EcN, and elevated catalase and SOD activities. Additionally, it was able to reduce hepatic lipid peroxidation along with enhanced catalase, SOD, G6PDH activities and GSH levels. We also found elevated hepatic mitochondrial content in rats fed with EcN-*pqq* as compared to untreated or native EcN groups. Additionally, EcN-*pqq* treatment to aging rats lowered blood triglyceride and cholesterol levels when compared to untreated. Purified PQQ treatment given daily along with rotenone rescued oxidative colonic and hepatic damage along with increase in hepatic mitochondrial content.

CONCLUSION: Protective efficacy of *E. coli* Nissle 1917 on oxidative stress in aging rats is enhanced by incorporation of *pqq* gene cluster. Additionally, it also prevents hepatic oxidative stress along with reduction in blood lipid levels. Purified PQQ could also prevent oxidative stress induced by rotenone used to create model of accelerated aging. Thus PQQ secreting probiotic *E. coli* Nissle 1917 could be used as nutritional supplement for preventing oxidative stress and hyperlipidemia especially in aging.

P1109 A COMBINATION OF PRE- AND PROBIOTICS, VITAMINS, MINERALS, ANTIOXIDANTS AND ANTI-INFLAMMATORY AGENTS AS A NEW THERAPEUTIC APPROACH FOR INCREASED INTESTINAL PERMEABILITY IN PATIENTS WITH IRRITABLE BOWEL SYNDROME WITHOUT CONSTIPATION

G. Ianiro[1,*], V. Ojetti[1], E. Gaetani[1], L. Laterza[1], F. Scaldaferri[1], F. Beghella Bartoli[1], S. De Martino[1], G. Dinoi[1], G. Gigante[1], G. Cammarota[1], G. Gasbarrini[2], A. Gasbarrini[1]. *[1]Dept of Internal Medicine, Division of Gastroenterology, CATHOLIC UNIVERSITY SCHOOL OF MEDICINE, ROME, [2]"Ricerca in Medicina" ONLUS Foundation, Bologna, Italy*

INTRODUCTION: Impairment of the intestinal barrier has been involved in the pathogenesis of several diseases. One of the most studied correlations is the one with irritable bowel syndrome (IBS). To date, there is no standard treatment for increased intestinal permeability.
AIMS&METHODS: Our aim was to assess the efficacy of a dietary complement containing pre- and probiotics, vitamins, minerals, antioxidants and anti-inflammatory agents in ameliorating the increased intestinal permeability and global state of health in subjects with IBS without constipation.
In this proof-of-concept study, a combination of pre- and probiotics (L. acidophilus NCFM, B lactis Bi-07), vitamins, minerals, antioxidants and anti-inflammatory agents (Nutrimonium®) was added to the common diet of 33 subjects (M/F:14/19, mean age 42 yo, range 19-72) with IBS-D or IBS-M and increased intestinal permeability (measured with ^{51}CrEDTA Test) at the dosage of 1 sachet per day for 60 days. After the treatment, each patient repeated the intestinal permeability test with ^{51}CrEDTA. Global health state with a slightly modified version of EQ-5D VAS (0-100 mm) was evaluated at baseline and after the treatment.
RESULTS: All the patients completed the treatment. Five patients were unable to repeat the ^{51}CrEDTA Test and were withdrawn from the study. In the remaining 28 patients, the mean ^{51}CrEDTA score was respectively 7,43 (SD: ±2,75) at baseline and 5,93 (SD: ± 2,7333) after the treatment (P=0.089). Mean EQ-5D VAS was respectively 40 (SD: ±14,86) at baseline and 64.61 (SD: ± 9) after the treatment (P<0.0001).
CONCLUSION: Restoring the impaired gut barrier may be challenging, especially since there are several therapeutic targets to hit, as gut microbiota, intestinal mucus, intestinal immune cells, tight-junction function, et cetera. A multimodal approach, with a combination of different healing agents, seems to be effective both in improving intestinal permeability and in ameliorating symptoms. Since this study has many limitations, further, randomized controlled trials, with an adequate sample size, are needed to confirm these results.

P1110 LACTIC ACID BACTERIA (LAB) MODULATE ANGIOPOIETIN-LIKE 4 (ANGPTL4) EXPRESSION IN HUMAN INTESTINAL EPITHELIAL CELLS

E. Jacouton[1,2], N. Lapaque[2], J. E. Van Hylckama Vlieg[1], J. Doré[2,3], T. Smokvina[1], H. M. Blottière[2,3,*]. *[1]Danone Research, Palaiseau, [2]UMR 1319 Micalis, [3]US 1367 MetaGenoPolis, INRA, Jouy en Josas, France*

INTRODUCTION: Over the last decades, an increase of metabolic diseases (obesity, type-2 diabetes) has been reported with dramatic consequences on human health. Scientific interest has extended for a better understanding of LAB regulation of host energy balance. ANGPTL4, also known as Fiaf (fasting-induced adipose factor), is an adipokine expressed in several tissues including liver, intestine and heart. ANGPTL4 (overexpressed in fasting and in hypoxia) displays a role in angiogenesis, lipid metabolism and glucose tolerance. ANGPTL4 inhibits lipoprotein lipase (LPL), an enzyme that converts triglycerides in monoglycerides and fatty acids (FA) and promotes lipolysis resulting in increased triglyceride serum level and decreased FA and cholesterol uptake into tissues. *In vivo* and *in vitro* studies have shown the regulation of ANGPTL4 by bacteria. As an example an ANGPTL4-dependent decrease of fat storage under high fat diet supplemented with *L.paracasei* bacteria in a gnotobiotic mice model has been described (Aronsson et al, PLoS one, 2010).
AIMS&METHODS: These data underline the pivotal role of the bacterial regulation of ANGPTL4 in energy balance and lipid storage. However, molecular mechanism and microbial factors regulating its expression are still poorly understood.
The aim of this study was to assess the mechanisms by which LAB are able to modulate ANGPTL4 expression in intestinal epithelial cells.We selected the intestinal epithelial cells HT-29 as a relevant *in vitro* model, being in direct contact with luminal content including bacteria. Twenty LAB strains have been selected belonging to *Lactobacillus rhamnosus* and *Lactobacillus paracasei* species and tested.
RESULTS: We identified strains modulating ANGPTL4 expression in intestinal epithelial cells. The molecular mechanisms involved in the modulation of ANGPTL4 expression by LAB strains have been studied, and it seemed to be independent of PPARγ activity..
CONCLUSION: In conclusion, these strains may be useful tools to modulate lipid metabolism *in vivo*.

P1111 GAMMA CAMERA IMAGING FOR STUDYING INTESTINAL ABSORPTION AND WHOLE-BODY DISTRIBUTION OF SELENOMETHIONINE

J. L. Madsen[1,*], K. Sjögreen-Gleisner[2], D. R. Elema[3], P. Rasmussen[3], L. R. Søndergaard[1], S. Fuglsang[1], M. Ljungberg[2], M. Damgaard[4]. *[1]Department of Clinical Physiology and Nuclear Medicine, Hvidovre Hospital, Hvidovre, Denmark, [2]Department of Medical Radiation Physics, Lund University, Lund, Sweden, [3]Hevesy Laboratory, DTU Nutech, Roskilde, Denmark, [4]Department of Clinical Physiology and Nuclear Medicine, Køge Hospital, Køge, Denmark*

INTRODUCTION: Selenium (Se) is recognised as a nutrient that is essential to human health. Se metabolism in humans is not well characterised. Currently, estimates of Se absorption, whole-body retention, and excretion have been obtained from balance and tracer studies. We used gamma camera imaging to evaluate whole-body retention and distribution of radio-labelled selenomethionine (SeMet), the predominant form of Se present in food.
AIMS&METHODS: Eight healthy young men participated in the study. After a meal that contained 4 MBq ^{75}Se-L- selenomethionine (^{75}Se-SeMet), whole-body gamma camera scanning was performed for 45 min every hour over a 6-hr period, every second hour for the next 18 hr, and once on each of the subsequent 6 days. Blood, urine, and faeces samples were taken to determine the plasma content of ^{75}Se-SeMet as well as its excretion in urine and faeces.
RESULTS: Imaging showed that 87.9 ± 3.3% (mean ± standard deviation) of the administered activity of ^{75}Se-SeMet was retained within the body after 7 days. For comparison, the measured excretion in urine and faeces for the 7-day period was 8.2 ± 1.1% of the activity. Time-activity curves were generated for whole-body, stomach, liver, abdomen (other than the stomach and the liver), brain, and thigh muscle.
CONCLUSION: Gamma camera imaging allows for the assessment of postprandial absorption of SeMet. This technique may also permit concurrent studies of organ turnover of SeMet.

P1112 THE ROLE OF LACTOSE AS AN IMMUNOMODULATOR:IMPLICATIONS FOR HUMAN HEALTH

J. Honkanen[1,*], M. Paasela[1], K.-L. Kolho[2], O. Vaarala[1]. *[1]Department of Vaccination and Immune Protection, National Institute for Health and Walfare, [2]Children's Hospital/University of Helsinki, Helsinki, Finland*

INTRODUCTION: Our interest in lactose as a new immunomodulatory molecule results from studies showing that TIM-3/Gal-9 pathway is crucial in the regulation of T cell responses both *in vitro* and *in vivo* [1-6]. In animal models, *in vivo* administration of lactose has been shown to mediate similar effects on T cell immunity and disease state as specific silencing of the interaction between TIM-3 and Gal-9 [4]. *In vitro,* lactose can block the anti-allergic effects of IgE-binding Gal-9 [5], and is capable of disrupting Gal-9 mediated regulatory T cell (Treg) control over cytotoxic CD8+ T cells [6].
AIMS&METHODS: We wanted to study the role of lactose as a possible inhibitor of human Treg-mediated immune regulation. We enriched from peripheral blood of healthy donors (n=20) $CD4^+CD25^{high}$ Tregs and $CD4^+CD25^{low}$ effector T cells by magnetic column separation. We tested the effect of lactose in co-cultured Treg and effector T cells stimulated with anti-CD3+anti-CD28. Sucrose was used as a control sugar. We used RT-qPCR and ELISA to measure effector T cell cytokine production.
RESULTS: In the presence of Tregs, the levels of secreted IFNγ and IL-17 in T effector cells were decreased from median of 8.8 to 3.9 units for IFNγ (p=0.003) and from 0.7 to 0.64 units for IL-17 (p=0.04). When lactose was added, Treg-mediated suppression was inhibited, which led to elevated levels of secreted IFNγ and IL-17 (median 16.4 vs 3.9 units and 0.74 vs 0.64 units; p<0.0001 and p=0.005, respectively).
CONCLUSION: The inhibition of Treg function with lactose enhanced Th1 and Th17 immunity. Since lactose is the main carbohydrate in breast milk it could promote the induction of mucosal immune protection, i.e Th1 and Th17 immunity, and be beneficial as an immunostimulator during infancy. However, later in life dietary lactose could induce harmful pro-inflammatory mechanisms by disrupting Treg-mediated tolerance in the gut. The uncontrolled Th1 and Th17 responses and the inability of Treg cells to down-regulate immune responses have been implicated in the pathogenesis of many human immune mediated diseases [7,8]. In the light of current knowledge and our recent findings further studies are needed to reveal the possible beneficial and/or harmful effects of dietary lactose.

P1113 WHEAT BRAN IMPROVES REGULARITY AND SYMPTOMS OF DIGESTIVE DISCOMFORT WITHIN 3-5 DAYS

K. R. O'Sullivan[1,*], J. Walton[2]. [1]*Dr O'Sullivan Nutrition Consultancy Ltd,* [2]*Nutrition, Kellogg Company, Manchester, United Kingdom*

INTRODUCTION: Average intakes of fibre in Europe are lower than the recommended 25g/day and in countries like the UK, 29% suffer from constipation and 43% from digestive discomfort as a result of fibre deficiency. Although not life threatening, sub optimal gut function affects physical and emotional quality of life and are common place amongst clinical referrals. Dietary fibre intervention can improve gut function and motility by reducing transit time and increasing faecal bulk but amongst non-constipated individuals with poor fibre intakes can also improve well being and quality of life. Wheat bran compared to other fibre sources is considered the gold standard for promoting laxation and regularity. Indeed the EUropean Food Standard Agency recently approved 2 health claims for wheat bran and faecal bulking and transit time.
AIMS&METHODS: Amongst healthy adults, the objective was to assess the length of time required to demonstrate the benefits of consuming wheat bran fibre as a serving of Kellogg's All-Bran breakfast cereals on transit time, faecal bulking and symptoms of digestive discomfort. A systematic review of the scientific literature was conducted to evaluate dose and time response of wheat bran on physiological and psychological function. MEDLINE and bibliographic searches identified 20 relevant human intervention trials, many using Kellogg'All-Bran as the wheat bran source dating back to 1942.
RESULTS: Wheat bran intervention in the form of a serving of Kellogg's All-Bran cereals reduces transit time and increases faecal bulk within as little as 3-5 days in healthy adults. It also reduces symptoms of digestive discomfort such as bloating and feelings of sluggishness as well as improves psychological well being with levels as low as 3.5g of wheat bran.
CONCLUSION: The Kellogg's All-Bran range of breakfast cereals provide 4-10g of wheat bran fibre (up to a third of daily fibre requirements). This additional fibre can reverse the consequences of fibre deficiency by increasing stool weight and reducing transit time. In addition symptoms of digestive discomfort and feelings of wellness can be improved within as little as 3-5 days. This could be expected to be translated into increased feelings of well being of an estimated 43% of the UK population who report symptoms of digestive discomfort

P1114 ASSOCIATIONS WITH WATER-SOLUBLE VITAMINS DEFICIENCIES AND PATIENTS WITH COMPLICATED PEPTIC ULCERS IN THE EARLY PHASE AFTER THE ONSET, EVEN IN PRESENT-DAY JAPAN: TIME COURSE OF THESE CHANGES

M. Kusakabe[1,*], K. Miyake[1], W. Sato[1], A. Yamada[1], Y. Kodaka[1], H. Nagoya[1], T. Shindo[1], N. Ueki[1], M. Kusunoki[1], T. Kawagoe[1], S. Futagami[1], C. Sakamoto[1]. [1]*Gastroenterology, Nippon Medical School, Tokyo, Japan*

INTRODUCTION: To investigate whether patients with complicated peptic ulcers (PUs) have deficiencies of water-soluble vitamins (WSVs) in the early phase after the onset, even in present-day Japan.
AIMS&METHODS: This prospective cohort study included the inpatients who had confirmed PUs. Concentrations of fasting serum WSVs (vitamins B1, B2, B6, B12, C, and folic acid) and homocysteine were measured at 3 time points (at admission, hospital discharge, and 3 months after hospital discharge).
RESULTS: Ten consecutive patients (58.4 ± 15.1 years, 3 gastric/7 duodenal ulcers, fasting period after hospitalization 4.0 ± 1.6 days, and duration of hospitalization 12.2 ± 4.6 days,. 8 *H. pylori* / 2 NSAID users) who met the inclusion criteria and completed measurements of blood samples at all 3 time points were enrolled in the study.
The mean levels of vitamins B1, B2, B6 and C, but not those of vitamin B12 and folic acid, were low normal at the time of admission. Time-dependent effects during the time course of changes in serum levels of the WSVs were statistically confirmed for vitamin B1 ($P < 0.01$) and vitamin B6 ($P < 0.05$), but not vitamins B2, B12, C and folic acid.
Vitamin B1 and B6 levels were significantly higher at 3 months after discharge that at admission (vitamin B1: 45.4 ± 12.2 vs. 33.7 ± 10.7 ng/ml, $P < 0.01$, vitamin B6: 11.2 ± 5.4 vs. 6.6 ± 2.9 ng/ml, $P < 0.05$). Furthermore, vitamin B1 and B6 levels were significantly higher at 3 months after discharge than at discharge (vitamin B1: 45.4 ± 12.2 vs. 31.5 ± 11.0 ng/ml, $P < 0.01$, vitamin B6: 11.2 ± 5.4 vs. 6.3 ± 3.7 ng/ml, $P < 0.05$).
The proportion of patients with a deficiency of serum WSVs were as high as 50% for vitamin B6 and vitamin C (5 patients each) at admission and 60% (6 patients) for vitamin B6 and 40% (4 patients) for vitamin C at discharge. Time-dependent changes in the proportion of patients with a deficiency of serum WSVs were statistically confirmed by the Friedman test for vitamin B6 ($P < 0.05$), but not for vitamins B1, B2, B12, vitamin C and folic acid. Therefore, the proportion of patients with vitamin B6 deficiency were compared between the measurement time points and were found to be significantly higher at admission and discharge (50% and 60%, respectively, $P < 0.05$) than at 3 months after discharge (10%).
CONCLUSION: Till date, most Japanese patients with complicated PUs have deficiencies in some WSVs in the early phase after the onset of PUs. Supplementation with WSVs should be considered for complicated PUs requiring dietary restrictions.

P1115 EFFECT OF YOGURT CONTAINING POLYDEXTROSE, LACTOBACILLUS ACIDOPHILUS NCFM AND BIFIDOBACTERIUM LACTIS HN019: A RANDOMIZED, DOUBLE-BLIND, CONTROLLED STUDY IN CHRONIC CONSTIPATION

L. Credidio[1,*], C. S. R. Coy[1], J. Simoes Neto[2], D. O. Magro[3], I. Bernasconi[4], M. D. S. Ruela[3], I. K. Barcelos[3], R. F. Leal[3], M. D. L. S. Ayrizono[1], J. J. Fagundes[1], L. B. Teixeira[5], A. C. Ouwehand[6]. [1]*Surgery, UNIVERSIDADE DE CAMPINAS,* [2]*Surgery, Pontificia Universidade Catolica de Campinas,* [3]*UNIVERSIDADE DE CAMPINAS,* [4]*Pontificia Universidade Catolica de Campinas, Campinas,* [5]*Surgery, DuPont Nutrition and Health,* [6]*DuPont Nutrition and Health, Sao Paulo, Brazil*

INTRODUCTION: Constipation is a frequent complaint and the combination of a prebiotic and probiotics would have a potentially synergic effect on the intestinal transit. The present study therefore aims to investigate the combination of polydextrose (Litesse®), *L. acidophilus* NCFM® and *B. lactis* HN019 in a yogurt on intestinal transit in subjects who suffer from constipation
AIMS&METHODS: Patients with constipation were randomly divided into two groups, Control Group (CG) and Treatment Group (TG), and had to eat 180 ml of unflavored yogurt every morning for 14 days. Those in the CG received only yogurt, while the TG received yogurt containing polydextrose, *L. acidophilus* NCFM® (ATCC 700396) and *B. lactis* HN019 (AGAL NM97/09513)
RESULTS: There was a decrease in the colonic transit time (CTT) when comparing initial and final transit time. However, this reached only statistical significance for the treatment group (TG) (t-test, p=0.001). The subjects in the treatment group also had a shorter transit time at the end of the intervention compared to the control group (p=0.01).
CONCLUSION: The product containing yogurt with polydextrose, *B.* lactis HN019 and *L. acidophilus* NCFM® significantly shortened colonic transit time after two weeks. This was also a significant reduction colonic transit time compared to the placebo group.

P1116 BOWEL FUNCTION AND DIGESTIVE SYMPTOMS DURING THE MENSTRUAL CYCLE

L. Dye[1,*], F. Garner[1], C. Lawton[1], R. Schnell[2]. [1]*Institute of Psychological Sciences, University of Leeds, Leeds, United Kingdom,* [2]*Institut für Soziologie, Universität Duisburg-Essen, Duisburg, Germany*

INTRODUCTION: There is limited research which suggests that women experience variations in digestive discomfort and bowel function during the menstrual cycle. Harder stools are more likely during the luteal (premenstrual) phase with looser, more frequent stools during menstruation.
AIMS&METHODS: This series of studies examines bowel function and digestive discomfort during the menstrual cycle using data from an online UK survey of 1012 premenopausal women, representative of the female population for age and socio-economic status. It is corroborated by results from a prospective diary study of 57 women selected from the original survey, who completed online questionnaires for one whole menstrual cycle. 24 women using oral contraceptives were included in the prospective study to examine the effect of oral contraceptive use on bowel function. The Bristol Stool Form Scale was used in both studies to describe form and frequency of bowel movements during each phase of the menstrual cycle and other symptoms and behaviours including fibre intake were recorded in the online questionnaires.
RESULTS: Graphical data analysis was used to analyse the patterns of stool form across menstrual cycle phases. Only a third of women showed the typical pattern of bowel function during the menstrual cycle. More than 160 different patterns of stool form changes were observed during the cycle presenting a confusing and complex experience for many women. Use of hormonal contraceptive methods is associated with more stable stool form suggesting that female hormonal fluctuations do affect bowel function.
CONCLUSION: Greater awareness of cycle related fluctuations in stool form and bowel habits would help women to identify changes and alert them to possible underlying problems. Dietary strategies could be helpful in some cycle phases to aid stool form and reduce digestive symptoms.

P1117 WHAT ABOUT THE COMBINED CONSUMPTION OF ETHANOL AND FRUCTOSE ON LIVER STEATOSIS AND HEPATIC METABOLIC PROFILE? 1H HRMAS SPECTROSCOPIC STUDY IN THE RAT LIVER.

M.-C. Beauvieux[1,*], H. Gin[2], M. Urdaci[3], C. Castain[4], E. Richard[5], P. Couzigou[6], J.-L. Gallis[1]. [1]*RMSB UMR5536, CNRS-UNIVERSITÉ BORDEAUX2, BORDEAUX,* [2]*Nutrition, CHU Bordeaux, Bordeaux,* [3]*Microbiologie, BSA, Gradignan,* [4]*Laboratoire Pathologie,* [5]*Biochimie,* [6]*Hépatologie, CHU Bordeaux, BORDEAUX, France*

INTRODUCTION: Liver steatosis (LS) can precede steatohepatitis. Diets induce LS in rat: ethanol (EtOH) and high-fructose (HF) with insulinoresistance (IR). Non-alcoholic fatty liver disease patients often have high fructose supply (soft drinks) [1]. Little is known about the large consumption of beverages with fructose+ethanol, mainly in the young population. Inversely resveratrol (RSV) suppresses LS in fat-diet mice [2]. Liver metabolic profile was studied by ^{1}H HRMAS in rat eating combinations of HF, moderate EtOH and RSV.
AIMS&METHODS: 7wks-old male Wistar rats (n=60) were pair-fed (10wks, 10g/d$_*$100g body weight). Control: standard chow; HF: 60% fructose (instead of starch); EtOH: 11mmol/d$_*$kg body weight in drinking water; HF+EtOH; HF+EtOH+RSV: +30mg/l RSV force-feeding. At the 3rd, 6th and 10th wks, blood was withdrawal. A piece for histology was removed before livers freeze-clamping (N_2). NMR (Brucker AVANCE500 11.7T; 6min acquisition) was performed on 20mg liver.
RESULTS: HF or EtOH alone induced IR (normoglycaemia+hyperinsulinemia) from 3wks, partly counteracted by RSV. At 10wks, all HF groups had (i) macro- and micro- LS and inflammation, (ii) oxidative stress with plasmatic αtocopherol 2-fold higher (26.38±0.67µmol/l, $p<0.05$) than control (transaminases were normal). EtOH alone induced no histological or αtoco change. HF+EtOH increased interleukins ($p<0.001$ *vs* control). Histology was improved with RSV added to HF+EtOH. By HRMAS, the number of fatty acids (FA) were similar in EtOH (+5±2.7%) *vs* control, but increased in HF+EtOH (+23±4.7%), in HF (+42±5.3%) and HF+EtOH+RSV (+47±10%). In all HF groups, choline/Pcholine ratio increased (2.50±0.23 *vs* 1.35±0.06 in control and EtOH), correlated to αtoco (R^2=0.96).
CONCLUSION: NMR was in agreement with histology: HF led to steatosis and inflammation, moderate EtOH induced no change, except increase in IR and TNFα. In HF+EtOH, fructose effects were the largest. Chol/Pchol was increased by fructose supply (in contrast to EtOH alone) and underlined early membranes changes which could explain later functional impairments, perhaps linked to inflammation. Chol/Pchol changes could converge with the steatohepatitis seen in methionine/chol deficient diet [3] but also with change in protein expression involved in LS observed in Lieber-de-Carli diet [4]. P1118 GASTROPARESIS RECOGNIZED BY THE GASTROPARESIS CARDINAL SYMPTOM INDEX (GCSI) ASSESSMENT, DOMINATING SYMPTOM AND METABOLIC CONTROL IN DIABETES AND IDIOPATHIC GASTROPARESIS

P. M. Hellström[1,*], M. Degerblad[2]. [1]*Department of Medical Sciences, Uppsala University, Uppsala,* [2]*Department of Surgery and Molecular Medicine, Karolinska Institutet, Stockholm, Sweden*

INTRODUCTION: Gastroparesis predominantly occurs in diabetics as a result of long-standing disease, but also in otherwise healthy subjects in an idiopathic form believed to be due to a passing viral infection. Gastroparesis is cumbersome as the disease entails severe symptoms of nausea and vomiting in its idiopathic form and in diabetics an even worse situation with metabolic derangement.
AIMS&METHODS: The aim of the study was to identify clinical characteristics in order to predict gastroparesis in diabetes types 1 and 2, as well as in its idiopathic form.
Patients with diabetic and idiopathic gastroparesis were evaluated using the gastroparesis cardinal symptom index (GCSI) and dominating symptoms of gastroparesis. In diabetics, symptom scoring was evaluated against glycaemic control (A1c) as well as scintigraphic gastric emptying test. Patients were studied at a tertiary referral centre with symptoms suggestive of gastroparesis. Totally 120 patients (87 females, 33 males) were evaluated by scintigraphic measurement of gastric emptying and symptoms scored using the standardized GCSI as well as HbA1c for glycaemic control.
RESULTS: Of a total of 72 diabetic patients (type 1 58, type 2 14) with symptoms from the upper gastrointestinal tract, 63 were found to have a derangement of gastric emptying profile. Of these, 44 had gastroparesis with gastric retention $>60\%$ at 120 min or $>10\%$ retention at 240 min. Among these, there was relationship between gastric retention and GCSI >2.50 $r=0.43$, $p<0.01$). The dominating symptoms were stomach fullness (84%), followed by loss of appetite (60%) and nausea (55%). Only about one tenth had overt vomiting (9%). A severe finding among the gastroparesis diabetics was a greatly deranged A1c (>80 mmol/mol in 53%, and >10 mmol/mol in 11%). Only 5 diabetics displayed a rapid gastric emptying, displayed GCSI <2.66 and A1c $<6\%$, thus presenting a separate issue. The symptom profile of idiopathic gastroparesis did not differ from that in diabetics in terms of GCSI.
CONCLUSION: High global GCSI scores as well as stomach fullness and loss of appetite and nausea scores correlated with gastroparesis. In addition, high A1c supports the presence of gastroparesis, most likely due to a long-lasting postprandial hyperglycemia. The GCSI symptom score can be used along with dominant symptoms such as an indicator of gastroparesis.

P1119 EVIDENCE OF BENEFICIAL EFFECTS OF MULTICOMPONENT PROBIOTICS CONSUMPTION ON PANCREATITIS-LIKE SYMPTOMS UPON LONG-TERM HYPOCHLORHYDRIA

S. E. Vakal[1], K. O. Dvorshchenko[1], T. V. Borodina[1], L. I. Ostapchenko[1,*]. [1]*ESC "Institute of Biology", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine*

INTRODUCTION: Hypochlorhydria is a frequent pluricausal disorder of gastrointestinal tract (GIT), which is caused, in most cases, by chronic proton-pump inhibitors (PPI) or antacids consumption, *H. pylori* infection or atrophic gastritis [1]. Low stomach acidity is associated with a range of negative consequences, such as colonization of GIT by opportunistic microbiota favouring inflammatory processes both in GIT and associated organs, such as pancreas [2]. Oxidative stress is a non-specific mechanism leading to pancreatitis-like symptoms in these conditions. Cure of dysbiosis by probiotic nutrient additives can be an effective way for pancreatic protection upon long-term hypochlorhydria.
AIMS&METHODS: The **aim** of work was to establish the effects of multistrain probiotics preparation "Symbiter" on the state of rat pancreas upon long-term gastric hypochlorhydria.
All experiments were performed with non-strain white male rats. 28-day long abdominal injection of PPI omeprazole (14 mg/kg once a day) was used for gastric hypochlorhydria induction (second group). "Symbiter" was administrated daily *per os* (third group). Control animals were treated with water. Indices of lipid functional groups were selected as markers of oxidative stress development. Total lipids were extracted from the pancreas by standard procedure. In the obtained fraction the spectrums of lipid functional groups, such as hydroxyl (HG), carbonyl (CG), aldehyde (AG), methyne (MG), methylene (MLG) and phosphate (PG) groups, were studied with infrared Fourier-spectroscopy. It was also measured the amount of fatty acid cis- and trans-isomers (FACI and FATI, respectively). The rate of superoxide (SO) and hydrogen peroxide (HP) generation, as well as xanthine oxidase activity were determined in pancreatic cells by established assays.
RESULTS: It was established the escalation of SO, HP, FATI, HG and AG content, as well as XO activity after prolonged injection of omeprazole – on 53%, 35%, 85%, in 3 times and on 25%, respectively. At the same time, FACI, CG, MG, MLG, and PG levels were lower than control on 58%, 31%, 20%, 64% and 50%, correspondingly.
The quantity of SO, HP, HG, FATI, AG and XO activity in animals of third group were lower on 17%, 43%, 39%, 25%, 99% and 28%, while level of FACI, CG, MG, MLG and PG was higher on 60%, 22%, 15%, 71% and 50% in relation with the second group animals.
CONCLUSION: So, there is clear evidence of beneficial action of multicomponent probiotic "Symbiter" on the state of rat pancreas upon conditions of experimental long-term hypochlorhydria suggesting the capability of probiotics to restore impaired functions of not only gut, but also associated organs.

P1120 EFFECT OF THE BITTER AGONIST DENATONIUM BENZOATE ON GASTRIC ACCOMMODATION IN RATS

S. Verschueren[1,*], A. Maes[1], C. N. Andrews[1], J. Tack[1,2]. [1]*TARGID, KU Leuven,* [2]*Gastroenterology, UZ Leuven, Leuven, Belgium*

INTRODUCTION: Intragastric administration of bitter receptor agonists decreased food intake in mice (Janssen *et al.*, PNAS 108(5): p2094). In man, the bitter agonist denatonium benzoate (DB) decreased nutrient tolerance and impaired gastric accommodation (Verschueren *et al.*, Gastroenterol 2012 142(5) S294).
AIMS&METHODS: Our aim was to study the effect of DB on gastric accommodation in conscious rats.
Nine Wistar rats were surgically equipped with a gastric fistula and given 1 week for recovery and adjustment to restraint. After an overnight fast, the rats were treated with a subcutaneous injection of the NO-donor molsidomine (M, 20 mg/kg) or vehicle (0.9% NaCl). After 1 hour, animals received DB (70 mg/kg) or placebo (PLA, water) via intragastric gavage. The fistula was then opened and connected with a manometry probe to measure intragastric pressure (IGP, a surrogate marker of gastric accommodation) as well as an infusion system to directly administer a liquid meal into the stomach, and rats were positioned in a restraint device. Fifteen min after gavage, meal infusion (Nutridrink®, 150 kcal/100ml) was initiated at a constant rate of 0.5 mL/min for 20 min. IGP was recorded before and during nutrient infusion. Comparisons of 1) DB vs PLA, and 2) M vs M+DB, were made separately using a linear mixed model analysis with time and treatment as factors. Results were compared in 5-minute blocks between groups (0-5 min, 6-10 min, 11-15 min, 16-20 min), with Bonferroni correction for multiple testing.
RESULTS: In all groups, IGP initially increased in response to nutrient infusion. For comparison 1, DB and PLA had similar IGP increases initially, then diverged after 15 minutes, with increasing IGP in the DB compared to a plateau effect in the PLA group ($p=0.011$). This suggests that the accommodation response is attenuated in response to DB. IGP values between molsidomine and molsidomine + DB did not differ ($p>0.1$ for all 5-min blocks).
CONCLUSION: Bitter treatment increases IGP during nutrient infusion, suggesting an attenuation of the gastric accommodation response in rats. DB did not affect IGP in the presence of a NO-donor, suggesting either a modest effect or a mechanism that does not involve NO pathways.

P1121 EFFECT OF SOY MILK ON GASTRIC ACCOMMODATION, GASTRIC EMPTYING, SATIATION AND SATIETY IN SUBJECTS WITH DYSPEPTIC SYMPTOMS

S. Verschueren[1,*], C. N. Andrews[1], A. Maes[1], K. Verbeke[1], J. Tack[1,2]. [1]*TARGID, KU Leuven,* [2]*Gastroenterology, UZ Leuven, Leuven, Belgium*

INTRODUCTION: Gastric accommodation (GA) is impaired in 40 % of patients suffering from functional dyspepsia, and is associated with early satiety and weight loss. Consumer research suggests that the public perceives soy milk as easier to digest and gives a lighter feeling in the stomach compared to cow's milk. Previously we showed that gastric emptying (GE) of soy milk was faster than cow's milk in healthy subjects, but this was not accompanied by a change in GA or differences in sensation during and after the milk meal.
AIMS&METHODS: We aimed to investigate the effect of soy milk on GA, GE and abdominal symptoms compared to cow's milk in subjects with dyspeptic symptoms.
16 patients (6 male, age 33 ± 3 yrs, BMI 23.8 ± 1.1 kg/m^2) with uninvestigated dyspeptic symptoms (postprandial fullness, early satiation, epigastric pain or burning, for at least 3 months) were recruited. After an overnight fast, a manometry probe to measure intragastric pressure (IGP) and an infusion catheter were positioned through the nose into the proximal stomach. After a stabilization period, cow's milk (45 kcal/100 ml) or soy milk (38 kcal/100 ml) was infused into the stomach at a constant speed (60 ml/min). At 1-minute intervals, subjects scored their satiation on a scale graded from 0–5. At 5-minute intervals subjects scored epigastric symptoms (hunger, expected amount to eat, satiation, bloating, fullness, nausea, belching, abdominal cramps and pain) using a visual analogue scale (VAS). Milk infusion was stopped at maximal satiation. We analyzed volume intake, maximal IGP decrease (nadir IGP) and time to nadir using paired t-test. GE was tested using the ^{13}C-octanoic acid breath test. Breath samples were collected before and every 15 minutes after the milk infusion started until 6 hours thereafter. Samples were measured by isotope ratio mass spectrometry and GE half-time was analyzed using paired t-test. Symptoms were scored using a VAS.
RESULTS: Subjects tolerated similar volumes of both milks (997 ± 73 ml cow milk vs. 1064 ± 92 ml soy milk; $p=0.36$). During infusion, nadir IGP ($p=0.9$) and time to nadir ($p=0.6$) were not different between milk types. Satiation scores during milk infusion were not different. GE of soy milk was significantly faster

than GE of cow's milk (GE half-time 82.4±5.9 min vs. 139.9±13.3 min, respectively; p=0.026). No differences were seen in symptom scores during and after milk infusion.
CONCLUSION: Soy milk empties faster compared to cow's milk, but does not affect GA or abdominal sensation in uninvestigated dyspepsia.

P1122 DIETARY INTERVENTION WITH A DIET RICH IN ARABINOXYLANS AND RESISTANT STARCH MODULATES T-CELL ACTIVATION ESTIMATED BY CD25 EXPRESSION IN METABOLIC SYNDROME

S. Hald[1,*], A. Dige[1], S. Stoy[1], M. Bendix[1], A. G. Schioldan[2], K. Hermansen[2], S. Gregersen[2], K. E. Bach Knudsen[3], J. Agnholt[1], J. F. Dahlerup[1]. [1]*Hepato-gastroenterology Department V, Aarhus University Hospital, Denmark,* [2]*Department of Medicine and Endocrinology MEA, Aarhus University Hospital, Aarhus,* [3]*Department of Animal Sience, Aarhus University, Tjele, Denmark*

INTRODUCTION: Arabinoxylans and resistant starch are substrates known to stimulate colonic short chain fatty acids production of which especially butyrate is suggested to exert an anti-inflammatory function in the colon. Metabolic syndrome is characterized by abdominal obesity, dyslipidaemia, elevated blood pressure and hyperglycaemia and is associated with a chronic low-grade colonic inflammation.
AIMS&METHODS: To investigate a four-week dietary intervention with arabinoxylans and resistant starch on mucosal T-cell activation estimated by their CD25 and CD69 expression in subjects with metabolic syndrome.
Methods: Nineteen subjects with metabolic syndrome were included in the study and followed the dietary intervention. Sigmoideoscopy with tissue samples was performed before and at the end of the four-week dietary intervention. Lamina propriae cells were isolated using enzymatic digestion of mucosal specimens. Isolated cells were stained for CD3 (T-cell marker), CD4, CD25 and CD69 expression.
RESULTS: T-cells showed decreased CD25 expression following a four-weeks intervention (p=0.01) but had unchanged CD69 expression. Also CD4+ T-cells and non-CD4+ T-cells showed decreased CD25 expression but unchanged CD69 expression (p=0.05 and p=0.009, respectively).
CONCLUSION: Dietary intervention with arabinoxylans and resistant starch in subjects with metabolic syndrome seems to be associated with reduced activation in intestinal mucosal T-cells.

P1123 THE EFFECT OF ADJUVANT SYNBIOTIC COMBINATION ON INDUCTION OF REMISSION IN PATIENTS WITH MILD-MODERATE ULCERATIVE COLITIS

T. Karakan[1,*], M. TAHTACİ[1], S. UNAL[1]. [1]*GASTROENTEROLOGY, GAZI UNIVERSITY, Ankara, Turkey*

INTRODUCTION: Ulcerative colitis (UC) is a chronic disease that characteristically has a relapsing and remitting course. Probiotics might possibly induce remission in the treatment of active UC. Aims of our study were to assess the efficacy of Probiotic Gold NBL® (*Lactobacillus acidophilus, Lactobacillus rhamnosus, Bfidobacterium bifidum, Enterococcus faecium, Bfidobacterium longum,* fructooligosaccharide, lactulose) on clinical response in patients with active UC.
AIMS&METHODS: Twenty-two patients (mean age 42±13 (17-67), M/F: 13/9) were enrolled. These patients had clinical and endoscopy score 4 and above levels. All patients received mesalazin 4 grams/day plus Probiotic Gold NBL® one sachet per day. After 8 weeks of treatment, patients were re-assesed for clinical and disease activity. We have compared these data with a historical cohort of 16 UC patients.
RESULTS: Among 22 patients, 2 patients did not have endoscopy control, and the remaining 20 patients were re-assesed after 8 weeks. Two patients had flare-up under probiotic plus mesalazin treatment in the first week and these patients were switched to steroid treatment. Intention-to-treat analysis (ITT) showed that, complete remission was achieved in 81.1% (18/22) vs 62.5% (10/16) (p<0.01) in study and control groups, respectively. Partial remission was achieved in 9% (2/22) vs 31.2%(5/16) (p<0.01) and non-response was seen in 9% (2/22) vs 6.25%(1/16) (NS) in study and control groups, respectivey. The mean decrease in the clinical activity score was 5.89±1.22 vs 4.35±1.56 (p=0.044), respectively.
CONCLUSION: Our study demonstrated that Probiotic Gold NBL® is effective in achieving clinical responses and remissions in patients with mild-to moderately active UC, further supporting the potential role in UC therapy.

P1124 EARLY PEAK OF HYDROGEN DURING LACTOSE BREATH TEST PREDICT INTESTINAL MOTILITY

V. Ojetti[1,*], T. A. Di Rienzo[1], G. D'Angelo[1], V. Cesario[1], M. C. Campanale[1], G. Rizzo[1], A. Gasbarrini[1]. [1]*cathollic university of rome, rome, Italy*

INTRODUCTION: Lactose breath test (LBT) is considered the gold standard for the diagnosis of lactose malabsorption. The test is considered positive for a peak over 20 ppm above the baseline. Some patients (pts) showed a rapid peak between 30 and 90 after lactose ingestion. Aim of the these study was to evaluated the predictive value of an early peak during a LBT and an accelerated orocecal transit time (OCTT).
AIMS&METHODS: From January to September 2012 we retrospectively analyzed all pts who referred to our Gastroenterology unit for IBS who were submitted to a LBT with an early peak (between 60-90 min) and to a lactulose BT. We considered a normal OCCT a peak of hydrogen ≥10 ppm between 40- 170 min after lactulose load. The breath test were performed according to the guidelines. Correlation between LBT and OCTT was evaluated by Pearson score.
RESULTS: 93 pts (65F/28M mean age 47+/-6 yrs) with a positive LBT who performed also a lactulose breath test were analyzed: 46 pts (32F/14M; mean age 48+/-6 yrs) with early peak of H2 (≥ 20 ppm) were used as case, and 47 pts matched for sex and age with peak of H2 (≥ 20 ppm) after 90 min were used as controls. 71% (33/46) of the group with an early peak showed an accelerated, 17% (8/46) a normal and 10% (5/46) a delayed OCTT. Meanwhile, in control group 40.4% (19/47) showed a normal, 57.5% (27/47) a delayed and just 1 pts (2.1%) an accelerated OCTT. The specificity and sensibility of LBT for an accelerated OCTT was 97.9 and 71.7% respectively. The positive predictive value of LBT for an accelerated OCCT is 97.1%; the negative predictive value is 78 %. There is a significant correlation between LBT and OCTT (p<0.05)
CONCLUSION: The presence of an early peak of H2 between 30 and 90 min after the ingestion of 25 gr of lactose could predict the presence of an accelerated OCTT in 97% of pts. If confirmed by further study, in this subset of pts lactulose breath test for evaluating OCTT could be avoided.

P1125 COMBINATION OF ENDOSCOPIC LITHOTOMY AND EXTRACORPOREAL SHOCK-WAVE LITHOTRIPSY OR ELECTROHYDRAULIC LITHOTRIPSY FOR CHRONIC PANCREATITIS

K. Ito[1,*], Y. Igarashi[1], T. Mimura[1], Y. Kishimoto[1], S. Hara[1], K. Takuma[1], N. Okano[1]. [1]*Division of Gastroenterology and Hepatology, Toho University Omori Medical Center, Tokyo, Japan*

INTRODUCTION: The efficacy of extracorporeal shock wave lithotripsy (ESWL) electrohydraulic lithotripsy (EHL) is well documented for the treatments of chronic pancreatitis lithiasis when endoscopic lithotripsy failed. To evaluate the efficacy of the combination of endoscopic lithotomy and ESWL or EHL for the treatment of pancreatic duct stones, we retrospectively evaluated the patients with symptomatic pancreatic duct stones that was treated at our institution.
AIMS&METHODS: Standard ERCP was performed for the treatment of pancreatic duct stones, and ESWL was considered in cases with endoscopically unremovable stones. If the ESWL and endoscopic lithotomy combination failed, EHL and ESWL on an outpatient basis was performed and was considered a second attempt. The Spyglass peroral pancreatoscopy system has been used for EHL since 2010 in our hospital. X-Ray guided EHL (using a 7Fr. outer sheath) was performed when a Spy glass system delivery catheter (10Fr) was difficult to insert.
RESULTS: A total of 98 patients with symptomatic chronic pancreatitis underwent endoscopic lithotomy for chronic calcific pancreatitis at our center between May 2005 and December 2012 (24 cases in single lithiasis group, 74 cases in diffuse lithiasis group). Fragmentation was successful in 80 (81.6%) patients (single 17 vs diffuse 63; p = 0.87). The successful results were obtained in 67 of 98 patients (74.5%) by combination treatment, 7 of 14 patients (7.1%) by EHL (Spyglass system 3, X-Ray guided EHL 4), and 6 of 6 patients (6.1%) by ESWL on an outpatient basis, respectively. Sixteen patients were out of indication, 12 cases had radiolucent stones, and 4 cases failed in selective pancreatic duct cannulation with radiolucent stones. Seventy-four of 92 patients (90.2%) with painful lithiasis reported complete pain relief and no analgesic use (single 17 vs diffuse 57; p = 0.89). On multivariate analysis, negotiating the guidewire through a severe MPD stricture was significantly associated with a higher rate of stone fragmentation (p = 0.0003).
CONCLUSION: EHL using the Spy glass system was effective in cases with MPD stricture when an ENPD or Endoscopic pancreatic stenting (EPS) could be placed and visualised directly. Combination EL and ESWL is safe and effective for the treatment of pancreatic duct stones. However further prospective randomized studies are needed to perform.

P1127 ENDOCOPIC APPLICATION OF THE OTSC MACROCLIP: INDICATIONS AND OUTCOMES - A 3 YEAR EXPERIENCE

E. Wedi[1,*], M. Delvaux[1], J. Huppertz[1], J. Hochberger[1]. [1]*Hepatogastroenterology, NHC, UNIVERSITY HOSPITAL OF Strasbourg, Strasbourg, France*

INTRODUCTION: The OTSC (OVESCO, Germany) is a novel endoscopic device successfully applied for severeGI bleeding, perforations, fistulas and experimental NOTES procedures.
AIMS&METHODS: We performed a retrospective analysis of all OTSC applications from February 2009 to October 2012 using our endoscopy database, hospital PIS and individual patient records. IRB was obtained for unpersonalised evaluation of patient's data and outcome.

RESULTS: Eighty-four patients [median 71 y (2-98) 34 women, 50 men, ASA 2-4] were treated with 101 OTSC clips (12/6 T-type: n=75; 14/6 T-type: n=26). In 59 patients (69 %), OTSC was placed to treat digestive bleeding: 41 severe upper GI bleeding (48.8 %), 3 lower GI bleeding (3.6 %), 12 patients after successful primary haemostasis (14.3 %) for prevention of re-bleeding in high risk situations after EMR/ESD. In 38/41 patients, upperGI bleeding was related to peptic ulcer disease, in 2 cases to a malignant gastric ulcer (1 adenocarcinoma, 1 lymphoma). One patient bled from a muscle laceration after balloon dilation for achalasia. Among the 44 patients with bleeding, 13 (29.5%) received an OTSC after failure of standard haemostasis (haemoclip or injection). OTSC placement allowed permanent haemostasis in 38/44 (86.3%). Despite OTSC application, 5 patients (11.4 %) died because of persistent or recurrent severe bleeding.
In 25 cases (29.7 %) the OTSC was used for closure of a wall defect: In 7 patients (8.3 %) OTSC was placed to treat a perforation, with successful closure in 4 (57.1%). In 18 patients OTSC was used for prevention of a secondary defect after EMR/ESD (21.4 %) with closure of the defect in all cases. In 3 patients with fistula, closure was achieved in all cases. Complications related to OTSC placement occured in 3 patients: In 1 case, the grasper was caught within the teeth of the OTSC due to an insufficient retrieval of the grasper before firing the OTSC. In 1 case, the clip was prematurely released in the stomach due to adhesion of the traction string to the grasper and uneventfully retrieved. One patient with right colon perforation after EMR underwent successful local treatment using two 14/6 t OTSC devices. However, a secondary perforation occurred due to a narrow diverticulosis of the sigmoid colon and patient underwent uneventful sigmoid resection.
CONCLUSION: The OTSC system is a promising new tool for the management of GI emergencies and complications. Further clinical experience will help to identify optimal indications.

P1128 THE NEW TECHNIQUE OF HYBRID APC FOR THE ABLATION OF BARRETT'S ESOPHAGUS: INTERMEDIATE RESULTS OF A PILOT SERIES

H. Manner[1,*], I. Kouti[1], A. May[1], A. Behrens[1], M. Vieth[2], C. Ell[1]. [1]*Department of Internal Medicine II, HSK Hospital Wiesbaden, Wiesbaden,* [2]*Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: Thermal ablation techniques such as radiofrequency ablation (RFA) or argon plasma coagulation (APC) have been shown to be effective in Barrett's esophagus. However, stricture formation is reported to occur in 5-15% of patients treated. Therefore, new ablation techniques are under evaluation.
AIMS&METHODS: The aim of the present trial was to evaluate efficacy and safety of the new technique of Hybrid APC which is a combination of APC with submucosal injection of sodium chloride pior to ablation.
Patients who had undergone endoscopic resection of early Barrett's neoplasia (adenocarcinoma or high-grade dysplasia) and in whom a Barrett's remainder of at least 1 cm in length was present were included into the present pilot series. After submucosal injection of sodium chloride in a dilution of 0.9% using a water-jet system (ERBE JET 2, Erbe Elektromedizin, Tuebingen, Germany), the remaining non-neoplastic Barrett's mucosa was ablated dynamically using APC with a wattage of 50 to 60 (pulsed effect 2). Three months after completion of Barrett's ablation, upper GI endoscopy was carried out (1) for evaluation of treatment-related strictures and (2) for taking 4-quadrant biopsies from the whole area of the former Barrett's segment including the Neo-Z-line.
RESULTS: A total of 60 patients were included into the study (male 55 (92%), female 5 (8%)). The mean age of patients was 62.2 years (range 42-78). 5/60 patients were excluded from analysis (insufficient wound healing during ablation / wrong inclusion). 19 of the 55 remaining patients were still under ablation treatment at the date of analysis. In 36 of the 55 patients complete macroscopic Barrett's ablation was achieved after a mean of 3.4 treatment sessions (range 1-10). In 17 patients, 3-month follow-up was obtained, and the rate of histologically complete Barrett's ablation was 88% (15/17). In none of the patients stricture formation was observed after hybrid APC.
CONCLUSION: According to the intermediate results of this pilot series on Hybrid APC for Barrett's ablation, this new ablation technique appears to be effective and safe, with a stricture rate that may be lower than rates known from conventional ablation techniques. Randomized trials comparing the various ablation techniques available would be helpful to clarify the value of Hybrid APC.

P1129 PER ORAL ENDOSCOPIC MYOTOMY: THE FIRST EXPERIENCE IN THE CZECH REPUBLIC

J. Martinek[1,*], T. Rösch[2], E. Kieslichova[3], R. Janousek[4], M. Smejkal[5], J. Spicak[1]. [1]*HEPATO-GASTROENTEROLOGY, INSTITUTE FOR CLINICAL AND EXPERIMENTAL MEDICINE, Praha 4, Czech Republic,* [2]*Interdisciplinary Endoscopy, University Hospital Hamburg-Eppendorf, Hamburg, Germany,* [3]*Anaesthesiology, Resuscitation and Intensive Care,* [4]*Radiology, INSTITUTE FOR CLINICAL AND EXPERIMENTAL MEDICINE, Praha 4,* [5]*Surgery, University Hospital Motol, Praha 5, Czech Republic*

INTRODUCTION: Peroral endoscopic myotomy (POEM) is an endoscopic alternative to laparoscopic myotomy. This promising procedure is still considered experimental. Herein, we report the short-term results of the prospective study of POEM in the Czech Republic.
AIMS&METHODS: A single center study. POEM procedure was conducted under general anesthesia. For mucosotomy, dissection and myotomy, a triangle knife was used. We analyzed short term results of 13 consecutive patients (8 female, 5 male, mean age 46 years, range 22-71). A 3-months follow-up was completed for all patients. The primary outcome was symptom relief at 3 months defined as an Eckhard score ≤ 3. All patients had a diagnosis of achalasia based on endoscopic, manometric (high resolution or standard manometry) and radiologic examinations. Seven patients (53%) had undergone treatment previously with limited success (4x balloon dilatations (BD), 3x BD with botulinum toxin (BT) injection).
RESULTS: *A. PROCEDURE*: POEM was completed in all patients. The mean length of procedure (LOP) was 96 ± 12 minutes. The mean myotomy length was $9{,}6 \pm 1{,}3$ cm (range 8-12). In two patients (1x after previous BD and 1x after previous BD+BT), an inadvertent mucosotomy occurred in the gastric cardia. These minor complications were repaired intraoperatively with clips. In 5 patients (38%), capnoperitoneum was decompressed by using a standard venous cannula. One patient had radiologic evidence of minor leakage at the mucosotomy site which resolved spontaneously. No serious intraoperative or postoperative complications occurred and all patients were dismissed 2nd or 3rd postoperative day.
B. TREATMENT RESULS: Three months after POEM, treatment success (Eckhard score ≤ 3) was achieved in 12 patients (92%; mean score pre- vs. post-treatment $6.6 \pm 1{,}6$ vs. $0{,}8 \pm 0{,}7$; $p < 0{,}001$). The mean percentage of overall improvement was $88\% \pm 9$. Manometric parameters (IRP for HRP or LES pressure for standard manometry) improved in 12 patients. One patients (8%) developed minor reflux symptoms (heartburn). This patients has been treated with a proton pump inhibitor on demand. A pathological gastro-esophageal reflux (DeMeester score >14) was detected in 6 (46%) patients.
CONCLUSION: POEM is a safe and effective treatment modality in patients with achalasia with excellent short term results. There is a significant (though almost) asymptomatic reflux postoperatively in 46% of patients in 3-months pH metry studies.

P1130 CLINICAL AND PROCEDURAL FACTORS PREDICTIVE OF COMPLETE SYMPTOMS RELIEF AFTER PERORAL ENDOSCOPIC MYOTOMY (POEM). RESULTS OF A SINGLE CENTER EXPERIENCE

P. Familiari[1,*], M. Marchese[1], G. Gigante[1], I. Boskoski[1], A. Tringali[1], V. Bove[1], C. Marmo[1], R. Landi[1], V. Perri[1], G. Costamagna[1]. [1]*Digestive Endoscopy Unit, Gemelli University Hospital, Rome, Italy*

INTRODUCTION: Peroral Endoscopic Myotomy (POEM) is gaining international consensus in the treatment of achalasia. The severity of achalasia is summarized by Eckardt score (ECK), that includes data on dysphagia, regurgitation, pain and weight loss. Clinical success is usually defined by ECK < 3. The reasons why some patients have residual symptoms after treatment (ECK >1) and other do not is unknown.
AIMS&METHODS: Aim of this study is to identify clinical, manometric and procedural factors associated with complete symptoms relief (CSR) after POEM. Sixty-three patients underwent POEM in our tertiary referral center between 2011 and April 2013. Fifty-three patients (18 men, mean age 46 years) completed a 3-month follow-up (mean 8 months) and were included in the study. Patients underwent scheduled follow-up 3, 6, 12, 18 and 24 months after POEM. Demographics (sex and age), data on the clinical history (symptoms duration, preoperative ECK and previous treatments), the esophageal manometry (preoperative and postoperative basal LES pressure, achalasia type and absolute variation of basal LES pressure after POEM) and the procedure (length of myotomy) were prospectively collected and analyzed. ECK was used to evaluate response to therapy. Chi-square and ANOVA test were used to identify factors related with CSR after POEM.
RESULTS: Forty-six patients had classic- type achalasia, 7 vigorous-type. Mean symptoms duration before POEM was 29 months (3-120 months). Nine patients had received previous endoscopic treatments. Mean preoperative basal LES pressure and ECK were 40.2 mmHg (11-97.4 mmHg) and 7.7 (4-11), respectively. Mean length of myotomy was 11.6cm (7-17cm). POEM was clinically successful in 98% patients (ECK < 3). No major complications occurred. After POEM, mean basal LES pressure decreased by 23.4mmHg; 29 patients had CSR (ECK=0), 24 had some residual symptoms (ECK > 1).
At univariate analysis CSR was positively associated only with the duration of symptoms before POEM (35 months (ECK 0) vs 21 months (ECK >1), p=0.05). Variation of the basal LES pressure was substantially higher in the CSR group (30.2 mmHg vs 19.0 mmHg, p=0.07). CSR was not associated with sex, age, preoperative ECK, preoperative and postoperative basal LES pressure, previous treatments, vigorous-type achalasia
CONCLUSION: POEM procedure is associated with very good mid-term outcomes. Treatment failure occurred in 1 patient (2%) only, but mild residual dysphagia remained in up to 43% of patients (ECK $>1<3$). CSR may be associated with the duration of symptoms before treatment
Disclosure of Interest: None Declared

P1131 FLEXIBLE ENDOSCOPIC TREATMENT OF ZENKEŔS DIVERTICULUM: A SAFE AND EFFICIENT METHOD

P. Diez Redondo[1,*], H. Núñez Rodríguez[1], I. Peñas[1], A. Vargas Garcia[1], C. De la Serna Higuera[1], P. Gil Simón[1], M. Pérez-Miranda[1]. [1]*Gastroenterology, Universitary Hospital "Rio Hortega", Valladolid, Spain*

INTRODUCTION: Zenkeŕs diverticumlum (ZD) is a cause of dysphagia and can cause serious complications such as aspiration pneumonia and malnutrition. Treatment is usually surgical or by rigid endoscopic diverticulotomy.
AIMS&METHODS: We present the results of a serie of patients treated with ZD flexible endoscopic mucomyotomy using an electric generator, as a forceps, which allows vessel sealing, autologous and permanent, before the section of the septum between the diverticulum and the esophagus, which prevents bleeding and tissue dissection. (Ligasure, Valleylab, Boulder, CO).
RESULTS: Prospective study. 27 ZDs mucomyotomies from may 2010 to april 2013 in 24 patients: 17 males and 7 females, median age 74.8 years (54-92). All with dysphagia (71% solids, 25% mixed and 4.2% for liquids) and other symptoms as regurgitation 42%, chronic cough 21%, aspiration pneumonia 12.5% or weight loss 12.5%. Mean length of ZD was 23 mm. Under propofol sedation a wire is housed in the esophagus to facilitate isolation of the diverticular septum with placement of a rubber bivalve diverticuloscope (Cook Medical) previously to his section with Ligasure device inserted through the diverticuloscope. Each patient received an average of 1.3 cuts/ session (1-3). After the procedure, one or more clips (Boston Scientific®) was placed in 70% of cases with profhylactic sense but two: to sealling a small perforation or to hemostasis in the other. Immediate complications: two mild (moderate cervical pain and minimun bleeding easily controlled with a clip) and a major complication (pneumomediastinum secondary to small perforation without require surgery) and no subsequent complications. The procedure was entire ambulatory except in the two patients who suffered severe neck pain or pneumomediastinum. A month after the procedure 23 of 24 patients reported no dysphagia. During the follow-up (18.8 months, 1-36) there were two recurrences: one month early, after a slight initial improvement, and another in the form of regurgitationat 8 months. In both cases there was a new session mucomiotomía getting a poor result in the first case, she was a woman of 92 years in which neither third session later got the resolution of her dysphagia because it was associated a severe dysmotility, and in a male with a diverticulum larger than 3 cm were treated effectively in a second session.
CONCLUSION: The flexible endoscopic mucomyotomt of ZD with Ligasure device provides a safe and effective treatment of Zenker's diverticulum. The use of this technique, usually ambulatory, it is probably most cost-effective than conventional surgical treatment.

P1132 A NEW DEVICE TO EXPEDITE ENDOSCOPIC SUBMUCOSAL DISSECTION PROCEDURES: A RANDOMIZED ANIMAL STUDY OF EFFICACY AND SAFETY

S. Leblanc[1,*], A. Brehm[2], A. Rouquette[3], F. Prat[1]. [1]*Gastroenterology, CHU COCHIN, Paris, France,* [2]*Institute of Medical and Polymer Engineering, Technical University of Munich, Munich, Germany,* [3]*Pathology Department, CHU COCHIN, Paris, France*

INTRODUCTION: Endoscopic Submucosal Dissection (ESD) is a recognized method for the curative treatment of superficial neoplasia, but its use is limited by lengthy procedures and the lack of versatility of existing knives. We developed a prototype ESD device with the ability to work as a needle, as a hook or as a "scythe". This new device was compared to regular ESD knives in a randomized animal study.
AIMS&METHODS: Eight pigs (4 pigs in the serie 1 and 4 pigs in the serie 2) underwent 2 gastric ESD procedures each, similar in size and difficulty, one with a standard ESD device (Dual Knife, Olympus in serie 1, and FlushKnife 1.5mm, Fujifilm Corporation in serie 2) and the other with the new device (prototype 1 in serie 1, and prototype 2 in serie 2, with additionnal features as a flushing port and a modified tip). The order and location of each ESD, as well as the performing operator, were randomized. Primary judgment criterion was safety of procedures. Overall and submucosal dissection procedure times were measured. Time to surface ratios were measured and estimated for ESDs larger than those performed. Histopathology of the resected tissue and remaining stomach was done after each experiment.
RESULTS: No complication was observed throughout the study and all resections were completed en-bloc and uneventfully. The submucosal extension of resections was similar with both the standard and the new devices. Table A shows characteristics of gastrics ESDs in the serie 2. A comparison of time-consumption between groups did not show statistically significant differences, but a dramatic reduction of procedure duration was observed in some procedures with the new device; based on observed data, a potential time-saving of up to 66% was anticipated, with a relatively short learning curve.
CONCLUSION: This new versatile device proved to be as safe as regular ESD knives, and seems likely to help reducing procedure durations.

P1133 BLUE LASER IMAGING (BLI) FOR DETERMINING EARLY GASTRIC CANCERS

S. Kiriyama[1,*], H. Naitoh[1], M. Fukuchi[1], T. Fukasawa[1], Y. Tabe[1], H. Yamauchi[1], M. Suzuki[1], T. Yoshida[1]. [1]*Surgery, Gunma Chuo General Hospital, Maebashi, Japan*

INTRODUCTION: Blue LASER Imaging (BLI) is a new endoscope system with two semiconductor lasers as a light source instead of xenon lamp. BLI might enhance images of the irregular mucosal structures and micro-vessels of neoplasia. BLI could be considered as a more clinically useful endoscopy system in detection and diagnosis for gastrointestinal neoplasia including gastric cancer.
AIMS&METHODS: This study aimed to evaluate the usefulness of BLI observation for early gastric cancer. The first 7 cases of BLI observation for early gastric cancers in our institution were enrolled and analyzed retrospectively in this study. The procedures were performed using BLI system (LL-4450, Fujifilm Co., Tokyo, Japan) and an endoscope (EG-L590WR). Written informed consents for chromo-endoscopy examination and endscopic submucosal dissection (ESD) were received from all patients. All ESD were attempted under deep sedation using propofol. Three different type of endoscopic images using BLI, white light mode (WL) and white light mode after indigo-carmine dye-spray(IC) were obtained at just prior to ESD. Afterwards ESDs were performed. The images obtained by each method were ranked on the basis of the ease of recognition of demarcation using a 4-point system (1: unclear, 2: visible, 3: good, 4: excellent).
RESULTS: Mean tumor size and resection size were 19mm and 33mm, respectively. All lesions were able to be recognized and removed en bloc. All tumors were diagnosed as differentiated-type of early gastric cancer and as curative histopathologically. Further, the lateral and vertical margins of all specimens were free of neoplasia. The mean score of BLI images was significantly higher than that obtained from WL images (3.7 and 2.4, respectively, $p<0.05$). There was no significant different between the mean score of BLI images and IC Images. However, the scores of BLI images were higher than IC images in tumors located anterior wall of lower third where is difficulty in viewing because of retained indigo-carmine.
CONCLUSION: BLI appears to be a feasible endoscopy system to determine differentiated-type of gastric cancerous lesions.

INTRODUCTION: Large sessile or flat intestinal lesions >2cm are optimally removed en-bloc for accurate histology and complete resection. Current

submucosal dissection devices are technically challenging to use, resulting in long and sometimes incomplete procedures with a relatively high risk of major complication. We describe, a simple to use, multi-modality endoscopic device (''Speedboat'') for wide-field, en-bloc mucosal resection.
AIMS&METHODS: The 'Speedboat' cuts in forward, lateral and oblique planes using bipolar radio frequency (RF) cutting, provides haemostasis with microwave coagulation and incorporates a retractable needle for submucosal injection and tissue irrigation. The instrument blade has an insulated 'hull' to prevent thermal injury and the device catheter is partially torque stable allowing rotation and orientation of the hull to protect the underlying muscularis propria. The electrosurgical generator is comprised of 2 power sources, one operating at 400KHz (RF) and the other at 5.8GHz (microwave).
Speedboat submucosal dissection technique (SSD) was performed and video recorded on 4 consecutive 60kg pigs. Mucosal areas to be resected were marked prior to submucosal injection. The mucosa was then circumferentially incised and resected by SSD. The time taken to complete resection, complications encountered and power settings used were recorded. Immediately after the procedure, the animals were euthanized, and the resection defects measured and assessed histologically.
RESULTS: Eight consecutive resections were performed (2 per animal), 7 in the colorectum and 1 in the antrum of the stomach. The median time to complete a resection was 37 minutes range (30-60 minutes) using RF cutting 24W, voltage circa 300Vrms. Median defect size (longest diameter) was 53.5mm, range 40-80mm. Microwave coagulation was applied for either minor bleeding or visible vessels on 32 occasions (mean energy 7.5W). An endoclip was used once to control arteriolar bleeding but no other haemostatic device was required. There were no perforations and histology showed an intact and viable muscle layer with some remaining submucosa in all cases.
CONCLUSION: This initial evaluation of the ''Speedboat'' suggests that it facilitates rapid and safe en-bloc mucosal resection in the large bowel and gastric antrum.

P1135 FOLLOW UP AFTER COMPLETE ENDOSCOPIC RESECTION OF SUBMUCOSAL INVASIVE COLORECTAL CARCINOMAS

E. Bories[1,*], F. poizat[2], F. caillol[1], C. pesenti[1], B. lelong[1], C. de chaisemartin[3], G. monges[4], J. R. delpero[5], M. giovannini[1]. [1]*ENDOSCOPY,* [2]*Department biopathology,* [3] *Department of Oncological and Digestive Surgery,* [4] *Department biopathology,* [5]*Department of Oncological and Digestive Surgery, INSTITUT PAOLI CALMETTES, MARSEILLE, France*

INTRODUCTION: The aim of this study was to evaluate the efficacy and outcomes of treatment by endoscopic resection (ER) of patients with colorectal carcinoma with submucosal involvement.
AIMS&METHODS: Datas of patients with endoscopically resected colorectal carcinoma with submucosal invasion from 2006 to 2012 were retrospectively reviewed. Submucosal invasion was classified according as the Paris classification[1]. Patients staged SM1 with poor prognostic factors (budding, poorly differenciated, embols) or SM2/SM3 were referred to surgery while SM1 patients were purposed for follow up.
RESULTS: 41 patients (16 female, median age = 30 yr [35-88]) were treated by ER for 43 colorectal adenocarcinoma with submucosal invasion (rectum=17, colon=26).
Median tumor size was 30mm (range 10-50mm). Endoscopically complete resection rate was 100%, En bloc in 51%. Complications occurred in 14% (hemorrhages=4, perforations=2) and all were managed conservatively.
Histological examination showed adenocarcinoma in all cases, poorly differenciated in 0%. Budding, vascular or lymphatic embols was found respectively in 5%, 11% and 2%. Clear deep resection margins were found in only 58%. Lateral resection margins was free in 77% of evaluable specimen (only after en bloc resection). Submucosal invasion was classified SM1, SM2 or SM3 respectively in 32%, 28% and 5%. In 15 cases (35%), it was not possible to precise the level of submucosal invasion (SMx).
Surgical resection (27%) were performed for 11 patients (27%; 4 SM2, 6 SMx, 1 SM1 (budding+). No residual parietal tissue was found in all cases then postoperative staging was pT0N0 in 9 cases, pT0N+ in 2.
18 patients were followed during median follow up period of 27 months (range 4-73): SM1=9, SM2=3, SM3=1, SMx=5. Local recurrence was found in only 1 case (5%) treated endoscopically. No distant metastasis was observed.
12 patients were lost during follow up.
CONCLUSION: Endoscopic resection is a safe and efficient treatment for colorectal adenocarcinoma with submucosal invasion. Endoscopic examination of resection margins seems to be superior to the histopathological examination to predict R0 resection. A better knowledge of prognostic factors would improve identification of patients with risk of lymph node metastasis and thus to avoid unnecessary surgeries.

P1136 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) UP TO 19 CM FOR 116 LARGE LATERALLY SPREADING TUMORS OR LOCAL RECURRENCES IN THE RECTO-SIGMOID, A SINGLE CENTER PROSPECTIVE TRIAL

J. Hochberger[1,*], E. Wedi[1], J. Huppertz[1], M. Delvaux[1], E. Kruse[2]. [1]*Hepatogastroenterology, NHC, UNIVERSITY HOSPITAL OF Strasbourg, Strasbourg, France,* [2]*Hepatogastroenterology, St Bernward Hospital, Hildesheim, Germany*

INTRODUCTION: After piecemeal-EMR of lateral spreading tumors (LST) larger than 2cm in the colo-rectum, recurrence rate is about 15%. Moreover, adenomas have a size-dependent progressive risk of malignant transformation. ESD provides an 'en bloc' specimen allowing a precise vertical and lateral pathological evaluation of resection margins. We report in the present study the indications, technical data and outcomes of 116 consecutive recto-sigmoid ESD.
AIMS&METHODS: PATIENTS & METHOD: From 03/2006 to 09/2012, all patients referred for treatment of LST in the rectosigmoid were included in a prospective cohort. Data were obtained for patient demographics, technical conditions of the procedure, follow-up and outcome.
RESULTS: 116 ESDs were performed in 113 patients (Median age 68 years (47-90 y) - 41 women, 72 men). In one patient, 3 lesions were resected in 2 sessions. 22 patients (19.4%) had previous treatment by EMR (n=15) or surgical full-thickness resection (n=7). 61 (52.6%) lesions were located in the rectum, 36 (31%) at the rectosigmoid junction and 19 (16.4%) in the sigmoid colon. En bloc resection was possible for 107 lesions (92.2%) with tumour-free margins confirmed in 80 (71.5%). In 5 (4,3%), pathological assessment was not possible due to thermal artefacts. The size of the formalin-fixed specimen ranged from 2.5x1.5 to 19x13.9 cm. Pathology revealed 11 adenocarcinomas (9.5%), 6 pTis (5.2%), 1 neuroendocrine tumor and 1 lymphoma. 40 lesions (34.5%) were low grade dysplasia adenomas and 56 (48,3%) high grade ones. Median follow-up was 550 days (17-2362 days). Two patients died from unrelated causes and 7 pT1 cancers underwent surgery. All other cases were followed conservatively, no recurrence being observed at control endoscopies. In one case (1.8%) a secondary 6 mm LGD adenoma was resected at month 12 close to resection scar. Four perforations during or following ESD (3.4 %) were managed conservatively. In one case, ESD was accompanied by a rare colonic methan gas explosion and the patient operated on for safety reasons (prior ESD specimen R0). 5 minor bleedings (4.3%) occurred, no patient requiring blood transfusion.
CONCLUSION: ESD appears to be an effective treatment for LST in the rectosigmoid, even in patients having previously undergone other therapeutic attempts. The high rate of lesions with high grade dysplasia or malignancy on the resected specimen (66%) highlights the importance of an 'en bloc' resection for lesions >3 cm. The low local recurrence rate of 0-3% underlines the potential value of the technique.

P1137 THE LEARNING CURVE FOR IN-VIVO CHARACTERISATION OF SMALL COLONIC POLYPS: COMPARISON BETWEEN EXPERT AND TRAINEE ENDOSCOPIST

P. J. Basford[1,*], G. Longcroft-Wheaton[1], P. Bhandari[1]. [1]*Gastroenterology, PORTSMOUTH HOSPITALS NHS TRUST, Portsmouth, United Kingdom*

INTRODUCTION: The learning curve for a new technology for real-time characterisation of small colonic polyps has not been determined. The ASGE has set performance criteria for 'resect and discard' and 'do not resect' policies for diminutive colonic polyps.
AIMS&METHODS: We aimed to assess the learning curve of a novel electronic in-vivo characterisation technology (Pentax i-Scan). Patients presenting for colonoscopy were prospectively recruited. Colonoscopies were either performed by an expert endoscopist or a trainee endoscopist. Both had no prior experience of i-Scan. Polyps <10mm in size were assessed using high definition white light (HDWL) followed by i-Scan.
Predicted histology with each modality was compared to the final histopathological diagnosis. Results were unblinded and fed back to the endoscopist after each 50 polyps. To assess any learning effect, results were analysed in sets of 100 consecutive polyps for overall accuracy and PIVI criteria performance.
RESULTS: 598 polyps found in 233 patients were eligible for inclusion in the study. 400 polyps were examined by the expert endoscopist and 198 by the trainee. Mean polyp diameter was 4.1mm, median 3mm. 249 polyps were non-neoplastic, 347 were adenomatous and 1 cancer.
For the expert endoscopist a $>90\%$ accuracy was achieved with both modalities once 200 polyps had been examined. Expert accuracy was significantly higher for polyps 201-300 compared to polyps 1-200 on both HDWL (92% vs 79% respectively, p=0.005) and iScan (93% vs 82% respectively, p=0.014). The ASGE threshold of $>90\%$ negative predictive value for adenomatous histology for a 'do not resect' policy in diminutive rectosigmoid polyps (DRSP) was achieved consistently by the expert endoscopist after 200 polyps and by the trainee from the first 100 poylps. However the ASGE threshold of $>90\%$ correct surveillance interval prediction for a 'resect and discard' policy of all diminutive polyps was not achieved by either endoscopist in the first 200 polyps, but was achieved after 200 polyp assessments by the expert endoscopist.

Table 1 - Accuracy rates with HDWL & iScan. E = Expert, T=Trainee

Polyp number		1-100	101-200	201-300	301-400
WL Accuracy %	E	75	83	92	95
	T	83	81		
i-Scan Accuracy %	E	82	82	93	97
	T	86	82		
WL NPV DRSP%	E	96	94	100	100
	T	88	90		
i-Scan NPV DRSP %	E	96	85	100	100
	T	92	93		
WL Surveillance interval accuracy %	E	77	89	95	93
	T	86	82		
i-Scan Surveillance interval accuracy %	E	81	87	95	98
	T	81	80		

CONCLUSION: 1) In expert or trainee hands there is a significant learning curve when using a new technology for the in-vivo characterisation of small colonic polyps.
2) The PIVI threshold for a 'resect and discard' policy may require a longer training period than for a 'do not resect' policy

P1138 COMPLICATIONS AFTER ERCP USING A SHORT DOUBLE BALLOON ENTEROSCOPE (DB-ERCP) IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY: A RETOROSPECTIVE EVALUATION OF 473 PROCEDURES

M. Shimatani[1,*], M. Takaoka[1], T. Ikeura[1], T. Mitsuyama[1], M. Matsushita[1], K. Okazaki[1]. [1]*The Third Department of Internal Medicine, Kansai Medical University, Hirakata, Japan*

INTRODUCTION: ERCP is technically challenging for patients with altered gastrointestinal anatomy. With a conventional endoscope, ERCP was very difficult for the patients with altered gastrointestinal anatomy. A recently introduced double balloon enteroscope (DBE) has made ERCP possible for these patients. Although ERCP using DBE (DB-ERCP) has been established as an effective tool, little has been known about the complications after DB-ERCP.
AIMS&METHODS: The aim of this study was to evaluate the result of DB-ERCP and to highlight complications after DB-ERCP. Between February 2006 and February 2013, we performed ERCP with the use of a short type DBE in 269 patients with various anatomic variations (473 procedures; 248 procedures for Roux-en-Y reconstruction (R&Y), 95 procedures for Billroth II gastorectomy (BII), 65 procedures for pancreatoduoderectomy (PD), 40 procedures for pylorus preserving pancreaticoduodenectomy (PpPD), and 25 procedures for others), evaluated the technique and revealed complications after DB-ERCP.
RESULTS: Deep insertion of the DBE to the blind end was successful in 463 of the 473 procedures (97.9%). The success rate was 97.2% (241/248) for R&Y, 100% (95/95) for BII, 98.5% (64/65) for PD, 95.0% (38/40) for PpPD, and 100% (25/25) for others. Deep biliary cannulation was successful in 440 of the 463 procedures (95.0%). The success rate was 97.1% (234/241) for R&Y, 93.7% (89/95) for BII, 98.4% (63/64) for PD, 97.4% (37/38) for PpPD, and 96.0% (24/25) for others. Therapeutic intervention was achieved in all of the 440 procedures of successful deep cannulation (100%). Complications occurred in 20 of the 473 procedures (4.2%) (20 procedures; 11 procedures for R&Y, 7 procedures for BII and 2 procedures for PD), including perforation (12 procedures; retroperitoneal perforation (n=3), post ES perforation (n=3), intestinal perforation (n=5), and subcutanus emphysema with pneumothrax (n=1)), laceration (n=4), acute pancreatitis (n=3), and carbon dioxide narcosis (n=1). Although two patients (one with intestinal perforation and the other with juxtrapapillary duodenal diverticula perforation) required urgent surgery, the other 18 patients were managed successfully with conservative treatments, including nothing per mouth, placement of nasojejunal tube, endoclip closure and placement of chest tube. Although severe pancreatitis occurred in one patient, the patient recovered with conservative treatments.
CONCLUSION: Complications after DB-ERCP were revealed and showed in the details. DB-ERCP is highly effective and relatively safe for patients with altered gastrointestinal anatomy.

P1139 PERORAL PANCREATOSCOPY WITH SPYGLASS INFLUENCES CLINICAL DECISION MAKING IN SUSPECTED INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS (IPMN)

U. Arnelo[1,*], A. Siiki[1,2], F. Swahn[1], R. Segersvärd[1], L. Enochsson[1], M. del Chiaro[1], C. Verbeke[3], M. Löhr[1]. [1]*Dept of CLINTEC, Div of Surg, Karolinska Institutet, Stockholm, Sweden,* [2]*Dept. of Gastroenterology and Alimentary Tract Surgery, Tampere University, Tampere, Finland,* [3]*Dept. of Pathology, Karolinska Institutet, Stockholm, Sweden*

INTRODUCTION: The prompt diagnosis and evaluation of intraductal papillary mucinous neoplasms (IPMN) remain an important clinical challenge to pancreatologists, in spite of advanced imaging modalities employed. There are only few studies about peroral (SpyGlass) pancreatoscopy in the evaluation of IPMN or cystic tumours of pancreas
AIMS&METHODS: To assess the usefulness and impact on clinical decision-making of peroral pancreatoscopy in suspected IPMN.
The study included all consecutive cases with suspected IPMN in which ERCP and peroral pancreatoscopy were performed between July 2007 and March 2013 in a single tertiary centre (Karolinska University Hospital, Huddinge). Three cases with unsuccessful pancreatic cannulation were excluded.
RESULTS: SpyGlass investigation was performed to 41 patients (median age 65 years, 41% female) with suspected IPMN (44% incidental findings). The desired part of the pancreatic duct was reached in all cases. Brush cytology was taken in 88% and directed biopsies in 39% (4% and 10% of which showed malignancy, respectively). Of 21 cases consequently operated, the most common diagnoses were IPMNs with moderate (42%) and high-grade dysplasia (29%). During follow-up (median 1.8 years), 3 more cases were referred to operation due to radiologic progression after 1-3 years from pancreatoscopy. Endoscopy gave additional information in up to 95% and strongly affected the clinical decision-making in 76% of all cases. The incidence of post-ERCP pancreatitis was 17%.
CONCLUSION: Peroral pancreatoscopy with directed biopsies is an expert technique complementing the diagnostic imaging in this group of patients. It allows for the evaluation of IPMNs extent and main duct involvement. It is also guiding the clinical decision-making between follow-up and surgery. The post-ERCP pancreatitis rate, even in the hand of experts, needs careful consideration in the selection of patients.

P1140 EMERGENT EUS GUIDED DRAINAGE OF SYMPTOMATIC PANCREATIC PSEUDOCYST UTILIZING NASOCYSTIC CATHETER WITH CONTINUOUS NEGATIVE PRESSURE

X. Zhang[1,*], X. Guo[1], Z. Liu[1], Y. Pan[1], X. Wang[1]. [1]*Institute of Digestive Diseases,, Xijing Hospital, Xian, China*

INTRODUCTION: Endoscopic ultrasound-guided transmural drainage (EUS-GTD) has become the first line therapy for symptomatic pancreatic pseudocysts.
AIMS&METHODS: The aim of this pilot study was to evaluate the efficacy and safety of emergent nasocystic catheter drainage with a continuous negative pressure for early stage pseudocysts. From Feb 2009 to Oct 2012, 27 patients (23 M; median age 46) with symptomatic pancreatic pseudocysts found during the previous 6 weeks were treated with EUS-guided insertion of a 7 Fr nasocystic catheter between the gastric wall and the pseudocyst after making a fistula by electrocautery. The nasocystic catheter was connected to an aspirator to produce negative pressure, and the negative pressure was kept constant before the catheter was pulled out.
RESULTS: With this method, we obtained a 100% cure rate. After a median drainage time of 24 days, 11 patients showed complete pseudocyst resolution, while the other 16 patients showed a reduction in the pseudocyst size (to less than 3 cm in diameter) and complete resolution of symptoms. For infected pseudocysts (11/27), the nasocystic catheter remained longer (median 36 days) than those (16/27) without infection (median 21 days) (P=0.032). Intermediate bleeding occurred in one case and was stopped by clips. Three patients had fevers after the procedure, which were alleviated with short- term antibiotics. Only one pseudocyst was recurred 12 months after treatment, but it was asymptomatic.
CONCLUSION: Emergent nasocystic catheter drainage with a continuous negative pressure was an effective and safe treatment for early stage pancreatic pseudocysts.

P1141 TEMPORARY ENDOSCOPIC HEPATICO-GASTROSTOMY (EHG) WITH COVERED SELF-EXPANDABLE METAL STENTS (SEMS) AS A THERAPEUTIC ACCESS FISTULA (TAF) IN BENIGN BILIARY OBSTRUCTION NOT AMENABLE TO ERCP.

I. Penas[1,*], N. Alcaide[1], P. Diez-Redondo[1], P. Gil-Simon[1], C. De la Serna-Higuera[1], M. Perez-Miranda[1]. [1]*ENDOSCOPY UNIT, HOSPITAL DEL RIO HORTEGA, VALLADOLID, Spain*

INTRODUCTION: There is a growing experience with EUS-guided biliary drainage for palliation of malignancy after failed ERCP. Preliminary experience with EHG as an alterantive to the percutaneous approach in patients with altered anatomy and anastomotic strictures or refractory bile-duct stones is limited.
AIMS&METHODS: To assess the feasibility and efficacy of EHG using temporary transmural covered SEMS to provide interval biliary drainage and to act

as a transhepatic entry port (or therapeutic access fistula, TAF) for biliary endotherapy under cholangioscopic or fluoroscopic guidance in patients with complex anatomy. Two time periods (early and late) were compared to assess trends in clinical use.
18 patients were reviewed (9male; 66.5[47-91] years old) in whom EHG was performed with covered-SEMS to provide therapeutic access route and interval drainage. Indications, technique, complications, interventions and final therapeutic success were compared between early (2006-2011) and late periods (2011-2012).
RESULTS: Temporary EHG was considered in 12 patietns in the early (E) and 10 in the late (L) periods. 4 Patients were excluded from analysis, 3 E (no puncture in 2 because of insufficient dilation, no follow-up data in 1) and 1 L (pending SEMS removal), leaving 9 for comparison in each group. Indications grouped by stones (hepatholithiasis) and strictures (transections) in E Vs L was 3 (0) and 6(4) Vs 3(1) Vs 6(3) was similar for both groups, as was the number of cases with EHG just for interval drainage (1 each). SEMS could be removed uneventfully in 7/9 in E (one inward migration) Vs 9/9 in L. The therapeutic burden (number of failed sessions), incidence of complications, and time to remove EHG appeared greater in group E (8 Vs 4, 66% Vs 33%, 129[51-277] Vs 40[11/130] days) but no statistical difference was found. Final clinical success (stone removal, stricture-transection remodelling) appeared greater in group L Vs E (88% Vs 33%), but again no significance was found.
CONCLUSION: A select group of patients with bile-duct transections and refractory stones not amenable to ERCP can be treated using temporary SEMS hepaticogastrostomy as TAF for serial endotherapy without external drains. This shift from percutaneous to EUS-guided anastomoses for benign disease replicates prior experience in malignancy. Our data show increased use of EUS-guided HG as TAF and trend to improved effectiveness. Hepatectomy or surgical diversion can be avoided in select instances, although this novel approach carries morbidity and is labour-intensive.

GENETICS OF GI AND LIVER DISEASES III – Poster Area

P1142 THE EARLY GROWTH RESPONSE GENES (EGR) CAUSE CELL CYCLE ARREST AND INDUCE APOPTOSIS IN COLON CANCER

A. Koulouris[1,*], P. Wang[2]. [1]*Gastroenterology-Experimental Immunology, Queen Mary, University of London, Great Yarmouth,* [2]*Gastroenterology-Experimental Immunology, QUEEN MARY, UNIVERSITY OF LONDON, London, United Kingdom*

INTRODUCTION: The Egr familly (Early Growth Respone Genes) of zinc finger transcription factors, which consists of four members; Egr-1, -2, -3 and -4, have been proved to have dynamic functions in the regulation of cell growth and the immune responses. Moreover, in a number of malignancies-which is a cell growth and immune related process- it seems that Egr1 and 2 are able to induce cell cycle arrest and apoptosis. The importance of such an observation relies on the fact that -by definition- a cell becomes malignant when the cell cycle arrest mechanism is not functional.
AIMS&METHODS: The present study was designed to answer the question whether the colon cancer cells stop dividing and undergo apoptosis when the EGR genes are exogenously introduced and if the presence of a mutant p53-a common tumor suppressor gene- can affect this apoptotic pathway.
Two cell lines deriving from human colon cancer; one p53 negative (DLD1) and another p53 positive (HCT116) were transfected with Egr-1, -2 and -3 and a fluorescent protein which was used as marker of the transfection. The transfected cells were incubated for 48 hours. Flow cytometry was used to create a pure population of transfected cells and 24hours later these cells were examined in the fluoroscopic microscope and compared with the controls. The transfected cells were also tested one week later to identify if they are viable.
RESULTS: We found that all the transfected cell stop undergoing divisions. In addition, their morphology was changed to round shape indicating of senescence. Interestingly, in one week time there were no viable transfected cells in our wells. It was also noticeable that both cell lines (P53-positive and P53-negative) used to undergo cell cycle arrest and apoptosis in the same rate, suggesting that the process was p53-independent or that other tumor suppressor genes could be involved.
CONCLUSION: This suggests that Egr molecules are important to control the unwanted growth in response to malignant transformation. Our results not only demonstrated an important function of Egr molecules but also indicate the therapeutic potential for the treatment of tumour.

P1143 LOW DETECTION RATES OF GENETIC TESTING FOR HEREDITARY COLORECTAL POLYPOSES: SEARCH FOR NEW GENES A PRIORITY FOR PROPER CANCER SURVEILLANCE IN PATIENTS AND THEIR RELATIVES

D. Colussi[1], S. Miccoli[1], V. Gismondi[2], L. Varesco[2], F. Bazzoli[1], D. Turchetti[1], L. Ricciardiello[1,*]. [1]*Department of Medical and Surgical Sciences, University of Bologna, Bologna,* [2]*National Institute for Cancer Research, Genoa, Italy*

INTRODUCTION: Hereditary colonic polyposes are all characterized by increased risk for cancer development, but display variable phenotypes, genetic heterogeneity, and assorted inheritance patterns. The most well-known of these conditions include familial adenomatous polyposis (FAP), attenuated adenomatous polyposis (AFAP), MutYH-associated polyposis (MAP), Peutz-Jeghers syndrome (PJS), Juvenile Polyposis Syndrome (JPS) and Cowden Syndrome (CS). An optimal patient management is ensured by the combination of the genetic evaluation and the endoscopic diagnosis, resulting in an accurate classification of these syndromes and early detection in other family members.
AIMS&METHODS: To clarify the genetic basis and to evaluate the detection-rate of available genetic tests in a series of 90 patients with clinical and endoscopical diagnosis/suspicion of hereditary colonic polyposes, studied between March 2004 and September 2012. Sixty-three patients were eligible for genetic testing and were divided in two groups based on polyps' histological pattern. One group consisted of 56 patients with adenomatous polyps: mutational analysis of APC was performed in 25 patients with clinical/familial diagnosis of FAP, analysis of both APC and MutYH in 18 patients with suspicion of FAP/AFAP/MAP, search for MutYH mutations in 13 patients with clinical suspicion of MAP. The other group consisted of 7 patients with hamartomatous polyps: two patients with clinical suspicion of PJS were screened for germ-line STK11 mutations, while two patients with clinical suspicion of JPS were screened for germ-line SMAD4, BMPR1A and PTEN mutations, and 3 with suspicion of CS for germ-line PTEN mutations.
RESULTS: The causative germline mutation was identified in 30 out of 63 tested patients (48%). When considering each group, the detection-rate was 72% for patient with clinical diagnosis of FAP, 28% for patients where the differential diagnosis of FAP/AFAP/MAP was uncertain, 31% for MAP, 50% for PJS, 50% for JPS, 33,3% for CS. Thirty-one at risk relatives underwent genetic testing of the familial mutation, which was detected in 58% of them, thus leading to early or pre-symptomatic diagnosis.
CONCLUSION: The detection rates of genetic testing for hereditary polyposes vary significantly, showing highest concordance with clinical suspicion for classic FAP and lowest for AFAP/MAP. The failure to identify a genetic mutation might be due to the presence of mutations in unknown genes, or to unusual genetic alterations that cannot be detected by current techniques.

P1144 INTRATUMORAL VARIATIONS IN PIT PATTERNS REFLECT GENETIC HETEROGENEITY REVEALED BY HIGH-THROUGHPUT SEQUENCING OF COLORECTAL TUMOR

E. Yamamoto[1,*], H. Yamano[2], R. Maruyama[1], T. Sawada[3], T. Harada[1], T. Sugai[4], Y. Shinomura[1], H. Suzuki[1]. [1]*SAPPORO MEDICAL UNIVERSITY, sapporo,* [2]*AKITA RED CROSS HOSPITAL, akita,* [3]*NAGOYA CITY UNIVERSITY, nagoya,* [4]*IWATE MEDICAL UNIVERSITY, morioka, Japan*

INTRODUCTION: The detection of high-risk precursor lesions is essential for preventing colorectal cancers (CRCs), and pit pattern observation using magnifying endoscopy enables us to detect neoplastic lesions with malignant potential. Colorectal tumors are composed of genetically diverse cells with branched evolutionary growth; however, little is known about the association between intratumoral genetic heterogeneity and endoscopic findings.
AIMS&METHODS: Our aim in this study is to analyze the intratumoral variability of the endoscopic and genetic alterations in colorectal tumors. All colorectal lesions were analyzed by high-resolution magnifying endoscopy. Colorectal tumors (n=160), which consisted of at least two subcomponents with different pit patterns, were analyzed. Based on the differences, more than 2 biopsy specimens were obtained from respective portions. *KRAS, BRAF* and *TP53* mutations were analyzed by pyrosequencing and direct sequencing. Whole exome sequencing and array-based comparative genomic hybridization (array CGH) have been carried out.
RESULTS: Intratumoral heterogeneities in *KRAS* mutation (e.g., portion 1, G12D; portion 2, G13D) and *TP53* were frequently observed (early tumor; *KRAS* 60%, *TP53* 59%: advanced tumor; *KRAS* 23%, *TP53* 14%) in colorectal tumors, while such heterogeneities were rarely observed for *BRAF* mutations (8%). Particularly, we observed unexpectedly frequent intratumoral variations in *KRAS* and *TP53* mutations in early colorectal tumors. Our exome sequencing identified a large number of somatic mutations and revealed that most somatic mutations were not commonly observed among the two or more subcomponents with different endoscopic features. Array CGH analysis revealed that copy number alterations were exclusively observed in the malignant potions.
CONCLUSION: Our results may provide a model that morphological and molecular alterations are directly linked each other and intratumoral variation in pit patterns could be predictive of the extent of the molecular abnormalities in a given tumor.

P1145 THE CHARACTERISTICS OF GENETIC AND EPIGENETIC ALTERATIONS IN LATERALLY SPREADING COLORECTAL TUMORS.

E. Sakai[1,*], S. Uchiyama[1], E. Yamada[1], T. Higurashi[1], H. Ohkubo[1], H. Endo[1], H. Takahashi[1], A. Nakajima[1], N. Matsuhashi[2], A. Kaneda[3,4]. [1]*Gastroenterology, Yokohama City University School of Medicine, Yokohama,* [2]*Gastroenterology, Kanto Medical Center, NTT East,* [3]*Genome Science, Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo,* [4]*CREST, Japan Science and Technology Agency, Tiokyo, Japan*

INTRODUCTION: Laterally spreading tumors (LST) characterized by lateral extensions along the luminal wall with a low vertical axis, are categorized into 2 subtypes based on their morphological appearance: granular type (LST-G) and non-granular type (LST-NG). The relationship between their macroscopic appearance and the genetic or epigenetic alterations has been rarely reported.
AIMS&METHODS: Previously, we identified two groups of methylation markers through genome-wide analyses of DNA promoter methylation, and classified colorectal adenoma and cancer into three distinct methylation epigenotypes (HME, IME and LME, respectively). Group 1 markers including most of the previously established CIMP markers were characterized to be methylated only in HME colorectal adenomas/cancers. In contrast, group 2 markers were characterized to be methylated in both HME and IME, but not in LME colorectal adenomas/cancers. In this study, we evaluated mathylation rates of 7 group1 and 14 group2 markers in 108 LST (51 LST-G and 57 LST-NG) samples using pyrosequencing method, and epigenotyped according to the result of unsupervised two-way hierarchical clustering. In addition, mutation of *BRAF*, *KRAS*, *p53* and *PIK3CA* were evaluated to confirm whether LST could be classified into distinctive clusters.
RESULTS: LST could be classified into two distinct epigenotypes; IME with higher frequency of *KRAS* mutation and associated with LST-G morphology, and LME with less frequency of *KRAS* mutation and associated with LST-NG morphology. *BRAF* mutation was hardly observed in both in LST-G and LST-NG, suggesting that LST do not show HME as well as conventional adenomas. Although there was no significant difference of the frequency of *p53* mutation between LST-G and LST-NG, *p53* mutation positive LST showed advanced pathology compared with *p53* mutation negative LST. As the results of logistic regression analysis, LST-NG with central depression was revealed to be significantly associated with the frequency of submucosal invasion (OR 18.7; 95% CI 4.15 – 83.9, $P = 0.0001$).
CONCLUSION: Although the macroscopic appearance of LST-G and LST-NG are similar, their genetic and epigenetic background was widely different, suggesting that they probably develop through distinct carcinogenic process. The sizes of LST-NG were relatively smaller than those of LST-G, however, they were associated with advanced pathology, especially they showed central depression. Therefore early detection and subsequent endoscopic resection of these lesions may be clinically meaningful to reduce colorectal cancer mortality.

P1146 A NON-INVASIVE CITOGENETIC BIOMARKER FOR COLORECTAL NEOPLASTIA PREDICTION

E.-M. Ionescu[1,*], M. Ciocirlan[2], T. Nicolaie[1], M. Diculescu[2]. [1]*Gastroenterology, Elias Emergency Hospital,* [2]*Gastroenterology, Fundeni Clinical Institute, Bucharest, Romania*

INTRODUCTION: The aim of our study was to identify a feasible, non-invasive method to predict the presence of significant colorectal neoplastic lesions in patients undergoing colonoscopy.
AIMS&METHODS: We included patients about to have colonoscopy in our departments between January 2011 and March 2012. Patients with known neoplastic disease, inflammatory bowel disease or prior radiation exposure were excluded. Blood samples for cytogenetic analysis using Cytogenetic-Bloked Micronucleus Assay (CBMN) technique were taken from patients. An expression of lymphocytic proliferation in specific stimulated cultures - the Nuclear Division Index (NDI) – was calculated trough this method. NDI represents a measure of general cytotoxicity. For statistics we used SPSS 11.0 software.
RESULTS: 94 patients were included. Their mean age was 55.1 years, men and women were equally represented, 47 each (50%). There were: 37 patients with normal colonoscopy, 4 patients with hyperplastic polyps, 30 patients with adenomas (from these 9 were advanced: size over 10mm, with high grade dysplasia or with a villous component larger than 25%), 23 patients with colorectal cancer. NDI was significantly lower in patients with adenomas and cancer than in patients with normal colonoscopy or hyperplastic polyps (AUC ROC = 0.637, p = 0.036). Secondly, NDI was also significantly lower in patients with advanced adenomas or cancer than in patients with normal colonoscopy, hyperplastic polyps or non-advanced adenomas (AUC ROC = 0.0677, p = 0.005). Finally, patients with colorectal cancer had a significantly lower NDI than patients with no colorectal cancer (AUC ROC = 0.655, p= 0.026).
CONCLUSION: A lower Nuclear Division Index calculate by CBMN technique may predict the presence of significant colonic lesions in a population undergoing colonoscopy.

P1147 EFFECTS AND MECHANISMS OF THALIDOMIDE ON THE GROWTH AND MIGRATION OF HUMAN COLORECTAL CANCER CELL HCT116

H. Chen[1,*], H. Liu[2], Y. Zhan[2], L. Zeng[2], Y. Lin[2], Z. Wen[2]. [1]*Department of Gastroenterology, The Sixth Affiliated Hospital of Sun Yat-sen University,* [2]*Department of Gastroenterology, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

INTRODUCTION: Colorectal cancer recurrence or metastasis is the major cause of clinical treatment failure and mortality. Thalidomide was formerly used as a non-barbiturate sedative drug against vomiting of early pregnancy in the 1950s, since Singhal reported its curative effects on treatment of multiple myeloma in 1999 [3], following studies have shown its therapeutic effects on hematological malignancies and some solid tumors [4-6]. To date, there were only few studies on colorectal cancer.
Cell cycle is closely related to the proliferation of tumor cells. The p53-p21-CDK-cyclin pathway is a typical pathway of DNA repair. The p21 protein, as the most important downstream protein of p53, is also involved in the regulation of cell cycles at G1 and G2 phases[8-10]. VEGF plays important role and CXCR4 was found to be involved in colorectal cancer liver metastases homing[13-16].
This study was to examine the effects of thalidomide on the growth and migration of human colorectal cancer cell HCT116, and analyze its relationships with expression of p53, p21, VEGF and CXCR4.
AIMS&METHODS: To investigate the effects of thalidomide on proliferation and migration of human colorectal cancer cell HCT116 and reveal the underlying molecular mechanisms.
MTT assay, colony formation assay were performed to examine the effects of thalidomide on HCT116 growth and proliferation. Flow cytometry was used to analyze the cell cycle of the treated cell. Transwell chamber assay was done to detect the influence on cell migration. Expression of p53, p21 and CXCR4 proteins were detected by Western blot. The levels of secretory VEGF protein were assessed by ELISA.
RESULTS: MTT assay showed thalidomide had no effect on growth of HCT116 cells. Thalidomide inhibited the plate colony formation of HCT116 cells. Flow cytometry (FCM) showed that cells treated with thalidomide were arrested in G2/M phase. The migration capability was decreased significantly after thalidomide treatment. Western blot showed that there were no changes in the p53, p21 and CXCR4 proteins levels. ELISA showed that VEGF was significantly reduced by thalidomide.
CONCLUSION: The inhibition of colorectal cancer cell colony formation line by thalidomide is likely to be associated with cell cycle arrest, independent on p53 and p21 proteins. Inhibition of migration by thalidomide was significantly correlated to VEGF, but not CXCR4 protein expression.

P1148 CLINICAL PATHOLOGY AND RECENT FOLLOW-UP STUDY ON GASTRIC INTRAEPITHELIAL NEOPLASIA AND GASTRIC MUCOSAL LESIONS

J. Wu[1,*]. [1]*The Central Hospital of Wuhan, Wuhan, China*

INTRODUCTION: Our aim was to explore the correlations between endoscopic gastric mucosal lesions and pathological gastric intraepithelial neoplasia, and to investigate outcomes of gastric intraepithelial neoplasia after various treatments.
AIMS&METHODS: A total of 18566 Chinese patients undergoing diagnostic gastroscopy, and biopsies were taken from every patients. Typing and grading of endoscopic and pathological diagnosis were performed. Among them, 130 cases of patients were given various treatments, including medication, endoscopic treatment and surgery. Three months later, re-gastroscopy was carried out, and biopsies were taken to evaluation the efficiency.
RESULTS: There were 433 patients with GIN by initial pathological diagnosis. Among them, there were 367 LGIN and 66 HGIN, 348 cases accompanied with chronic gastritis, and 85 cases accompanied with localized foci. Eighty cases of Hp-positive patients with LGIN were given anti-Hp therapy. Three months later, re-gastroscopy was carried out and biopsies were taken. Our results showed that 45 cases of intraepithelial neoplasia disappeared with only chronic inflammation left. and also, 33 cases were given the original diagnoses and two cases developed into intraepithelial neoplasia of higher grade. Surgery was then performed, after that, one case of them was confirmed to have early gastric carcinoma, and the other case was diagnosed as advanced gastric carcinoma. Pathological examinations were carried out undergoing EMR or ESD treatment for 18 cases of patients with localized foci accompanied with LGIN. Results showed four cases of only chronic inflammation, 11 cases with original diagnoses maintained, and three cases of HGIN. Three months later, re-gastroscopy was carried out and biopsies were taken, the results revealed no intraepithelial neoplasia. Surgery and pathological examinations were performed for 32 cases of patients with HGIN. Our result showed that 15 cases maintained the original diagnoses, 12 cases of early gastric carcinoma and five cases of advanced gastric carcinoma. Three months later, re-gastroscopy was carried out and no relapse of foci was observed.
CONCLUSION: There were various endoscopic findings of gastric intraepithelial neoplasia, which occurred frequently in localized foci and atrophic gastritis. NBI magnifying endoscopy had a value of targeted biopsy. Meanwhile, GIN occurred frequently in patients with more severe pathological inflammations under endoscope, which also had certain correlations with intestinal metaplasia.

P1149 IDENTIFICATION OF A GEN RESPONSIBLE OF THE FAMILIAL GASTRIC CARCINOID TYPE 1 BY EXOME ULTRASEQUENCIATION

J. Reyes[1,*], O. Calvete[2], S. Zuniga[3], V. Fernández[2], J. J. Torres[4], J. Benitez[2]. [1]*GASTROENTEROLOGY UNIT, HOSPITAL COMARCAL DE INCA, Inca,* [2]*Human Genetics Department, Spanish National Cancer Research Center, Madrid,* [3]*Sistemas Genómicos, Valencia,* [4]*Department of Pathology, Hospital Comarcal de Inca, Inca, Spain*

INTRODUCTION: Carcinoids belong to neuroendocrine tumors family. Its incidence is rare (0,1%). Gastric carcinoids represents 7%. Multifocal gastric carcinoid type I (MFGC-I) present hypergastrinemia, chronic gastritis and achloridia. In some cases, MFGC-I develops mucosa invasion that can progress into tumor. The majority are sporadic and their genetic basis is unknown.
AIMS&METHODS: We present a study of a family with consanguineous healthy parents of ten sons, five with MFGC-I (ages between 24 and 37), three of them with nodal infiltration. We performed an exome sequencing of both parents and three affected sons.
Pipeline: Exome deep sequencing was permormed with SoliD Technology. Reads obtained were mapped with Bioscope v1.3 against the human reference genome GRhg37/hg19. PCR duplicates and redundant reads were removed using Picard tools. Variant calling was performed using a combination of three different algorithms: VarScan [1], GATK [2] and Bioscope. 'In- house' scripts were developed to combine, filter and variant annotation (using Ensembl release 64 database). In order to identify new potential candidate genes assuming a recessive model (parents being heterozygous and their progeny homozygous for the variant) the following allele frequency thresholds were set up: <0.2 for homozygous for the reference, 0.2-0.85 heterozygous variants and >0.85 homozygous for the alternative allele.
RESULTS: Candidate gene. A variant (C > T) was founded segregating as (T/T) in affected patients and C/T in non-affected parents. The other non affected members of the family segregate as C/C or C/T. The variant is a NON_SYNONIMOUS missense and produces an Arginina > Valina change and is putative patological (CONDEL tools). The missense was located in the 14th exon of a 22-exon gene which was annotated as conseved cytoplasmatic Dehalogenase-Domain. The variant could be inactivating this Domain.
The gene codifies a protein which is related with the metabolic pathway of gastrin and stomach acidification. Gastrin up- regulates enterochromaffin cells which up-regulate parietal cells throw histamine.
CONCLUSION: The described mutation is within a gene which acidificates stomach. The achloridia found in patients could be explained with this mutation in parietal cells. This achloridia would explain hypergastrinemia.

• A recessive heredity mutation could explain MFGC type I
• To relate this missense with the disease and to identify potential diagnostic markers, we are: a) analyzing the gene in other patients with carcinoid type I, b) performing immunohistochemistry with our gene and gastrin in tumor samples from patients.

P1150 DOES A PROSPECTIVE INTENSIVE SURVEILLANCE PROGRAMME REDUCES INTERVAL COLORECTAL CANCER RATE AMONG PATIENTS WITH LYNCH SYNDROME?

P. Guillaume[1,*], E. Samaha[1], G. Rahmi[1], A. Zaanan[2], P. Laurent-Puig[2], C. Cellier[1]. [1]*Gastroenterology,* [2]*Oncogenetics, Hôpital Européen Georges Pompidou, Paris, France*

INTRODUCTION: Patients with Lynch Syndrome have a lifetime cumulative colorectal cancer incidence of 40%. Interval colorectal cancer is still high despite recommanded colonoscopic surveillance. An optimized surveillance programme is needed in order to reduce interval cancer rate.
AIMS&METHODS: All patients with a genetically confirmed Lynch Syndrome subscribed at our center were prospectively included and offered an optimized colorectal surveillance programme as follow: Colonoscopy with indigo carmin chromoendoscopy was proposed to all patients with a 2-year interval. If adenoma was detected, the interval surveillance colonoscopy was reduced to one year. If the bowel preparation was poor or insuffisant, or if chromoendoscopy was not performed, a 6-month colonoscopy interval was then required. We also retrospectively analysed prior colonoscopy data for each patient and compared them with the actual ones. Data were analysed separately for each patient and for each colonoscopy. When criteria for the optimized surveillance program were all present, colonoscopy was considered to be observant. In the other case, il would be considered as non-observant. Interval cancer detection rate (ICDR), adenoma detection rate (ADR) and polyp detection rate (PDR) were calculated using Fisher's Exact test.
RESULTS: Between january 2010 and april 2013, 108 patients (M/F=37/71, mean age = 44 years [21-74]) with genetically confirmed Lynch Syndrome (MLH1=42.6%, MSH2=37.9%, MSH6=17.6%, PMS2=1.9%) were prospectively included. A total of 134 prospective and 196 prior colonoscopies were analysed. Five were excluded because of colorectal cancer diagnosed at first colonoscopy. Mean Follow-up was 43.6 [12-74] months. We identified 168 observant colonoscopies and 157 non-observant ones. PDR was 58.9% (99/168) in the observant group (OG) vs 35.0% (55/157) in the non-observant group (NOG)

($p<0.0001$, OR=2.6 [1.6-4.2]). ADR was 32.7% (55/168) in the OG vs 21.0% (33/157) in the NOG ($p=0.018$, OR=1.8 [1.1-3.1]). ICDR was 0.6% (1/168) in the OG vs 4.5% (7/157) in the NOG ($p=0.03$, OR=0.12 [0.003-1.02]. All interval cancers were stage 1 or 2. The only interval cancer in the OG was a local recurrence after colectomy for a T4N1 tumor. The cancer was probably missed because of extrinsic colonic invasion 22 months after a normal colonoscopy.

CONCLUSION: Optimized colonic surveillance program in Lynch patients members of a specialized network, increases polyp and adenoma detection rates and decreases significantly interval cancer occurrence. This strategy should be validated in a larger prospective population.

INTRODUCTION: Familial Colorectal Cancer type X (FCCTX) defines families who fulfill Amsterdam-1 criteria(AC1), but are not mismatch repair (MMR) deficient (Lynch syndrome families-LS), according to either tumor testing (microsatellite instability and/or MMR proteins immunohistochemistry) or gene sequencing. Few studies suggested that these families demonstrate lower CRC and extra-colonic cancer incidence, with less affected family members then MMR deficient families. Age of onset for CRC is older in FCCTX families then for LS families.

AIMS&METHODS: Our aim was to compare cancer phenotype between FCCTX and LS families in Israel. Families which fulfill the AC, and in which LS was ruled out by tumor testing for microsatellite instability(MSI) and MMR-immunohistochemistry(IHC) were collected from 3 major referral centers in Israel. Pedigree was studied for detailed cancer history.

RESULTS: 46 FCCTX families (612 family members) were studied and compared with 42 LS families (537 family members). Data is shown in Table 1. CRC laterality and age of CRC onset in the family were the only significantly different parameters between the groups. There was no difference in regard to extra-colonic cancer occurrence and number of cancer affected family members between the groups, as well as cancer onset age.

Table 1

	LS	FCCTX	P
Number	42	46	
Right sided CRC	33(78.6%)	15(32.6%)	<0.001
Extra Intestinal Tumor in proband	8(19%)	7(15.2%)	0.7
Earliest age of CRC in family	45.7± 17.1	53±16.6	0.047
Earliest age of any cancer in family	40.7±13.84	41.3±13.33	0.83

Number family members with cancer before age 50	1.66±1.525	1.36±1.11	0.28

CONCLUSION: The clinical phenotype of FCCTX families in Israel is very similar to LS families. Colonic and extracolonic cancer surveillance recommendations for these FCCTX families may be more vigorous then previously recommended.

INTRODUCTION: The epigenetic inactivation of MLH1 has been reported in a small number of cases of CRC with a phenotype similar to Lynch Syndrome. However, the prevalence of MLH1 constitutional epimutations in patients with CRC is unknown.

AIMS&METHODS: To assess the prevalence of MLH1 constitutional epimutations as a cause of Lynch Syndrome in unselected consecutive cases of CRC. Patients from a prospective, population-based, observational cohort including 871 CRC patients from the Epicolon II cohort and 1,513 cases from Hospital General Universitario de Alicante were included. From them, 121 patients showed loss of expression of MLH1. For comparisons, a group of 973 selected CRC patients fulfilling revised Bethesda guidelines was also included, 122 showed loss of MLH1 expression. Somatic *MLH1* methylation and germline *MLH1* mutations were assessed. Constitutional *MLH1* methylation was studied with Methylation Specific-MLPA of MLH1 in patients with somatic *MLH1* methylation.

RESULTS: A total of 110 (45.2%) patients with loss of expression of MLH1 showed somatic MLH1 methylation, 43 (39%) from selected population and 67 (61%) from unselected population. The frequency of fulfilment of the revised Bethesda guidelines in the group of unselected consecutive patients was 26%. In the group of unselected consecutive CRC cases none constitutional epimutation was found. Whereas, in the group of selected patients we found 4 out of 43 (9.3%) cases with *MLH1* epimutation (p=0,002).

CONCLUSION: We did not find any case of MLH1 constitutional epimutation in an unselected population of 2,384 CRC cases. However, there are a considerable number of cases of constitutional MLH1 epimutations between selected patients fulfilling revised Bethesda guidelines. These results could suggest that the analysis of MLH1 constitutional epimutation should be included in the screening for Lynch Syndrome only in selected cases with high risk of this syndrome.

P1153 A DEDICATED FAMILY HISTORY OF COLORECTAL CANCER CLINIC IMPROVES ADHERENCE TO COLONOSCOPIC SCREENING GUIDELINES

S. Qiu[1,*], A. Hunt[1], I. Beveridge[1], J. Mawdsley[1], K. Sundaram[1], C. Collins[1], K. J. Monahan[1]. [1]*West Middlesex University Hospital, London, United Kingdom*

INTRODUCTION: In 2010, the British Society of Gastroenterology (BSG) published guidelines for colonoscopic screening of people with family history (FH) of colorectal cancer (CRC). In the UK, most patients anxious about their FH of CRC are referred by primary care doctors to non-specialist hospitals. Previous studies indicate guideline adherence is poor. This could be due to a lack of dedicated genetic services to triage and counsel patients for appropriate screening. We compare guideline adherence before and after introducing a CRC FH clinic in a non-specialist hospital.

AIMS&METHODS: Guideline adherence was assessed in a hospital with catchment population of ~300,000. Data was collected from all colonoscopies in which FH was the primary indication over a 32-month period from guideline publication up to August 2012. The FH clinic was started in April 2011. Data from the 16 months periods before and after its initiation were compared.

RESULTS: In total 146 screening colonoscopies were performed. Following the establishment of the dedicated FH Clinic there was a reduction in inappropriate colonoscopies (40% vs 11%, $p=0.0004$, X^2) ; screening took place at a more appropriate age (11.80 vs 6.47 years early, $p=0.013$, t-test); and neoplasia detection rate was also significantly enhanced (18% vs 35%, $p=0.03$, X^2).

Risk	Life time risk of CRC death	*n* (%)		Number screened early (Mean years screened early)			Polyp/ CRC cases found	
Before/After FH clinic		**Before**	**After**	**Before**	**After**	***p***	**Before**	**After**
Appropriate for screening								
High (i.e. known familial syndrome)	1 in 2-5	11 (12%)	14 (20%)	-	-	-	2	5
Moderate	~1 in 6-12	44 (48%)	35 (63%)	18 (4.57)	18 (6.13)	0.806	8	11
Inappropriate for screening								
Low	>1:12	36 (40%)	6 (11%)	36 (23.73)	6 (23.60)	0.982	6	3
Total		**91**	**55**	**54 (11.80)**	**24 (6.47)**	**0.013**	**16 (18%)**	**19 (35%)**

CONCLUSION: The BSG guidelines are based on robust evidence. Despite this, in the first 16 months after its publication, 40% of patients undergoing screening in our centre did not meet guideline criteria and were on average screened 11.8 years too early. These patients were exposed to the risk of colonoscopy earlier than recommended without justifiable benefits. Non adherence to guideline occurred at multiple levels from referral onwards. Clinicians often lacked awareness of the BSG guidelines and felt compelled to offer unnecessary screening to reassure anxious patients. After the introduction of FH clinics in our non-specialist centre, there was better evaluation of patients' risks of CRC, resulting in a significant reduction in inappropriate colonoscopic screening. It also allowed counselling of anxious patients about their risks of CRC.

P1154 N-MYC DOWNSTREAM-REGULATED GENE 2 (NDRG2): A CANDIDATE TUMOR SUPPRESSOR FOR COLORECTAL CANCER

S. N. Hong[1,*], S. J. Kim[1], D. K. Chang[2], P.-L. Rhee[2], J. J. Kim[1], Y.-H. Kim[1]. *[1]Internal medicine, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Identification of hyper-methylated tumor suppressor genes is an appealing strategy for the noninvasive detection of colorectal cancer (CRC). In the previous genome-wide expression array, we identified that the promoter hypermethylation of N-Myc downstream-regulated gene 2 (NDRG2) and its down-regulation in CRC. Because the expression of NDRG is repressed by the proto-oncogenes Myc, NDRG2 considers as a new class of Myc-repressed genes. Here we examined the role of NDRG2 as a novel tumor suppressor in CRC.

AIMS&METHODS: NDRG2 promoter methylation was confirmed by using methylation-specific PCR. mRNA and protein expression were identified using RT-PCR, western blot and immunohistochemistry. After the cloning of NDRG2 gene, human CRC cell lines were stably transfected with an NDRG2 expression construct. To investigate the exact function of NDRG2, colony formation, cell viability, proliferation, invasion assays, and xenograft was performed using stable transfectants.

RESULTS: The promoter of NDRD2 was methylated and reversed by demethylation in human CRC cell lines DLD-1 and RKO. The NDRG2 promoter was methylated in 80% of CRC (24/27), whereas that in 7% of non-cancerous colonic mucosa (2/27, $p<.001$). In RT-PCR, western blot, and immunohistochemistry, NDRG2 expression were decreased in CRC significantly compared to those in noncancerous colonic mucosa. Over-expression of NDRG2 in stable tansfectants inhibited colony formation ($p=.012$), cell viability ($p<.001$), proliferation ($p<.001$), and invasion ($p=.045$). Tumor volume in NDRG2 xenograft mice was smaller than that in control mice.

CONCLUSION: NDRG2 may act as tumor suppressor in CRC carcinogenesis and might serve as novel prognostic marker and therapeutic target in CRC.

P1155 DIFFERENCES OF METHYLATION, HISTOLOGY AND ENDOSCOPIC MORPHOLOGY BETWEEN PROXIMAL AND DISTAL COLORECTAL LESIONS WITH BRAF MUTATIONS

T. Sawada[1,2,*], E. Yamamoto[1], H.-O. Yamano[3], T. Harada[1], R. Maruyama[1], T. Sugai[4], H. Suzuki[1]. *[1]Department of Molecular Biology, Sapporo Medical University, Sapporo, [2]Department of Gastroenterology and Metabolism, Nagoya City University Graduate School of Medical Sciences, Nagoya, [3]Department of Gastroenterology, Akita Red Cross Hospital, Akita, [4]Department of Pathology, Iwate Medical University, Morioka, Japan*

INTRODUCTION: Sessile serrated adenomas (SSAs), which are characterized by their preferential locations in the proximal colon and frequent *BRAF* mutation, are thought to be precursor lesions of colorectal cancer with microsatellite instability and CpG island methylator phenotype (CIMP), while other serrated lesions such as traditional serrated adenomas (TSAs) and mixed polyps (MPs) also exhibit frequent *BRAF* mutation.

AIMS&METHODS: In the current study, we carried out quantitative methylation analysis of cancer-associated genes in a cohort of *BRAF*-mutant precancerous lesions (n=124) using bisulfite pyrosequencing and compared with clinicopathological variables including locations, histologies and magnifying endoscopic findings.

RESULTS: Although majority of the *BRAF*-mutant precursors were found in the proximal colon, a considerable number of lesions were observed in the distal colon and rectum. In concordance with the proximal predominance of CIMP and *MLH1* methylation, a number of cancer-associated genes showed greater methylation levels in the proximal lesions than those in the distal colon. Histologically, SSAs and MPs were enriched in the proximal colon, while TSAs were prevalent in the distal colorectum. With magnifying endoscopy, flat lesions with type II-open (type II-O) pit pattern were frequently seen in the proximal colon, while protruded lesions with type IV plus serration pit pattern were predominantly observed in the distal colorectum.

CONCLUSION: Our data suggest that, among *BRAF*-mutant precursors, DNA methylation patterns are significantly associated with their locations and histologies as well as their endoscopic findings.

P1156 DOWN-REGULATION OF CLAUDIN-18 IS ASSOCIATED WITH PROLIFERATIVE AND INVASIVE POTENTIAL OF GASTRIC CANCER AT THE INVASIVE FRONT

Y. Nando[1,*], T. Oshima[1], J. Shan[1], T. Okugawa[1], X. Chen[1], K. Hori[1], K. Ikeo[1], H. Ikehara[1], T. Tomita[1], H. Fukui[1], J. Watari[1], H. Miwa[1]. *[1]Internal Medicine, Hyogo College Of Medicine, Nishinomiya, Japan*

INTRODUCTION: Claudins are tight junction proteins and claudin-18 expression is relatively restricted to gastric epithelial cells. Causal relationship between expression patterns of claudin-18 and gastric cancer is still far from clear.

AIMS&METHODS: The aims of this study were to investigate expression pattern of claudin-18 and Ki-67 in early gastric cancer at the invasive front and surrounding normal gastric mucosa and to investigate the biological function of claudin-18 on the proliferation and migration of cancer cells. Fifty three early gastric cancer lesions removed via endoscopic mucosal resection or endoscopic submucosal resection were evaluated. All of the gastric cancer is diagnosed with well to moderate differentiated adenocarcinoma in the Japanese Classification of Gastric Carcinoma. To assess epithelial proliferation, immunostaining of Ki-67 was performed and the labeling index was calculated. To assess the expression of epithelial tight junction proteins, immunofluorescent staining of claudin-18 was performed. The immunoreactivity of claudin-18 was graded according to the number of stained cells (grade 0 to 4). Correlation analysis was performed by Spearman's rank correlation coefficient (rs). The subject gave informed consent and patient anonymity was preserved. Small interfering RNA (siRNA) mediated knockdown of claudin-18 was transfected to MKN74, a claudin-18 positive gastric cancer cell line, to examine the influence of claudin-18 on proliferation and invasion of cancer cells.

RESULTS: Claudin-18 in gastric cancer was significantly down-regulated compared to surrounding gastric normal mucosa or intestinal metaplasia. Ki-67 labeling index of gastric cancer at invasive front was inversely correlated with claudin-18 expression ($rs = -0.596$, $p < 0.01$) but that at mucosal lesion was not correlated ($rs = 0.104$). The expression level of claudin-18 was inversely correlated with claudin-4 expression ($rs = -0.369$, $p < 0.05$). Claudin-18 siRNA transfection significantly down-regulated the level of claudin-18 on MKN74. Claudin-18 knockdown significantly promoted the proliferation of MKN74 compared with control siRNA transfected cells. The invasion of MKN74 significantly increased by claudin-18 siRNA transfection compared with control siRNA transfection.

CONCLUSION: Down-regulation of claudin-18 is associated with proliferative potential at the invasive front of gastric cancer, suggesting a pivotal role in the progression of gastric cancer.

P1157 SPONTANEOUS BACTERIAL PERITONITIS AND BACTERASCITES IN CIRRHOTIC PATIENTS – CHARACTERIZATION OF 100 EPISODES

A. Casela[1,*], N. P. Almeida[1], A. Fernandes[1], N. Silva[2], A. Oliveira[1], A. R. Alves[1], L. Elvas[1], C. Sofia[1]. *[1]Gastroenterology, [2]Clinical Pathology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: Spontaneous Bacterial Peritonitis (SBP) and bacterascites are serious complications of cirrhosis with high mortality. Traditionally, the major pathogens involved are Gram negative enteric bacteria.

AIMS&METHODS: To determine the clinical, analytical and microbiological characteristics in a cohort of cirrhotic patients with SBP/Bacterascites admitted to a gastroenterology department. We evaluated, retrospectively, 100 inpatient episodes diagnosed with SBP/bacterascite with positive microbiological study. The characteristics of the ascitic fluid concerning differential cell count and culture results were registered.

RESULTS: We included 100 hospital admissions/ascitic fluid samples from 88 patients (male sex – 78%; Mean Age – 58 ± 11 years). All patients had hepatic cirrhosis mainly of alcoholic etiology (88%) with previous episodes of SBP/bacterascites in 19 cases. The median value of leukocytes in the ascitic fluid was 3150/mm3 (100-22300) with 75% of neutrophils (1-99). The infection was monomicrobial in 92% of cases and polymicrobial in the others. The major etiologic agents were: *Escherichia coli* – 25%; *Staphylococcus aureus* – 17%; *Streptococcus* spp – 13%; *Enterococcus faecium* – 8%; *Klebsiella pneumoniae* – 6%; *Enterococcus faecalis* – 5%; *Pseudomonas aeruginosa* – 5%; *Candida* spp – 4%, *Staphylococcus epidermidis* – 4%. The bacteria had resistance to at least one of the tested antibiotics in 78% of isolates (71/91). Mortality rate was 45% considering all 100 admissions.

CONCLUSION: In this series of cirrhotic patients with SBP/bacterascites there was a similar distribution between Gram-positive and Gram-negative agents. The observed resistance rates are significant and could jeopardize the efficacy of current recommended empirical antibiotic therapy that must be redefined to consider more effective coverage of Gram-positive microorganisms.

P1158 MULTISTRAIN PROBIOTICS AND LACTULOSE IN THE TREATMENT OF MINIMAL HEPATIC ENCEPHALOPATHY: A CONTROLLED TRIAL

A. Shavakhi[1,*], H. Hashemi[1], S. Shavakhi[2], M. Minakari[1], A. Gholamrezaei[2]. [1]*Department of Internal Medicine,* [2]*Medical Students' Research Center, Isfahan University of Medical Sciences, Isfahan, Iran, Islamic Republic Of*

INTRODUCTION: Some evidence has shown benefits of probiotics in the management of minimal hepatic encephalopathy (MHE).
AIMS&METHODS: We evaluated the efficacy of a multistrain probiotic compound, alone and in combination with lactulose, in the treatment of MHE. Consecutive adult patients with MHE were randomized to receive lactulose (30-60 ml/day) + probiotic (200 million colony forming units of seven bacteria species/day) (Gp-LPr) or lactulose + placebo (Gp-L). Another non-randomized group of patients received probiotic alone (Gp-Pr). Medication duration was for two weeks and patients were followed-up for another eight weeks. Improvement in MHE status was assessed by psychometric hepatic encephalopathy score (PHES). Development of overt encephalopathy, hospitalization, and death were considered as secondary outcomes.
RESULTS: Sixty patients (80% male, mean age 38.4±9.6 years) completed the intervention. PHES significantly improved after medication in all the three groups (Gp-LPr: -3.8±3.9 to -1.6±3.0; Gp-L: -4.8±4.1 to -1.6±2.9; and Gp-Pr: -4.9±3.7 to -2.1±2.5, $P<0.001$). After 8 weeks follow-up, improvement maintained in Gp-LPr and Gp-Pr, but there was deterioration in those who did not receive probiotic (Gp-L: reverse to -4.8±4.2). Two patients (one in each of the Gp-L and Gp-Pr) experienced overt encephalopathy. One patient was hospitalized due to worsening of ascites (Gp-LPr) and one due to spontaneous bacterial peritonitis (Gp-L). Side effects were mild and the same among the groups.
CONCLUSION: Lactulose and probiotics are effective for the treatment of MHE; however, probiotics, but not lactulose, has long-term effects. More studies are required before suggesting probiotics for the standard treatment of MHE.

P1159 IN-HOSPITAL MORTALITY IN SPONTANEOUS BACTERIAL PERITONITIS: PREDICTIVE VALUE OF THE MODEL OF END-STAGE LIVER DISEASE

B. Kraja[1,*], A. Babmeto[1], N. Dhigoi[1], E. Osja[1], I. Kellici[1], S. Prifti[1]. [1]*University Service of Gastrohepatology, University Hospital Center Mother Theresa, Tirana, Albania*

INTRODUCTION: Spontaneous bacterial peritonitis (SBP) is a frequent complication among patients with cirrhosis. Because of the significant morbidity and mortality related to SBP, it is of great interest to identify predisposing factors. The model for end-stage liver disease (MELD) relies on few data, easily available and may predict the short-term survival**.**
AIMS&METHODS: In order to improve stratification of patient care in Albania, we assessed the predictive value (determined by in-hospital mortality) of MELD score in SBP patients.
We included 111 consecutive patients (82 men and 29 women) hospitalized at the University Hospital Center ''Mother Theresa'' in Tirana diagnosed with SBP from January 2009 to December 2012. SBP was defined upon admission as a neutrophil count of $\geq$250 cells/mm^3 in the ascitic fluid, and then cefotaxime was immediately started. MELD score was based on laboratory parameters [bilirubin, International Normalized Ratio (INR) and creatinine levels] and determined by using the UNOS Internet site MELD calculator. General Linear Model was used to compare mean values and their respective 95% confidence intervals (95%CI) of MELD scores by case - fatality status.
RESULTS: In-hospital mortality rate was 30.6% (*n=34*). MELD score was significantly higher in fatal patients than non-fatal patients: age-adjusted mean score: 27.7 (95%CI=25.1-30.3) vs. 18.1 (95%CI=16.4-19.8), $P<0.001$. The association of MELD score with case-fatality was stronger in men (28.0 in fatal cases vs. 17.0 in non-fatal cases; $P<0.001$) than in women (26.3 vs. 20.7, respectively, P=0.12) [P-value for sex - case - fatality interaction: 0.158].
CONCLUSION: Our findings confirm the good predictive value of MELD score in patients with SBP, as assessed by in-hospital mortality. Therefore, this new model can be effectively employed to stratify patients upon hospital admission.

P1160 ASCITIC DRAINS, ADVERSE EVENTS AND ABDOMINAL ULTRASOUND

C. Shekhar[1,*], A. Ramakrishnan[2], L. Claridge[3]. [1]*Gastroenterology, University Hospital of North Staffordshire, Stoke on Trent Hospital,* [2]*Gastroenterology, University Hospital North Staffordshire, Stoke on Trent,* [3]*Gastroenterology, St Jame's University Hospital, Leeds, United Kingdom*

INTRODUCTION: Ascites is the most common cause of hospital admission in patients with cirrhosis.1 Ascites refractory to diuretics is often managed by therapeutic paracentesis. Although, considered a relatively safe procedure, 2 serious life threatening complications can occur.3 Paracentesis practice often differ between centres. Moreover, in many European countries gastroenterologists are trained in the use of abdominal ultrasound and utilize this when inserting paracentesis catheters.
AIMS&METHODS: To obtain a snapshot of current UK trainee practice and experience of paracentis including serious complications and their views on abdominal ultrasound training. A cross sectional survey was conducted of current UK trainees in gastroenterology over a 3 week period(Dec2012-Jan2013).
RESULTS: 92 trainees completed the survey. 76%(70/92) of respondents have more than 3 yrs' experience in gastroenterology at registrar level. 41% (38/92) report having performed or supervised >100 procedures and a further 42% (39/92) have performed >50 procedures. 32% (29/92) reported to have witnessed serious complications; 14% (13/92) report significant haemorrhage requiring blood transfusion, 15% (14/92) have encountered bowel perforation and 7% (6/92) attribute a patient's death to a paracentesis. Only 11%(10/91) of trainees routinely take informed written consent. 62% (49/92) of trainees exclusively use a suprapubic 'Bonnano' catheters despite the fact that this product is unlicensed for use as a paracentesis catheter. The majority of trainees 77% (71/92) estimate a failure rate requiring ultrasound guided catheter placement is <10%. 73% (67/92) report that radiology colleagues are unwilling to insert catheters in patients with INR >1.5 without administration of fresh frozen plasma. 87%(80/92) of trainees expressed desire to learn basic abdominal ultrasound if provided as part of gastroenterology training and 50%(49/92) feel that this would also improve the safety and efficiency of paracentesis.
CONCLUSION: The number of UK trainees reporting serious adverse events due to paracentesis is higher than expected, perhaps due to the fact that this survey reflect their cummlative experince of complicatons. It is therefore of concern that very few trainees are taking written consent for this procedure. Abdominal paracentesis has been recently added to list of potentially life threatening procedure in medical training curriculum in the UK. The majority of trainees are still using the unlicensed 'Bonnano' catheter. The majority of UK gastroenterology trainees express a desire to be trained in abdominal ultrasonography and believe this would improve the safety of paracentesis.

P1161 SHORT TREATMENT WITH RIFAXIMIN IMPROVES BLOOD CEREBRAL FLOW AT TRANSCRANIAL DOPPLER AND PSYCHOMETRIC TESTS IN CIRRHOTIC PATIENTS WITH MINIMAL HEPATIC ENCEPHALOPATHY

G. Caracciolo[1,*], M. A. Zocco[1], A. Lupascu[2], B. E. Annicchiarico[1], M. Garcovich[1], D. Roccarina[1], M. E. Ainora[1], F. D'Aversa[1], D. Ferrarese[1], M. Siciliano[1], P. Tondi[2], A. Gasbarrini[1]. [1]*Internal Medicine and Gastroenterology,* [2]*Internal Medicine and Angiology, Catholic University - Gemelli Hospital, Rome, Italy*

INTRODUCTION: Minimal hepatic encephalopathy (MHE) includes a number of cognitive deficits such as alterations of psychomotor speed and executive functions, detectable in patients with liver cirrhosis only by psychometric or electrophysiological techniques. It has been shown that a long term treatment with rifaximin improves psychometric tests, quality of life and driving ability in these patients.
Cerebral blood flow seems to be decreased in patients with chronic liver disease and cerebral vascular resistance indices (resistive index, RI and pulsatility index, PI) are closely correlated with the severity of cirrhosis, hepatic encephalopathy and ascites.
AIMS&METHODS: The aim of this study was to evaluate the effect of a short treatment with rifaximin on psychometric tests, cerebral hemodynamic parameters and blood ammonia levels in cirrhotic patients with MHE.
Sixteen cirrhotic patients (10 male and 6 female) that resulted positive to at least one of the three psychometric tests performed in our Unit (TMT A, TMT B and DST) were enrolled in this study. All the patients enrolled were treated with rifaximin 1200 mg/die per os for 15 days. Transcranial Doppler (TCD) with measurement of RI and PI of both mean and posterior right cerebral arteries (MCA, PCA respectively), psichometric tests and blood ammonia levels measurement were performed at baseline and after 15 days of treatment. Data were analyzed with ANOVA test.
RESULTS: All patients completed the treatment with no side effects.
The short treatment with rifaximin was associated with a significant improvement of psychometric tests and in particular of TMT-B (mean±SD, 111±74 *vs* 123±77 seconds; $p<0,05$) and DST (mean±SD, 31±12 *vs* 27±9 seconds; $p<0,05$)
Among TCD parameters, we found a significant reduction of PCA-RI (mean±SD, 0,57±0,08 *vs* 0,61±0,07; $p<0,05$) and a trend toward reduction of PCA-PI (p=0,06). Blood ammonia levels after treatment were lower than before but the differences were no statistically significant.
CONCLUSION: A short term treatment with rifaximin could be effective in improving psychometric tests and cerebral hemodynamic parameters in patients with MHE.
These results indicate that the cerebral vascular resistance may reflect functional reversible changes rather than anatomical irreversible damage. We can hypothesize that rifaximin treatment and in particular the effects on intestinal microflora could be associated with a reduced production of toxins with consequent improvement of cerebral metabolism.

P1162 ROLE OF TRANSCRANIAL DOPPLER (TCD) IN THE EVALUATION OF CEREBRAL HEMODYNAMIC IN CIRRHOTIC PATIENTS: CORRELATION WITH SEVERITY OF THE DISEASE AND MINIMAL HEPATIC ENCEPHALOPATHY (MHE) DEVELOPMENT

G. Caracciolo[1,*], M. A. Zocco[1], A. Lupascu[2], B. E. Annicchiarico[1], M. Garcovich[1], M. E. Ainora[1], D. Roccarina[1], F. D'Aversa[1], D. Ferrarese[1], M. Siciliano[1], P. Tondi[2], A. Gasbarrini[1]. [1]*Internal Medicine and Gastroenterology,* [2]*Internal Medicine and Angiology, Catholic University - Gemelli Hospital, Rome, Italy*

INTRODUCTION: Several studies showed that cerebral blood flow is decreased in patients with chronic liver disease, especially in the presence of hepatic encephalopathy.
Recently, it has been suggested that, in cirrhotic patients, cerebral vascular resistance indices (resistivity index, RI and pulsatility index, PI) are good indicators of cerebral hemodynamic abnormalities and are closely correlated with the severity of cirrhosis, hepatic encephalopathy and ascites. However there are still poor data about cerebral vascular indices and MHE.
AIMS&METHODS: The aim of this study was to correlate cerebral arteries resistance indices with the seerity of liver disease and the development of MHE. 19 consecutive cirrhotic patients (13 male and 6 female) were enrolled in this study. Exclusion criteria were overt hepatic encephalopathy (West Haven >0), age <18 years, active alcohol consumption, sepsis, cerebrovascular diseases, cerebral neoplasms, cardiac diseases, peripheral vascular diseases, treatment with rifaximin and lactulose in the previous 30 days.
All patients underwent TCD with the detection of right mean and posterior cerebral artery (MCA and PCA) and measurement of RI and PI. Blood samples were collectd for detection of ammonia, bilirubin, creatinine, INR and albumin levels and the Child-Pugh score was calculated. Psychometric tests (TMT-A, TMT-B and DST) were performed in order to assess the presence of MHE.
RESULTS: Among the patients enrolled 12 had MHE (63%). When we compared patients with and without MHE we found a statistically significant difference in MCA-RI (mean±SD: 0,58±0,05 vs 0,65±0,08; $p<0,05$), MCA-PI (mean±SD: 0,96±0,1 vs 1,18±0,2; $p<0,05$) and blood ammonia levels (mean±SD: 107±54 vs 58±16; $p<0,05$). Differences in PCA-RI and PCA-PI between the two groups showed a trend toward significancy ($p=0,06$).
MCA-RI and MCA-PI were also correlated with Child-Pugh score (MCA-RI: 0.58±0.05, 0.68±0.07, 0.68±0.8 in Child A, B and C respectively; $p<0,05$) (MCA-PI: 0.96±0.13, 1.3±0.28, 1,27±0.19 in Child A, B and C respectively; $p<0,05$).
CONCLUSION: Cerebral vascular resistance indices assessed by TCD seem to be related with the severity of liver disease and could be useful for the diagnosis of MHE in cirrhotic patients.

P1163 VALIDATION OF LIVER STIFFNES MEASUREMENT BY FIBROSCAN VALUES IN PORTAL HYPERTENSION

I. Ratiu[1,*], A. Goldis[1], D. Lazar[1], I. Sporea[1], R. sirli[1]. [1]*UMF V Babes, Timisoara, Romania*

INTRODUCTION: Among patients with cirrhosis, those with advanced disease, with complications such as significant (at least grade II) esophageal varices (EV) have a shorter survival and a high risk to develop variceal bleeding. Thus it seems reasonable to screen this patients for EV. In an anterior study we establish some cut-off values obtained by transient elastography measurement (FibroScan, Echosense, Paris) for significant portal hypertension
AIMS&METHODS: Our aim is to validate the anterior established Fibroscan values in another batch of patients.
We have a group of 773 patients admitted in ourclinic, 302 females and 471 males with liver cirrhosis, mean age 59.3+/- 11 years in which we performed liver stiffness measurement by transient elasography.
RESULTS: Dividing the batch in patients without significant portal hypertension (EV grade 0 and 1) and with significant portal hypertension (EV grade 2 and 3) we obtained the following mean values:
27.35 ± 0.7471 (305 patients without significant portal hypertension) versus 48.79 $\pm$ 0.9989 (468 patients with EV grade 2 and 3), $P< 0.0001$ ES
In a study from our group that included 1000 cirrhotic patients, we found out that for a cut-off value of >40 kPa can predict significant portal hypertension with a positive predictive value of more than 85%. In patients with TE values <40 kPa, 5/10 cases had significant esophageal varices (NPV 54.9%) A cut-off value of 17.1 kPa excluded patients with EV grade 2 and 3 with a negative predictive values close to 90%.
Starting with these cut-off values previously established we analyzed the batch of 773 patients obtaining the following results:
>40 kPa criterion we had 332 pacients, 288 with significant portal hypertension 86.7%, PPV 86,7%
<17 kPa criterion 100 cases, of which 75 patients without significant portal hypertension - 75%, NPV 72.12. We analized those 25 patients with significant portal hypertension from this group and we observe that the majority, 80% (20 patients), had decompensated liver cirrhosis (Child-Pugh class B or C)
CONCLUSION: According to our data, in patients with TE values >40 kPa almost 9/10 cases will have significant portal hypertension. Therefore it is reasonable to recommend prophylactic beta-blocker therapy without endoscopy. Below the cut-off value of 17 kPa the chance of those patients having significant EV is only 1 in 10 (NPV 89.3%) in the previous study but, in this batch of patients, the 17 KPa criteria misclassify 3 of 10 patients. However, from those misclassified patients, 80% had decompensated liver disease, thus we recommend endoscopy for screening for portal hypertension in all patients with B and C Child Pugh class regardless of Fibroscan values

P1164 CIRRHOTIC CARDIOMYOPATHY IS A FREQUENT COMPLICATION OF CHRONIC LIVER DISEASE AND IS ASSOCIATED WITH A WORSE PROGNOSIS.

J. Vlachogiannakos[1,*], D. Karagiannakis[1], G. Anastasiadis[2], A. Karlaftis[1], G. Karamanolis[1], I. Vafiadi-Zoumbouli[1], S. D. Ladas[1]. [1]*Academic Department of Gastroenterology, Medical School, University of Athens, Laiko General Hospital,* [2]*Cardiology, Laiko General Hospital, Athens, Greece*

INTRODUCTION: Cirrhotic patients present features of cardiac dysfunction, a clinical term that is already known as "cirrhotic cardiomyopathy" (CC). However, the frequency of the disease as well as its relevance to the clinical course of the cirrhosis has not adequately investigated.
AIMS&METHODS: We assessed the frequency and the characteristics of CC in our cohort of cirrhotic patients and we prospectively evaluated its impact on the clinical outcome of cirrhosis. In a period of 6 months, we enrolled 45 cirrhotics (73.3% males; mean age 57.2±12.4 years; 46.6% alcohol-related; 48.9% decompensated cirrhosis) after excluding those with known heart or pulmonary diseases, hypertension, recent gastrointestinal bleeding, clinical or laboratory signs of active infection and hepatocellular carcinoma. A Pulsed-wave Doppler echocardiography with Tissue Doppler imaging was used to assess the cardiac function of these patients. The diagnosis of left ventricular diastolic dysfunction (LVDD) was made according to the latest guidelines of the American Association of echocardiography. All patients were followed-up for a period of 2 years. The end-points of the study were death, liver transplantation and decompensation of cirrhosis.
RESULTS: LVDD was diagnosed in 17 (37.7%) patients (20% grade I, 17.7% grade II), while 28 (62.3%) patients had no evidence of diastolic dysfunction. LVDD was diagnosed in 8/23 patients (34.78%) with compensated cirrhosis and in 9/22 patients (40.90%) with decompensated liver disease. Patients with decompensated cirrhosis and LVDD had more severe cardiac dysfunction (grade II) as compared to patients with compensated cirrhosis and LVDD (7/9, 77.77% vs. 1/8, 12.5%, $p=0.015$). At the end of follow-up, 13 patients reached the composite end-point; 8 patients with LVDD (8/17, 47%) and 5 patients without LVDD (5/28, 17.8%). On Kaplan-Meier analysis, the actuarial probability of reaching the composite end-point was significantly increased in patients with LVDD ($p=0.032$, log rank: 4.607). On multivariate analysis, albumin levels ($p=0.003$) and the development of LVDD ($p=0.034$) were independently associated with the deterioration of liver disease during follow up.
CONCLUSION: Cirrhotic cardiomyopathy is a common complication of liver cirrhosis independently of the stage and the etiology of the disease. The development of cardiomyopathy seems to be associated with more rapid deterioration of liver disease and a worse prognosis.

P1165 SPLENIC ARTERIAL RESISTIVE INDEX IS USEFUL FOR THE DIAGNOSIS OF SIGNIFICANT PORTAL HYPERTENSION IN CIRRHOTIC PATIENTS WITHOUT SPLENOMEGALY

J. H. Sohn[1,*], W. K. Jeong[2], T. Y. Kim[1]. [1]*Gastroenterology, Hanyang University Guri Hospital, Guri,* [2]*Radiology, Samsung Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Most but not all cirrhotic patients with significant portal hypertension have splenomegaly. It is clinically important to determine, if possible noninvasively, whether a cirrhotic patient especially without splenomegaly has significant portal hypertension.
AIMS&METHODS: Aims: To investigate if the splenic arterial resistive index (SARI) correlates with hepatic venous pressure gradient (HVPG; a surrogate marker of portal hypertension) measured in cirrhotic patients, and to determine the role of SARI in diagnosing significant portal hypertension in patients who have same or less than 12 cm of spleen size measured by ultrasonography.
Total of 51 patients (mean age, 52 years; M:F=39:12), who underwent HVPG measurement for risk stratification of portal hypertension, also underwent splenic US and Doppler to measure the spleen maximum diameter and SARI at the same day. First we calculated the correlation coefficients of spleen size and SARI with HVPG by Pearson correlation respectively, and then tested their difference statistically by z-test. And to investigate the diagnostic performance of spleen size and SARI in diagnosing significant portal hypertension (HVPH$\geq$10mmHg), we did the receiver operating characteristic (ROC) curve analyses and compared the areas under the ROC curves (AUC). Finally, after dividing patients into two groups by spleen size in length as 'same or less than 12 cm', and 'more than 12 cm', and then we calculated the correlation coefficient of SARI with HVPG value. And we also calculated the diagnostic performances of SARI in diagnosing significant portal hypertension in patients who have spleen size same or less than 12 cm.
RESULTS: The correlation coefficient of spleen size and SARI with HVPG were 0.17 ($p=0.23$) and 0.44 ($p<0.01$) respectively, and there was no significant difference between them ($p=0.14$). And the AUC values of spleen size and SARI in diagnosing significant portal hypertension were 0.627 and 0.779 respectively, and also there was no significant difference ($p=0.27$). And in patients who have spleen size same or less than 12 cm (n=23), the correlation coefficient with HVPG value was 0.62 ($p<0.01$), and the AUC value was 0.794.

CONCLUSION: SARI had significant correlation with HVPG value. It also showed a good diagnostic performance in diagnosing significant portal hypertension in the patients without splenomegaly (same or less than 12 cm of spleen size).

P1166 USEFULNESS OF SUPERSONIC SHEAR WAVE ELASTOGRAPHY TO MONITOR THE IMPROVEMENT OR AGGRAVATION OF PORTAL HYPERTENSION IN CIRRHOTIC PATIENTS

J. H. Sohn[1,*], W. K. Jeong[2], T. Y. Kim[1]. [1]*Gastroenterology, Hanyang University Guri Hospital, Guri,* [2]*Radiology, Samsung Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: It is clinically important to monitor, if possible noninvasively, the improvement or aggravation of portal hypertension in cirrhotic patients. Supersonic shear wave elastography (SWE) is a new tool to measure the liver stiffness.
AIMS&METHODS: To investigate whether it is feasible to estimate the change of hepatic venous pressure gradient (HVPG) using SWE as a non-invasive tool in the cirrhotic patients with portal hypertension.
Twenty-three consecutive patients who were diagnosed with portal hypertension on initial HVPG measurement and who underwent follow-up measurement to evaluate response to treatment were enrolled in this retrospective study. Liver stiffness measurement was performed in all of the subjects, followed by HVPG measurement. The relationship between the HVPG and liver stiffness on initial measurement and on follow-up was investigated. Furthermore, we evaluated whether a change in the HVPG (ΔHVPG) was correlated with a change in the liver stiffness (ΔLS). The subjects were subdivided into the group with clinical improvement, no change or aggravation. The performance to determine the change of portal hypertension was investigated.
RESULTS: Liver stiffness was significantly correlated with HVPG at initial and follow-up measurements (r=0.501 and 0.527, respectively). The mean rate and difference of ΔLS were strongly correlated with ΔHVPG (r=0.863 and 0.707, respectively). To determine the change of portal hypertension, the area under the ROC curve was 0.79 of rate of ΔLS, and 0.78 of difference of ΔLS.
CONCLUSION: Supersonic SWE is a feasible non-invasive method to determine the improvement or aggravation of portal hypertension in cirrhotic patients.

P1167 EARLY PHASE OF THE 13C-AMINOPYRINE BREATH TEST RELIABLY PREDICT THOSE OBTAINED WITH THE CONVENTIONAL 2-HOUR STUDY. RESULTS OF ANALYSIS OF LARGE COHORT (292 SUBJECTS) FROM SINGLE CENTRE.

L. Miele[1,2,*], G. Marrone[2], M. Candelli[2], M. A. Zocco[2], M. Biolato[2], C. Cefalo[2], S. Racco[3], V. Vero[2], G. Rapaccini[2], A. Gasbarrini[2], A. Grieco[3]. [1]*Association Columbus,* [2]*Internal Medicine,* [3]*Catholic University of Sacred Hearth, Rome, Italy*

INTRODUCTION: In clinical settings, use of ^{13}C-aminopyrine breath testing (^{13}C-ABT) for noninvasive assessment of liver function is limited, largely because it is time-consuming for staff and tedious for patients.
AIMS&METHODS: To assess the feasibility of developing a simpler, less time-consuming ^{13}C-ABT, we administered the standard 2-h ^{13}C-ABT to a large cohort of patients with chronic liver disease.
METHODS: Isotope ratio mass spectrometry (IRMS) was used to measure the ratio of $^{13}CO_2$ to $^{12}CO_2$ in each breath sample. Cumulative ^{13}C recovery, expressed as a percentage of the administered dose (cPDR), was calculated for the entire 120-min test period (cPDR-120) and for the initial 15 and 30 minutes of the test (c-PDR-15 and c-PDR-30). Receiver operating curve analysis was used to assess the ability of the cPDR-15 and cPDR-30 to predict a c-PDR-120 in the 25th percentile (indicative of severely impaired liver function).
RESULTS: A cPDR-120 of 3.57% or less (indicative of severe impairment of liver function) was predicted with good sensitivity (81.27%) and specificity (86.11%) by a cPDR-15 of 0.245% or less. A cPDR-30 cut-off of 0.735% displayed even higher predictive accuracy (sensitivity 88.58%, specificity 90.28%). Data collected during the first 30 minutes of ^{13}C-ABT performed with IRMS seems to reliably predict results normally obtained on the basis of 120 minutes of testing. This experience indicates that a shorter, more tolerable version of this test might one day be developed as a reliable tool for measuring the functional hepatic reserve in patients with chronic liver disease.
CONCLUSION: Data collected during the first 30 minutes of ^{13}C-ABT performed with IRMS seems to reliably predict results normally obtained on the basis of 120 minutes of testing. This experience indicates that a shorter, more tolerable version of this test might one day be developed as a reliable tool for measuring the functional hepatic reserve in patients with chronic liver disease.

P1168 ENDOTHELIAL DYSFUNCTION IN CIRRHOSIS AND ITS RELATIONSHIP WITH PORTAL HYPERTENSION AND LIVER FAILURE

M. Garcovich[1,*], A. Lupascu[1], D. Roccarina[1], M. E. Ainora[1], G. Caracciolo[1], F. Ponziani[1], E. B. Annicchiarico[1], M. Siciliano[1], A. Gasbarrini[1], M. A. Zocco[1]. [1]*Internal Medicine and Gastroenterology, Catholic University of Sacred Heart, Rome, Italy*

INTRODUCTION: Brachial artery flow-mediated vasodilation (FMD) by ultrasound is the gold-standard for assessing systemic endothelial dysfunction (SED). It has been suggested that SED might play a role in the pathophysiology of the complications of cirrhosis but data are lacking in this field. In this study we assessed the relationship of SED with liver failure, portal hypertension and Doppler indices in cirrhotic patients undergoing measurement of portal venous pressure.
AIMS&METHODS: The examinations included a standard abdominal B-mode scan, Doppler ultrasound (US) examinations, presence of carotid plaques and FMD. Portal flow velocity, damping index of the hepatic vein, congestion and resistivity index of hepatic and splanchnic vessels were measured with Doppler US. According to literature systemic endothelial dysfunction was defined as FMD by BAUS $<$10%.
RESULTS: In 38 patients (25 men, 55$\pm$16 yrs) with cirrhosis (Child-Pugh score 7.2$\pm$2.3; MELD 12$\pm$5) we assessed on the same day the presence of portal hypertension (mean HVPG 17.6$\pm$4.5mmHg) and FMD by BAUS (mean value 8.0$\pm$3.0%). FMD increased in parallel with worsening of liver function as measured by Child-Pugh and MELD score (r=0.39). The proportion of patients with systemic endothelial dysfunction decreased with deterioration of Child class, being higher in patients belonging to Child A class (83%) and the lowest in Child C decompensated cirrhosis (25%). Moreover, SED decreased progressively with the severity of portal hypertension and a significant difference was found between patients with HVPG $<$10 mmHg and those with HVPG $>$10 mmHg (6.4$\pm$3.8% vs 8.6$\pm$3.3). Carotid plaques were more prevalent in patients with SED (25% vs 3%). No significant correlation was found between SED and intra- and extra-hepatic Doppler flow parameters.
CONCLUSION: Endothelial dysfunction measured with FMD correlates inversely with the severity of portal hypertension and liver failure. In patients with cirrhosis FMD increases as liver function deteriorates, and it decreases according to cardiovascular risk. Further studies to elucidate role of FMD in cirrhotic patients are warranted as hyperdynamic syndrome of advanced cirrhosis may alter vascular reactivity.

P1169 HYALURONIC ACID (HA) LEVEL IN ASCITIC FLUID OF CIRRHOTIC PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS (SBP)

Z. E.-A. A. Sayed[1,*]. [1]*Internal Medicine. Gastroenterolgy Unit, Assiut University Hospital. Assiut. Egypt, Assiut, Egypt*

INTRODUCTION: Spontaneous bacterial peritonitis (SBP) is a common problem that affects liver cirrhotic patients. It is also, a major contributor to the deterioration and aggrevation of liver failure complications. Complement deficiency considered as a major complication of liver cirrhosis and bacterial overgrowth in the intestine is the major source of bacterial peritonitis. Hyaluronan or hyaluronic acid (HA) is a connective tissue polysaccharide, synthesized by many cell types, although mesenchymal cells are believed to be predominant. The serum level of HA is regulated by the influx from the tissues via lymphatic system and its receptor-mediated clearance by liver endothelial cells. So, marked increase in serum levels are noted in liver diseases, especially in patients with cirrhosis, when the clearance is impaired. The hyaluronic acids (HA) have an important role in controlling tissue permeation, bacterial invasiveness and macromolecular transport between cells. HA was observed to enhance cellular infiltration and migration by facilitating cell detachment. It also, increase the proinflammatory cytokines TNF-α and IL-8 production. It is interesting to note that HA not only can promote the inflammation, but also can moderate the inflammatory response, which may contribute to the stabilization of granulation tissue matrix. The innate immune system uses TLRs to recognize microbes and initiate host defense. The repeating disaccharide structure of HA has features of pathogen-associated molecular patterns. Many pathogen-associated molecular patterns on pathogens utilize Toll-like receptors to initiate innate immune responses.
AIMS&METHODS: To measure the level of complement-3 (C3) and hyaluronic acid in ascetic fluid of liver cirrhosis patients with and without spontaneous bacterial peritonitis
RESULTS: In our study we found that there was a significant decrease in C3 level in ascetic fluid of cirrhotic patients in comparison to ascetic fluid of patients with other causes (i.e. Nephrotic syndrome, and cardiac failure) ($P<0.05$). Also, HA level shows significant decreased in ascetic fluid of cirrhotic patients in comparison to ascetic fluid of patient with other causes (i.e. Nephrotic syndrome, and cardiac failure) ($P<0.05$). HA level in serum of liver cirrhosis patients have a highly significant increase ($p<0.001$) in comparison to control group.
There was a highly significant decrease in HA level in ascetic fluid of cirrhotic patients with SBP in comparison to HA level in ascetic fluid of cirrhotic patients without SBP ($p<0.001$).
CONCLUSION: C3 and HA are significantly decreased in ascetic fluid of cirrhotic patients. HA significantly decreased in ascetic fluid of cirrhotic patients with SBP in comparison to patients without SBP.

P1170 NOVEL PROGNOSTIC MODEL FOR PRIMARY SCLEROSING CHOLANGITIS

E. M. De Vries[1,*], K. Boonstra[1], M. Leeflang[2], C. Ponsioen[1]. [1]*Gastro-enterology and Hepatology,* [2]*Clinical Epidemiology, Biostatistics and Bioinformatics, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Primary Sclerosing Cholangitis (PSC) is a disease with no effective drug treatment options, eventually leading to biliary fibrosis, cirrhosis and liver failure. The MAYO risk score (MRS) is often used to estimate survival of PSC patients. However, MRS is based on a patient group derived from tertiary referral centres. Other limitations of MRS are the use of parameters that can be highly variable over the course of the disease, and a relatively short follow-up period with a median of 36 months. Aim of this study was to develop a prognostic model for survival of PSC patients based on intrinsic parameters.
AIMS&METHODS: 690 PSC patients were identified in a large geographically defined area of the Netherlands, comprising 50% of the Dutch population. Four independent hospital databases were searched in 44 hospitals. A range of variables, including date of PSC diagnosis, date and type of IBD, and follow up time were retrieved from patient records. All variables were assayed as potential predictors of survival by univariate analysis. To develop the survival model, time dependant Cox regression proportional hazard analysis was performed.
RESULTS: The median follow up time was 85 months (range 0-468 months). The variables PSC type, age at diagnosis PSC, co-existing inflammatory bowel disease (IBD), IBD-type, sex, auto-immune hepatitis overlap, cholelithiasis, cholecystectomy and appendectomy before diagnosis PSC and variceal bleeding were considered for the model. Using manual backward elimination in the multivariate analysis, the following formula was created: Prognostic Index (PI) =– 0.916*PSC Type$(0/1)^1$–0.480*Age at DiagnosisPSC^2-0.570*Ulcerative Colitis(UC)/IBD Unspecified (IBDU)$(0/1)^3$ –1.212*Crohn's Disease (CD)$(0/1)^3$ +1.082*Follow up time $(0/1)^4$ *UC/IBD U $(0/1)^3$+1.317*Follow up time$(0/1)^4$ * CD $(0/1)^3$. With this PI, estimations of survival up to 25 years can be made.
1: PSC type: Large duct PSC=0; Small duct PSC=1
2: Age at diagnosis PSC: >30 years=0; <30 years=1
3: IBD: No IBD =0; UC/IBDU/CD=1
4: Follow up time: <36 months=0; >=36 months=1
CONCLUSION: We have created a unique prognostic model based on an unselected group of 690 patients. This model consists of intrinsic variables and is thus applicable in all PSC patients and independent from disease stage. To confirm the accuracy of this prognostic model, validation in an independent patient cohort is warranted.

P1171 RISK FACTORS FOR THE ONSET OF PRIMARY SCLEROSING CHOLANGITIS

E. M. De Vries[1,*], K. Boonstra[1], C. Ponsioen[1]. [1]*Gastro-enterology and Hepatology, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Primary sclerosing cholangitis (PSC) is a cholestatic liver disease, affecting intra-and extrahepatic bile ducts. PSC is strongly associated with inflammatory bowel disease (IBD). Pathogenesis of both diseases is unknown. PSC and IBD are considered complex genetic diseases, meaning that environmental risk factors trigger disease in a genetic susceptible host. The aim of this study was to assess possible risk factors for PSC.
AIMS&METHODS: For this case control study, PSC patients and IBD controls from the population-based Epi-PSC-PBC database were asked to fill-out a questionnaire. Only patients that filled out the questionnaire were included. The following data could be obtained: smoking behaviour, history of appendectomy before diagnosis PSC and medical family history. Possible risk factors were analysed by Chi square analysis. Relative frequencies of risk factors were expressed as Odds Ratio (OR).
RESULTS: 342 PSC patients (46% Ulcerative colitis (UC), 15% Crohn's disease (CD), 3% IBD-Unspecified (IBD-U)) and 372 IBD patients (42% UC, 54% CD, 4% IBD-U) were included. In the PSC cohort there were significantly less current and former smokers compared to the control group, with 8,2 % vs. 22,6 %, OR 0,31 (95% CI 0,13-0,73) current smokers and 15,8% vs. 32,0%, OR 0,38 (95% CI 0,19–0,76) former smokers. Comparing PSC-UC patients with UC patients there were also significantly less current and former smokers in the PSC-UC group compared to the UC control group with 5.7% vs. 18.6 %, OR 0.24 (95% CI 0.09-0.67) current smokers and 17.1 % vs. 33.3 %, OR 0.42 (95% CI 0.21-0.81) former smokers. Comparing PSC-CD patients with CD patients this finding was again confirmed with 10.0% vs. 29.9%, OR 0,27 (95% CI 0.12-0.59) current smokers and 8,0% vs 25,9%, OR 0.26 (OR 0.11-0.60) former smokers. There were significantly more appendectomies in de PSC cohort compared to the IBD control group, 12,9 % vs. 4,0 %, OR 3,31 (95%CI 1,03–10,65). PSC patients had significantly more often a first degree relative with an autoimmune liver disease compared to IBD controls, 2,0% vs. 0,3%, OR 2,05 (95% CI 0,24-106,26), but significantly less often a first degree relative with IBD 10,2 % vs. 17,5%, OR 0,54 (95% CI 0,24-1,25).
CONCLUSION: Current and former smoking was associated with a decreased risk of PSC independent of IBD, as well as it was associated with a decreased risk of PSC-UC independent of UC and a decreased risk of PSC-CD independent of CD. PSC patients more often have a first degree family member with autoimmune liver disease then IBD control patients. For the first time appendectomy before diagnosis PSC was shown to be associated with an increased risk of PSC.

P1172 TARGETING STRATEGIES TO IMPROVE URSODEOXYCHOLIC ACID ACTION IN PRIMARY BILIARY CIRRHOSIS

I. Copaci[1,*], L. Micu[1], E. Mindrut[1], G. Ismail[1]. [1]*Center of Internal Medicine, FUNDENI CLINICAL INSTITUTE, Bucharest, Romania*

INTRODUCTION: Ursodeoxycholic acid (UDCA) has been shown to stabilize or significantly improve the grades of both ductular proliferation and lymphocytic piecemeal necrosis. Because of the multiple players, it may be anticipated that anti-inflammatory drugs with broad specificity are efficient in a subset of patients not responding to UDCA alone.
AIMS&METHODS: The aim of the study was to determine if the addition of budesonide or methotrexate to UDCA would improve liver histology. Secondary endpoints included comparison of treatment arms with respect to overall survival and time to clinical decompensation.
PBC stage I to III patients (n=58) were randomized into two treatment arms: UDCA 15 mg/kg/day and budesonide 6 mg/day (n=28, group A) or UDCA 15 mg/kg/day plus methotrexate 15 mg/week (n=30, group B). Patients were excluded if they had end-stage liver disease: serum bilirubin level greater than 10 mg/dl or serum albumin less than 3 g/dl; hepatic encephalopathy; hemorrhage from esophageal varices and/or portal gastropathy. Patients were followed-up for a median period of 5.5 years (range 4.2-7.6 years) or until treatment failure. Treatment failure was defined as: histological progression by at least two stages or to cirrhosis; death without liver transplantation; transplantation; variceal bleeding; development of ascites, hepatic encephalopathy or varices; a doubling of serum bilirubin levels.
RESULTS: Values for serum ALP, ALT and GGT improved in both groups. Bilirubin levels remained stable in group A and increased in group B (p=0.01). Analysis of liver histology after 36 months of therapy revealed a significant histological improvement in both groups when baseline was compared with the final biopsy. No patients in either group progressed to cirrhosis or extensive fibrosis. Overall, mean necro-inflammatory scores fell from 12.5 to 4.6 in group A and from 12.8 to 6.2 in group B. Fibrosis decreased 28.5% in group A (p=0.05) and 13.3% in group B (p=0.08).
CONCLUSION: 1. Combination therapy might be beneficial for all PBC patients with pre-cirrhosis liver disease. 2. Inflammation decreased in both groups, but the histological stage was significantly decreased in the group with budesonide and UDCA.

P1173 MALE GENDER IS ASSOCIATED WITH MORE RAPID PROGRESSION AND INCREASED RISK OF BILIARY DYSPLASIA IN PRIMARY SCLEROSING CHOLANGITIS

M. A. Färkkilä[1,*], S. Boyd[2], H. M. Isoniemi[3], J. Arola[2]. [1]*Gastroenterology,* [2]*Pathology,* [3]*Liver surgery, HELSINKI UNIVERSITY CENTRAL HOSPITAL, Helsinki, Finland*

INTRODUCTION: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by inflammation and fibrosis of bile ducts with unknown patogenesis. Association with other autoimmune disease, and at a genetic level the predominant HLA association suggest autoimmune etiology (1). Unlike in other autoimmune disorders, ~70% of patients with PSC are men. In Nordic countries 80 % of PSC patients have a concomitant IBD. In PSC patients without IBD, the M:F ratio is lower, 0.72:1 (2). Progression of the disease is varying and unpredictable with association of markedly increased risk of cholangiocancer with life time risk of 10-15 % (3). Factors associated with disease progression and development of biliary dysplasia are poorly known.
AIMS&METHODS: To evaluate the role of gender in the PSC progression and the risk of biliary dysplasia and transplantation. The study population consists of patients referred for ERCP for the first time to confirm the diagnosis of PSC during years 2006-3/2011 at Helsinki University Central Hospital due to the suspicion of PSC (S-ALP > UNL in conjunction with IBD or MRI/liver biopsy suggestive for PSC) irrespective of symptoms. ERCP findings were scored according to modified version of Ponsioen (4). Brush cytology (BC) from intra- and extrahepatic bile ducts was collected in every patient and a sample for DNA-flow cytometry was obtained in patients with advanced disease (ERC-score≥3). Moreover, also the sex distribution of the patients transplanted for PSC in Finland were analyzed.
RESULTS: Altogether 262 patients with confirmed PSC were included, of whom 129 were males (49.2%). Of the all patients, 81 % were asymptomatic. Concomitant IBD was diagnosed in 68 % of patients, in 79,1 % in males and in 57.1% in females. M:F ratio in patients(n=83) with more advanced disease (PSC-score≥3) was 51/32 (61.4%). Cytological dysplasia was detected in BC in 17 patients out of 262 (6.5%), of whom 12 were males (71%), and 2 (0,76%) were diagnosed with malignant cytology consistent with cholangiocancer, both males. Our patients transplanted for PSC (n=127) 80 (63%) are males.
CONCLUSION: In this large series of mostly asymptomatic patients with newly diagnosed PSC, no sex difference could be found (M:F=49.2/50.8%), in contrast to previous studies, but males had more commonly advanced disease (61.4%), cytological dysplasia or malignant cytology (74%) and male gender predominated in transplanted PSC-population (63%). Male gender seems to be associated with more rapid progression of PSC, increased risk of biliary dysplasia and for liver transplantation.

INTRODUCTION: IgG4-related sclerosing cholangitis (IgG4-SC) must be precisely distinguished from primary sclerosing cholangitis (PSC) and cholangiocarcinoma (CC)because the treatments are completely different. However, the pathological diagnosis of IgG4-SC is difficult. Therefore, highly specific non-invasive criteria such as serum IgG4 should be established. This study established a cut-off for serum IgG4 to differentiate IgG4-SC from respective controls using serum IgG4 levels measured in Japanese centers.
AIMS&METHODS: A total of 344 IgG4-SC patients were enrolled in this study. As controls, 245, 110, and 149 patients with pancreatic cancer, PSC, and CC, respectively, were enrolled. IgG4-SC patients were classified into 3 groups: type 1 (stenosis only in the lower part of the common bile duct), type 2 (stenosis diffusely distributed throughout the intrahepatic and extrahepatic bile ducts), and types 3 and 4 (stenosis in the hilar hepatic region) with 246, 56, and 42 patients, respectively. Serum IgG4 levels were compared, and the cut-offs were established.
RESULTS: The cut-off obtained from receiver operator characteristic curves showed similar sensitivity and specificity to that of 135 mg/dL when all IgG4-SC and controls were compared. However, a new cut-off value was established when subgroups of IgG4-SC and controls were compared. A cut-off of 182 mg/dL can increase the specificity to 96.6% (4.7% increase) for distinguishing type 3 and 4 IgG4-SC from CC. A cut-off of 207 mg/dL might be useful for completely distinguishing type 3 and 4 IgG4-SC from all CC.
CONCLUSION: Serum IgG4 is useful for the differential diagnosis of IgG4-SC and controls.

P1175 CORRECTION OF LOW-GRADE CHRONIC INFLAMMATION BY MULTIPROBIOTIC "SYMBITER" IN PATIENTS WITH TYPE 2 DIABETES AND NON-ALCOHOLIC FATTY LIVER DISEASE

T. Falalyeyeva[1], M. Kondro[2,*], G. Mykhalchyshyn[3], N. Kobyliak[3], P. Bodnar[3], T. Beregova[1], D. Yankovskyy[4]. [1]*TARAS SHEVCHENKO NATIONAL UNIVERSITY OF KYIV, Kyiv,* [2]*Danylo Halytsky Lviv National Medical University, Lviv,* [3]*National Bohomolets Medical University,* [4]*O. D. Prolisok, Kyiv, Ukraine*

INTRODUCTION: Obesity and diabetes are both characterised by low-grade inflammation of unclear origin. Bacterial lipopolysaccharide (LPS) is a gut microbiota-related factor that triggers secretion of proinflammatory cytokines. Continuous subcutaneous low-rate infusion of LPS led to excessive weight gain and insulin resistance in mice.
AIMS&METHODS: Evaluate the effect of multiprobiotic "Symbiter" on low-grade chronic inflammatory state in patients with type 2 diabetes (T2D) and non-alcoholic fatty liver disease (NAFLD).
Materials and methods: We examined 86 patients with T2D and NAFLD. All patients divided by us on the way of therapy into 2 groups. The main group (56 subjects) received oral antidiabetic therapy and multiprobiotic "Symbiter" within 30 days. Patients of comparison group (30 subjects) received only hypoglycemic drugs. Also in each group we identified patients with normal and elevated level of transaminases. The concentration of proinflammatory cytokines in the serum - IL-6, IL-8, IL-1β, TNF-α and IFN-γ - determined by ELISA using commercial kits "Cytokine Ltd." (Russia).
RESULTS: We observed 4-5 times increasing of cytokines in patients with NAFLD and elevated transaminase levels, compared to a 2-3-time increase in patients with normal transaminase levels. Our data shows that positive hepatoprotective effect of multiprobiotic "Symbiter" in patients of main group accompanied by decrease manifestations of low-grade systemic inflammatory response. We noted statistically significant reduction of proinflammatory cytokines in plasma, after 30 days of therapy, in patients with elevated levels of transaminases. In particular, the level of IL-6 decreased on 40% (p=0.041), IL-8 - 26.54% (p $<$0.001), TNF-α - 20.83% (p $<$0.001), IL-1β - 17.7% (p$<$0.001) and IFN-γ on 21.84% (p $<$0.001) respectively. In patients with normal levels transaminases and NAFLD were significantly decreased only IL-6 on 17.1% (p = 0.041), IL-8 - 21.4% (p $<$0.001) and TNF-α on 13.8% (p = 0.008). Significant changes in cytokines levels in patients of comparative group we don't observed.
CONCLUSION: Multiprobiotic "Symbiter" shows hepatoprotective effect which accompanied by decrease manifestations of low-grade systemic inflammatory response. That's why can be recommended for use in patients with different stages of NAFLD and T2D as an adjunct to standard treatment regimens.

P1176 SAFETY AND EFFICACY OF SUBCUTANEOUS HEPATITIS B IMMUNOPROPHYLAXIS USING"ON DEMAND"APPROACH:A SINGLE CENTER EXPERIENCE

S. Pecere[1,*], A. Grisolia[1], S. Fagiuoli[1]. [1]*Gastroenterology and Transplant Hepatology, H. Papa Giovanni XXIII, Bergamo, Italy*

INTRODUCTION: HB immunoglobulin(HBIG)administration is the backbone for prophylaxis of HBV re-infection after liver transplantation (LT). Long term effects and efficacy of HBIG are well known only for intravenous(IV)and intramuscular(IM)formulations. Aim:to investigate efficacy, safety and feasibility of "on demand" subcutaneous (SC) administration of the new formulation of HBIG BT088 (Zutectra®)LT patients
AIMS&METHODS: a total of 37 LT patients(9F,28M, mean age60±7years)were switched from IV or IM to SC HBIG administration during a period of 2 years from
January 2011. The conversion to SC administration occurred at a mean time of 44 months from the LT. They were prospectively enrolled and followed up for at least 48 weeks. The dose of HBIG was initially standardized to 1000IU/week. After a period of stabilization, patients were offered a"on demand"approach, with a targeted level of serum antiHBs of minimum100UI/L
RESULTS: all patients were HBV-DNA negative at the time of transplantation(5spontaneously-14%,32 under NUCs -86%). All patients were on a combination prophylaxis with HBIG and NUCs. All patients became rapidly independent for the weekly SC self-injection. The treatment was effective in maintaining trough anti-HBs levels greater than 100 UI/l in all patients. 90%of patients showed a mean HBsAb titer greater than 155 UI/l. Overall, mean values of HBsAb were 262 UI/l(±118). The mean HBsAb titre prior to switching to SC formulation was 318±124, with a mean monthly injection of 5000U/L. No drug related side effects or injection site problems were observed.
CONCLUSION: SC HBIG for long term prophylaxis of post LT HBV re-infection has proven to be safe, well-accepted and effective in maintaining the targeted protective anti-HBs levels. Moreover individualization of immuneprophylaxis according to the lowest protective anti-HBs titers is easily applicable with the SC formulation, allowing the exploration of new schedules in order to improve costs while maintaining efficacy.

P1177 LIVER STIFFNESS MEASUREMENTS BY MEANS OF SUPERSONIC SHEAR IMAGING (SSI) SHOULD BE PERFORMED IN FASTING CONDITION OR NOT?

A. Popescu[1,*], O. Gradinaru-Tascau[1], S. Bota[1], M. Popescu[1], R. Sirli[1], M. Danila[1], F. Motiu[1], M. Szilasky[1], T. Moga[1], F. Bende[1], C. Popescu[1], I. Sporea[1]. [1]*Gastroenterology and Hepatology, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania*

INTRODUCTION: SSI is a new method for non-invasive evaluation of liver fibrosis.
AIMS&METHODS: Aim: to assess the influence of food intake on liver stiffness (LS) measurements by means of SSI, knowing that food intake increase LS values assessed by means of other two elastographic methods (Transient Elastography and Acoustic Radiation Force Impulse elastography).
Patients and methods: Our study included 75 healthy volunteers, with a median age of 25 years (19-58 years), 58 women (77.3%) and 17 male (22.7%). SSI measurements were performed in fasting condition, then 1h and 3h after a standard meal. All subjects included in the study received the same meal: one sandwich and 500ml water. SSI measurements were performed in supine position. In each patient 5 valid SSI measurements were performed by intercostals approach, a median value was calculated and expressed in kilopascals (kPa).
RESULTS: In 3 patients we could not obtain 5 valid LS measurements assessed by means of SSI in at least one condition (fasting, 1h and 3 h after food intake), so in the final analysis were included 72 subjects (96% of all healthy volunteers). The mean LS values were similar in fasting condition, 1h and 3 h after food intake were: 6.1±1.3 kPa, 5.8±1.1 kPa and 5.7±1.1 kPa, respectively. No significant differences were observed between mean SSI values in the different food conditions: fasting vs. 1h after food intake: p=0.28, fasting vs. 3h after food intake: p=0.17 and 1h. vs. 3h after food intake: p=0.80 respectively.
CONCLUSION: LS values assessed by means of SSI had similar values in fasting condition and after food intake, so probably food condition is not an issue for SSI measurements, but further studies are still necessary.

P1178 ACCURACY OF INVALID FIBROSCANS IN DIAGNOSE SIGNIFICANT LIVER FIBROSIS

B. M. Gonçalves[1,*], A. C. Caetano[1,2], D. Fernandes[1], J. B. Soares[1], C. Rolanda[1,2], P. Bastos[1], R. Gonçalves[1]. [1]*Gastroenterology, Hospital de Braga,* [2]*Life and Health Sciences Research Institute (ICVS), School of Health Sciences, University of Minho, Braga, Portugal*

INTRODUCTION: Transient liver elastography (Fibroscan ® - FS) is an instrumental method for noninvasive assessment of liver fibrosis. One limitation of this procedure is the need to get at least 10 valid measurements with IQR/liver stiffness ratio < 30% and success rate > 60%, which limits the interpretation of the exam.
AIMS&METHODS: The presente study proposes to evaluate the diagnostic accuracy for significant liver fibrosis of the invalid fibroscans.
Retrospective analysis of patients with invalid FS who underwent liver biopsy (LB) between 2008 and 2013. Significant fibrosis was defined as Metavir F ≥ 2. It was determinated the capacity (sensitivity, specificity, positive and negative predictive values and AUROC) of invalid FS for the diagnosis of F ≥ 2, using the cut-off of liver stiffness for significant fibrosis according to the underlying pathology. Statistical analysis was performed with SPSS 20.0 for Mac®.
RESULTS: Included 56 patients (mean age 47±11 years, 62.5% males) with invalid FS, 18 due to IQR/liver stiffness ratio > 30% (median 40.5%, min 34%, max 136.8%), 29 with success rate <60% (median 43%, min 5%, max 56%) and 9 due to both. The indication for FS was chronic hepatitis B in 21 patients, chronic hepatitis C in 15, non-alcoholic fatty liver desease in 8 and other reasons in 12. Liver biopsy revealed F0, F1, F2, F3 and F4 in 19, 20, 11, 3 and 3 cases, respectively. The sensitivity, specificity, positive and negative predictive values and AUROC for the diagnosis of F ≥ 2 was 76% (95% CI: 50-93%), 92% (95% CI: 79-98%), 81.2% (95% CI: 54.3 to 95.7%), 90% (95% CI: 76.3 to 97.1%), 0.84 (95% CI: 0.71 to 0.97, p <0:01). The reason for invalid FS was not associated with significant change in the negative predictive value, which remained > 88%.
CONCLUSION: In our series, the results show a good accuracy of invalid FS for exclusion of significant liver fibrosis.

P1179 THE USEFULNES OF ACOUSTIC RADIATION FORCE IMPULSE (ARFI) ELASTOGRAPHY (ARFI) FOR EVALUATION OF LIVER FIBROSIS – LARGE MONOCENTRIC EXPERIENCE

I. Sporea[1,*], S. Bota[1], R. Sirli[1], A. Popescu[1], M. Danila[1], A. Jurchis[1], O. Gradinaru-Tascau[1]. [1]*Gastroenterology and Hepatology, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania*

INTRODUCTION: ARFI is an ultrasound elastographic method for non-invasive evaluation of liver fibrosis.
AIMS&METHODS: Aim: To assess the value of liver stiffness (LS) measurements by means of ARFI as a predictive factor for the severity of fibrosis.
Methods: Our study included 1150 subjects with an median age of 55 years (18-87): 652 patients (56.7%) diagnosed with liver cirrhosis by clinical, ultrasound, endoscopy criteria; 244 subjects (21.2%) without known liver disease, 133 patients (11.6%) with chronic hepatitis C in whom liver biopsy (LB) was performed, 72 chronic hepatitis B patients (6.3%) with LB and 49 patients (4.2%) with non-cirrhotic ascites. Ten LS valid ARFI measurements were performed in each subject and a median value was calculated, expressed in meters/second (m/s). Reliable LS measurements were considered the median of 10 valid measurements with a success rate≥60% and an interquartile range interval<30%.
RESULTS: Reliable LS values by means of ARFI measurements were obtained in 1076/1150 (93.5%) subjects.
In . . .normal subjects" the mean LS value assessed by ARFI was 1.22 ± 0.31 m/s (median 1.19 m/s)
In patients with LB, the best LS ARFI cut-offs values for predicting different stages of liver fibrosis were: F≥2 – 1.48 m/s (AUROC=0.671), F≥3 – 1.61 m/s (AUROC=0.709) and F=4 – 1.75 m/s (AUROC=0.824).
The mean LS values were significantly higher in cirrhotic patients with significant esophageal varices (al least grade 2) as compared with those without or with grade 1 varices: 2.96±0.71 m/s vs. 2.81±0.71 m/s, p=0,01; also in cirrhotic with ascites as compared with those without ascites: 3.01±0.70 m/s vs. 2.78±0.68 m/s, p=0.0001.
The mean LS values assessed by ARFI were significantly higher in cirrhotic patients with ascites as compared with patients with non-cirrhotic etiology of ascites: 3.01±0.70 m/s vs. 1.43 ±0.49 m/s, p<0.0001.
CONCLUSION: ARFI is a good method for noninvasive liver fibrosis assessment.

P1180 WHICH ARE THE CUT-OFF VALUES OF LIVER STIFFNESS MEASUREMENTS ASSESSED BY SUPERSONIC SHEAR IMAGING (SSI) FOR PREDICTING SIGNIFICANT FIBROSIS AND LIVER CIRRHOSIS?

I. Sporea[1,*], O. Gradinaru-Tascau[1], S. Bota[1], A. Popescu[1], R. Sirli[1], A. Jurchis[1], M. Popescu[1], M. Danila[1]. [1]*Gastroenterology and Hepatology, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania*

INTRODUCTION: SSI is a new ultrasound elastographic method used for non-invasive assessment of liver fibrosis.
AIMS&METHODS: Aim: to identify the cut-off values of liver stiffness (LS) assessed by SSI for predicting significant fibrosis (F≥2) and liver cirrhosis (F=4), considering Transient Elastography (TE) as the reference method.
Methods: 383 consecutive subjects were evaluated by means of TE and SSI. Reliable TE measurements were defined as: median value of 10LS measurements with a success rate≥60% and an interquartile range interval<30%, values expressed in kPa. Reliable LS measurements by means of SSI was definied as the median value of 5 LS measurements expressed in kPa. To discriminate between various stages of fibrosis by TE we used the liver stiffness (LS) cut-offs (kPa) proposed in the most recently published meta-analysis (1): F1-6, F2-7.2, F3-9.6 and F4-14.5.
RESULTS: Our subjects were: healthy volunteers-14.6%; patients with chronic hepatitis B -17.6%; with chronic hepatitis C – 25.8%; with coinfection (B+C or B+D) – 1.6%; with non-viral chronic hepatopathies (most of them with non-alcholic fatty liver disease)-29.2%; and with liver cirrhosis diagnosed by means of clinical, biological, ultrasound and/or endoscopic criteria-11.2%. The rate of reliable LS measurements was statistically similar for TE and SSI: 73.9% vs. 79.9%, p=0.06. Reliable LS measurements by both elastographic methods were obtained in 65.2% of patients. The distribution of liver fibrosis in this cohort of patients, using TE prespecified cut-off values were: F0-40.8%, F1-14.8%, F2-19.2%, F3-12.8%, F4-12.4%. The best SSI cut-off value for predicting significant fibrosis was 7.8 kPa (AUROC=0.859 with 76.8% Se and 82.6% Sp), while the best SSI cut-off value for predicting liver cirrhosis was 11.5 kPa (AUROC=0.914 with 80.6% Se and 92.7% Sp).
CONCLUSION: The best SSI cut-off values for predicting significant fibrosis (F≥2) and cirrhosis were 7.8 kPa and 11.5 kPa, respectively.

P1181 THE FEASIBILITY OF SHEAR-WAVE ELASTOGRAPHIC METHODS FOR NON-INVASIVE ASSESSMENT OF LIVER FIBROSIS IN CHRONIC VIRAL HEPATITIS PATIENTS

I. Sporea[1,*], O. Gradinaru-Tascau[1], S. Bota[1], A. Popescu[1], R. Sirli[1], A. Jurchis[1], M. Popescu[1], M. Danila[1]. [1]*Gastroenterology and Hepatology, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania*

INTRODUCTION: Ultrasound elastographic methods are more and more used for non-invsive evaluation of liver fibrosis
AIMS&METHODS: Aim : to assess the feasibility ("intend to diagnose") of the 3 shear waves elastographic methods (Transient Elastography-TE, Acoustic Radiation Force Impulse-ARFI and SuperSonic Shear Imaging-SSI) in chronic viral hepatitis patients.
Methods: Our study included 172 patients with chronic viral hepatitis, in which liver stiffness (LS) was evaluated by means of TE (using the standard M-probe), ARFI and SSI. Reliable measurements were defined as: median value of 10 (TE, ARFI) LS measurements with a success rate≥60% and an interquartile range interval<30%, values expressed in kPa (TE) or m/s (ARFI). Reliable LS measurements by means of SSI were definied as the median value of 5 LS measurements expressed in kPa.
RESULTS: The etiology of liver disease was: chronic hepatitis C – 99 patients (57.6%), chronic hepatitis B – 67 patients (38.9%), coinfection (B+C virus or B+D virus) – 6 patients (3.5%). Reliable LS measurements were obtained in a significantly higher percentage of patients by means of ARFI elastography as compared with TE and SSI: 92.5% vs. 79.1%, (p=0.0007) and 92.5% vs.81.9%, (p<0.0001), respectively. The rate of reliable LS measurements was similar for TE and SSI: 79.1% vs. 81.9%, (p=0.60).
CONCLUSION: The most feasible shear-waves ultrasound elastographic method for non-invasive assessment of liver fibrosis in chronic viral hepatitis patients was ARFI.

P1182 EARLY PREDICTION OF RESPONSE TO SORAFENIB IN PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA: THE ROLE OF DYNAMIC CONTRAST ENHANCED ULTRASOUND

M. Garcovich[1,*], A. Lupascu[1], D. Roccarina[1], E. Di Stasio[2], M. E. Ainora[1], G. Caracciolo[1], F. Ponziani[1], E. B. Annicchiarico[1], M. Siciliano[1], G. L. Rapaccini[2], M. Pompili[2], A. Gasbarrini[1], M. A. Zocco[1]. [1]*Internal Medicine and Gastroenterology,* [2]*Catholic University of Sacred Heart, Rome, Italy*

INTRODUCTION: Sorafenib has become the standard first-line treatment for patients with advanced hepatocellular carcinoma (HCC). This molecularly targeted therapy acts not only by inhibiting proliferation but also by inducing alterations in tumor vascularity that cannot be evaluated by traditional morphological criteria to assess tumor response. Contrast enhanced ultrasound (CEUS) is now recognized as a functional imaging technique able to evaluate tumor vascularization. In particular, recently developed quantitative approaches able to measure the amount and the time course of contrast uptake have shown great promise in revealing effective tumour response to anti-angiogenic drugs before tumour changes occur.
AIMS&METHODS: We wanted to evaluate the feasibility of dynamic CEUS (D-CEUS) as a predictor of early tumor response to Sorafenib and to correlate these functional parameters with clinical efficacy endpoints.

Twenty-eight HCC patients treated with Sorafenib 400 mg bid were prospectively enrolled. CEUS was performed at baseline (T0) and after 15 (T1) and 30 (T2) days of treatment. Tumor vasculature was assessed in a specific harmonic mode associated with a perfusion and quantification software (Q-Lab, Philips). Variations between T1/T2 and T0 were calculated for five D-CEUS functional parameters (peak intensity, PI; time to PI, T_P; area under the curve, AUC; slope of wash in, P_w; mean transit time, MTT) and were compared for responders and non responders. The correlation between D-CEUS parameters, overall survival (OS) and progression free survival (PFS) was also assessed. A p value < 0.05 was considered statistically significant.

RESULTS: The percentage variation at T1 significantly correlated with response in three D-CEUS parameters (AUC, PI and P_{wi}; $p = 0.002$, <0.001 and 0.003 respectively). A decrease of AUC ($p= 0.045$) and an increased/unchanged value of T_P ($p=0.029$) and MTT ($p=0.010$) were associated with longer survival. Three D-CEUS parameters (AUC, T_P, P_w) were significantly associated with PFS.

CONCLUSION: Dynamic US provides a more reliable and early measure of efficacy for antiangiogenic therapies and could be an excellent tool for selecting patients who will benefit from treatment. Further studies with a greater number of patients are required to confirm these results.

P1183 META-ANALYSIS OF CONTRAST-ENHANCED ULTRASOUND FOR DIFFERENTIATION OF BENIGN AND MALIGNANT FOCAL LIVER LESIONS

M. Friedrich-Rust[1,*], T. Klopffleisch[1], J. Nierhoff[2], E. Herrmann[2], M. D. Schneider[1], J. Vermehren[1], S. Zeuzem[1], J. Bojunga[1]. [1]*Department of Internal Medicine 1, J. W. Goether University Hospital,* [2]*Institute of Biostatistics and Math. Modelling, Faculty of Medicine, J. W. Goethe-Univ, Frankfurt, Germany*

INTRODUCTION: International guidelines of Ultrasonography (EFSUMB) recommend the performance of contrast-enhanced ultrasound (CEUS) as the first method of choice for the diagnostic work up of focal liver lesions, which are unclear on conventional ultrasound. However, these recommendations are based on the results of multiple single studies and only few large multicenter studies.

AIMS&METHODS: The aim of the present meta-analysis was to assess the overall sensitivity and specificity of CEUS for the diagnosis of malignant liver lesions.

Literature databases were searched up to March 2012. Inclusion criteria were: evaluation of CEUS, assessment of sensitivity and specificity of CEUS for the diagnosis of malignant liver lesions. The meta-analysis was performed using the random-effects model based on the DerSimonian Laird method. In addition, quality analyses were carried out to assess sources of heterogeneity.

RESULTS: 45 studies with 8147 focal liver lesions were included in the analysis. Overall sensitivity and specificity of CEUS for the diagnosis of malignant liver lesions was 93% (95%>CI: 91%, 95%) and 90% (95%>CI: 88%, 92%), respectively. A significant heterogeneity was found between the single studies. However, funnel plot evaluating publication bias showed symmetric distribution of studies. Subanalysis revealed no significant difference when evaluating studies using histology for all liver lesions, when comparing high quality and low quality studies, and blinded versus non-blinded studies. Comparison of CEUS and CT/MRI was possible using data of seven studies with overall 838 focal liver lesions. No significant difference of specificity (88% vs. 83%, p= 0.11) was found between CEUS and CT/MRI for the diagnosis of malignant liver lesions.

CONCLUSION:

The results of this meta-analysis support the EFSUMB recommendations to use CEUS as first method of choice in the diagnostic work-up of liver lesions following conventional ultrasound selecting patients who need further diagnostics (MRI, fine-needle biopsy).

The results of this meta-analysis support the EFSUMB recommendations to use CEUS as first method of choice in the diagnostic work-up of liver lesions following conventional ultrasound selecting patients who need further diagnostics (MRI, fine-needle biopsy).

P1184 IS ACOUSTIC RESONANCE FORCE IMPULSE (ARFI) A GOOD TECHNIQUE FOR IMAGING LIVER CIRRHOSIS AND FIBROSIS? AN OBSERVATIONAL STUDY IN AN AUSTRALIAN TERTIARY HOSPITAL LIVER CLINIC SERVICE.

N. Ding[1,*], E. E. Clarebrough[1], M. Stokes[1], K. Astill[1], C. Glennon[1], J. Watson[1]. [1]*Gastroenterology, Geelong Hospital, Geelong, Australia*

INTRODUCTION: Current investigations of hepatic fibrosis include liver biopsy and the AST Platelet Ratio Index (APRI). However, liver biopsies can be plagued by sampling error, are invasive and associated with some serious complications (1, 2). APRI has been widely accepted as a noninvasive tool for clinical use (3). A newer technique, ARFI imaging is a modality of transient elastography which has been validated for the assessment of hepatic fibrosis (4, 5)

AIMS&METHODS: In this study we evaluated the use of ARFI as a tool for assessing hepatic fibrosis in a heterogenous population of 87 patients presenting to a tertiary hospital liver clinic.

An observational study was performed through The Geelong Hospital Liver Clinic. 87 subjects were recruited over a 12 month period. The subject population consisted of 50 males and 37 females, with a mean age of 51 years. 45/87 (51%) had chronic hepatitis C virus (HCV) alone, 26 (37%) had concurrent alcohol abuse. Other diagnoses included HBV in 6 (7%) cases, NASH in 7 (9%) and autoimmune chronic active hepatitis (1 case).

The ARFI score was compared against predictors of liver fibrosis such as the APRI and liver biopsy measurements where available. The ARFI scores correlated with increasing grades of fibrosis.

RESULTS: 17/87 patients were found to be cirrhotic based on their ARFI score. When correlated with their APRI score, 12 of these 17 patients were confirmed cirrhotic. The average APRI score in the ARFI-deemed cirrhotic group was 2.16, which was well above the APRI cut off score of >1.0 for cirrhosis. 7/87 patients had severe fibrosis based on the ARFI score, and the average APRI score was 1.28, just above the APRI cut off score for cirrhosis. 56/87 patients had mild or moderate fibrosis based on the ARFI score, and the average APRI score in this group was 0.62, well below the APRI cut off score for cirrhosis.

CONCLUSION: In this group tested, patients with a higher ARFI score suggesting cirrhosis or severe fibrosis also had a higher APRI score. This and other early studies suggest that ARFI may be a useful non-invasive modality to help clinicians assess hepatic fibrosis.

INTRODUCTION: E2F-1 transcription factor induces expression of genes controlling G1/S phase transition, DNA synthesis/repair, and apoptosis. E2F-1 activation depends on pRb phosphorylation. We have shown that E2F-1 is overexpressed and pro-apoptotic in hepatocellular carcinoma (HCC)*, while others have suggested that increased apoptosis in HCC could be indirectly oncogenic. The prognostic significance of E2F-1 immunoexpression in human HCC has not as yet been clarified.

AIMS&METHODS: Aim of the present study was to evaluate the prognostic significance of E2F-1 immunoexpression in human HCC.

Immunohistochemistry for E2F-1 and phospho(Ser795)pRB was employed on 57 surgically resected HCCs (grade I:8,II:24,III 16,IV:9). Patients were followed for 39.7±27.2 months.

RESULTS: Nuclear E2F-1 (nE2F-1) immunoexpression was observed in 32/57(54.3%) HCCs and correlated with phospho(Ser795)pRB immunoexpression ($p=0.045$), indirectly suggesting E2F-1 transcriptional activity. E2F-1 cytoplasmic immunoexpression (cE2F-1) was observed in 46/57(80.7%) HCCs. There was no significant correlation of nE2F-1 or cE2F-1 with clinico-pathological parameters. Portal vein thrombosis and nE2F-1 immunophenotype were correlated with poor overall survival ($p=0.05$ and $p=0.0001$, respectively), but not with recurrence-free survival. Stepwise Cox regression analysis highlighted nE2F-1 as an independent marker of poor prognosis in HCC (95% CI=2.55-52.43, $p=0.002$).

CONCLUSION: E2F-1 is expressed and transcriptionally active in the majority of human HCCs. E2F-1 immunophenotype is an independent marker of poor overall patient survival in a cohort of Greek HCC.

P1186 LIVER CANCER MORBIDITY IN RELATION TO CHANGES IN THE DIET IN POLAND IN THE YEARS 1980-2010

M. Jarosz[1,*], W. Sekula[1], E. Rychlik[1]. [1]*NATIONAL FOOD AND NUTRITION INSTITUTE, Warsaw, Poland*

INTRODUCTION: Liver cancer occurs in approximately 1% of Poles affected by all cancers. In 2010 its standardised incidence rate amounted to 2.9/100 thousand for males and 1.4/100 thousand for females.
AIMS&METHODS: The aim of the study was to identify the dietary factors, which could contribute to trends in liver cancer morbidity in Poland.
Standardised liver cancer incidence rates according to gender were derived from the National Cancer Registry. The information source on the dietary trends was data derived from the national food balance sheets showing food quantities available for consumption per capita/year. The Spearman rank correlation coefficient was used as a measure of the relationship between examined variables. Dietary variables included the consumption of fruit, cereals (as potential source of aflatoxins) and alcohol.
RESULTS: High adverse correlations were found for liver cancer incidence rates and fruit consumption, (-0.69 for males and -0.64 for females). Fruit consumption significantly increased in studied period – from 37.7 to 55.5 kg. Positive correlations (0.45 for men and 0.57 for women) were noted with respect to cereals consumption, which decreased from 130.2 to 110.0 kg.
Obtained results do not indicate positive correlations between liver cancer incidence rates and alcohol consumption. However in the in the early 80's an important decline in alcohol consumption was noted and could contribute to later decrease in liver cancer morbidity.
CONCLUSION: It seems that the trends in liver cancer incidence rates in 1980-2010 in Poland were affected by the growing fruit consumption. The decline in cereals consumption could play a protective role also. Improvement of cereal grains storage and implementation of food quality systems into cereal production could lead to decline in aflatoxins content in grains and thus strengthen this protective effect.
It is difficult to determine the influence of alcohol consumption on liver cancer morbidity. It is not unlikely that downward trends observed since beginning of the 90's were affected among others by earlier decline in alcohol consumption, but statistical analysis did not confirm it.

P1187 SERUM ENDOCAN AS A NOVEL PROGNOSTIC BIOMARKER IN HEPATOCELLULAR CARCINOMA PATIENTS

N. Toshikuni[1,*], K. Ozaki[1], J. George[1], M. Tsutsumi[1], T. Arisawa[1]. [1]*Department of Gastroenterology, Kanazawa Medical University, Ishikawa, Japan*

INTRODUCTION: Endocan is a vascular endothelium-derived factor regulated by angiogenic factors. Recent studies have shown that endocan is overexpressed at the mRNA and/or protein levels in various types of tumours.
AIMS&METHODS: We examined whether serum endocan can be a prognostic biomarker for survival in hepatocellular carcinoma (HCC) patients. Serum endocan levels were measured for 64 naïve HCC patients (median age 71 years, male 41; female 23) and 15 non-HCC subjects. Prognostic factors for survival were investigated by univariate and multivariate analyses using the Cox proportional hazard model. The following variables recoded into binary categories were assessed as potential prognostic factors: age (<70 years vs. ≥ 70 years), gender (female vs. male), etiology of liver disease (non-viral vs. viral), tumour stage (stage I/II vs. III/IV), Child-Pugh grade (A vs. B/C), treatment option (curative vs. non-curative), serum endocan (<2.20 ng/mL vs. ≥ 2.20 ng/mL), serumα-fetoprotein (AFP) (<100 ng/mL vs. ≥ 100 ng/mL) and serum des-γ-carboxy prothrombin (DCP) (<26 mAU/mL vs. ≥ 26 mAU/mL). The overall survival rates were calculated using Kaplan–Meier analysis, and the differences were evaluated by the log-rank test.
RESULTS: Serum endocan levels were 3.73 (0.74–10.95) ng/mL in HCC patients and 1.25 (0.93–3.54) ng/mL in non-HCC subjects, respectively ($P = 0.0002$). Elevated serum endocan levels were significantly associated with poor hepatic function ($P = 0.015$), a higher number of tumours ($P = 0.034$) and presence of vascular invasion of HCC ($P = 0.043$). During a median follow-up period of 23.0 months, 33 patients died due to the following causes: HCC in 23 patients, hepatic failure in 7 patients, other diseases in 2 patients and unknown cause in 1 patient. The cumulative overall survival rates were 78.8%, 56.5% and 37.9% at 1, 3 and 5 years, respectively. On multivariate analysis, elevated serum endocan levels, as well as elevated serum AFP and DCP levels, were significantly associated with poor survival (hazard ratio 2.36, 95% confidence interval 1.22–5.36, $P = 0.008$). When combining serum endocan and tumour markers, increase in number of elevated markers provided a worse survival ($P < 0.0001$).
CONCLUSION: Serum endocan may be a promising prognostic biomarker for survival in HCC patients. The combined use of serum endocan with serum AFP and DCP can allow a better prognostic stratification for such patients.

P1188 CANCER-STEM CELL-LIKE SPHERE CELLS INDUCED FROM A CELL LINE DERIVED FROM POORLY-DIFFERENTIATED HEPATOCELLULAR CARCINOMA EXERTS LIVER METASTATIC POTENTIAL AND CHEMORESISTANCE

R. Tsunedomi[1,*], K. Yoshimura[1], N. Hashimoto[1], Y. Watanabe[1], M. Oka[1]. [1]*Digestive Surgery and Surgical Oncology, YAMAGUCHI UNIVERSITY, Ube, Japan*

INTRODUCTION: It is thought that cancer-stem cell (CSC) plays important roles in carcinogenesis, recurrence, metastasis, and chemoresistance. Recently, it was suggested that the possible existence of plasticity between CSCs and their more differentiated derivative cancer cells. We hypothesized that poorly-differentiated hepatocellular carcinoma (HCC) has potential that convert to CSC, which would responsible for metastasis and recurrence.
AIMS&METHODS: Human HCC cell lines, SK-HEP-1, HLE, HuH-7, and Hep 3B, were used for sphere induction. Sphere induction was accomplished by using specified medium based on the medium for neural stem cells. Liver metastatic potential was examined by injection of the cells to immune-deficient mice spleen. Cell viability was measured by MTS assay. 9 anti-cancer agents (5-Fluorouracil, Cisplatin, Carboplatin, Docetaxel, Doxorubicin, SAHA, Irinotecan, Sorafenib, Sunitinib) were used. The mRNA and protein levels were examined by real-time PCR and flow cytometry analyses. ALDH activity was measured by ALDEFLUOR assay. Reactive oxygen species (ROS) activity was measured with the cell-permeable fluorogenic probe, 2', 7'-Dichlorodihydrofluorescin diacetate.
RESULTS: A cell line derived from poorly-differentiated HCC, SK-HEP-1, formed Sphere, although cell lines derived from well-differentiated HCCs, HuH-7 and Hep 3B, could not form sphere. Sphere cells induced from SK-HEP-1 cells (SK-sphere) showed higher mRNA levels of NANOG, LIN28A, and ABC transporters and ALDH activity compared to SK-HEP-1 cells. SK-sphere cells also showed increased liver metastatic potential compared to parental cells. SK-sphere cells represented obvious decreased-sensitivity to 5-Fluorouracil, Docetaxel, Doxorubicin, and SAHA. Sorafenib was effective in both SK-HEP-1 and SK-sphere cells. SK-sphere cells showed induced P21 mRNA and cell cycle arrest in G0/G1 phase. The ROS activity in SK-sphere cells was lower than those in SK-HEP-1 cells. On the other hand, the HIF1-alpha expression in SK-sphere cells was higher than those in SK-HEP-1 cells. Increased expression of Vimentine and decreased expression of EpCAM were observed in SK-sphere cells compared to parental cells. Higher SNAI1 mRNA level of SK-sphere cells was also observed.
CONCLUSION: Our induced sphere cells, SK-sphere, showed increased metastatic potential, chemoresistace, and epithelial-mesenchymal transition.

P1189 MOLECULAR INVESTIGATIONS BY RAMAN IMAGING FOR A RELIABLE DIAGNOSIS OF HEPATOCELLULAR CARCINOMA

T. Tolstik[1,*], C. Marquardt[1], C. Matthäus[2], C. Beleites[2], C. Bielecki[1], C. Krafft[2], O. Dirsch[3], J. Popp[2], A. Stallmach[1]. [1]*Department of Gastroenterology, Hepatology and Infectious Diseases, Jena University Hospital, [2]Institute of Photonic Technology, [3]Institute of Pathology, Jena University Hospital, Jena, Germany*

INTRODUCTION: Patients with hepatocellular carcinoma (HCC) can only be treated curatively at early stages thus providing a favorable prognosis of this often fatal disease. However, histopathological examinations of different liver lesions remain a challenge for pathologists. Because of its high information content Raman spectroscopy is particularly suitable for investigating cellular and subcellular constituents. By using recognition and classification algorithms tissue-specific patterns can be discovered in order to develop an independent model for secure HCC prediction.
AIMS&METHODS: The aim of the present study is to investigate molecular information about HCC and non-malignant liver tissue by Raman imaging in order to use the obtained spectral patterns for diagnosis.
Human hepatic tissue sections were measured with the confocal Raman microscope. A parallel section of each sample was stained with HE to assign tissue regions to HCC (n=12), fibrotic tissue (n=14) and regenerative nodules (n=4). Raman spectra were acquired and the average and difference spectra of each region were calculated. A training data set including the spectral data from regions of HCC (n=6) and fibrosis (n=7) were used to generate a classification model based on a support vector machine algorithm. The obtained classifier was applied to independent validation data sets of HCC regions (n=6) together with regions of fibrosis (n=7) and the same HCC regions (n=6) together with regenerative nodules (n=4).
RESULTS: Analyzing the difference spectra of malignant and non-malignant tissue, distinct spectral differences in the negative bands at 1676, 1387, 1345, 1241, and 936 cm^{-1} and in the positive bands at 1739, 1653, 1436, 1300, 1076, 890, and 721 cm^{-1} were identified. The classification model based on the training data set calculated a prediction accuracy of the classification model of 81%. The developed classifier was able to predict previously unknown HCC and fibrotic tissue with an accuracy of 90% (sensitivity 78%, specificity 100%). The performance of the same classification model to predict regions of HCC and regenerative nodules resulted in an accuracy of 82% (sensitivity 72%, specificity 83%).
CONCLUSION: In this study Raman imaging spectroscopy was for the first time applied successfully to tissue of the cirrhotic liver with the aim to differentiate, classify and predict with high accuracy malignant and non-malignant tissue regions. The demonstrated results highlight the enormous potential which light scattering techniques have for future diagnostics of cancer.

P1190 CAPSAICIN IMPAIRS CARCINOGENESIS OF HUMAN CHOLANGIOCARCINOMA CELLS

A. Wutka[1,*], V. Palagani[1], P. Bozko[1], M. El Khatib[1], H. Belahmer[1], N. Malek[1], R. R. Plentz[1]. [1]*Department of Internal Medicine I, Medical University Hospital Tuebingen, Tübingen, Germany*

INTRODUCTION: Capsaicin, the most abundant pungent molecule produced by pepper plants, represents an important ingredient in spicy foods consumed throughout the world. Previous studies have shown that capsaicin has anti-proliferative effects on various human malignancies like leukemia, esophageal carcinoma, gastric and pancreatic cancer, as well as colon carcinoma and breast cancer. In contrast, capsaicin has also been considered to promote the growth of cancer cells. It is also known that capsaicin application can relieve inflammation and pain.
AIMS&METHODS: The aim of the present study is to explore the anti-tumor activity of capsaicin in human cholangiocellular carcinoma (CC) cell lines (TFK1, SZ1). We analyzed the effect of capsaicin by testing different dosages on CCs growth and epithelial plasticity by using WST-1 assay, wound healing assay and invasion assay respectively.
RESULTS: The effect of capsaicin by using different dosages on CCs growth, migration and metastasis was analyzed using WST-1 assay, wound healing assay and invasion assay respectively.
CONCLUSION: Our data demonstrate that treatment with capsaicin can successfully decrease the carcinogenesis of CC cells *in vitro* and suggest an appealing potential therapeutic strategy for human CCs *in vivo*. Further studies are needed to confirm our preliminary results.

P1191 VARIATION IN PRACTICE OF HEPATOCELLULAR CARCINOMA (HCC) SURVEILLANCE

A. Sugumaran[1,*], C. Ch'ng[1]. [1]*Singleton hospital, Swansea, United Kingdom*

INTRODUCTION: The annual risk for development of HCC in cirrhotics range between 1% and 6%. EASL guidance (2012) recommends implementation of surveillance program for all cirrhotics[1]
AIMS&METHODS: We wanted to determine if there is difference in practice of HCC surveillance in cirrhotics among hospitals in Wales, UK. Invitation to participate in an online survey was sent via email link to all WAGE members (Welsh Association for Gastroenterologists and Endoscopists). 42 members responded and results analysed. There were total of 10 questions with focus on belief in surveillance, selection of target group and methodology used. Among the respondents, there were 1 hepatologist, 2 hepatology specialist nurses and 2 radiologists; rest all gastroenterologists with interest in hepatology.
RESULTS: Three gastroenterologists did not believe in the policy and would not routinely offer surveillance to any cirrhotics (no comments given). Rest 39 believe in surveillance, but 9 not for all cirrhotics. 71% offer 6 monthly Ultrasound (US) and alphafetoprotein (AFP) measurements as method for surveillance, 5% 6 monthly US only; 5% 6 monthly AFP only; 10% yearly US only and 9% skipped this question. Only 78.5% believed surveillance for all cirrhotics; 13% would offer to cirrhotics who are abstinent from alcohol and 4.3% to viral hepatitis cirrhotics only. 4 members admitted age cut-off for surveillance. 66.6% do surveillance depending on patients co-morbidities and 57.1% practice based on patients wishes. 73.8% arrange surveillance from review during follow-up clinic, 9.5% through recall system from database and 16.6% arrange during hospital admissions. The Consultant organises surveillance according to 51.9%, while the hepatology nurse contribute 21.6% and other doctors in 9.5%. Any radiographer performs surveillance imaging as per 40.4%, any radiologist in 47.6% and a dedicated liver radiographer / radiologist only in 11.9%. 43.5% believe that the surveillance program in their hospital is not funded and rest are not aware of any funding.
CONCLUSION: There is wide variation in belief and practice of HCC surveillance in Wales. There is need to standardise surveillance method as there is risk of missing interval cancers. Whether the difference in opinions apply universally and whether mortality / morbidity of patients is affected by early HCC detection need to be explored further.

P1192 HEPATOCELLULAR CARCINOMA (HCC) DEVELOPED ON NON-FIBROUS LIVER (F0-F1): EPIDEMIOLOGIC, CLINICAL, HISTOLOGICAL AND PROGNOSTIC PARTICULARITIES. A MONOCENTRIC STUDY OF 142 CASES. COMPARISON TO HCC DEVELOPED ON FIBROUS LIVER (F2-F3) AND CIRRHOTIC LIVER.

C. Gauthier[1,*], C. Blanc-Bisson[1], L. Possenti[1], C. Castain[2], T. Carteret[3], J. Saric[4], C. Balabaud[1], P. Bioulac-Sage[2], J.-F. Blanc[1]. [1]*Hepatology, gastroenterology, Hopital Saint Andre, CHU bordeaux,* [2]*Pathology, Hopital Pellegrin, CHU Bordeaux,* [3]*radiology,* [4]*surgery, Hopital Saint Andre, CHU bordeaux, bordeaux, France*

INTRODUCTION: HCC on non fibrotic liver (nfHCC) is uncommon and risks factors, clinical feature as well as prognosis remain poorly known. The aim of this study was to analyse a cohort of 141 cases of nfHCC compared to HCC on fibrotic or cirrhotic liver.
AIMS&METHODS: From a prospective database of 1009 consecutive patients diagnosed with HCC since 2005, 141 cases of nfHCC (histologically proved F0-F1) were identified and compared to 93 patients F2-F3, and 470 cirrhotic patients CHILD A. Epidemiological, clinical, biological, pathological data were recorded. Follow-up included CT-Scan or RMI every 3 to 6 months.
RESULTS: Usual risk factors of HCC (alcohol, hepatitis B/C, metabolic syndrome (MS)) were found in 2/3 of nfHCC. MS was present in 37% of F0/F1 vs 50% (F2/F3) and 33.5% (F4). Pathological features of NASH were observed in F2/F3 patients but not in F0/F1 patients. Diagnosis is delayed in nfHCC due to the lack of screening (7,8%). Tumors were larger at diagnosis (74 mm F0/F1 vs 50 F2/F3 vs 35 F4 $p < 0.05$). The rate of patients eligible to curative treatment is higher in nfHCC (68% vs 43%) leading to a better overall survival (OS) (4.01 years F0/F1 vs 2.14 F4 $p = 0.02$). After curative treatment, time to recurrence (TTR) and OS are similar in both groups (1.31 years vs 1.06 $p = 0.88$ and 60 months vs 54 respectively). Patients F0-F1 without known risk factors (34%), were younger (62.4 vs 65.7 year old F4) with a different sex ratio (female 44% vs 14.9% F4) and tumors massively expressed the glutamine synthase (86.4% of patients). This group exhibited a better prognosis in OS (6.35 years vs 2.13 F4 Child A) and TTR (2.03 years vs 1.06 F4).
CONCLUSION: Usual risk factors of HCC are observed in 2/3 of nfHCC including MS in 1/3 of cases. Prognosis is better in nf-CHC frequently eligible to curative treatment. However, after curative treatment, OS and TTR are similar to those observed in patients with cirrhosis. In the subgroup of nfHCC without identified risk factor, tumors occur in a younger and female population, and the prognosis is better.

P1193 COMPARISON OF DIFFERENT MACHINE LEARNING SYSTEMS IN CLASSIFYING FOCAL LIVER LESIONS BASED ON CLINICAL AND DYNAMIC IMAGING DATA

C. T. Streba[1,*], M. Ionescu[1], C. C. Vere[1], L. Sandulescu[1], A. Saftoiu[1], D. I. Gheonea[1], L. Streba[1], T. Ciurea[1], I. Rogoveanu[1]. [1]*Gastroenterology, UMF CRAIOVA, Craiova, Romania*

INTRODUCTION: Early diagnosis of hepatocellular carcinoma (HCC) is of upmost importance for ensuring best chances of survival for the patient. A suspicion can be raised from routine clinical investigation; however, only experienced clinicians may suspect an underlying HCC in some cases. Machine learning (ML) and especially artificial neural networks (ANNs) and support vector machines (SVMs) are currently employed in various medical settings.
AIMS&METHODS: Our aim was to test two ML approaches in a typical clinical setting for the diagnosis and possible prognosis of HCC. Based on our extensive experience with ANNs in HCC diagnosis [1,2], we extended our study on a lot of 486 patients with focal liver lesions who underwent diagnostic work-up in a large main referral center (University County Hospital of Craiova, Romania) between January 2009 – September 2012. Final diagnosis was obtained through pathology, post-treatment evaluation or six months follow-up. Relevant demographic and clinical data (sex, age, alcohol consumption, viral hepatitis infections, cirrhosis/Child-Pugh parameters, laboratory data) and imaging data from dynamic investigations, CE-CT/MRI or CEUS – time-intensity curve (TIC) parameters (time to peak, rise time, fall time, mean transit time, area under the curve), calculated as previously described [1,2], were imputed. We thus constructed two distinct models, one with only clinical data (ML1) and one with combined clinical and dynamic imaging data (ML2).
RESULTS: We included 178 cases of HCC, 26 intrahepatic cholangiocarcinomas, 243 liver metastases (102 hypovascular), 16 liver hemangiomas and 23 focal fatty changes. We employed a SVM and an ANN for ML1 and attempted classification into malignant and benign lesions. The SVM correctly classified 401/486 (82.5%) and the ANN 447 (91.9%) cases. For ML2 we used an ANN system to classify lesions into six distinct categories, obtaining an overall accuracy of 92.7%. Their specificity/sensitivity 95.5/89.7%, while the training and testing accuracy were 92.5/87.2% respectively. Both TIC data and clinic parameters proved to be good classifiers, significantly improving the diagnostic accuracy of the ANN system.
CONCLUSION: ANNs seem more appropriate than other approaches when employed in medical classification problems. More parameters improve the accuracy of diagnosis. ANNs can provide data on which are the most suitable prognostic factors for HCC.

P1194 HEPATOCELLULAR CARCINOMA (HCC) AND METABOLIC SYNDROME: CLINICAL, BIOLOGICAL, PATHOLOGICAL FEATURES AND PROGNOSIS. ANALYSIS OF A PROSPECTIVE COHORT OF 925 HCC

A. Le-Cleach[1], L. Possenti[1], C. Blanc-Bisson[1], C. Laurent[2], H. Trillaud[3], B. Le-Bail[4], P. Bioulac-Sage[4], C. Balabaud[1], J.-F. Blanc[1,*]. [1]*Hepatology And Digestive Oncology,* [2]*Digestive Surgery Unit,* [3]*Radiology Unit,* [4]*Pathology Unit, UNIVERSITY HOSPITAL OF BORDEAUX, Bordeaux, France*

INTRODUCTION: Metabolic syndrome (MS) is a risk factor of HCC usually via underlying NASH/NAFLD. The aim of this study was to compare clinical, biological, pathological features as well as prognosis of HCC in patients with or without MS.
AIMS&METHODS: 941 consecutive patients with HCC were included between 01/2005 and 03/2012. Clinical, biological, pathological, radiological data were recorded and compared between patients with and without MS (NCEP ATP III). Follow-up included CT-Scan or RMI every 3/6 months (median follow-up 16.5 months)
RESULTS: MS was present in 29% of patients who were older (68.3 vs 64.48 years $p < 0.001$) and often male (90% vs 82% p=0.02). Underlying liver disease was less advanced and HCC was developed more often on non-cirrhotic livers (28.8 vs 21.5% $p = 0.01$). Diagnosis is delayed in the MS group, with a low screening rate (28 vs 40% in non-MS ($p < 0.01$)).
Overall survival (OS) was similar in the 2 groups (2,68 years (MS) vs 3,23 p=0,44). Recurrence free survival (RFS) after curative treatment was similar in the 2 groups (2,18 years (MS) vs 2,49 p=0,509) but late recurrences (> 2 years) were more frequent in the MS group.
A subgroup analysis was performed, comparing patients with MS only ($n = 80$), with those with alcoholic disease ($n = 271$) or hepatitis C ($n = 106$). HCC occurred more often on non-cirrhotic livers in the MS group (49 %) vs 15% (HCV) and 13% (OH) ($p = 0.01$). Overall survival was similar for MS group and HCV group (36 months) but inferior for alcoholic disease group exhibiting a more severe underlying liver disease (22 months). No difference was observed between the 3 groups for the RFS after curative treatments.
CONCLUSION: One third of patients diagnosed with HCC had MS, frequently associated with an excessive alcohol intake. In 9% of cases, MS was the only risk factor found. HCC with MS occurred more often on non-cirrhotic livers. In spite of a less severe hepatic disease in the MS group, OS was not better and the rate of recurrence, especially late recurrences (> 2years) are high.

P1195 PROGNOSIS OF PATIENTS WITH HEPATOCELLULAR CARCINOMA (HCC) IN THE NONCIRRHOTIC LIVER (NCL)

K. Schütte[1,*], J. Poranzke[1], J. Bornschein[1], K. Antweiler[2], T. Bretschneider[3], J. Arend[4], H. Lippert[1], J. Ricke[3], P. Malfertheiner[1]. [1]*Department of Gastroenterology, Hepatology and Infectious Diseases,* [2]*Institute for Biometry,* [3]*Dept. of Radiology and Nuclear Medicine,* [4]*Dept of General. Abdominal and Vascular Surgery, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany*

INTRODUCTION: In 15-20% of patients with HCC the malignancy arises in the absence of liver cirrhosis (LC). In patients with LC, liver function strongly influences patient survival.
AIMS&METHODS: Aim: To analyse clinical characteristics and course of disease in patients with HCC in the noncirrhotic liver and to compare their outcome to patients with HCC and LC.
Methods: A retrospective analysis of medical records of 664 patients with HCC with respect to epidemiological data, tumor characteristics, tumor stage at diagnosis according to BCLC classification and survival was performed, comparing 93 patients (14.01%) without LC to 571 pts (85.99%) with LC.
RESULTS: Results: The median age of patients with LC was 66 years (y) compared to 69 y in patients with NCL ($p = 0.004$). In patients with LC 18 % were female compared to 27% in patients with NCL (p=0.045). Statistically significant differences were depicted concerning tumor stage at diagnosis (LC: BCLC-A 17.5%, -B 29.6%, -C 42.4%, -D 10.5%; NCL: BCLC-A 14%, -B 34.4%, -C 51.6, -D 0%, p=0.006) with more patients diagnosed in intermediate and advanced stage in NCL. Overall survival according to BCLC-stage (median values in days of survival: BCLC-A 951 (LC) vs 945 (NCL) days (d); BCLC-B 501 (LC) vs 925 (NCL) d; BCLC-C 209 (LC) vs 229 (NCL) d) did not show statistically significant differences between patients with HCC in LC and patients with HCC in NCL (p=0.061). Both, the tumor stage according to BCLC ($p = 0.011$) and the Clip score ($p = 0.010$) correlated with survival in patients with HCC in NCL. While statistically significant differences were found concerning concentrations of bilirubin, albumin, quick and platelets, no statistically significant differences were found concerning concentrations of creatinine, alcalic phosphatase, alpha-fetoprotein, alanin-aminotransferase and ferritin.
CONCLUSION: Patients with HCC in NCL are diagnosed at higher age and with a larger proportion of female patients. Absence of LC leads to diagnosis in more advanced tumor stages. Patients with HCC in NCL show a trend towards longer survival in intermediate tumor stage.

INTRODUCTION: The global, prospective, non-interventional GIDEON study of >3200 patients (pts) with unresectable (u) HCC treated with sorafenib (SOR) in real-life practice conditions evaluated the safety/efficacy of SOR in a diverse range of settings and pt groups where data are currently limited. We describe the safety/efficacy in uHCC pts, treated with SOR in Europe, according to prior transarterial chemoembolization (TACE) and concomitant (ct) TACE.
AIMS&METHODS: Patient demographics, disease characteristics and treatment history, were recorded at enrolment; SOR dose, liver function, adverse events (AEs) and efficacy were recorded at follow-up.
RESULTS: In Europe, 1113 pts were enrolled and valid for safety. A third of pts (33%) received prior TACE, and 5% received ctTACE. The proportion of ECOG PS 0 was slightly higher in patients who had prior TACE or ctTACE than others (52.7%, 41.6%, 55.8%, 44.9% in patients with prior TACE, no prior TACE, ctTACE and no ctTACE respectively). Median daily SOR dose was 780 mg (n=1026) and similar across all the groups. Duration of treatment was longer in patients who had prior TACE or ctTACE than others (20.1 weeks [wks], 16.0 wks, 31.8 wks and 16.4 wks in patients with prior TACE, no prior TACE, ctTACE and no ctTACE, respectively). AEs and serious AEs (SAEs) were similar across these groups. There is no new unexpected AE. Median OS was 66.3 wks, 44.1 wks, 70.6 wks and 48.0 wks in patients with prior TACE, no prior TACE, ctTACE and no ctTACE respectively.
CONCLUSION: The data suggest AE profiles of sorafenib in patients treated with TACE prior to sorafenib or concurrently are consistent with the safety profiles observed in previous clinical trials with monotherapy as well as combination therapy with TACE. Sorafenib treatment in combination with TACE appears to be tolerable and feasible.

P1197 RESIDUAL VIABLE TUMOR VOLUME MEASUREMENT FOR EARLY PROGNOSTIC ASSESSMENT OF HEPATOCELLULAR CARCINOMA PATIENTS TREATED WITH SORAFENIB

R. Sacco[1,*], I. Bargellini[2], A. Scionti[2], G. Masi[3], C. Caparello[3], B. Ginanni[2], C. Vivaldi[3], A. Romano[1], G. Bresci[1], A. Falcone[3], C. Bartolozzi[2]. [1]*Gastroenterology,* [2]*Radiology,* [3]*Oncology, Pisa University Hospital, Pisa, Italy*

INTRODUCTION: The introduction of the targeted agent Sorafenib with anti-angiogenic activity has not only changed the way advanced hepatocellular carcinoma (HCC) is treated, but also how it is monitored.
AIMS&METHODS: To evaluate the prognostic value of early radiological tumor response to sorafenib treatment according to Response Evaluation Criteria in Solid Tumors (RECIST), modified RECIST (mRECIST), European Association of Liver Disease (EASL) criteria and arterial enhancing tumor volume ratio (Rvol: 2 months/baseline) in patients with HCC.
Twenty-two patients (18 male, mean age 68 years) with HCC treated with sorafenib were enrolled in this retrospective study. The 2-months response to treatment was evaluated by RECIST, mRECIST, EASL, Rvol and alfa-fetoprotein ratio (2 months AFP / baseline AFP) and compared to survival. Two independent blinded readers evaluated radiological tumor response twice to assess measurements' reproducibility.
RESULTS: At 2-months follow-up, rates of objective response (complete and partial response), stable disease and progressive disease were 18.2%, 22.7% and 72.7% for RECIST, 18.2%, 22.7% and 59.1% for mRECIST and 9.1%, 31.8% and 59.1% for EASL. A good intra- and inter-observer agreement was observed in the assessment of tumor response (k=0.83-0.86) and in maximum (k=0.95-0.96) and total diameter calculation (k=0.93-0.94). Mean post-processing time for volume calculation was 1.8 ± 1.2 minutes (range, 0.5-5.5), with high reproducibility of volume measurements (k=0.99). Mean Rvol was 1.76 ± 2.17, and it was >1 in 12/21 patients (57.1%). Mean AFP ratio was 14 ± 37, and it was >1 in 15 patients (68.2%). The 1-year cumulative survival rate was 65.9%. Overall

survival was significantly associated only to Rvol, with an identified Rvol cut-off value of 1.17 (AUC 0.71); the 12-month cumulative survival rate was 90% in patients with Rvol £1,17 and 40% in Rvol >1.17 (p=0.04).
CONCLUSION: Assessment of arterial enhancing tumor volume variation should be considered as an alternative to RECIST, mRECIST and/or EASL for early assessment of tumor response and prognosis of patients with HCC treated with sorafenib.

P1198 PROGNOSTIC FACTORS FOR SURVIVAL IN PATIENTS WITH HEPATOCELLUAR CARCINOMA AFTER CURATIVE SURGERY INCLUDING THE INFLAMMATION-BASED PROGNOSTIC SCORES

Y. Okamura[1,*], H. Kanemoto[1], T. Mizuno[1], T. Sugiura[1], K. Uesaka[1]. [1]*Division of Hepato-Biliary-Pancreatic Surgery, Shizuoka Cancer Center Hospital, Sunto-Nagaizumi, Japan*

INTRODUCTION: Several studies have shown that inflammation-based prognostic scores, including Glasgow Prognostic Score (GPS), neutrophil to lymphocyte ratio (NLR), and Prognostic Nutritional Index (PNI) are correlated with survival in patients with hepatocellular carcinoma (HCC).
AIMS&METHODS: The aims of this study are to validate the power of prognostic scores, which are based on preoperative inflammation status and widely used score systems, of patients who underwent curative and initial hepatectomy for HCC. Inflammation-based prognostic scores and established clinical scores were retrospectively analyzed in 242 patients.
RESULTS: In multivariate analysis elevated AFP (Hazard Ratio [HR] 1.89, 95% Confidence interval [CI] 1.19-3.00, $P = 0.007$), NLR > 5 (HR 2.41, 95% CI 1.07-5.39, $P = 0.033$), and PNI < 45 (HR 2.26, 95% CI 1.34-3.81, $P = 0.002$) remained as significant independent predictors of overall survival in HCC. On the contrary, elevated AFP (HR 1.89, CI 1.34-2.69, $P < 0.001$), high Barcelona Clinic Liver Cancer score (HR 5.48, 95% CI 1.19-25.4, $P = 0.029$), larger tumour (HR 1.50, 95% CI 1.04-2.16, $P = 0.031$), multiple tumour (HR 2.37, 95% CI 1.19-4.71,$P = 0.014$), and presence of microsatellite lesions (HR 2.74, 95% CI 1.81-4.15, $P < 0.001$) remained as significant independent predictors of recurrence-free survival in HCC.
CONCLUSION: The present study reveals that the prognostic scores based on preoperative inflammation status (NLR and PNI) but not tumour factors are validated for predictor of overall survival in the patients who underwent curative and initial hepatectomy for HCC.
Disclosure of Interest: None Declared

P1199 TREATMENT STRATEGY FOR COLORECTAL LIVER METASTASIS BASED ON GENETIC PROFILES

Y. Umeda[1,*], T. Nagasaka[1], Y. Mori[1], H. Sadamori[1], S. Shinoura[1], R. Yoshida[1], D. Nobuoka[1], M. Utsumi[1], K. Takagi[1], T. Yagi[1], T. Fujiwara[1]. [1]*Gastroenterological Surgery, Transplant and Surgical Oncology, OKAYAMA UNIVERSITY, Okayama, Japan*

INTRODUCTION: Discovery of practical biomarkers is important to realize personalized medicine for patients with malignant neoplasia, including colorectal cancer (CRC). Liver is the most frequent metastatic sight in CRC. The treatment strategy for colorectal liver metastases (CRLM) based on genetic profiles is essential for further improvement of CRC prognosis.
AIMS&METHODS: Genomic DNA was obtained from a cohort of 240 CRC patients with distant metastasis. *KRAS*/*BRAF*-mutation (Mt) spectrum and microsatellite instability (MSI) status were analyzed by direct sequence and multiplex PCR. And these genetic profiles were compared with their clinical outcomes.
RESULTS: The cohort of 240 CRC patients with distant metastasis consisted of 148 synchronous and 92 metachronous metastasis. And 149 patients had liver metastasis alone and 91patients had extra-liver spreading with/without liver metastasis. In MSI analysis, only 3 cases (1.2%) revealed evidence of MSI. As regard to genetic profiles about *KRAS*/*BRAF*, the proportions of *KRAS*-Mt/*BRAF*-Mt/ wild type were 28/4/63 (%) in the group of liver metastasis alone and 17/11/72 (%) in the group of extra-liver spreading, respectively. Liver resection was performed for 106 patients with CRLM, the resectabilities of which were 67.5% in wild type, 38.5% in *KRAS*-Mt, and 20% in *BRAF*- Mt, respectively. Recurrence rate after liver resection was 59% in *KRAS*-Mt, which was comparable to that in wild type. However *KRAS*-Mt showed the higher risk of extra-hepatic sight recurrence. Furthermore, all CRLM with *BRAF*-Mt showed intractable extra-hepatic sight recurrence after liver resection. In survival analysis, the overall 1-, 3-, and 5- year survival rates were 94.1%, 77.1%, and 65.1% in wild-type, 84.9%, 54.3%, and 43.4% in *KRAS*-Mt, and 33.3%, 0%, and 0% in *BRAF*-Mt, respectively.
CONCLUSION: The cohort of CRLM patients were mainly occupied by non-MSI tumors. These supported that MSI cancer in primary CRC would rarely have metastatic potential. *BRAF* mutations are suggested to be extremely poor prognostic factor in CRLM. Genetic information could play a key role as a prognostic marker and could contribute to the decision of treatment strategy for CRLM.

P1200 COMPARISON OF SELF EXPANDING METAL STENTING WITH RADIOFREQUENCY ABLATION VERSUS STENTING ALONE IN THE TREATMENT OF MALIGNANT BILIARY STRICTURES: IS THERE AN ADDED BENEFIT?

R. Z. Sharaiha[1,*], J. Widmer[1], N. Natov[1], M. Gaidhane[1], M. Kahaleh[1]. [1]*Gastroenterology and Hepatology, Weill Cornell Medical Center, New York, United States*

INTRODUCTION: Radiofrequency ablation (RFA) has been reported to be a beneficial treatment option for palliation of malignant biliary strictures. Both pancreatic and cholangiocarcinoma carry a poor prognosis with a median survival of less than a year even with palliative therapy.
Biliary obstruction is a common complication and many require stenting for definitive decompression. The added benefit of RFA to stenting is unknown.
AIMS&METHODS: The objective of this study was to compare the safety, efficacy and survival of patients with RFA and metal stent versus stent alone.
Methods: A prospectively collected database was reviewed identifying 64 patients with malignant biliary strictures from July 2010 to March 2013. Cases were patients who underwent RFA with metal stenting. Controls were patients who were treated conventionally with metal stenting. The groups were matched on age, diagnosis and palliative chemotherapy. The Habib TM EndoHPB catheter (Emcision Ltd., Hitchin Herts, UK) was used for ablation. All patients received covered or uncovered self expanding metal stents (SEMS). Immediate and 30-day complications were recorded. Patient status and last known date was collected for survival and cox proportional hazard analysis.
RESULTS: RFA and control groups were closely matched- age 65.5±13.4 vs. 66.8±12.16yrs, p=0.0.69; and diagnosis (36 patients with cholangiocarcinoma and 28 patients with pancreatic cancer), (29 in stent group vs 13 in RFA group, p=0.3). Technical success rate for the both groups was 100%. Multivariable cox proportional regression analysis showed RFA to be independently predictive of survival (HR 0.29 (0.11-0.76) p=0.012) as well as age, and chemotherapy (1.04 (1.01-1.07)p=0.011, 0.26 (0.10-0.70)p=0.007). Overall SEMS patency rates were the same across both groups. Complications of RFA were few (1 pancreatitis, 1 cholangitis) vs 3 cholangitis in the non RFA group, p=NS.

	Univariate HR ratio (95% CI)	P value	Multivariable HR ratio (95% CI)	P value
rfa	0.77(0.41-1.45)	0.424	0.29 (0.11-0.76)	0.012
age	1.04 (1.01-1.07)	0.002	1.04 (1.01-1.07)	0.011
chemotherapy	0.37 (0.0.97-0.71)	0.002	0.26 (0.10-0.70)	0.007
Stricture improvement	0.81 (0.64-1.02)	0.067	0.84 (0.65-1.09)	0.208

CONCLUSION: The use of RFA appears to improve survival in patients with endstage cholangiocarcinoma and pancreatic cancer. In a disease with limited treatment options, this modality may prove to be beneficial as compared to stenting alone. Randomized controlled trials and evaluation of quality of life measures should be performed to confirm these findings.

P1201 COMPARISON OF ACCURACY AMONG ENDOSCOPIC ULTRASONOGRAPHY, MULTIDETECTOR COMPUTED TOMOGRAPHY AND MAGNETIC RESONANCE IMAGING FOR PREOPERATIVE STAGING OF CHOLANGIOCARCINOMA

S. S. Park[1,*], H. J. Kim[1], J. H. Park[1], D. I. Park[1], Y. K. Cho[1], C. I. Sohn[1], W. K. Jeon[1], B. I. Kim[1]. [1]*Department of Internal Medicine, Sungkyunkwan University Kangbuk Samsung Hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Preoperative imaging modalities including multidetector computed tomography (MDCT), magnetic resonance imaging (MRI) and endoscopic ultrasonography (EUS) can visualize the bile duct tumor and predict unresectability with variable degree of accuracy. The role of EUS as a preoperative staging work-up compare to MDCT and MRI for bile duct tumor remains less clear. The aim of the present study was to evaluate the utility of EUS for preoperative staging of cholangiocarcinoma compared to MDCT and MRI.
AIMS&METHODS: Twenty nine patients with cholangiocarcinoma who underwent curative surgical resection between February 2007 and May 2012 at our institution were enrolled in the current study. The medical records, laboratory data, radiologic imagings and endosopic results were retrospectively reviewed.
RESULTS: Mean (standard deviation, years) age of enrolled patients was 68.3 (9.3) and 20 (69.0%) were male. The final diagnoses according to surgical pathology were cholangiocarcinoma (n=28, 96.6%) and gallbladder adenocarcinoma (n=1, 3.4%). The locations of the bile duct stricture were distal (n=19, 65.5%), mid (n=5, 17.5%) common bile duct (CBD) and common hepatic duct (hilar, n=5, 17.5%). The primary mass lesion was only detected by EUS and not by MDCT in Six (20.7%) patients. Compared to finally reported AJCC staging results of surgically resected specimens, the accuracy of tumor (T) staging of EUS, MDCT and MRI were 89.7%, 31.0% and 75.0%, respectively. The accuracy of node (N) staging of EUS, MDCT and MRI were 93.1%, 79.3% and 75.0%, respectively. The accuracy of AJCC stage grouping of EUS, MDCT and MRI were 79.3%, 41.4% and 58.3%, respectively.
CONCLUSION: EUS is more sensitive in the detection of bile duct tumor than MDCT. The accuracy of EUS for the preoperative AJCC tumor staging of cholangiocarcinoma is higher than MDCT and MRI.

P1202 A TRIAL OF NON-SELECTIVE BETA-BLOCKER: IS A VIABLE OPTION FOR MAKING THE PERCUTANEOUS LIVER BIOPSY POSSIBLE IN CHILDREN WITH THROMBOCYTOPENIA DUE TO HYPERSPLENISM

U. Poddar[1,*], U. Shava[1], J. Agarwal[1], A. Thakral[2], M. Verma[2], S. Kumar[2], S. K. Yachha[1], A. Srivastava[1]. [1]*Pediatric Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India,* [2]*Radiology, sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, India*

INTRODUCTION: Thrombocytopenia due to hypersplenism precludes liver biopsy in many cases of chronic liver disease. So far there is no study on using non-selective beta-blockers to ameloriate hypersplenism to make percutaneous liver biopsy possible.
AIMS&METHODS: The aim of this study was to assess whether normalization of platelet count ($\geq$100,000/mm^3) and subsequent liver biopsy was possible with the use of non-selective beta-blocker in children with intrahepatic portal hypertension or not.
Methods: From January 2005 to December 2012, 51 children with intrahepatic portal hypertension with hypersplenism were recruited. Hypersplenism was defined as decrease in platelet counts $<$100,000/mm^3 and total leucocyte counts $<$ 4000/mm^3. These children were started on long-acting beta-blocker (propranolol), at a dose of 1.5 to 2 mg/kg/day (maximum 80mg) and 4 weeks later repeat platelet counts and whenever possible percutaneous liver biopsy was done. Resting heart rate, blood pressure and spleen size were measured before and 4 weeks after starting propranolol therapy.
RESULTS: The mean age was 11.5 $\pm$ 3.0 years, with 34 boys. Etiology was chronic liver disease 38 (autoimmune hepatitis 13, hepatitis B 9, Wilson disease 3, hepatitis C 1, cryptogenic 12), non-cirrhotic portal fibrosis (NCPF) 10 and congenital hepatic fibrosis (CHF) 3. Thirty two (62.7%) children responded to propranolol therapy (platelet counts $>$ 100,000/mm^3) and their mean platelet counts increased from 57.5 $\pm$ 13.0 x 10^3 /mm^3 to 140.7 $\pm$ 43.3 x 10^3/mm^3, p= 0.0001. Liver biopsy was done in 29 and associated coagulopathy precluded biopsy in 3. Comparing the responders with non responders, spleen size (7.4 $\pm$ 3.3 *vs* 12.7 $\pm$ 4.5 cm, p=0.0001) and baseline platelet counts (57.5 $\pm$ 13.0 x 10^3 *vs* 39.5 $\pm$ 14.5 x 10^3, p=0.0001) were the two factors which determined the effectiveness of therapy. With beta-blocker therapy, mean arterial pressure (MAP) reduced significantly (p=0.01) and also spleen size (7.40 $\pm$ 3.36 *vs* 5.68 $\pm$ 3.25 cm, p=0.0001) in responders but not in non-responders.
CONCLUSION: Beta-blocker therapy corrected thrombocytopenia (hypersplenism) and made liver biopsy possible in two-third of cases by reducing MAP and splenic size. The baseline spleen size and platelet counts determine the effectiveness of therapy. A trial of beta-blocker is worth in cases where percutaneous liver biopsy is contraindicated due to hypersplenism related thrombocytopenia.

P1203 A DETAILED PATHOLOGICAL INVESTIGATION OF THE MURINE BILIARY ATRESIA MODEL: PROOF OF CONCEPT?

C. M. Keyzer-Dekker[1], R. G. Kox[1], F. H. Morsink[2], G. J. Offerhaus[2], F. J. Ten Kate[2], J. F. Kuebler[3], C. Petersen[3], H. J. Verkade[4], J. B. Hulscher[1,*]. [1]*Pediatric Surgery, University of Groningen, University Medical Center Groningen, Groningen,* [2]*Pathology, University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Pediatric Surgery, Hannover Medical School, Hannover, Germany,* [4]*Pediatric Gastroenterology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands*

INTRODUCTION: The murine biliary atresia (BA) model is widely used for examining BA pathogenesis, but morphological characteristics of the model have not yet been described in detail, and the development of fibrosis in this model is debated. This ongoing fibrosis in BA is important to examine, because it leads to liver transplantation in 70% of children with BA. Aims of the study were to describe the model using the Biliary Atresia Research Consortium (BARC) histological assessment system and to investigate the development of fibrosis.
AIMS&METHODS: In newborn mice Rhesus Rotavirus (RRV) was injected intra-peritoneally within 15 hours after birth. Animals were sacrificed at 7 or 14 days after birth (N=17) and compared with healthy mice of the same age (N=29). Two experienced pathologists without knowledge of the state of disease scored the most important morphological features using the BARC items. Development of fibrosis was further investigated using immunohistochemistry for CK19, collagen type I, and aSMA (e.g. negative/weak/moderate/strong). Scores were analysed with Chi-square test for trend or Fisher's test when applicable. All experimental procedures were approved by the Ethical Committee for Animal Experiments of the Hannover Medical School and the University Medical Center Groningen.
RESULTS: In the RRV group, a strong portal lymphoplasmacytic cellular infiltrate was found at 7 days, which decreased to moderate at 14 days (p=0.058). In the healthy group there was minimal cellular infiltrate. The morphological differences between RRV and control animals were significant at 7 and 14 days ($p<0.001$). Bile plugs or necrosis were not observed. CK19 bile duct staining was mainly absent/weak in the RRV group but moderate in the control group ($p<0.001$). Only in the RRV group fibrous expansion of most portal areas with focal bile duct proliferation was found, in 2/17 animals (12%) there was focal portal-to-portal bridging. Although expression of aSMA was present in the portal tracts of control mice, there was more expansion of aSMA staining in the RRV group ($p<0.001$). Portal staining of collagen type I was more pronounced in the RRV group (p=0.020).
CONCLUSION: Morphological features of the murine BA model are mostly in accordance with the features found in (early) BA. In addition, we have demonstrated the presence of (portal) fibrosis. Therefore, this model is considered applicable for investigating early pathogenesis of BA, including the development of BA related fibrosis.

P1204 INFANT STOOL COLOR CARD: THE INTEROBSERVER VARIABILITY BETWEEN PARENTS AND MEDICAL CAREGIVERS.

M. Witt[1,*], C. M. Keyzer-Dekker[1], H. J. Verkade[2], P. Peeters[3], J. B. Hulscher[1]. [1]*Pediatric Surgery,* [2]*Pediatric Gastro-enterology,* [3]*Hepatobiliary surgery and liver transplantation, UMCG, Groningen, Netherlands*

INTRODUCTION: Because early recognition of biliary atresia remains a challenge, the Infant Stool Color Card (ISCC) has been implemented in several countries. This non-invasive screening tool leads to higher surgical success rates and improved long-term outcomes. However, the validity and optimal administration method of the ISCC are unknown. Therefore, we examined the interobserver variability of the ISCC.
AIMS&METHODS: A prospective longitudinal study on the ISCC assessment of stool samples was conducted. In total 83 children aged 2 weeks to 2 years admitted at the Beatrix Children's Hospital Groningen were included. The stool color in the nappy was independently scored by one parent, one nurse and two doctors using the ISCC. Kappa coefficients (κ–value) were calculated as indicators of the interobserver variability of the ISCC and values were compared between parents, nurses and doctors (scores 1-3: abnormal; 4-7: normal). Sensitivity and specificity of the ISCC were determined. The eight children with clinically and biochemically proven cholestatic disease were considered as the group *with* disease.
RESULTS: The κ -values between doctors and between doctors and nurses were 1.00 and 0.93 respectively. The κ –values between doctors and parents, and between parents and nurses were 0.72 and 0.67 respectively. The sensitivity and specificity of the ISCC for doctors were 100%, for nurses 100% and 99% respectively, with one false-positive score. The sensitivity and specificity for the parents were 75% and 97% respectively, with two false-positive scores and two false-negative scores.
CONCLUSION: The ISCC seems a reliable tool for screening for BA. Because of the lower sensitivity and specificity for parents, in combination with the average interobserver variability between parents and caregivers, we recommend the ISCC used by parents should be confirmed by caregivers.

P1205 DEOXYCHOLIC ACID INDUCES APOPTOSIS IN PRIMARY RAT HEPATOCYTES VIA JNK1/P53/MIR-34A/SIRT1

D. M. S. Ferreira[1], M. B. Afonso[1], P. M. Rodrigues[1], P. M. Borralho[1,2], C. M. P. Rodrigues[1,2], R. E. Castro[1,2,*]. [1]*iMed. UL, Faculty of Pharmacy, University of Lisbon,* [2]*Department of Biochemistry and Human Biology, Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal*

INTRODUCTION: microRNAs (miRNAs or miRs) are being increasingly implicated in the pathogenesis of human liver diseases. In fact, we have recently shown that the miR-34a/Sirtuin1(SIRT1)/p53 pathway correlates with non-alchoholic fatty liver disease severity and apoptosis, and that ursodeoxycholic acid, an endogenous hydrophilic bile acid, counteracts this pro-apoptotic pathway. In turn, hydrophobic bile acids, such as deoxycholic acid (DCA), are know to modulate the expression of several apoptosis-related proteins, including c-Jun N-terminal kinase (JNK), leading to cell death.
AIMS&METHODS: The purpose of this study was to evaluate whether DCA-induced apoptosis of primary rat hepatocytes occurs *via* miR-34a-dependent pathways and whether they connect with JNK induction. Primary rat hepatocytes were incubated with 100 microM DCA, and transfected with a specific miRNA-34a inhibitor or with a p53 overexpression plasmid. p53 transcriptional activity was assessed in nuclear extracts and by using target reporter constructs. JNK function was evaluated by immunoblotting and silencing experiments. Viability, caspase-3 activity and apoptosis were determined using the ApoTox-Glo^T Triplex Assay and Hoechst staining.
RESULTS: Our results show that DCA enhances miR-34a/SIRT1/p53 pro-apoptotic signalling in cultured primary rat hepatocytes, in a dose- and time-dependent manner. In turn, miR-34a inhibition and SIRT1 overexpression significantly rescued cells from targeting of the miR-34a pathway and apoptosis by DCA. In addition, p53 overexpression activated the miR-34a/SIRT1/p53 pathway, further induced by DCA. DCA increased p53 expression, as well as p53 transcriptional activation of PUMA and miR-34a itself, providing a functional mechanism for miR-34a activation. Finally, JNK1, but not JNK2, was shown to be a major target of DCA, upstream of p53, in engaging the miR-34a pathway and apoptosis.
CONCLUSION: In conclusion, our results support a link between liver cell apoptosis, miR-34a/SIRT1/p53, and JNK signalling. JNK1-mediated activation of p53 is the key mechanism behind induction of miR-34a by DCA. The JNK/miR-34a/SIRT1/p53 pro-apoptotic pathway may represent an attractive pharmacological target for the development of new drugs to arrest metabolic and apoptosis-related liver pathologies.

P1206 NON-CONJUGATED BILE ACIDS INHIBIT THE ION TRANSPORTER ACTIVITIES IN HUMAN COLONIC CRYPTS

É. Pallagi-Kunstár[1,*], K. Farkas[1], Z. Rakonczay Jr[1], F. Nagy[1], T. Molnár[1], Z. Szepes[1], V. Venglovecz[2], Z. Rázga[3], J. Maléth[1], T. Wittmann[1], P. Hegyi[1]. [1]*First Department of Medicine,* [2]*Department of Pharmacology and Pharmacotherapy,* [3]*Department of Pathology, UNIVERSITY OF SZEGED, Szeged, Hungary*

INTRODUCTION: Under pathophysiological conditions, such as short bowel syndrome, bile acids can reach the colon in high concentrations and can induce diarrhea.
AIMS&METHODS: Our **aim** was to investigate whether impaired ion transport activities are involved in the pathomechanism of bile acid-induced diarrhea.
Methods: Colonic biopsies were obtained from control patients (with negative colonoscopic findings) and from cholecystectomised/ileum-resected patients with/without diarrhea. Colonic crypts were isolated by collagenase digestion, and intracellular pH (pH_i), Ca^{2+} concentration ($[Ca^{2+}]_i$) and ATP levels (ATP_i) were measured by microspectrofluorometry. Na^+/H^+ exchangers (NHEs), Na^+/HCO_3^- cotransporter, Cl^-/HCO_3^- exchanger (AE) activities were determined. Changes of the mitochondrial transmembrane potential (MTP) was measured by confocal microscopy. Intracellular mophological changes were analysed with transmission electron microscopy (TEM).
RESULTS: The non-conjugated chenodeoxycholate (CDC) and the conjugated glycochenodeoxycholate (GCDC) caused dose-dependent acidosis in colonic crypts. The pH_i decrease was significantly greater in case of CDC vs. GCDC. 0.3 mM CDC strongly inhibited the activities of acid/base transporters. TEM showed mitochondrial damage after 1 mM CDC-treatment, but no such alteration was detected in case of lower concentrations of CDC or 1 mM GCDC. 0.3 mM CDC significantly but reversibly reduced ATP_i and MTP. CDC caused dose-dependent increase of the $[Ca^{2+}]_i$. Inhibition of Ca^{2+} release from the endoplasmic reticulum or plasma membrane Ca^{2+} channels decreased the CDC-induced increase of $[Ca^{2+}]_i$. Chelation of intracellular Ca^{2+} did not prevent, but ATP_i depletion mimicked the inhibitory effect of CDC on ion transporter activities. Impaired NHE and AE activities were observed in cholecystectomised/ileum-resected patients suffering from diarrhea compared to control patients.
CONCLUSION: Non-conjugated bile acids inhibit the function of ion transporters, disturb the energy level and Ca^{2+} homeostasis of colonic epithelial cells. These processes may reduce fluid and electrolyte absorption in the colon and promote the development of diarrhea.

P1207 ENDOTHERAPY OF CHRONIC CALCIFIED PANCREATITIS BY ESWL+ERCP: PRELIMINARY LONG-TERM RESULTS

C. Marmo[1], A. Tringali[1,*], P. Familiari[1], I. Boskoski[1], V. Perri[1], V. Bove[1], M. Mutignani[1], G. Costamagna[1]. [1] *Catholic University of Rome, "A. Gemelli" Hospital, Italy, Rome, Italy*

INTRODUCTION: Most studies on pancreatic extracorporeal shock wave lithotripsy (ESWL) and ERCP for the treatment of chronic calcifying pancreatitis (CCP) report on a medium-term follow-up (6 months-6 years).
AIMS&METHODS: Aim of this study is to evaluate the long-term clinical outcome after combined treatment of CCP with ESWL and ERCP, focusing on ductal clearance and pain relief. 348 patients with painful CCP treated by ESWL + ERCP were identified from a prospectively collected database. Before ERCP, patients underwent ESWL of the pancreatic stones using an electro-hydraulic lithotripter with radiological focusing. ESWL was repeated until signs of stone fragmentation were evident on X-ray pictures. ERCP with pancreatic sphincterotomy was performed with a sphincterotome over the wire. Stone fragments were extracted with small Dormia baskets and by flushing with sterile saline. After stone clearance a pancreatic stent was inserted in case of a main pancreatic duct (MPD) stricture associated with stones. Primary objective was evaluation of the success rate in pancreatic stone clearance and MPD drainage. Secondary objectives were evaluation of pain after treatment, need for surgery, occurrence of endocrine insufficiency and mortality.
RESULTS: Preliminary results of 172 patients (76.4% male, mean age 50.3 years) that completed the follow-up (mean 8.36 years, SD 4.1 years) are reported. Follow-up of the remaining patients is ongoing. Alcohol abuse was present in 38.3% of the cases and 65% were smokers. According to Cremer's classification 83.7% had type IV CP; 87.2% had the pancreatic stones located in the head of the pancreas. MPD drainage and stone fragmentation was obtained in all patients with a mean of 3.8 (SD ± 2.9) ERCPs and 2 (SD ± 1.4) ESWL for patient. ESWL related complication were mild and resolved by interruption of the procedure or medical therapy. No cases of ERCP related pancreatitis were recorded. Procedures related mortality was absent. Follow-up results in 172 patients are reported in **table 1**.

Table 1. Follow-up results (172 patients treated by ESWL+ERCP for calcified chronic pancreatitis)

Mean follow-up (years)	8,36 ± DS 4,1	
Complete pain relief	99	57.6%
Partial pain relief (yearly/monthly pain)	52	30.2%
No pain relief (weeklt, daily pain)	12	12.2
Need for surgery	19	11%
Deaths	**36**	**20.9%**
Pancreatic cancer	10	5.8%

CONCLUSION: The combined therapy of CCP with ESWL + ERCP provides long-term complete pain relief in two thirds of the patients in our experience. Endotherapy of CCP can be considered the first line approach for painful CCP since it is repeatable and do not preclude future surgical approach.

P1208 IS THE ASSOCIATION OF THE P.N34S SPINK1 VARIANT EXPLICABLE BY A HIGH RISK HAPLOTYPE RATHER THAN THE POLYMORPHISM?

J. Nicholson[1], J. Grant[2], M. Johnstone[1], S. Harrison[1], C. Halloran[1], M. Raraty[1], P. Ghaneh[1], R. Sutton[1], R. Chaudhuri[3], J. Neoptolemos[1], R. Mountford[2], W. Greenhalf[1,*]. [1]*NIHR Pancreas Biomedical Research Unit, University of Liverpool,* [2]*Molecular Genetics, Liverpool Women's Hospital,* [3]*Biological Sciences, University of Liverpool, Liverpool, United Kingdom*

INTRODUCTION: The p.N34S polymorphism of the SPINK1 gene (PSTI) is associated with idiopathic chronic pancreatitis however there is no clear functional effect of the sequence variant. It has been suggested that the polymorphism is associated with a high risk haplotype but this is widely disputed.
AIMS&METHODS: Aim: To identify whether a haplotype exists that distinguishes pancreatitis cases from controls where both cohorts have the p.N34S variant.
Methods: DNA from patients with chronic pancreatitis of no known aetiology (idiopathic) and controls were analysed by PCR Restriction Fragment Length Polymorphism analysis and or direct sequencing to test for the p.N34S variant. 20 control patients and 38 cases all heterozygous for the p.N34S variant were then used for long range PCR followed by sequencing between 146Mb and 148Mb of chromosome 5 (build 37). Haplotypes based on 7 single nucleotide polymorphisms within this region were constructed. These were analysed using the "haplo.stats" package.
RESULTS: 29 haplotypes were identified; only haplotype 13 was significantly associated with pancreatitis (p=0.0009, hapscore: -3.31).
CONCLUSION: It is possible that a high-risk haplotype rather than a simple base variant is responsible for SPINK1 associated pancreatitis.

P1209 THE DIFFERENT FACETS OF PANCREATIC PAIN: A SYSTEMATIC COMPARATIVE STUDY OF 1032 PATIENTS WITH PANCREATIC DISORDERS

J. G. D'Haese[1,*], M. Hartel[1], I. E. Demir[1], U. Hinz[2], F. Bergmann[3], M. W. Büchler[4], H. Friess[1], G. O. Ceyhan[1]. [1]*Department of Surgery, KLINIKUM RECHTS DER ISAR, München,* [2]*unit for Documentation and Statistics, Department of Surgery,* [3]*Institute of Pathology,* [4]*Department of General Surgery, University of Heidelberg, Heidelberg, Germany*

INTRODUCTION: Abdominal pain is a major clinical feature in chronic pancreatitis/CP and pancreatic cancer/PCa. Little is known about pain sensations in pancreatic tumors other than PCa and CP.
AIMS&METHODS: With this study, we aimed to systematically characterize the specific pain pattern in the most frequent pancreatic diseases. Pain pattern of patients with CP (n=314), PCa (n=469), and other pancreatic tumors (n=249) including mucinous/MC (n=20) and serous cystadenoma/SC (n=31), invasive / IPMNi (n=37) and non-invasive intraductal papillary mucinous neoplasia/ IPMN (n=48), benign/NTb (n=18) and malignant/NTm neuroendocrine tumors (n=44), and ampullary cancer/AmpC (n=51) was registered and correlated with clinicopathological data.
RESULTS: 49.1% of all PCa patients revealed no pain, whereas in CP only 18.3% were pain free. In contrary, moderate to severe pain was registered in 15.1% in PCa patients that was noticeable increased in CP with up to 34.2%. SC was asymptomatic in the majority of cases (58.1%), whereas 78.9% of all MC patients suffered pain. In NT abdominal pain seems not to be a key clinical symptom since 64% of NTb and 59% of NTm patients did not reveal any pain. Tumor localization in the pancreatic body led to more frequent and more severe pain. Patients with malignant pancreatic neoplasms suffered from more severe pain than patients with benign disease. Tumor grading and stage did not show any impact on pain. Only in PCa, pain was directly associated with impaired survival.
CONCLUSION: Pancreatic pain depicts different patterns of abdominal pain sensation according to the respective pancreatic disorder and does not allow a unification of the term *pancreatic pain*. Since pancreatic pain is not uniform it may be used as an additional diagnostic tool.

P1210 IGG4-RELATED DISEASE IN THE PROSTATE: A CASE-CONTROL STUDY

J. Buijs[1,*], L. Maillette de Buy Wenniger[2], A. van Leenders[1], J. Verheij[2], I. van Onna[3], B. Hansen[1], M. van Heerde[1], N. Krak[1], U. Beuers[2], M. Bruno[1], H. van Buuren[1]. [1]*Erasmus University Medical Center, Rotterdam,* [2]*Academic Medical Center, Amsterdam,* [3]*Amphia Medical Center, Breda, Netherlands*

INTRODUCTION: IgG4-related disease (IgG4-RD) is characterized by elevated serum levels of IgG4, increased numbers of tissue IgG4-positive plasma cells and excellent response to prednisone. The most frequent manifestation is autoimmune pancreatitis (AIP), but the disease can affect multiple organs including the prostate. The histopathology of prostatic IgG4-RD has not been well established.
AIMS&METHODS: The aim of this study was to evaluate the occurrence and histopathological characteristics of IgG4-related prostatic involvement in patients diagnosed with AIP. We performed a cross search for AIP patients with prostatitis symptoms in our AIP database. Histology was examined by two blinded pathologists. As a control group patients with prostatitis without a history of IgG4-RD were assessed. All tissue samples were immunostained for IgG4 and evaluated for the following characteristic pathologic features of IgG4-RD: maximum number of IgG4+ cells/high power field (HPF); dense lymphoplasmacytic infiltrate; fibrosis, arranged at least focally in a storiform pattern; phlebitis with or without obliteration of the lumen; and increased number of eosinophils.
RESULTS: We identified 9 cases of prostatitis (median age 67, IQR 64-73) among 116 men with established AIP. All cases had a history of lower urinary tract symptoms (LUTS). In 5/9 (56%) these symptoms preceded a diagnosis of AIP; the interval between the diagnoses did not exceed 3 years. Median serum IgG4 was 7.3 g/L (IQR 3.3-13.6). The histological findings were compared with those obtained in 18 control patients (median age 68, IQR 62-74). Specimens evaluated had been obtained by biopsy (n=8) and prostatectomy (n=17). In IgG4-RD patients, the median number of IgG4+ cells in prostatic tissue was 150 (IQR 20-150), compared with 3 (IQR 1-11) in control patients (p=0.008). Furthermore, eosinophil numbers were more often elevated (>10/HPF) in IgG4-RD patients compared to control patients ($p<0.001$). Dense lymphoplasmacytic infiltrate was not discriminating and storiform fibrosis, a characteristic histological finding in AIP, was only sporadically found. Two patients were treated with corticosteroids and responded well.
CONCLUSION: We report on 9 patients with IgG4-related prostatitis. The histological hallmark is an elevated number of IgG4+ cells. Our results suggest that this is a relatively frequent entity among men diagnosed with AIP. A proportion of AIP patients presenting with symptoms of prostatitis or prostate enlargement may suffer from IgG4-related prostatitis and benefit from corticosteroid treatment.

P1211 THE THERAPEUTIC EFFECT OF PNP THERAPY IN CHRONIC PANCREATITIS CLINICAL COURSE IMPROVEMENT. CLINICAL PANCREATIC INDEX.

L. Umnova[1,*], G. Orļikovs[1], J. Voicehovska[1], I. Pļaviņa[2]. [1]*Internal diseases department, Rīga Stradiņš University,* [2]*Center of Gastroenterology, Pauls Stradins Clinical University Hospital, Rīga, Latvia*

INTRODUCTION: Recently developed PNP-therapy for chronic pancreatitis (CP) involves a combination of enteric-coated pancreatic enzymes (ECPE), proton pump inhibitor (PPI) and non-steroidal anti-inflammatory drug (NSAID). CP PNP-therapy is rational because it is basically justified, effective and easy to apply in clinical practice and has few side effects.
Integral CP severity index – clinical pancreatic index (CPI) has been developed. CPI formulizes the next criteria: the number of surgeries due to CP complications, out-patient treatment efficiency, hospitalizations due to CP, weight loss, pain severity (evaluated by the doctor), steatorrhea intensity, defecations per day, other complaints (postprandial discomfort, bloating, nausea, etc.), glucose tolerance. Maximal CPI accounts 25 points. CP severity evaluation by CPI: mild - 6-8 points, moderate - 9-15 points, severe - 16-25 points.
AIMS&METHODS: The aim of this study was to determine PNP therapy efficiency in CP clinical course improvement, using CPI.
The study included 105 patients with confirmed small duct CP, who had no indications for endoscopic and surgical treatment. Patients were divided into three groups according to the treatment applied: P group received ECPE at a dose of 25 000 V (lipase) three times daily (n = 20); PP group received ECPE in a dose of 25 000 V (lipase) three times a day and PPI at a dose of 20 mg twice daily (n = 46); PNP group received ECPE in a dose of 25 000 V (lipase) three times a day, PPI at a dose of 20 mg twice a day, and Aceclofenac 100 mg twice daily (n = 39). Before and after 1-month therapy CPI was calculated and abdominal pain (VAS, evaluated by the patient) was determined in all the patients. Before treatment, patients were similar according to CPI as well as considering indicator of abdominal pain (VAS, evaluated by the patient). Statistical analysis was performed using the Mann-Whitney, Kruskal-Wallis test, Pearson's correlation and Cronbach's alpha.
RESULTS: After the treatment CPI difference was revealed between the groups (p=0.000), CPI decreased in all the groups: in P group - by 2 points (p=0.068), in PP group - by 7 points (p=0.000), in PNP group - by 9 points (p=0.000). CPI correlation with abdominal pain severity (VAS, evaluated by the patient) ($r=0.394$; $p<0.01$) before and after the treatment ($r=0.701$; $p<0.001$) was revealed. The value of Cronbach's alpha in this study was 0.68, after removing hospitalizations due to CP it was 0.711.
CONCLUSION: PNP-therapy is more effective in improving CP clinical course, compared with monotherapy by ECPE and ECPE/PPI combination. CPI reflects severity of the clinical course of CP and medical treatment efficiency.

P1212 AUTOIMMUNE PANCREATITIS AND THE ROLES OF IGE: A RETROSPECTIVE STUDY WITH 19 PATIENTS

L. Zhang[1], Y. H. Huang[1], T. L. Wang[2], L. M. Guo[2], K. Wang[1,*]. [1]*Gastroenterology,* [2]*Peking University Third Hospital, Beijng, China*

INTRODUCTION: Autoimmune pancreatitis (AIP) is a special type of chronic pancreatitis, which is characterized by diffuse or focal enlargement of pancreas, hyperglobulinemia, specific pathological features, and responded to corticosteroid therapy, but the pathogenesis is still unknown.
AIMS&METHODS: In this retrospective study, we evaluate the clinical manifestations, radiological characteristics and histologic presentations of AIP in adult patients in Chnia. Nineteen patients diagnosed as AIP were admitted to our hospital from May, 2007 to Jun, 2012. All patients with autoimmune pancreatitis fulfilled the 2006 revised clinical diagnostic criteria proposed by Japan's Pancreas Society. These patients' clinical records were reviewed and analyzed.
RESULTS: the ratio of male: female was 16:3, and the age of the patients from 41 to 82, the mean age was 63.3 years. The duration of symptoms prior to diagnosis ranged from one week to three years, Epigastric pain (13/19, 68.4%), Jaundice (11/19, 57.9%) and weight loss (14/19, 73.7%) were the most common symptoms. Two patients were misdiagnosed as pancreatitic cancer and receive partly pancreatectomy. 11(57.9%) patients had elevated level of CA19-9. IgG was elevated in 42.1% (8/19) of patients, and IgG4 was in 72.7% (8/11) of patients. Interesting, the level of serum LgG4 was in normal limit when the patients diagnosed as AIP, but was elevated after corticosteroid therapy in two patients. IgE was elevated in 18(94.7%) of the 19 patient. Imaging studies showed diffuse enlargement of pancreas in 42.1% (8/19) of patients, and tumor like local swelling can occur. The patients with diffuse enlargement seemly had a higher level of serum lgE than the patients with local enlargement had. Pancreatic duct is diffusely or segmentally narrowed. All patients showed narrowed common bile duct, and among them, 9(47.4%) patients were found with thicken of wall of bile duct. Thirteen patients were treated with prednisone, while 15 underwent stents in bile duct or pancreatic duce. The symptom remission and imaging improving were found in all patients. The level of IgE got decreased after therapy. Two patients suffered relapse during the follow up, and the IgE elevated in the meantime
CONCLUSION: IgE maybe play an important role in the pathogenesis of AIP, and the level of serum IgE is a useful marker for monitoring therapeutic response and recurrence of the disease.

Disclosure of Interest: None Declared

P1213 THE FREY PROCEDURE FOR THE TREATMENT OF CHRONIC PANCREATITIS ASSOCIATED WITH COMMON BILE DUCT STRICTURE: BE AWARE OF DUCT REINSERTION INTO THE RESECTION CAVITY OR CHOLEDOCHODUODENOSTOMY.

L. Rebibo[1,*], T. Yzet[2], C. Cosse[1], R. Delcenserie[3], E. Bartoli[3], J.-M. Regimbeau[1]. [1]*Digestive surgery,* [2]*Radiology,* [3]*Gastro-enterology, Amiens North Hospital, Amiens, France*

INTRODUCTION: The Frey procedure (FP) is the treatment of choice for symptomatic, chronic pancreatitis (CP). In cases of biliary stricture, biliary derivation can be performed by choledochoduodenostomy, Roux-en Y choledochojejunostomy or, more recently, reinsertion of the common bile duct (CBD) into the resection cavity. The objective of the present study was to evaluate the outcomes associated with each of these three types of biliary derivation.
AIMS&METHODS: We retrospectively analyzed demographic, CP-related, surgical and follow-up data for patients having undergone FP for CP with biliary derivation between 2004 and 2012 in our university medical center. The primary efficacy endpoint was the rate of CBD stricture recurrence. The secondary endpoints were surgical parameters, postoperative complications, postoperative follow-up and the presence of risk factors for secondary CBD stricture.
RESULTS: Eighty patients underwent surgery for CP during the study period. Of these, 15 (males: 12 (80%); median age: 51; median BMI: 19.8 kg/m^2; mean time (range) to onset of CP: 6 years (1-20)) received biliary derivation with the FP. Eight of the FPs (53.3%) were combined with choledochoduodenostomy, 4 (26.7%) were combined with choledochojejunostomy and 3 (20%) were combined with reinsertion of the CBD into the resection cavity. The mean operating time was 390 min. Eleven complications (73.3%) were recorded, including one major complication (6.6%) that necessitated radiologically-guided drainage of an abdominal collection. The mean (range) length of stay was 17 days (8-28) and the median (range) follow-up time was 35.2 months (7.2-95.4). Two patients presented stricture after CBD reinsertion into the resection cavity; one was treated with radiologically-guided dilatation and the other underwent revisional Roux-en-Y choledochojejunostomy. Three patients presented alkaline reflux gastritis (37.5%), one (12.5%) presented cholangitis and one presented CBD stricture after FP with choledochoduodenostomy. No risk factors for secondary CBD stricture were identified.
CONCLUSION: As part of a biliary derivation, the FP gave good results. We did not observe any complications specifically related to surgical treatment of the biliary tract. However, CBD reinsertion into the resection cavity appeared to be associated with a higher stricture recurrence rate. In our experience, choledochojejunostomy remains the "gold standard" treatment for CBD strictures.

P1214 PROPOSAL OF THERAPEUTIC STRATEGY FOR PATIENTS WITH TYPE 1 AIP DEVELOPED CYSTIC FORMATION

M. Hirao[1,*], Y. Fujita[1], Y. Sekino[1], K. hosono[1], A. Nakajima[1], K. Kubota[1]. [1]*Gastroenterology, Yokohama City University, Yokohama, Japan*

INTRODUCTION: AIP with cyst formation (ACF) is rare complication and often shows refractory course to corticosteroid treatment (CST), however, the therapeutic strategy and risk factor for these AIP patients has not been fully elucidated.
AIMS&METHODS: We conducted a cohort study to determine if the predictive factors might be related to the ACF and propose the therapeutic strategy. The diagnosis of AIP was made according to the international consensus diagnostic criteria for AIP (*Pancreas* 2011;40:352-358). We conducted a study on 115 consecutive patients with type 1 AIP followed up at average 60 months, to determine whether the factors might be related to cyst formation of the pancreas, such as the presence of diabetes mellitus, abdominal pain, elevation of pancreatic enzymes, IgG4 seropositivity, diffuse pancreatic swelling, presence of extra-pancreatic involvement, splenic vein/artery involvement, presence of varix, and history of relapse.
RESULTS: There were 10 ACF (8.7%;10/115); pseudocyst were 7, retention cyst was one, wall-off like cyst formation in one and one was mucinous cancer. Regarding the location, body and tail of the pancreas were 9 patients, the one in the head was mucinous cancer. Male and female ratio was 9:1. Serum IgG4 was positive in 70% of the ACF (422mg/dl in average). Diffuse pancreas swelling noted in 70%. CST was administered to 70% (7/10) of the patients, however, relapse was noted in 40% (4/10) of these patients. The results of univariate analysis revealed significant association of ACF with presence of abdominal pain, elevation of pancreatic enzyme, splenic vein and/or artery involvement and varix formation ($p<0.05$), and multivariate analysis revealed the presence of abdominal pain (OR4.389, $p=0.0377$), elevation of pancreatic enzyme (OR4.677, $p=0.0345$), abdominal pain (OR4.389, $p=0.0377$), splenic vein and/or artery involvement (OR105, $p=0.001$) and varix formation (OR34.5, $p=0.043$) as the significant independent are factors predictive of ACF.
CONCLUSION: AIP presented with abdominal pain and pancreatic enzyme elevation, strong inflammation at the background of splenic vein and/or artery involvement accompanied with varix has independent risk for cyst formation. AIP with large cystic lesions over 60mm in diameter, may be irreversible stage, involving splenic vessels tended to show refractory course even if CST was administered. Those AIP patients should be treated by surgical operation rather than CST. However, cystic neoplasm could encounter in those AIP patients.

P1215 ALTERED BONE METABOLISM AND BONE DENSITY IN PATIENTS WITH CHRONIC PANCREATITIS AND PANCREATIC EXOCRINE INSUFFICIENCY

S. L. Haas[1,*], S. Krins[1], A. Hedström[1], J.-M. Löhr[2]. [1]*Department of Gastroenterology and Hepatology; Gastrocentrum Medicin Huddinge (K63), Karolinska University Hospital Huddinge,* [2]*Department of Surgery, Gastrocentrum Kirurgi Huddinge/CLINTEC, Karolinska University Hospital, Stockholm, Sweden*

INTRODUCTION: Chronic pancreatitis is characterized by a progressive inflammatory destruction of pancreatic parenchyma with concurrent increasing fibrosis. Established chronic pancreatitis harbors the risk of pancreatic exocrine insufficiency (PEI) due to diminished production of pancreatic enzymes. PEI can potentially lead to malnutrition. Maldigestion of fat and malabsorption of fat-soluble vitamines are key features of PEI.
AIMS&METHODS: To prospectively study a cohort of male patients with chronic pancreatitis and pancreatic exocrine insufficiency regarding parameters of maldigestion, bone metabolism, and bone mineral density. Female patients were excluded to rule out a bias as a consequence of hormonal effects. A standardised questionnaire for osteoporosis was applied. Parameters of bone metabolism and vitamin D were measured. Bone mineral density was measured by conventional X-rays of the vertrebrate column. Statistical analysis was done with the SPSS package (version 10.0).
RESULTS: A total of 50 male patients with proven chronic pancreatitis (36/50 alcohol; 42/50 smokers) and PEI (28/50; fecal elastase-1 < 200 ug/g) were studied. Fifty percent (25/50) had pain radiating from the bones, 21/50 a history of fractures. Calcium in the urine, 25-OH cholecalciferol, and desoxy-pyridinoline were significantly decreased whereas serum calcium, phosphate, alkalic phosphatase, PTH were normal. Conventional X-ray of the vertebra ($N = 42$) demonstrated normal in three, discrete reduction in 32, significant reduction in 6, and maximal reduction of bone mineral density (BMD) with fracture in one patient. Reduced BMD upon conventional X-ray correlated with low fecal elastase-1 ($p < 0.05$).
CONCLUSION: Bone mineral density was reduced in the majority of patients with chronic pancreatitis and correlated with pancreatic exocrine function. This patient group should be closely monitored for malnutrition and and an optimal pancreatic enzyme replacement therapy should be a mainstay of treatment to prevent complications such as osteopathy.

P1216 A SHORT ENDOSCOPIC SECRETINTEST GIVES USEFUL ADDITIONAL INFORMATION IN CYSTIC FIBROSIS PATIENTS

T. Engjom[1,2,*], B. N. Lærum[3], F. Erchinger[2,4], E. Tjora[5,6], L. Aksnes[5,6], O. H. Gilja[1,2], G. Dimcevski[1,2]. [1]*Department of Medicine, Haukeland University Hospital,* [2]*Department of Clinical Medicine, University of Bergen,* [3]*Department of Thoracic Medicine, Haukeland University Hospital, Bergen,* [4]*Department of Medicine, Voss Hospital, Voss,* [5]*Department of Pediatrics, Haukeland University Hospital,* [6]*Department of Clinical Science, University of Bergen, Bergen, Norway*

INTRODUCTION: Faecal elastase (FE) is a simple and widespread test for determining exocrine pancreatic function in Cystic fibrosis (CF) patients. New short endoscopic secretin tests are not validated in CF.
AIMS&METHODS: We aimed to evaluate the diagnostic quality and possible additional diagnostic information using a concentration-based EST in a small CF population. Consecutive patients attending regular control at the CF clinic, and healthy controls underwent EST. Endoscopic collection of duodenal juice was performed between 30 and 45 minutes after secretin stimulation. Duodenal juice was analysed for bicarbonate concentration and lipase-, amylase-, chymotrypsin- and elastase-activities. Stool was analysed for FE. Information of CF genotype was collected from patient journal.
RESULTS: Thirty seven consecutive CF patients were included in a protocol for extended pancreas function testing. 30 patients fulfilled EST and are presented here. 25 healthy controls (HC) were also tested. Using FE cut-off of 200µg/g, patients were classified as exocrine pancreatic sufficient (CFS, n=17) or insufficient (CFI n=13). Both bicarbonate-concentrations and enzyme activities in duodenal juice differentiated CFI patients from CFS patients and HC ($p<0.001$). Calculating ROC curves, we get a sensitivity of 100% and a specificity of 88% for EST using the usual cut-off of 80meq/L for duodenal bicarbonate. The population displays strong correlation between severe CF genotype in both alleles and pancreatic insufficient phenotype ($p<0.001$).
CONCLUSION: Pancreatic exocrine insufficient CF patients could be differentiated from exocrine sufficient patients and healthy controls using this new test. EST supplied detailed information on duodenal peak concentration of HCO_3- and pancreatic enzymes. We observe the phenomenon of decreased bicarbonate and hyper-concentrated duodenal pancreatic enzymes in 2 patients, indicating that EST is capable of demonstrating early ductal failure in patients where acinar function is still intact.

P1217 PANCREAS-PRESERVING SURGERY FOR PARADUODENAL PANCREATITIS. WHEN AND HOW? EXPERIENCE OF 61 CASES OF DUODENAL DYSTROPHY TREATMENT .

V. I. Egorov[1,*], A. Vankovich[2], N. Yashina[3], R. Petrov[1]. [1]*Surgical Oncology,, Ostroumov 14th City Hospital, Sechenov First State Medical University,* [2]*HPB, Vishnevsky Institute of Surgery,* [3]*Radiology, Vishnevsky Institute odf Surgery, Moscow, Russian Federation*

INTRODUCTION: Paraduodenal pancreatitis or duodenal dystrophy (DD) is infrequent disease, characterized by chronic inflammation of the aberrant pancreatic tissue in the duodenal wall which may be isolated or accompanied by chronic pancreatitis in the orthotopic pancreas. Different treatment options of DD treatment are debated.
Objective: To assess the efficacy of pancreas-preserving surgery for treatment of duodenal dystrophy different approaches to judge the advisability of amalgamating the above-mentioned pathologies
AIMS&METHODS: To assess the efficacy of pancreas-preserving surgery for treatment of duodenal dystrophy different approaches to judge the advisability of amalgamating the above-mentioned pathologies
1. Prospective analysis of 61 cases of DD (2004-2012), comparing preoperative assessment and histopathological findings in 37 surgical specimens; 2. Assessment of clinical presentation and the results of DD treatment.
RESULTS: No case of groove pancreatitis was revealed throughout the observation. Correct diagnosis was made in all the cases except one suspected cystic tumor of the pancreatic head (1,9%). Patients presented with abdominal pain(100%), weight loss(76%), vomiting(30%) and jaundice(18). CT,MRI and endoUS were the most useful diagnostic modalities. Patients underwent 25 pancreatoduodenectomies (PD), pancreatico- and cystoenterostomies(7), Nakao procedures(4), duodenum-preserving pancreatic head(DPPH) resections(5) and 9 pancreas-preserving duodenal resections(PPDR). No mortality. Full pain control was achieved after PPRDs in 83%, PDs in 85%, and after PPPH resections and draining procedures in 18% of cases. Diabetes mellitus developed thrice after PD.
CONCLUSION: 1. PPDR is effective procedure for treatment of DD with mild changes in orthotopic gland; 2. The diagnosis of DD can be confidently determined with the aid of modern-day techniques prior to surgery; 3. The effectiveness of PPDR provides compelling proof that DD is a duodenal entity distinct from groove and orthotopic pancreatitis.

P1218 EXPRESSION OF BCL-2, P53 PROTEINS AND CD31 IN HUMAN CHRONIC PANCREATITIS

V. Klopova[1,*], I. Samsonova[1]. [1]*Pathology, Vitebsk State Medical University, Vitebsk, Belarus*

INTRODUCTION: Objective. To study bcl-2, p53 and CD31 expression in pancreas at chronic pancreatitis (CP).
AIMS&METHODS: Materials and methods. Using morphological, immunohistochemical, morphometric methods, we investigated the pancreas specimens of 45 patients with CP who underwent duodenum saving resection of the pancreas head. Control group included 7 pancreas head specimens without any pancreas pathology from people died by accidents. Statistic analysis included Mann-Whitney's, Kruskal-Wallis 's, and Spearman's tests. All p value ≤ 0.05 was considered statistically significant.
RESULTS: Results. Histological examination of the pancreas specimens with CP revealed interlobular and perilobular fibrosis, degenerative changes of pancreatic parenchyma, foci of lymphocytic infiltrates. The nerves have been found to be damaged by the inflammatory process.
Depending on fibrosis area all patients were subdivided into 3 groups: I group – <25%, II group – 25-50%, III group – >50%. Fibrosis area of control specimens was <10%
The evaluation of lymphocytic inflammatory infiltration of the pancreas specimens with CP has distinguished 4 degrees of the inflammation as follows: absent (0), mild (1+), moderate (2+) or severe (3+).
Degree of bcl-2 expression varied from 1.12 up to 38.77 points. Our research has shown more than 5-fold increasing the bcl-2 expression degree in pancreatic tissue of patient with CP in comparison with control group. The p53 expression was very low in investigated and control groups. The degree of CD31 expression changed in limits from 0.2 up to 8.9 points and was more low in samples of pancreas at CP. The results of the markers expression are displayed in Table 1.
Table 1. The marks of the expression of markers *(Me (LQ-UQ))*

Groups	Bcl-2 expression, points	P53 expression, points	CD31 expression, points
Chronic pancreatitis	10.55 (7.99 – 14.67)	0.0015 (0.00005 – 0.19)	2.86 (2.21 – 3.49)
Control group	1.81 (0.6 – 4.57)	0.00013 (0 – 0.0004)	7.16 (4.95 – 8.85)
p value (Mann-Whitney)	**0.003052**	0.085528	**0.003115**

There was no correlation between expression of markers and fibrosis and inflammation. However, we found negative correlation of CD31 expression with pancreas nerve tissue total area ($r = -0.3$).
CONCLUSION: Conclusions. The CP is characterized by increasing of the bcl-2 expression, thus degree of the expression is not connected with fibrosis and inflammation degree. Low p53 expression degree at CP shows about low risk of malignisation.
The revealed changes of the apoptosis markers (bcl-2, p53) expression and angiogenesis marker CD31 at CP underlie in morphogenesis of diseases and define progressive degenerative changes and structural reorganization in the pancreas with disturbance of regeneration processes.

P1219 DO THE DIFFERENT IMMUNOGLOBULIN G SUBCLASSES HAVE SIGNIFICANCE IN AUTOIMMUNE PANCREATITIS?

V. Terzin[1,2,*], S. L. Haas[2], V. Liu[2], R. Pozzi-Mucelli[3], N. Kartalis[3], M. Del Chiaro[2], R. Segersvärd[2], C. S. Verbeke[4], L. Czakó[1], J.-M. Löhr[2]. [1]*First Department of Internal Medicine, University of Szeged, Szeged, Hungary,* [2]*Gastrocentrum,* [3]*Department of Pathology,* [4]*Department of Radiology, Karolinska Institute University Hospital, Stockholm, Sweden*

INTRODUCTION: We observed that not only immunoglobulin (Ig) G4 subclass but also the other IgG subclasses could be elevated in autoimmune pancreatitis (AIP).
AIMS&METHODS: The aim of our study is to further investigate the importance of the elevation of different IgG subclasses in AIP. Patients treated at Karolinska University Hospital with different types of pancreatitis were involved in the study. Group of cases with AIP (both type 1 and type 2) were compared to a control group of patients with chronic pancreatitis caused by other reasons and/or with recurrent acute pancreatitis. Serum samples were taken all of them and IgG and its subclasses (IgG1, IgG2, IgG3 and IgG4) were measured. Other organ involvement (OOI), jaundice, response to steroid therapy and relapse after the therapy were observed.
RESULTS: Twenty-seven patients were enrolled in our study (16 male, 11 female, mean age: 54.5±15.2 year), 19 into the AIP and 8 into the control group. There was no significant difference between the two groups according to the age and gender ($p=0.605$ and $p=0.824$, respectively). We found significantly elevated IgG2-level in case of jaundice among all the patients (3.9±1.7 g/L vs. 6.4±3.8 g/L, $p<0.04$), and significantly more cases were accompanied by elevated IgG2 in the icteric AIP group ($p<0.04$), but not in the control group. In the group of AIP patients in case of jaundice only the IgG3-level was significantly elevated (0.5±0.2 g/l vs. 1.0±0.5 g/L, $p<0.03$), while there was no significant difference in the control group. In point of the other three observed clinical signs we did not find any significant difference either in the total group of patients or between the AIP and the control group.
CONCLUSION: Serum IgG2 and IgG3 seem to be in relation to jaundice in chronic or recurrent acute pancreatic patients; however more cases are needed for further investigations and for confirmation of our results.

P1220 FATTY PANCREAS IS A RISK FACTOR FOR PANCREATIC PRECANCEROUS LESIONS (PANIN)

V. Rebours[1,*], S. GAUJOUX[2], G. d'Assignies[3], A. Sauvanet[2], P. Ruszniewski[1], P. Levy[1], A. Couvelard[4]. [1]*Pancreatology Unit,* [2]*Pancreatic Surgery Unit,* [3]*Radiology Unit, BEAUJON HOSPITAL, Clichy,* [4]*Pathology Unit, Bichat Hospital, Paris, France*

INTRODUCTION: Obesity was recently described as a risk factor of pancreatic cancer with a specific link with significant metabolic abnormalities including insulin resistance, glucose intolerance and diabetes.
AIMS&METHODS: Aims: To characterize the frequency of pancreatic intraepithelial neoplasia (PanIN) in case of fatty pancreas, to correlate pathological findings with dysmetabolic characteristics and tobacco intake.
Methods: Consecutive pancreatic specimens of patients operated on for neuroendocrine tumors (NETs) (ductal tumors, ie adenocarcinomas and IPMN were excluded)) from 2009 to 2011 were analyzed. The pancreatic parenchyma was analyzed at least 2 cm apart from the tumor. Fatty infiltration and fibrosis of the parenchyma in intra and extra lobular locations were assessed by two investigators according to specific scores. Dysplastic lesions were described according to the WHO 2010 PanIN classification. General characteristics of the patients were collected, especially the body mass index (BMI), diabetes and tobacco intake.
RESULTS: Results: 110 pancreatic specimens of patients (males: 42%) were analyzed (median surface per specimen: 7.5 cm^2). Median age at surgery was 53.8 [17-85] years. Arterial hypertension, diabetes, tobacco consumption were found in 19%, 10% and 26%, respectively. Median BMI was 24 [16-37]. PanIN lesions type 1, 2 and 3 were observed in 62, 38 and 1% of cases, respectively. Fatty pancreas was found in 56% of cases (extralobular 30%, intralobular 51%). Intralobular fibrosis was noticed in 24% of cases. PanIN lesions were correlated to fatty pancreas (either extra- (0.005) or intra lobular (0.0001)), intralobular fibrosis (0.002), tobacco intake (0.05) and age at surgery (0.05). Fatty pancreas was associated with age (0.0001), higher BMI (0.05), intralobular fibrosis (0.009), hypertension (<0.001), hyperlipidemia (0.01) and diabetes

(0.09). We found no correlation between PanIN lesions and dysmetabolic disorders.
CONCLUSION: Conclusion: Fatty pancreas is an independent risk factor of PanIN lesions, especially in case of intralobular location. These results suggest that fatty infiltration itself plays a specific role in pancreatic oncogenesis.

P1221 RELATIONSHIPS AMONG PLASMA AMINO ACID LEVELS, PANCREATIC PAIN AND THE EFFECT OF A LOW-FAT ELEMENTAL DIET IN ALCOHOLIC CHRONIC PANCREATITIS

Y. Kawaguchi[1,*], M. Ogawa[1], A. Maruno[1], H. Ito[1], T. Mine[1]. [1]*gastroenterology, TOKAI UNIVERSITY SCHOOL OF MEDICINE, Isehara, Japan*

INTRODUCTION: We reported that patients with chronic pancreatitis (CP), especially those with exocrine insufficiency, exhibit alterations in levels of several amino acids, such as histidine, methionine and glutamate. These amino acid deficiencies seem to correlate with exocrine insufficiency and be improved by elemental diet. Relationship between amino acids and pancreatic pain had not been known yet.
AIMS&METHODS: Our aim was to examine their relationships among plasma amino acid levels, pancreatic pain, and the effect of a low-fat elemental diet in alcoholic chronic pancreatitis. We selected a total of 39 patients with a history of alcoholic CP, based on our criteria. CP patients were divided into an exocrine normal group (n=28) and exocrine insufficiency group (n=11) based on PFD (pancreatic functioning diagnostic) test results (normal range: more than 70%). And a low-fat elemental diet "elental®" was ingested for eleven consented patients with pancreatic exocrine insufficiency to observe the effect of the diet. This elemental diet was performed for two months. Before and after diet, selected clinical and laboratory values were examined and compared. We used Visual Analogue Scale (VAS) as assessment of pancreatic pain.
RESULTS: There was no significant difference in BMI between pre- and post-elemental diet. Serum albumin level of post-elemental diet was significantly higher than that of pre-elemental diet (P=0.041). There was no significant difference in HbA1c between pre- and post-elemental diet. Total amino acid concentration was significantly higher in post-elemental diet than in pre-elemental diet (P=0.032). The concentrations of serum histidine and methionine in post-elemental diet was significantly higher than that of pre-elemental diet (histidine: P=0.014, methionine: P=0.016). The concentration of serum glutamate in post-elemental diet was significantly lower than that of pre-elemental diet (P=0.024). The imbalance of amino acids was revised. And VAS was significantly lower in post-elemental diet than in pre-elemental diet (P=0.014), Correlation between amino acids and pancreatic pain was recognized (P=0.0096).
CONCLUSION: CONCLUSION: These amino acid deficiencies, such as histidine, methionine and glutamate, seem to correlate with pancreatic pain and be improved by elemental diet. Supplementation of these amino acids in patients with exocrine insufficiency may minimize the pancreatic pain.
Disclosure of Interest: None Declared

P1222 MICRORNA BIOMARKERS FOR EARLY DETECTION OF PANCREATIC CANCER FROM SAMPLES OBTAINED BY ENDOSCOPIC ULTRASONOGRAPHY-GUIDED FINE NEEDLE ASPIRATION (EUS FNA)

M. Vila[1], L. Moreira[2], E. VILA[2], M. Giráldez[2], A. GINES[3], G. Fernández-Esparrach[4], R. MIQUEL[5], O. SENDINO[4], A. Rodriguez-DJesus[2,*], I. ARAUJO[2], L. FERNÁNDEZ-CRUZ[2], A. CASTELLS[2], J. J. LOZANO[1], M. Gironella[2]. [1]*Bioinformatics Platform, CIBERehd,* [2]*Gastrointestinal & Pancreatic Oncology Team / CIBERehd / IDIBAPS,* [3]*Endoscopy Unit, Gastroenterology Department and Surgery Department.,* [4]*Endoscopy Unit, Gastroenterology Department,* [5]*Department of Pathology, Hospital Clínic. Barcelona., BARCELONA, Spain*

INTRODUCTION: Pancreatic ductal adenocarcinoma (PDAC) is the 4th cancer-related death cause in occidental countries. Effective early detection methods are needed in order to improve its prognosis. Many expectations in this sense have arisen since the discovery of microRNAs (miRNA), which are small non-coding RNAs that regulate gene expression. On the other hand, samples from pancreatic lesions may be easily obtained by EUS FNA.
AIMS&METHODS: 1- To investigate if EUS FNA samples are suitable for miRNome analysis and 2- To analyze the miRNome of PDAC and the preneoplastic lesion IPMN, in order to find new miRNA-based biomarkers for early detection of pancreatic cancer. **Methods:** EUS FNA was performed using a linear echoendoscope together with an Aloka Alpha-5 system. FNA was performed using a standard 22G needle. After sampling the lesion for diagnosis, an extra-sample was intended to determine genome-wide miRNA profiling. Biomarker discovery was done using genome-wide miRNA profiling by next-generation sequencing in a set of 18 tissue samples (11 PDAC; 4 IPMN; 3 Healthy, H). Biomarker validation was done in a different set of 53 samples (24 PDAC; 8 IPMN; 15 H) by qRT-PCR.
RESULTS: Genome-wide miRNA profiling by next-generation sequencing technology could be determined in all samples, as well as biomarker validation by qRT-PCR. A total of 592 and 387 miRNAs were found significantly deregulated (FDR <0.05) in NGS data in PDAC and IPMN samples vs H, respectively. 41 miRNAs were selected for further validation according to the following criteria: FC >2 and FDR <0.05 in PDAC and IPMN samples; mean counts >400 and IQRmax(intra-group) <1.4. Among them, upregulation of 31 miRNA was confirmed (22 with $p<0.05$, and 9 $p<0.1$) in PDAC samples from the validation set by qRT-PCR. Most of these miRNAs (27) were also significantly upregulated in the IPMN group.
CONCLUSION: 1- EUS FNA samples are suitable for miRNome analysis. 2- Genome-wide miRNome analysis shows that PDAC, IPMN and healthy pancreatic tissue have differential miRNA profiles. Moreover, PDAC and IPMN lesions share a large number of deregulated miRNAs, making them good biomarker candidates for early detection of pancreatic cancer.

P1223 CLINICAL UTILITY OF SERUM DUPAN-2 IN DIAGNOSIS OF PANCREATICO-BILIARY MALIGNANCY

J. W. Kim[1,*], J. H. Lee[1], M. H. Chae[1], H. J. Park[1], H. S. Kim[1]. [1]*Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of*

INTRODUCTION: Serum carbohydrate antigen (CA 19-9) is the most common tumor marker assessed in pancreatico-biliary disease and health examination. However, its clinical limitation were poor sensitivity, false negative results and increased false positivity. The objective of this study was to identify usefulness of Duke pancreatic monoclonal antigen type 2 (DUPAN-2) such as tumor marker that might compensate for the drawback of the CA 19-9 assay.
AIMS&METHODS: From October 2010 to April 2013, DUPAN-2 levels of one hundred thirty patients (53 men and 77 women) were measured due to elevated CA 19-9 levels in health examination (54 cases) or pancreatico-biliary malignancy (76 cases). The normal levels for each marker are as follows and were measured in each patient: CA 19-9, 37 U/mL or lower and DUPAN-2, 150 U/mL or lower. The mean age of the patients was 64 years (range 26-95). Measurement of DUPAN-2 was assayed with an enzyme immunoassay kit.
RESULTS: The sensitivity and specificity of DUPAN-2 to malignant disease in total 130 patients, were 52/78 (66.7%) and 49/52 (94.2%), respectively. The patients with malignant diseases were 78/130 (60%), including 34 pancreatic cancer, 25 bile duct cancer, 11 GB cancer, 6 ampulla cancer, 1 prostate cancer, and 1 Warthin's tumor. There was a positive correlation between CA 19-9 and DUPAN-2 in malignant disease (r=0.358, P=0.000). In 114 patients excluding sixteen patients with normal CA 19-9 levels, the sensitivity and specificity of DUPAN-2 were 44/62 (70.9%) and 49/52 (94.2%), respectively. Eight of 16 (50%) patients with negative CA 19-9 level and pancreatico-biliary malignancy, including 3 pancreatic cancer, 3 CBD cancer, and 2 GB cancer, were measured positive for DUPAN-2. In 54/130 (41.5%) healthy patients with asymptomatic elevated CA 19-9 levels, the sensitivity and specificity of DUPAN-2 were 2/6 (33.3%) and 47/48 (97.9%), respectively. The benign cause of asymptomatic elevated CA 19-9 levels, excluding six malignant patients, were 14 lung problems (DILD, Bronchiectasis, emphysema, COPD, tuberculosis), 12 gynecologic problems (ovarian cyst, endometrial hyperplasia, uterine myoma), 18 unknown origin, and 4 other problems (congestive heart failure, chronic B viral hepatitis, back sprain, chronic cholecystitis).
CONCLUSION: DUPAN-2 is useful method for differential diagnosis of asymptomatic elevated CA 19-9 levels. Also, the combined assay of CA 19-9 and DUPAN-2 are sufficiently independent to complement each other in diagnosing the malignant disease. But, each tumor marker cannot be used as substitutes one for the other.

P1224 LONG-TERM SURVIVAL AFTER PALLIATIVE RESECTION AND BYPASS PROCEDURE IN PATIENTS WITH PERIAMPULLARY ADENOCARCINOMA

J. Tol[1,*], W. Eshuis[1], M. Besselink[1], T. van Gulik[1], O. Busch[1], D. Gouma[1]. [1]*Surgery, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Non-radical resections (R1/R2) for cancer in the pancreatic head area may limit long-term survival. Aggressive surgery can lead to non-radical resections and discrepancy exists on the presumed survival benefit for these patients after R1/R2 resection compared to patients undergoing palliative bypass procedure due to locally advanced disease. Survival and postoperative outcomes for these patients were analyzed in this study
AIMS&METHODS: The study population consisted of all patients who underwent surgical exploration with intent to perform a resection between 1992 and 2012, with a histopathologically proven cancer in the pancreatic head area: pancreatic head, distal common bile duct, duodenum or ampulla. Patient characteristics, postoperative outcomes and median overall survival between patients with an R1/R2 resection and patients with locally advanced disease without metastasis undergoing a palliative bypass (PBP) were compared. R1 was defined as microscopically non-radical, tumor cells within 1.0 mm of the resection margin; R2 was defined as macroscopically non-radical.
RESULTS: 1195 patients underwent surgical exploration for a malignancy; 716 resections and 479 PBPs were performed. In 33% of the resected patients (n=234) an R1/R2 resections was performed, 222 patients underwent PBP due to locally advanced disease. Age and gender did not differ between R1/R2 group and PBP group. Morbidity rates (ISGPS grade B/C, Clavien-Dindo $\geq$II) were 53% in R1/R2 group and 35% in PBP group (p=0.001), mortality was 1.3% vs. 3.2% respectively (p=0.1). Median survival for patients after R1 resection was 17.2 months vs. 9.3 months after PBP (log rank $p<0.001$). Median survival after R2 resection (n=10) was 8.5 months.

CONCLUSION: Although morbidity after non-radical resection is higher than after PBP, survival of patients after R1 resection is significantly better than after PBP in case of locally advanced disease. Therefore R1 resection can be accepted as adequate palliative treatment. However R2 resections, probably confirmed by positive frozen sections performed perioperatively, should be discouraged.

P1225 OPTIMAL EMERGENCY INTERVENTION IN PATIENTS WITH LATE HAEMORRHAGE AFTER SURGICAL EXPLORATION FOR A PERIAMPULLARY TUMOR

J. Tol[1,*], A. Jilesen[1], O. Busch[1], O. van Delden[2], T. van Gulik[1], E. Nieveen van Dijkum[1], D. Gouma[1]. [1]*Surgery,* [2]*Radiology, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Mortality due to late haemorrhage after surgery for periampullary tumors is high, especially in patients with pancreatic fistula (PF) and abdominal sepsis. Patients often require an emergency intervention (EI). Both radiological interventions (RI) and surgical interventions (SI) have been proven to be effective treatment strategies for late haemorrhage. In this study risk factors for the need of an EI and potential selection for RI or SI for late haemorrhage were identified and outcome of different treatment strategies were analyzed
AIMS&METHODS: From a prospective database including 1513 patients who underwent curative pancreatoduodenectomy or palliative bypass for periampullary tumors in the period 1992-2012, 50 patients with late haemorrhage (> 24 hours after index operation) were identified. In patients with late haemorrhage, type of intervention and outcome were analyzed. In order to identify independent predictors for the indication for an emergency intervention patient, disease specific and operation characteristics were retrieved from charts of patients with late haemorrhage. EI was defined as SI or RI in hemodynamic unstable patients
RESULTS: Of the 50 patients (3.3%) with late haemorrhage after surgical exploration for periampullary tumors, 20 patients required an EI. Postoperative PF was a risk factor for the need for EI (p=0.001). No independent predictors were identified after multivariate analysis for undergoing an EI or for type of intervention. In the EI group, 4 patients (20%) were treated primarily with SI, however 2 patients died due to persistent hemodynamic instability. The remaining patients (n=16, 80 %) were treated primarily with RI. RI was successfully in 9 patients, but failed in 7; 1 patient died due to aspiration immediately after coiling, 6 patients still required SI to manage the bleeding and stabilize their condition
CONCLUSION: For patients with late haemorrhage after surgery for periampullary tumors, the need for EI and the type of intervention is unpredictable. Mortality is still seen after both interventions due to persistent hemodynamic instability. RI is preferred due to the minimal invasive character, but an immediate change of treatment to surgery when RI is not successful is difficult. Partly due to the transportation of the patient from the RI room to the operating room. This is however possible when the RI is initially performed in the operation room. In order to perform both interventions in one setting and have all the tools to resuscitate the patient, a hybrid operation room is desirable

P1226 RISK FACTORS FOR SECOND PRIMARY PANCREATIC CANCER IN COLORECTAL CANCER PATIENTS

J. W. Chung[1,*], J. Y. Park[2], M. J. Chung[2], S. Bang[2], S. W. Park[2], S. Y. Song[2,3], J. B. Chung[2]. [1]*Division of Gastroenterology, National Medical Center,* [2]*Division of Gastroenterology,* [3]*Brain Korea 21 Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Second primary cancer in colorectal cancer (CRC) is becoming an issue as overall survival is getting improved. In this study we tried to find risk factors associated with subsequent pancreatic cancer (PC) after CRC.
AIMS&METHODS: The observed incidence rate of subsequent PC in CRC patients, obtained from Severance Hospital in Seoul, Republic of Korea, was standardized using a CRC population in the Korean Central Cancer Registry (KCCR) by National Cancer Center. The expected incidence rate of PC was obtained by assuming that these persons experienced the same cancer incidence as prevailed in the corresponding general populations in KCCR. The standardized incidence ratio (SIR) with 95% confidence interval (CI) was calculated.
RESULTS: There were 4824 CRC patients in certain age from 45 to 74 years old, providing 16,727 person-years of follow-up. Fifteen patients diagnosed subsequent PC at a median follow-up of 38.21 months, and the age-adjusted-incidence rate of subsequent PC was 13.3 per 100,000 in general; 20.4 in men and 40.7 in women. The SIR of subsequent PC in CRC patients was not significant; 0.71 (95% CI 0.41-1.19) in general and 0.88 (95% CI 0.56-1.33) in men. But the SIR significantly increased to 2.84 (95% CI 2.05-3.80) in women. Subgroup analysis of diabetes patients revealed that the SIR increased to 12.81 (95% CI 11.27-14.52). In multivariate analysis for the risk factor of second primary PC, diabetes showed higher odds ratio (adjusted odds ratio 4.218, 95% CI 1.494-11.910), but smoking history, obesity and chemotherapy showed no significant association.
CONCLUSION: The risk of second primary PC after CRC was increased in women and diabetes patients. These groups need a special attention regarding second primary PC. Further studies are needed to understand carcinogenic process of second primary cancer and build a cancer survivor screening strategy.

P1227 FREQUENCY OF EXCESSIVE BODY-MASS INDEX IN PATIENTS WITH INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM OF THE PANCREAS: A SINGLE- REFERRAL CENTRE EXPERIENCE

D. Berretti[1], S. Pevere[1], M. Bulajic[1], M. Marino[1,1,*], M. Fabro[1], M. Zilli[1]. [1]*Gastroenterology Unit, UNIVERSITY HOSPITAL OF UDINE, Udine, Italy*

INTRODUCTION: Up to date no clinical reports have been able to identify any lifestyle (including excessive body weight) linked to IPMN. Elevated BMI can be a risk factor for the development of colonic polyps and colon cancer (CCR), which have been found to be one of the most frequent neoplasms associated with IPMN, thus suggesting the need for endoscopic surveillance. We estimated the frequency of excessive body mass index in patients with intraductal papillary mucinous neoplasm of the pancreas (IPMN) referred to a single tertiary centre in North-Eastern Italy
AIMS&METHODS: We reviewed all patients diagnosed with IPMN in our Centre from November 2008 to September 2012. IPMN was diagnosed by two imaging techniques (EUS and MRI) and in selected cases by EUS-guided FNA (fine-needle-aspiration)
RESULTS: There were 118 patients with IPMN, 41 males and 77 females, mean age 70 (33-90). Data on BMI were available in 109 on 118 pts with 7.5% missing. Twenty-seven patients (23%) had normal BMI (< 25), 67 (57%) were overweight (BMI ≥ 25 and < 30) and 15 (13%) were obese (BMI ≥ 30). The overall prevalence of overweight (BMI ≥ 25) was 70%. Colorectal cancer and/or colonic polyps were found in 27 patients (33%). Data on BMI were available for 26 patients on 27 with 4% missing. Four patients with CCR and/or colonic polyps (15%) had normal BMI (< 25), 18 (67%) were overweight (BMI ≥ 25 and < 30) and 4 (15%) were obese (BMI ≥ 30). The overall prevalence of overweight (BMI ≥ 25) in patients with CCR and/or colonic polyps was 82%.
CONCLUSION: Our series confirms a high prevalence of CCR and/or colonic polyps in patients with IPMN. A high proportion of our patients had excessive body weight and it becomes even higher in the subgroup with CCR and/or colonic polyps. The possible link between overweight and IPMN should require further investigation

P1228 MR BASED SCREENING PROGRAM FOR INDIVIDUALS AT RISK FOR PANCREAS CANCER

D. C. Marco[1], C. Verbeke[2], N. Kartalis[3], N. Albiin[3], S. Haas[4], R. Segersvärd[1], Å. Andren-Sandberg[1], M. Lohr[1,*]. [1]*Division of Surgery,* [2]*Pathology,* [3]*Radiology,* [4]*Gastroenterology and Hepatology, Karolinska Institute, Stockholm, Sweden*

INTRODUCTION: Ten % of all pancreatic cancers can be hereditary. A screening program for the individuals at risk (IAR) is recommended, but no defined surveillance modalities are available.
AIMS&METHODS: Aim: To analyze the frequence of findings in IAR
Methods: From 2010 to 2013, all the patients with a "genetic risk" to develop pancreas cancer and referred to the Karolinska University Hospital, were included in a MR based surveillance program. All patients were investigated for the most common genetic mutation associated with pancreas cancer.
RESULTS: Forty patients were enrolled. There were 24 female and 16 man. The mean age was 49.9. The mean length of follow-up was 12.9 (± xx) months. The number of relatives affected by pancreas cancer was 5 in 2 patients (5%), 4 in 5 (12.5%), 3 in 17 (42.5%), 2 in 14 (35%) and 1 in 2 (5%). In 4 patients (10%) a p16 mutation was found, in 3 a BRCA 2 mutation (7.5%), in 1 a BRCA 1 mutation (2.5%). In 16 patients (40%) a suspect lesion was found in the pancreas with MR. Fourteen (35%) had an IPMN and 2 (5%) a pancreas cancer. Three patients (7.5%) required surgery (two for PDCA and one for IPMN) and the remaining 37 continue with the surveillance program.
CONCLUSION: During a median follow-up of just about a year, we detected pancreatic lesions in about 40% of our patients, of which three underwent surgery. Despite the relatively short time, the surveillance program in IAR seems to be effective.

P1229 SERUM CHROMOGRANIN-A AS A NEW DIAGNOSTIC TEST IN PANCREATIC CANCER

H. S. Sengul[1], N. Oruc[2,*], C. Aktan[3], I. Turan[2], O. Tekesin[2], O. Ozutemiz[2]. [1]*Internal Medicine,* [2]*Gastroenterology department,* [3]*Molecular Biology, Ege university faculty of medicine, Izmir, Turkey*

INTRODUCTION: Pancreatic cancer has common diases with poor prognosis. There is still need for new, reliable serum markers for diagnosis of pancreatic cancer. Although serum Ca19-9 level are commonly used serum marker in pancreatic cancer it has low spesificity and sensitivity. Chromogranin A(CgA) is a

prohormon mainly released from neuroendocrine cells. It is commonly used for diagnosis of pancreatic neuroendocrine tumors. There is no study showing the diagnostic and prognostic significance of serum Cg A levels in pancreatic ductal adenocancer.
AIMS&METHODS: We aimed to study the diagnostic and prognostic significance of serum CgA levels in pancreatic ductal adenocancer. Seventy five patients with pancreatic adenocancer and 75 healthy controls were included to the study. Patients age, gender, age of diagnosis, stage of the disease, clinical symptoms, biochemical paremeters were recorded. Serum CgA levels were measured by ELISA method.
RESULTS: Pancreatic cancer patients has significantly higher levels of serum CgA levels then controls (299.4±460.9 vs 72.9±98.9 ng/ dl, $p < 0.001$). The cut of value of serum CgA levels over 75 ng/ml has 75% sensitivity and 79% specificity for diagnosis of pancreatic cancer (($p < 0.001$, AUC 0.79, %95 CI 3.4-17.1). Serum Cg A levels was positivly correlated with age, serum CRP and sedimantation rates while it was not correlated with serum Ca19-9 levels. Diabetes and chronic pancreatitis were independent risk factors beside pancreatic cancer that increase serum Cg A levels. Serum Cg A levels were not different with the stage of the disease and was high even in early stages.
CONCLUSION: Serum CgA level has high sensitivity and specifisity for diagnosis of pancreatic ductal cancers while it does not have prognostic significance.

P1230 CHARACTERISTICS AND OUTCOME OF ASYMPTOMATIC PANCREATIC CYSTS LESS THAN 3CM - EXPERIENCE FROM A REGIONAL HOSPITAL IN HONG KONG

S. C. Ng[1,*], S. W. Lai, K. K. Li. [1]*Medicine and Geriatrics, Tuen Mun Hospital, Hong Kong, China*

INTRODUCTION: Incidental pancreatic cysts are identified more frequently. Some would have malignant potential. The natural history of incidental pancreatic cyst is not clear and the optimal imaging surveillance interval is not well established.
AIMS&METHODS: To determine the natural history of incidental pancreatic cysts less than 3cm, the predictors of cyst growth and to evaluate an optimal imaging surveillance interval.
A retrospective study on patients with incidental pancreatic cysts detected by Computed-Tomography imaging from January 2000 to December 2010. Computer search through the radiology database containing all CT exam was performed. Patients with incidental, asymptomatic pancreatic cysts less than 3cm in size at presentation with follow-up interval more than 3 months were included. Patients with history of pancreatitis, pancreatic pseudocyst and systemic cystic disease were excluded. The demographic, biochemical and radiological features of pancreatic cysts at presentation were reviewed. Outcomes include increased in cyst size, development of new cystic features, symptoms related to pancreatic cyst, malignant transformation and death related to cystic neoplasm of pancreas.
RESULTS: Ninty-nine patients were included for analysis. The mean age was 66 and male-to-female 1:1. Over 50% of patients had non-pancreatic malignancy. The most common indication for imaging that detected incidental pancreatic cyst was staging for newly diagnosed malignancy (25.3%). The initial cyst size was 14.35mm, with 66% located over pancreatic body or tail region. Septation was present in nine patients (9.1%) while no patients had mural nodules. Over a mean follow-up duration of 22.2 months, eighty-two (82.8%) patients with pancreatic cysts did not show any significant growth, development of new cystic features or new symptom related to pancreatic cysts. By using multivariate logistic regression analysis, presence of septation (p=0.024, 95% CI 1.287-33.3, OR 6.536) and radiological follow-up duration (p=0.001, 95% CI 1.021 - 1.083, OR 1.051) were independently associated with cyst progression. Among seventeen (17.2%) patients with pancreatic cysts showed significant growth, malignant IPMN with metastasis was diagnosed in one (1.0%) patient after 54 months follow-up. The remaining cases were either within surgically resectable stage or clinically benign lesions. The majority of cyst growth occured after 18 months from baseline evaluation.
CONCLUSION: Eighty percent of incidental pancreatic cysts less than 3cm did not have significant growth during 22 months follow-up. A conservative approach with regular imaging surveillance is justified. The interval of follow-up imaging at 18 months after baseline evaluation is a safe duration.

P1231 HIGH INCIDENCE OF PANCREATIC CANCER IN PATIENTS WITH AUTOIMMUNE PANCREATITIS UNDERGOING SURGERY

P. Macinga[1,*], A. Pulkertova[2], J. Maluskova[3], E. Honsova[3], M. Oliverius[4], J. Spicak[1], T. Hucl[1]. [1]*Department of Gastroenterology and Hepatology, Institute for Clinical and Experimental Medicine, Prague,* [2]*Department of Clinical Oncology, Kolin Regional Hospital, Kolin,* [3]*Department of Pathology,* [4]*Department of Surgery, Institute for Clinical and Experimental Medicine, Prague, Czech Republic*

INTRODUCTION: Autoimmune pancreatitis (AIP) is a rare disease that may present with signs and symptoms mimicking pancreatic cancer. AIP is characterized by a dramatic response to corticosteroid therapy. Thus, patients diagnosed with AIP can avoid surgery and undergo immunosuppressive treatment. Only a few cases of pancreas cancer in AIP patients have so far been reported worldwide.
AIMS&METHODS: We performed a retrospective analysis of data of all patients who underwent pancreatic resection in our department for suspected cancer/focal pancreatic enlargement.
RESULTS: Two hundred and twenty pancreatic resections were performed in 153 males and 67 females (mean age 59 years, range 36-72 years). Indication for surgery was tumor suspicion based on clinical symptoms, imaging methods and laboratory findings. In 14 patients (6.4%, 9 males, 5 females), autoimmune pancreatitis was diagnosed based on histology of the resected specimen. In 5 patients, abundant IgG4 cells were present. In 3 AIP patients (21.4%, all males, one IgG4 positive), pancreatic adenocarcinoma was also present in the resected tissue. No differences were observed in the preoperative characteristics of patients with and without cancer (CT, EUS, ERCP, bile duct involvement, laboratory findings including CA 19-9). In none of the patients the diagnosis of AIP was made prior to surgery; however the diagnostic algorithm was not fully completed.
CONCLUSION: AIP patients may develop pancreatic cancer. The preoperative diagnosis of autoimmune pancreatitis in patients with focal pancreatic enlargement may not always rule out the simultaneous presence of cancer

P1232 ARE DIAGNOSTIC ERRORS IN CYSTIC TUMORS OF THE PANCREAS CLINICALLY RELEVANT?

D. C. Marco[1], C. Verbeke[2], E. Rangelova[1], C. Ansorge[1], J. Blomberg[1], N. Albiin[3], R. Segersvärd[1,*]. [1]*Division of Surgery,* [2]*Pathology,* [3]*Radiology, Karolinska Institute, Stockholm, Sweden*

INTRODUCTION: Diagnostic errors in the preoperative evaluation of cystic neoplasm of the pancreas (CNP) are not uncommon. Only limited data is available regarding the impact of these errors on clinical management.
AIMS&METHODS: Aim:
This study aims to evaluate the clinical impact of these diagnostic errors.
Methods:
A series of 141 patients undergoing surgery for CNP at Karolinska University Hospital was retrospectively analyzed. There were 60 males; the mean age was 60.3 yrs. CT was performed in 138 patients (97.8%), MR in 85 (60.3%), and EUS in 31 (21.9%).
RESULTS: Histology confirmed the pre-operative diagnosis in 60.9% of patients. The concordance rate between pre-operative diagnosis and histology was similar for asymptomatic and symptomatic lesions (60.5% vs 61.4%; p=NS). The rate of correct diagnosis increased over time (2004-2006: 54.5%, 2007-2012: 61.7%, 2010-2012: 63.5%). Lymphoepitelial cysts (2/2) were misdiagnosed most frequently, followed by serous cystic neoplasia (24/33, 72.2%), solid pseudopapillary neoplasia (5/8, 62.5%), mucinous cystic neoplasia (7/25, 28%), and IPMN (17/56, 23.3%). Reevaluating the surgical indication in view of the histological diagnosis, surgical resection was not required in 13 patients (9.2%). There was no mortality in this patient group, and morbidity amounted to 53.8%.
CONCLUSION: The results confirm that preoperative diagnostic errors are quite common in CNP, however, the percentage of patients who unnecessarily undergo surgery is low (9.2%). The error rate is similar for symptomatic and asymptomatic patients.

ENDOSCOPY AND IMAGING III – Poster Area

P1233 THE OUTCOME OF PHARYNGEAL CANCER TREATED BY ENDOSCOPIC SUBMUCOSAL DISSECTION

A. Takahashi[1], T. Oyama[1,*]. [1]*Gastroenterology, SAKU CENTRAL HOSPITAL, Nagano, Japan*

INTRODUCTION: Majority of pharyngeal cancer has been diagnosed in advanced stage. The standard treatment for advanced pharyngeal cancer is pharyngectomy, and the patients lost their vocal function. On the other hand, the vocal function could be kept if the patient could be treated by endoscopic submucosal dissection (ESD). However, the outcome of pharyngeal cancer treated by ESD is unknown.
AIMS&METHODS: The aim of our study is to investigate the outcome of pharyngeal cancer treated by ESD. The indication of pharyngeal ESD was epithelial (EP) and subepithelial (SEP) cancer without lymph node metastasis (LNM). CT and cervical US were done for checking LNM. 53 lesions in 36 patients treated by ESD from January 2006 to December 2012 were enrolled into this retrospective study. The median age was 67 (50-79) years, 35 were males and 1 was female. The median follow up period was 69 (5-89) months. 25 and 28 lesions were located in oropharynx and hypopharynx, respectively. 0-I, 0-IIa, 0-IIb and 0-IIc were 2, 17, 31 and 3, respectively.
RESULTS: 1. The median diameter of the resected specimens and lesions were 22 (10-90) and 3 (1-48) mm, respectively. EP and SEP cancers were 38 and 15, respectively.
2. En-bloc resection and R0 resection rate was 100% and 96% (51/53), respectively. Lateral margin was positive in 2 lesions and decided as R1.
3. Complication; There weren't severe complications such as bleeding needed blood transfusion. Delayed bleeding was occurred 2.8% (1/36), and the patient was treated by endoscopic hemostasis under tracheal re-intubation.
4. Local recurrence rate was 1.9% (1/53). The only patient was SEP cancer, and R0 resection was performed. However, local recurrence was diagnosed at 3 months after ESD. The case had lymph duct involvement.
5. LNM rate was 0% (0/24) and 8.3% (1/12) in EP and SEP groups, respectively. The only patient was SEP cancer, and neck LNM was diagnosed at 6 months after ESD. The patient was treated by LN dissection and chemo radiotherapy.

6. Distant metastasis was 0%.
7. Prognosis: No patient died of pharyngeal cancer, and 1 of 12 (8.3%) patients in SEP group died of pharyngeal cancer.
CONCLUSION: EP and SEP pharyngeal cancer is a good candidate of ESD. However, detailed follow up is recommended for SEP pharyngeal cancer.

P1234 SUBLINGUAL VERSUS ORAL ALPRAZOLAM AS CONSCIOUS SEDATION FOR ESOPHAGOGASTRODUODENOSCOPY: A RANDOMIZED PLACEBO-CONTROLLED TRIAL

A. Shavakhi[1,*], M. Khodadoostan[1], M. Minakari[1], S. Soleiman[1], A. Tahery[3], S. Shavakhi[2], A. Gholamrezaei[2]. [1]*Department of Internal Medicine,* [2]*Medical Students' Research Center, Isfahan University of Medical Sciences, Isfahan,* [3]*Department of Radiology, Shahrekord University of Medical Sciences, Shahrekord, Iran, Islamic Republic Of*

INTRODUCTION: Diagnostic esophagogastroduodenoscopy (EGD) is an uncomfortable and stressful procedure for many patients.
AIMS&METHODS: We determined the efficacy of oral and sublingual alprazolam as conscious sedation during EGD in decreasing patients' pain/discomfort, and increasing patients' compliance and satisfaction with the procedure.
In a double-blinded, placebo-controlled, randomized trial, adult patients who were candidate for EGD were allocated to four groups of oral and sublingual alprazolam and oral and sublingual placebo (n = 55 in each group). Patients received one oral dose of alprazolam 0.5 mg (or placebo) at the night before the procedure and then one oral or sublingual dose at least 30 minutes before the EGD. Procedure related pain/discomfort and patients' satisfaction were assessed by 11-point numeric rating scale. Compliance was assessed from no compliance (0) to excellent compliance (4). Duration of the procedure was also recorded.
RESULTS: Mean age was 43.4±12.6 years and 60.9% were female. The pain/discomfort score was significantly lower in the sublingual (3.2±2.0) and oral (3.4±1.6) alprazolam groups than in the oral placebo group (5.1±2.3), $P < 0.001$; but difference with the sublingual placebo group (4.1±1.8) was not significant ($P > 0.1$). Frequency of needing intravenous sedation (with midazolam) was 10.9%, 9%, 10.9%, and 12.7% in the sublingual and oral alprazolam and sublingual and oral placebo groups, respectively ($P = 0.946$). Compliance was better in the sublingual alprazolam group than other three groups ($P = 0.001$), but oral alprazolam group was not different with the placebo groups in compliance ($P > 0.1$). Satisfaction was greater in the sublingual alprazolam group (6.4±2.3), but not oral alprazolam (5.5±2.2), than in the sublingual (5.0±2.3) and oral placebo groups (4.7±2.4), $P < 0.05$. Duration of EGD (second) was also shorter in the sublingual alprazolam (271.1±33.1) than other three groups; oral alprazolam (297.5±33.6), sublingual placebo (307.4±41.5), and oral placebo (317.5±36.1), $P < 0.01$.
CONCLUSION: Although alprazolam did not reduce the need for intravenous sedation in our study, its sublingual administration reduced pain/discomfort related to EGD, reduced procedure duration, and increased patient's compliance and satisfaction with the procedure. We conclude that sublingual alprazolam is an effective conscious sedation method for EGD.

P1235 CLINICAL UTILITY OF GLASGOW BLATCHFORD SCORE IN ACUTE UPPER NON VARICEAL GASTROINTESTINAL BLEEDING AS A PREDICTOR OF LOW RISK FOR THE NEED OF CLINICAL INTERVENTION.

A. Bermejo[1,*], I. Guerra[1], A. I. Franco[2], A. Algaba[1], D. Alcalde[1], M. de Lucas[1], D. Bonillo[1], F. Bermejo[1]. [1]*Gastroenterology Department, Hospital Universitario de Fuenlabrada, Fuenlabrada,* [2]*Internal Medicine Deparment, Hospital de Torrejón, Torrejón de Ardoz, Spain*

INTRODUCTION: Upper gastrointestinal bleeding (UGIB) is a common indication for admission in the hospital. The Glasgow Blatchford Score (GBS) is a pre-endoscopic risk scoring system for patients presenting with acute non variceal UGIB based on clinical and laboratory variables. This score has been shown to be superior to Rockall Score for predicting the risk of rebleeding or death. A GBS of zero (GBS-0) has been related with low risk patients.
AIMS&METHODS: The aim of this study is to evaluate the capacity of GBS to predict the need of clinical intervention to control bleeding (blood transfusion, endoscopic treatment or surgery).
Methods: We performed a prospective observational study in all patients with UGIB attended at the Emergency Department in our hospital from March 2010 to June 2012. Inclusion criteria included patients aged 18 to 80 with signs of UGIB such as hematemesis, coffee-ground emesis or melena, with endoscopic confirmation. Exclusion criteria included anticoagulant therapy or portal hypertension. Patients were classified in two groups, GBS-0 or GBS > 0.
RESULTS: 129 patients were included (61.2% males, mean age 50±18 years). Clinical presentation was melena in 55%, hematemesis in 31% and others in 14%. Personal history of peptic ulcer was present in 10% of patients, and 30% of patients had recently used NSAIDs. Causes of bleeding were peptic ulcer in 46.5%, Mallory-Weiss syndrome in 10.1%, erosive gastritis in 9.3%, esophagitis in 8.5% and others in 25.6%. 20 patients were classified as GBS-0 and 109 as GBS > 0. Endoscopic therapy was required to control bleeding in 3 patients with GBS-0 and in 31 patients with GBS > 0 (15 vs. 28.4%, p=0.21). No patients with GBS-0, and 3 patients in GBS > 0 group presented rebleeding (0 vs. 2.8%, p=0.45). Blood transfusion was needed in 27 patients in the GBS > 0 group whereas no patients in the GBS-0 group required blood transfusion (24.8% vs. 0%, p=0.012). No patients needed surgery to control bleeding and no deaths where registered in any group. The global median length of stay was 24 hours (IQR 13-96). 52% of all patients were discharged after a 12-hours observation period after the endoscopy, with no rebleeding in the next 30 days in any patient.
CONCLUSION: A GBS of zero is related to a very low risk of blood transfusion, surgery and mortality in nonvariceal UGIB patients. Since endoscopic treatment could be needed to control bleeding in some GBS-0 patients, upper gastrointestinal endoscopy should be performed in all patients presenting with UGIB.

P1236 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR EARLY ESOPHAGEAL NEOPLASIA – EXPERIENCE IN A EUROPEAN CENTER

A. Probst[1,*], B. Maerkl[2], M. Anthuber[3], H. Messmann[1]. [1]*Department of Gastroenterology,* [2]*Institute of Pathology,* [3]*Department of Visceral Surgery, Klinikum Augsburg, Augsburg, Germany*

INTRODUCTION: ESD experience in the western world is still limited. Especially in esophageal lesions ESD only few European data are available so far. The role of ESD in the treatment of Barretts early neolasia needs to be further defined.
AIMS&METHODS: From 08/2007 to 05/2013 ESD was performed in 82 esophageal lesions. Lesions were early Barretts cancers (n=54), Barretts with high grade intraepithelial neoplasia (n=7) and early squamous cell cancers (SCC) (n=21). Resection was judged "oncologically adequate" when invasion depth was restricted to the m2 layer for SCCs and the mm layer for Barretts lesions. Data were collected prospectively (lesions diameter, en bloc resection, R0 resectio, "oncologically adequate" resection).
RESULTS: In 79/82 cases en bloc resection was technically possible (96.3%). In three lesions ESD was impossible due to non-lifting. 5 resections were performed as circumferential resection. The following table shows the diameter of the resection specimens and the the resection rates for the different groups.

	resection specimen - diameter Ø	en bloc resection	R0 resection	resection "oncologically adequate"
LSBE(n=17)	46mm	14 / 17 (82.4%)	13 / 17 (76.5%)	13 / 17 (76.5%)
SSBE(n=44)	38mm	44 / 44 (100%)	39 / 44 (88.6%)	34 / 44 (77.3%)
Barrett total (n=61)	41mm	58 / 61 (95.1%)	52 / 61 (85.2%)	47 / 61(77%)
SCC(n=21)	35mm	21 / 21 (100%)	20 / 21 (95.2%)	13 / 21 (61.9%)
all lesions (n=82)	39mm	79 / 82 (96.3%)	72 / 82 (87.8%)	60 / 82 (73.2%)

In 79 en bloc resections R1 resection was shown in 7 specimens (3 at the basal margin, 3 at the lateral margin and one at the basal and the lateral margin). In 72 R0 resections ...high-risk"-histology was found, the resection was judged ...oncologically inadequate" and surgery was recommended (7 SCCs > m3, 5 Barretts cancers with submucosal invasion). Resection was judged "oncologically adeqate" in 60/82 lesions (73.2%). Complications: stenosis n=9, bleeding n=1, no perforation. Three recurrences: lymph node metastasis 18 months after ESD of a Barretts carcinoma G3smR0, local recurrence 11 months after ESD of an SCC G2smR0), liver metastasis 29 months after ESD of an SCC m3G3. In all three cases surgery had been refused by the patient or had not been performed due to severe comorbidity.
Mean follow-up is 22 months (1-68).
CONCLUSION: ESD of early esophageal neoplasia shows high en bloc resection rates (96.3%) and high R0 resection rates (87.8%). R0 resection rates are high for SCCs but also for Barretts early neoplasia. When oncologic limitations are noticed strictly the rate of "oncologically adequate" resection is lower (77% for Barretts and only 61.2 for SCCs).

P1237 GASTROINTESTINAL ANGIODYSPLASIA IN CHRONIC RENAL FAILURE

B. Ihyane[1,*], N. kabbaj[1], I. serraj[1], L. amrani[1], M. salihoun[1], Z. chaoui[1], N. amrani[1]. [1]*EFD-Hepatogastroenterology Unit, UM5S, CHU Ibn Sina-Rabat, Morocco, rabat, Morocco*

INTRODUCTION: Gastrointestinal (GI) hemorrhage is a frequent and sometimes life-threatening complication of end-stage renal failure. Angiodysplasia

(AD) is the most common cause of recurrent lower-intestinal hemorrhage in patients with renal failure. Its Prevalence in chronic renal failure is 19 to 32% compared to 5% in individuals with normal renal function.
AIMS&METHODS: The aim of this study is to report the clinical, endoscopical and therapeutical characteristics of AD in these patients. All patients with chronic renal failure having angiodysplasia in endoscopy (upper digestive endoscopy, ileocoloscopy, small bowel videocapsule endoscopy) were included during 6 years.
RESULTS: Out of 411 patients with chronic renal failure, 73 patients (17.7%) had angiodysplasia. There were 45 men (61.6%) and 28 women (38,4%). Mean age was 63 years. Endoscopy was performed for anemia in 47 patients (64%), upper bleeding in 15 patients (20.5%), rectal bleeding in 8 patients (10.9%) and melena in 3 patients (4.1%). Angiodysplasia was localized in the stomach in 38 patients (52%), in the duodenum in 3 patients (4.1%), in the small bowel in 13 patients (17.8%), in the cecum in 4 patients (5.4%), in the colon in 11 patients (15%) and AD was diffuse in 4 patients (5.4%). All these patients underwent argon plasma coagulation with good clinical and biological outcome.
CONCLUSION: The Frequency of angiodysplasia as a cause of hemorrhage in chronic renal failure is 17.7% in our series. The frequent clinical sign was anemia and the predominant localization of angiodysplasia was the stomach followed by the small bowel. The diagnosis is based on endoscopy and treatment can be improved by argon plasma coagulation.

P1238 ENDOSCOPIC ASSESSMENT OF NEUROGENIC DYSPHAGIA: A NEW INSIGHT BY FUNCTIONAL ENDOSCOPY

D. Domagk[1,*], T. Warnecke[2], P. Lenz[1], J. Wessling[3], R. Dziewas[2], I. Herrmann[4]. [1]*Department of Medicine B,* [2]*Department of Neurology,* [3]*Department of Clinical Radiology, University of Muenster, Muenster,* [4]*Reflux Center Duesseldorf, Duesseldor, Germany*

INTRODUCTION: Dysphagia is a frequent and early symptom in neurologic diseases. Besides disturbance during food intake and dehydration, these patients often encounter a considerable risk of aspiration pneumonia. Functional endoscopy via transnasal route provides the endosopist an insight into the deglutition of neurologic patients suffering from dysphagia.
AIMS&METHODS: Functional endoscopy applying ultrathin video endoscopes (BF-3C160, Olympus Europe) was performed in 20 patients with neurologic dysphagia - including observation of the upper esophageal sphincter in inversed position of the endoscope. Especially, the esophageal phase of deglutition may be observed which has long be considered as black box in endoscopic assessment. Furthermore, diagnostics was completed by kinematography, high-resolution endoscopy and fiberoptic endoscopic evaluation of swallowing.
RESULTS: A varity of disorders was documented by functional endoscopy: Clearance disturbance of tubular esophagus, incomplete closure of the upper esophageal sphincter, bolus leakage, delayed swallowing reflex, and residues in valleculae and piriformes, esophageal hyperperistalsis and aspiration during food intake.
CONCLUSION: By interdisciplinary cooperation (gastroenterology, neurology and ENT) with additional assessment of the esophageal phase of deglutition using functional endoscopy, the diagnostic of neurologic disorders including dysphagia may tremendously be improved. Consequently, the clinical understanding of complex dysfunctional patterns is improved. Because primary and secondary opening disorders of the upper esophageal sphincter may often be observed in neurogenic dysphagia, this diagnostic comprehensive approach may be helpful to apply focussed prophylactic and therapeutic actions.

P1239 RELATION OF DISTANCE BETWEEN TWO FREE ENDS OF RING ENDS AFTER PERORAL ENDOSCOPIC MYOTOMY AND ACHALASIA SYMPTOM

E. Linghu[1,*], B. Bu[1]. [1]*Department of Gastroenterology and Hepatology, the Chinese PLA General Hospital, Beijing, China*

INTRODUCTION: Peroral endoscopic myotomy (POEM) is a new-developed minimally invasive endoscopic technique, expected to be the first choice for treating achalasia (AC). The relation of distance between two free ends of ring muscules after peroral endoscopic myotomy and achalasia symptom has not been reported. The aim of our study was to investigate the relation of distance between two free ends of ring muscules after peroral endoscopic myotomy and achalasia symptom
:EN-US;mso-fareast-language:ZH-CN; mso-bidi-language:AR-SA'>achalasia (AC).
AIMS&METHODS: To study the relation of distance between two free ends of ring muscules after peroral endoscopic myotomy and achalasia symptom. Fourty-six patients (male 28, female 18, age 16-63, mean±SD 40.6±13.0) with achalsia undergoing POEM during December 2010 to December 2012 was studied. According to the distance between two free ends of ring muscules after POEM, the fourty-six patients was divided into two groups. Preoperative and postoperative Eckardt scores of achalsia was compared between two groups.
RESULTS: Postoperative symptom Eckardt scores (6~9, mean 7.5) was significant lower than preoperative symptom scores (0-6, mean 2.6). The decreaing extent of Eckardt scores in achalsia with big distance between free ends of ring muscules was greater than that with small distance(7.1 vs 4.2 respectively, $P < 0.05$).
CONCLUSION: Peroral endoscopic myotomy is an effective method for achalasia, and the distance of two free ends of ring muscules after peroral endoscopic myotomy was positively associated with relief of achalsia symptom.

P1240 DOUBLE PERORAL ENDOSCOPIC RESECTION OF GASTRIC SUBEPITHELIAL TUMORS

E. Linghu[1,*], Z. Qin[1]. [1]*Department of Gastroenterology and Hepatology, the Chinese PLA General Hospital, Beijing, China*

INTRODUCTION: Endoscopic submucosal dissection (ESD) and surgery is efficacious technique for superficial gastrointestinal neoplasms. However, the procedure is long, complex, and associated with higher complication rates.
AIMS&METHODS: To evaluate the feasibility and efficacy of endoscopic resection of gastric subepithelial tumors originated from the muscularis propria layer with double peroral endoscopes. In this study 4 patients who presented with gastric subepithelial tumors were enrolled. Endoscopic resection was performed using preoral endoscopes. The four gastric subepithelial tumors were removed integrally and incision of muscularis propria layer were closed firmly by metal clips when ancillary endoscopy draw tumors or muscularis propria layer.
RESULTS: The four gastric subepithelial tumors originated from the muscularis propria layer were removed integrally, which were diagnosed pathologically as gastrointestinal stromal tumor and leiomyoma. The diameter of tumors were 22 mm. The mean procedure time was 48 minutes. No complications as perforation or bleeding occurred in all cases after the operation, who received successful closure with metal clips. The mean hospitalization time was 7 days.
CONCLUSION: Double peroral endoscopic resection, an efficacious and safe endoscopic surgical procedure to resect gastric subepithelial tumors originated from the muscularis propria layer integrally and close the incision of muscularis propria layer, is able to achieve the efficacy equivalent to ESD or surgery .

P1242 CONTRIBUTION OF UPPER DIGESTIVE ENDOSCOPY IN PATIENTS WITH CHRONIC KIDNEY DISEASE

H. Delsa[1,*], N. kabbaj[1], M. salihoun[1], M. acharki[1], I. serraj[1], Z. chaoui[1], M. guedira[1], M. nya[1], L. amrani[1], N. amrani[1]. [1]*EFD-Hepatogastroenterology unit, Ibn Sina Hospital, mohamed 5 souissi university, RABAT, Morocco*

INTRODUCTION: Digestive disorders are more common in kidney failure.
AIMS&METHODS: The aim of this study is to analyze the frequency and different types of endoscopic lesions in patients with chronic kidney disease.
We included all patients with chronic kidney failure at the stage of hemodialysis or not between January 2007 and April 2013. Endoscopy is systematically realized in patients planned for kidney transplantation. Other indications are represented by dyspepsia in 97 patients (26%), upper gastrointestinal bleeding in 58 patients (15.6%) and iron-deficiency anemia in 42 patients (11.3%).
RESULTS: Out of 12580 Upper digestive endoscopy performed, 372 (3%) patients have a chronic kidney failure. 204 are men and 168 are women with a sex ratio of 1,2. The mean age is 44.7 years.
The Upper digestive endoscopy objectified lesions in 313 cases (84%), it's a congestive gastritis in 156 patients (42%), ulcerative gastritis in 58 patients (15.6%), angiodysplasia in 43 patients (11.5%), peptic esophagitis in 26 patients (7%), signs of portal hypertension in 20 patients (5.4%), peptic ulcer in 18 patients (5%) and a hiatal hernia in 8 patients (2.1%). 59 patients (16%) have normal Upper digestive endoscopy.
CONCLUSION: Upper digestive lesions are common in patients with chronic kidney failure. 84% of these patients have lesions in our series. They are dominated by congestive and ulcerative gastritis followed by angiodysplasia.

P1243 TREATMENT OF ZENKER'S DIVERTICULUM WITH FLEXIBLE ENDOSCOPE: RESULTS AND TECHNICAL ASPECTS

H. Martinez[1], S. A. Carrica[1], A. Villaverde[1], F. Tufare[1], J. Epele[1], **G. Correa**[1,*], N. Chopita[1]. [1]*HIGA San Martín, La Plata, Argentina*

INTRODUCTION: In our country the Zenker's diverticulum is an entity known as heritage of surgery. In 1995, Ishioka and Mulder publish their experiences using flexible endoscopes.
AIMS&METHODS: To report our results and techniques modifications. We reviewed the database of 51 patients (33 men) with a mean age of 72.14 years (range 37-98 years) with symptomatic Zenker's diverticulum who underwent endoscopic myotomy between december 1997 and april 2013. All procedures were performed in our service by the same endoscopist (H. M.). The most common symptom was oropharyngeal dysphagia (96.1%), which was recorded by a 0-4 score (0 = no dysphagia, 1 = for solids, 2 = semisolids, 3 = liquid, 4 = saliva). First ten cases were done exposing the septum with a nasogastric tube and the others patients were performed with soft diverticuloscope. All procedures were performed under deep sedation by anesthesiologist then a myotomy was done in all cases with needle-knife using pure coagulation to prevent bleeding. Clips were placed to close mucosal flaps.
RESULTS: Sixty-four procedures were performed in 51 patients. The 95.83% of the patients had dissapearence or improvement of dysphagia score at 30 days.

Two patients with only regurgitation were completely resolved. Mean follow up was 31 months (1-99 months). Thirty-five patients were followed at least for 1 year and 97,1% had good outcome. In 13 cases (24.5%) a reintervention was needed. Bleeding ocurred in one patient (1,96%) who required surgery. Other patient required surgical intervention due to technical issues. There were no perforations or infections.

CONCLUSION: The treatment of Zenker's diverticulum with flexible endoscope is a safe and effective option, with good long-term results.

P1244 CAN SHORT LENGTH TRAINING PERIOD IN A JAPANESE SPECIALIZED CENTER IMPROVE THE DIAGNOSTIC YIELD OF EARLY GASTRIC CANCER IN WESTERN COUNTRIES?

J. J. Vila[1,*], T. Uraoka[2], M. Gómez[1], M. Basterra[1], E. Rubio[1], M. Garaigorta[1], F. J. Jiménez[1], N. Yahagi[2]. *[1]Endoscopy Unit. Gastroenterology Dpt., Complejo Hospitalario de Navarra, Pamplona, Spain, [2]Endoscopy Unit. Division of Research and Development of Minimally Invasive Treatment., Cancer Center. Keio University School of Medicine., Tokyo, Japan*

INTRODUCTION: Intensive training in early gastric cancer (EGC) detection improves detection of these lesions1.

AIMS&METHODS: We evaluated the diagnostic impact in a western population of a training period undergone by a western endoscopist (WE) in a japanese endoscopy unit specialized in the detection and treatment of EGC. In April 2012 a WE received intensive training in detection of EGC and endoscopic submucosal dissection (ESD) in a japanese reference unit. All gastroscopies performed by WE in his original hospital after that stay (IV/2012-IV/2013) were prospectively recorded (Case Group). The detection rate of EGC and precancerous lesions in this group was compared to a Control Group consisting in the same number of gastroscopies performed by WE prior to the stay (IV/2010-III/2012). Topical pharyngeal anaesthesia or conscious sedation were used. The technique varied from the Control Group (full evaluation of the stomach with lavage of the gastric wall when contents covered most of it) to the Case Group (thorough washing, distention, aspiration of gastric contents and observation of the mucosal surface). Therapeutic and urgent gastroscopies were excluded. Student t and chi-square test were used for comparison.

RESULTS: 254 patients were included in each group. There were no differences in age or sex distribution ($p > 0.05$). Sedation was more frequently used in Control Group (79vs104, p=0.006) and consequently tolerance was significantly better (p=0.03). Detection of gastric mucosal lesions in the Case Group was significantly higher [100(39.37%)vs32(12.59%), $p < 0.0001$]. These lesions included 7 advanced gastric cancers in the Case Group vs 4 in the Control Group (2.75%vs1.57%, $p > 0.05$). Of the 93 remaining lesions detected in the Case Group, 67 were Paris 0-II and only 11 in the Control Group (72%vs34.3%, p=0.002). Taken together, the diagnosis of precancerous lesions and EGC was not significantly different in both groups: 1 hyperplastic polyp > 3 cm, 1 adenomatous polyp and 11 EGC vs 4 adenomatous polyps and 1 EGC (p=0.1). EGC detection was significantly higher in the Case Group [11 (4.33%) vs 1 (0.39%), p=0.003]. These lesions were treated by means of ESD, endoscopic resection, surgery or medical treatment. The remaining mucosal lesions corresponded to inflammatory lesions, small hyperplastic polyps and mild dysplasia.

CONCLUSION: Training of a WE in a specialized center significantly improves the diagnostic rate of EGC in a western population by means of improving detection of subtle Paris type 0-II lesions, and allows curative endoscopic treatment.

P1245 PREDICTING RISK FACTORS FOR EARLY BLEEDING INCLUDING ASYMPTOMATIC EVENTS AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS

J. H. Kim[1,*], K. A. Kwon[1], M. Ha[1], M. Y. Rim[1], J. J. Lee[1], J.-W. Chung[1], Y. J. Kim[1], K. O. Kim[1], D. K. Park[1]. *[1]DEPARTMENT OF INTERNAL MEDICINE, GACHON UNIVERSITY GIL MEDICAL CENTER, Incheon, Korea, Republic Of*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been reported to be associated with a higher bleeding rate than conventional endoscopic mucosal resection. Bleeding is one of the major complications of endoscopic submucosal dissection (ESD). Previous reports focused on patients with symptomatic bleeding. There was no study clarified on the risk factors for early bleeding included patients with asymptomatic bleeding after ESD.

AIMS&METHODS: The aim of this study was to identify the risk factors for early bleeding associated with ESD for gastric neoplasms. This retrospective study was performed in a single tertiary referral medical center. The medical records were retrospectively reviewed 768 lesions in 703 patients who were underwent endoscopic submucosal dissection (ESD) for gastric neoplasm from February 2008 to August 2011. A total of 750 gastric neoplasms in 698 consecutive patients were included in the analysis.

RESULTS: The mean age of the patients was 64.2+10.0 years and 534 (76.5%) were male. The mean size of the resected specimens was 31.1+10.1 mm. The most common longitudinal and horizontal location was lower third (632/750, 84.3%) and lesser curvature (259/750, 34.5%) in included cases. The number of cases who were planned second look endoscopy (SLE) on the next day after ESD (pSLE group) were 576, and the npSLE group (who did not planned SLE) were 174 cases. There were more high occurrence of symptomatic early bleeding (within 24 hours after ESD) in the pSLE group (2.3% vs. 0%, p=0.045). In the pSLE group, early bleeding after ESD occurred in 78 cases (13.5%) including asymptomatic bleeding in 65/78 cases (83.3%). In all cases except for one case of early bleeding, immediate hemostatic therapy was successful. In multivariate analysis, the significant factors predicting early bleeding after ESD were resectecd specimen over 30 mm in size (odds ratio [OR], 1.796; 95% confidence interval [CI], 1.101–2.927) and young age (< 65 years) (OR, 1.692; 95% CI, 1.040–2.753).

CONCLUSION: It seems to be no need planed routine SLE on the next day after ESD in patients with gastric neoplasm However, the SLE on the next day after ESD may be beneficial for selected patients with risk factors of early bleeding such as large resected specimen (>30mm) and young age (< 65 years).

P1246 ARE HIGH DOSE SYSTEMIC STEROIDS EFFECTIVE IN PREVENTING LUMINAL STRICTURES AFTER LARGE ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR OESOPHAGEAL NEOPLASIA?

J. Hochberger[1,*], M. Delvaux[1], E. Kruse[2], J. Huppertz[1], E. Wedi[1]. *[1]Hepatogastroenterology, NHC, UNIVERSITY HOSPITAL OF Strasbourg, Strasbourg, France, [2]Hepatogastroenterology, St Berward Hospital, Hildesheim, Germany*

INTRODUCTION: ESD is effective for treatment of superficial oesophageal cancers. However, circumferential or large ESDs often induce luminal strictures, requiring repeated endoscopic dilations. Recently, literature reports suggested that systemic steroids could prevent such stenoses (Yamaguchi et al. GIE 2011). The aim of the present study was to evaluate the efficacy of systemic steroids in this indication and determine the best daily dose and administration protocole.

AIMS&METHODS: From 11/2009 to 07/2012, all patients referred for treatment of an early oesophageal cancer –squamous cell carcinoma or Barrett adenocarcinoma– were included and distributed over time in 3 treatment groups:

Group A was made of patients treated from 11/2009 to 06/2011, by repeated endoscopic dilation; Group B included patients treated from 07/2011 to 08/2011 who were prescribed oral prednisolone 10-30mg daily for more than 8 weeks; Group C included patients treated after 08/2011 who received IV prednisolone 100-150 mg daily followed by progressive discontinuation for at least 8 weeks. Primary outcome was the need for endoscopic dilations and the number of dilation attempts. Groups were compared by chi2 test.
RESULTS: 28 patients (21 men, 7 women, mean age 64 years) underwent large or circumferential ESD for Barrett early cancer/HG-IEN (n=18) or squamous cell carcinoma/HG-IEN (n=10). In Group A (n=13), a stricture developed in 10 (76.9%) and was treated by dilation. 4 patients (25%) had a temporary stent. In Group B (n=4) on oral prednisolone 10-30mg daily up to 8 weeks, a stenosis occurred in 3 patients (75%) and was treated by dilation. In Group C (n = 13) on oral prednisolone 100-150mg daily up to 8 weeks, no stricture was observed. The incidence of oesophageal stricture was significantly lower in group C as compared to Groups A and B (chi2 = 14.00; P = 0.0002). 3 complications occurred in Group A: 2 aspiration pneumonia and 1 bleeding, all resolving under medical treatment. In Groups B and C, 1 patient had reactivation of pulmonary tubreculosis, 1 a spinal fracture in context of osteoporosis and 15 (88.2%), monilial oesophagitis.
CONCLUSION: Systemic high dose steroids significantly reduced the occurence of strictures after circumferential ESD. Our results show that early high daily doses of steroids are more effective but side effects must be monitored and prevented (diabetes mellitus, osteoporosis, tuberculosis quantiferon test, systematic treatment by Fluconazol). Further evaluations in larger series are needed to validate this therapeutic option.

P1247 COMPARISON OF SUPERFICIAL GASTRIC NEOPLASIA DIAGNOSIS WITH A PROBE BASED CONFOCAL LASER ENDOMICROSCOPY (CLE) BETWEEN GASTROENTEROLOGY FELLOWS AND EXPERT ENDOSCOPISTS WITHOUT ANY CLINICAL EXPERIENCE OF CLE AFTER A BRIEF WEB-BASED TRAINING

K. Sumiyama[1,*], M. Kobayashi[2], M. Ogawa[2], H. Matsui[2], S. Kanba[2], Y. Mizuno[2], N. Tamai[1], T. R. Ohya[1], H. Toyoizumi[2], T. Kato[1], H. Tajiri[2]. [1]*Department of Endoscopy,* [2]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, JIKEI UNIVESITY SCHOOL OF MEDICINE, Tokyo, Japan*

INTRODUCTION: Confocal laser endomicroscopy (CLE) provides real-time histologic images of GI superficial lesions. However, it is surmised that the morphological interpretation of unstable ''super'' magnified images could be challenging especially for beginners. CLE has not been approved for clinical use in Japan yet. Our institution introduced a probe based CLE system for clinical researches in January, 2013.
AIMS&METHODS: Aims of this study were to compare CLE diagnosis of gastric superficial lesions between gastroenterology fellows and expert endoscopists without any clinical experience of CLE . Overall 27 video clips of a probe based CLE images (CellVisio, Maunakea technology, Paris) obtained from 5 patients with 10 adenocarcinomas and 1 adenoma in the stomach were studied. After an approximately 20 min web-based training of the CLE diagnosis (Cellvisio.net) of gastric lesions, demonstratives video clips of CLE obtained from either neoplastic mucosa (n=11) or non-neoplastic background mucosa (n=16) edited by CLE experts were reviewed by blinded 5 gastroenterology fellows and also blinded 5 staff endoscopists without any clinical experience of CLE. The reviewers made diagnosis of neoplasia or non-neoplasia while reviewing every movie clip less than 1 min. The results of the CLE diagnosis were compared with the corresponding histological diagnosis of biopsy specimens sampled from the studied sites.
RESULTS: The accuracy of CLE neoplastic diagnosis between the fellows and the staff endoscopists were not significantly different (85.9% 116/135 vs 88.9% 120/135, p=0.56). Overall Sens, Spec, PPV and NPV were 91.8%, 84.4%, 80.2% and 93.8% respectively. Metaplastic mucosa was misdiagnosed as neoplastic more frequently than non-metaplastic, non-neoplastic mucosa was so (17/80 and 8/80 respectively, p=0.05).
CONCLUSION: The results of this preliminary study conducted in the run-in period demonstrated that the knowledge base for on-site interpretation of mobile gastric CLE images could be established quickly with the brief web-based training regardless of readers' basal endoscopic experiences and pathological knowledge. However, further prospective studies are necessary to elucidate the true accuracy.

P1248 ESOPHAGEAL „OUTLET PATCHES": ENDOSCOPIC, HISTOLOGIC AND ELECTRONMICROSCOPIC DESCRIPTION OF NEW LESIONS (SMALL VESICLES CONTAINING GASTRIC METAPLASIA AND SUBMUCOSAL GLANDS) AT THE GASTROESOOPHAGEAL JUNCTION

K. Monkemuller[1,*], L. C. Fry[1]. [1]*University of Alabama at Birmingham, Birmingham, United States*

INTRODUCTION: The gastroesophageal junction (GEJ) is still an ill-defined, physiologically and pathologically highly active transition zone connecting the esophagus to the stomach. Although several endoscopic and histologic aspects such as the Z-line, cardia, tongues of zylindrical and/or tiny islands of zylindrical epithleium have been well described, we have often observed the presence of small yellow vesicles or tiny submucosal cysts above the Z-line in a significant number of patients. These lesions have not been described in the literature.
AIMS&METHODS: To evaluate the incidence of these lesions and characterize them endoscopically and histolgically.
200 patients were prospectively and consecutively enrolled. The endoscopies were performed using standard and high-definition white light endoscopes with magnification (up to x 110) capability (Olympus, Q160Z, Hamburg, Germany). Histology was performed using H&E. In 10 patients we also performed electron microscopy with magnification up tp 7000x (Phillips, Holland). All potential physiologic and pathologic lesions found in the esophagus and stomach were carefully searched and described for (e.g. inlet patches, glycogenic acanthosis, zylindrical epithelia, gastritis, atrophy, metaplasia, etc). The occurrence of these yellow vesicles was analyzed in the context of these lesions using univartiate and multivariate analysis, Mann-Whitney and Student t-test.
RESULTS: A total 197 were included (102 women and 95 men, mean age 55,5, SD+15) (thrre patiens were excluded). The incidence of yellow vesicles was30% of EGDs. Some lesions had a shape of a . . .volcano'' with zylidrical epithelium on its tip. Their sizes ranged from 3 mm to 10 mm. These yellow vesicles had a significant correlation with zylindrical esophageal epithelium (including Barrett esophagus) (p = 0,009) and inverse correlation with erosive esophagitis (p = 0.024) and female sex (p = 0,011). Histology and elctron microscopy demonstrated submucosal glands and zylindrical epithelium, including pancreatic and gastric metaplasia (the patholgist blinded to the study called these lesions . . .inlet patches'').
CONCLUSION: Yellow vesicles in the distal esophagus are found in 30% of patients undergoing EGD for clinical symptoms. Yellow vesciles are inversely associated with columnar lined epithelium (Barrett esophagus) and positively associated with female sex and less erosive esophagitis, suggesting a protective mechanism tof the GEJ. These lesions contain glands and gastric metaplasia and could be thus considered esophageal . . .outlet patches''.

P1249 MULTIPURPOSE USE OF THE "BEAR CLAW" (OVER-THE-SCOPE-CLIP, OTSC-SYSTEM) TO TREAT ENDOLUMINAL GASTROINTESTINAL DISORDERS

K. Monkemuller[1,*], S. Peter[1], D. Popa[1], J. Ramesh[1], C. M. Wilcox[1]. [1]*University of Alabama at Birmingham, Birmingham, United States*

INTRODUCTION: The ''bear-claw'' or over-the-scope clip system, OTSC (Ovesco Endoscopy, Tübingen, Germany) is a new clipping device developed for closure of large luminal gastrointestinal (GI) defects.
AIMS&METHODS: To evaluate the clinical outcomes of patients treated with the OTSC.
Observational, open-label, retrospective, single-arm case series conducted at two hospitals with tertiary care endoscopy. This study involved 26 clip applications in 22 patients patients (median age 64.3 years [range 28-90 years], 7 women) with GI defects from fistulas and anastomotic dehiscence and peptic ulcer bleeding.
RESULTS: The range of indications included gastrointestinal bleeding (n = 8), gastrocutaneous fistulas (n = 4), esophagotracheal and/or esophagopleural fistulae (n = 3), resection of submucoal tumors (n = 3), gastrocolonic fistulae (n=1), gastro-gastric fistula after gastric bypass (n = 1), stent fixation (n=1), and anastomotic leak after esophagectomy (n=1). The overall success rate for the OTSC device was 76% (17 out of 21 patients). The overall per procedure success rate was 80% (21 of 26 applications). There were no complications (0%) related to endoscopy, sedation or application of the clipping device.
CONCLUSION: The OTSC system is a useful device in a variety of clinical scenarios including the management of larger GI leaks, complex GI fistulas, GI bleeding and stent anchoring, even in very old and frail patients.

P1250 A RETROSPECTIVE STUDY OF THE SALVAGE SURGERY FOR EARLY GASTRIC CANCER UNCURED BY POST ESD PATHOLOGICAL ASSESSMENT

K. Furukawa[1,*], S. Kuwabara[2], H. Hashidate[3], O. Yoneyama[1]. [1]*Gastroenterology,* [2]*Surgery,* [3]*Pathology, NIIGATA CITY GENERAL HOSPITAL, Niigata, Japan*

INTRODUCTION: After many discussions about indication of ESD, it has been revealed that radical resection by ESD is expected up to so-called an extended indication lesion. Although standards of additional resection are based on the guidelines, a case of additional resection is not discussed adequately. Here, we compared each factor for an additional surgery by final diagnosis with pathological findings about additional resection, and examined problems of additional resection as a non-indication lesion by pathologic final diagnosis after ESD.
AIMS&METHODS: From December 2003 to April 2013, there were 957 cases and 1036 lesions which had ESD while aiming at the absolute cure of gastric cancer in our institution. From them, there were the actual additional surgery 79 non-indication lesions, positive stumps in deep part and positive vascular invasions, according to the pathological diagnosis after ESD classified by guidelines for Diagnosis and Treatment of Carcinoma of the Stomach 2004 edition edited by the Japanese Gastric Cancer Society Each factor which had required additional surgery was examined by comparison to the surgical pathology.
RESULTS: The details of target lesions are, as non-indication, (1) cancer deeper than 'sm2'or 'positive vertical stumps': 'sm2' 50 lesions, 'mp' 1 lesion, enclosed

VT(+) 10 lesions. (2) undifferentiated dominant cancer, 'm', over 2cm, sig mixed 1lesion, 'por' mixed 3 lesions, (3) positive vascular invasion: 'ly' single positive 16 lesions, 'v' single positive 7 lesions, 'ly v' co-positive 5 lesions. In the above, the additional surgery specimen for each factor had the local residual (%) of resected area / the positive vascular invasion (%) of local ESD / the positive lymph node metastasis (%); those were (1)5/5/6, (2)25/0/0, (3)0/4.3/8.7. As for (1), it was the vertical margin positive lesion at the time of ESD at 'mp' invasion, and the residual of local resection and 'ly' of the surrounding area of resection were positive. As for (3), one case of advanced stomach cancer complication was included, and there was a possibility of increased positive lymph node ratio.
CONCLUSION: In 'sm2', there is no local residual, there were significantly many cases in which invasion finding could not be obtained from the resected specimens even if they had been the vascular invasion positive at the time of ESD. The indication of additional resection as the definitive diagnosis of ESD needs reexamination, additional resection should be considered with exception for non-indication, and it is preferable to treat them as individual.

P1251 ACETIC ACID CHROMOENDOSCOPY FOR JUDGING THE EXTENT OF GASTRIC INTESTINAL METAPLASIA

K. H. Song[1,*], Y. M. Lee[1], K. C. Huh[1]. [1]*Konyang University, Deajon, Korea, Republic Of*

INTRODUCTION: The diagnosis of gastric intestinal metaplasia is currently possible with the histological assessment of multiple endoscopic biopsies or chromoendoscopy with methylene blue. But, both method is not practical; limited by accessibility or cost-effectiveness.
AIMS&METHODS: The acetic acid (vinigar) chromoendoscopy has not been used for this purpose. Therefore, we wanted to assess the diagnostic accuracy of acetic acid chromoendoscopy for detecting the extent of gastric intestinal metaplasia and interobserver variability of this chromoendoscopy. Consecutive 126 patients were enrolled. The participants underwent screening EGD with 1.5% acetic acid for detection of acetowhitic reactions. And targeting biopsies were performed subsequently at the five standardized intra-gastric locations according to the updated Sydney System. The accuracy of acetic acid chromoendoscopy was evaluated with biopsy report as the reference. Two endoscopists judged the presence or absence of acetowhitic reactions, blinded to the other physician's result.
RESULTS: There was substantial inter-observer agreement between the two endoscopists (k index =0.808, $P<0.01$). The diagnostic accuracy of acetic acid chromoendoscopy was 86.5% and 86.3%, respectively by two endoscopists . The overall sensitivity, specificity, positive predictive value and negative predictive values were 74.6%, 91.7%, 79.9% and 89.1%, respectively. The specificity of gastric body was over 92%. Bile stained gastric muocsa was 1.94(1.06-6.56) fold inaccurate using this chromoendoscopy.
CONCLUSION: The acetic acid chromoendoscopy is a valid tool for evaluating the extent of gastric intestinal metaplasia. It may serve as a practical method to discriminate population with high risk of gastric cancer.

P1252 DEVELOPMENT AND EXPERIENCE WITH USING A PERIPHERALLY INSULATED SCISSOR-TYPE FORCEPS (SB KNIFE)

M. Kobayashi[1,*]. [1]*YOKKAICHI MUNICIPAL HOSPITAL, Yokkaichi-city, Japan*

INTRODUCTION: Although knife-type instruments are primarily used to make incisions during ESD at present, it is necessary to be proficient in the procedure to perform endoscopic procedures simultaneous to electrification and incision. Scissor-type forceps are comparatively easy to manipulate. We have fabricated a scissor-type forceps (SB knife, SUMITOMO BAKELITE CO.) in which the periphery is coated with an insulator, and have used this device in clinical applications.
AIMS&METHODS: The periphery of rotatable monopolar scissors was coated with an insulator, the tips were smoothened and isolated from the electrodes, and only the central electrode portion was allowed to be electrified. Raising the tips and central electrified portion above the level of the base prevented pinching of the muscular layer, and cutting force was enhanced by centralizing the current. In addition, the overall shape is a pean type having a gentle curvature to facilitate penetration of the submucosal layer, and the tip shape is an L-shape having a thick hook on one side to avoid catching the muscular layer with the tip.
RESULTS: This developed scissor-type forceps was used on 98 gastric lesions. Although it was primarily used to detach the submucosal layer, it was also possible to cut away surrounding mucosa. There was no incidental occurrence of muscular layer damage or bleeding observed. The procedure itself was comparatively easy, and was particularly effect at distal sites, sites subjected to strong respiratory fluctuations and sites containing blood vessels where conventional devices encounter difficulties. There was no pinching of the muscular layer observed even if certain parts of the procedure had to be performed blindly due to the smooth shape. Although the procedure was basically performed with an incision wave, at sites containing blood vessels, the procedure was able to be performed with little bleeding by initially inserting a coagulant. There was also little thermal damage to surrounding tissue due to the insulating treatment that included the base of the instrument.
CONCLUSION: This peripherally insulated scissor-type forceps (SB knife) contributed to greater ease of the procedure was determined to be an effective device for ESD.

P1253 CLINICOPATHOLOGICAL PREDICTIVE FACTORS ASSOCIATED WITH LYMPH NODE METASTASIS IN INTRAMUCOSAL EARLY GASTRIC CANCER

M.-D. Xu[1,*], M.-J. He[1], L.-Q. Yao[1], P.-H. Zhou[1], Q.-L. Li[1], W.-F. Chen[1]. [1]*Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

INTRODUCTION: Endoscopic submucosal dissection (ESD) has been introduced as a curative treatment option for early gastric cancer (EGC). However, the potential major limitation of ESD is its disability of sweeping away the lymph node radically. Because lymph node metastasis of EGC is the most important factor that causes recurrence or distal metastasis, how to predict the metastasis, especially in intramucosal gastric cancer, is now becomes the restriction for the widely application of ESD in EGC.
AIMS&METHODS: 498 patients underwent radical gastrectomy and were histologically confirmed intramucosal gastric cancer from June 2006 to October 2011. Retrospectively collected the clinicopathological data of ruled-in patients, including gender, age, location, tumor size, histological type, depth of invasion, presentation of ulceration and vascular invasion. All the patients were divided into positive group or negative group according to the metastasis condition of the lymph node microscopically. Cox univariate and multivariate analysis were applied to determine the independent predictors of lymph node metastasis in EGC.
we aim to investigate the prediction factors of lymph node metastasis in intramucosal early gastric cancer and provide reference for treatment choice of early gastric cancer.
RESULTS: Forty-three of 498 patients (8.6%) had lymph node metastasis. There was no significant difference between positive group and negative group in patient characteristics, tumor location and vascular invasion. According to the multivariate analysis, lymph node metastasis is related to tumor size ($\leq$ 20mm vs. $>$20m and $\leq$30mm vs. $>$30mm; HR (95% CI), 1.525(1.040-2.236); P=0.042), histological type (severe dysplasia with focal canceration vs. well-differentiated adenocarcinoma vs. moderate-differentiated adenocarcinoma vs. undifferentiated adenocarcinoma; HR (95% CI), 1.656(1.158-2.368); $P<0.001$) and depth of invasion (confined into epithelium vs. confined into lamina propria vs. invasion to muscularis mucosae; HR (95% CI), 8.149(1.770-37.513); $P<0.001$). Particularly, no lymph metastasis occurred in 97 cases with lesions confined into lamina propria, no bigger than 20 mm, and well-differentiated.
CONCLUSION: Tumor size, histological type, and depth of invasion were the independent factors for the prediction of lymph node metastasis in EGC. ESD can be adopted as a curative treatment of choice only for the well selected patients.

P1254 AN ASSESSMENT OF FOUR WATER-JET TOOLS IN SUBMUCOSAL CUSHION FORMATION FOR ENDOSCOPIC SUBMUCOSAL DISSECTION

N. Patel[1,*], G.-Z. Yang[1], A. Darzi[1], J. Teare[1]. [1]*Hamlyn Centre, Imperial, LONDON, United Kingdom*

INTRODUCTION: One of the most difficult steps of endoscopic submucosal dissection (ESD) is dissection of a lesion in the submucosal plane. Repeated submucosal cushions are required to allow safe dissection through the submucosa whilst ensuring the muscularis layer remains intact. A submucosal cushion is created by injecting lifting solution (e.g. normal saline) into the submucosal layer. Relatively recently a number of water-jet tools have been introduced making this step quicker, easier and more effective. Four water jet tools are reviewed in this study, the primary outcome is the time required to create a submucosal cushion. Secondary outcomes include the volumes of lifting solution used to create a submucosal cushion and subjective measurements of the four water-jet tools from six endoscopists.
AIMS&METHODS: Simulated gastric lesions were created by marking 2 x 2cm lesions in porcine gastric body and antral specimens. Porcine upper gastrointestinal specimens were placed into a validated endoscopic surgery simulator tray (EASIE-R, ENDOSIM). Six endoscopists used the ERBE Hybridknife, T-type and I-type, Fuijinon Flush Knife and Pentax Splash needle to raise three simulated lesions with each tool. The lifting solution used was a litre of normal saline with 5 millilitres of methylthioninium chloride. Finally, a survey was completed by the endoscopists once they had finished using the four tools.
RESULTS: The average time taken to lift a 2 x 2cm gastric lesion was 3.0 seconds, 2.9 seconds, 3.8 seconds and 4.5 seconds using the Hybridknife, T type, Hybridknife I-type, Flush knife and Splash needle respectively. 5, 4,7 and 5 millilitres of lifting solution were needed to lift lesions using a Hybridknife, T-type, Hybridknife I-type, Flush knife and Splash needle respectively.
The Hybrid knife, I-type was considered the best water-jet tool to use overall by four out of the six endoscopists. Table 1 shows the average Likert scale scores for four qualities of the tool.

	HybridKnife, T-type	HybridKnife, I-type	Flush Knife	Splash Needle
Ease of insertion	4.7	5	4.8	5
Ease of cushion formation	4.2	4.7	3.7	4.2
Quality of cushion formation	4.7	4.7	3.7	4.2
Ease of use of the distal tip	3.8	4.7	3.3	4.5

Table 1: average Likert scores for the four water-jet tools (1 - easiest/fastest,5- most difficult/slowest) for six endoscopists

CONCLUSION: All water-jet tools were shown to create a quick and adequate submucosal cushion. The Hybridknife, I-type was shown to produce the quickest submucosal cushion with the lowest volume of lifting solution and was also deemed to be the easiest to handle generally. Comparison studies in humans are warranted to further review water-jet tools enabling safe and effective ESD.

Disclosure of Interest: None Declared

P1255 THE INTRAGASTRIC BALLOON FOR PRE-OPERATIVE WEIGHT LOSS IN LAPAROSCOPIC GASTRIC BYPASS

N. Veloso[1], S. Pires[1], J. Dinis Silva[1], M. Carvalho[2], R. Senhorinho[2], J. Patrício[2], L. Gonçalves[1], R. Godinho[1], **I. Medeiros**[1,*]. [1]*Gastroenterology,* [2]*Surgery, Hospital Espírito Santo, Évora, Évora, Portugal*

INTRODUCTION: INTRODUCTION: Intragastric balloon (IGB) is indicated as a temporary treatment for weight loss, in super-obese patients (body mass index, BMI $>50Kg/m^2$), who are candidates for bariatric surgery to lose weight and to reduce their surgical and anesthetic risks. We evaluated the potential benefit of preoperative IGB on the outcome of laparoscopic Roux-en-Y gastric bypass (LGB) in super-obese patients.

AIMS&METHODS: Aims & Methods: Retrospective analysis, case-control, of 80 consecutive super-obese patients submitted to a LGB between 2008 and 2012, with preoperative IGB (cases) or without (controls). Clinical success of IGB was defined as a weight loss (WL) $\geq$10%, and clinical success of LGB as an excess weight loss (EWL) $\geq$25%. The anesthetic risk was assessed by ASA physical status classification system. Adverse event was categorized as the need for conversion to laparotomy, hospitalization $>$15days or ICU admission.

RESULTS: Results: 80 patients were included (80% women; average age of 45,7years old), 18 cases and 62 controls. 81,3% presented comorbidity. The initial mean BMI and overweight was $57.4Kg/m^2$ and 84.6kg for cases versus (Vs) $53.1Kg/m^2$ and 71.1kg for controls ($p<0.001$). In case group, the IGB was inserted for a mean time of 191.3 days, obtaining a 100% success in its placement and removal. IGB induced a mean reduction of 9.1 kg/m^2 in BMI, mean WL of 26.4Kg, and EWL of 29%, achieving clinical success in 83.3% and improvement of ASA and comorbidities in 22.2% of cases. The mean time between IGB removal and LGB was 133.8 days, resulting in mean weight gain of 5.4kg. Mean operative time was lower in the cases group (118.94 Vs 142.6 minutes; $p<0,05$). Clinical success of LGB was achieved in 100% of patients without adverse events. The mean EWL on follow-up at 6, 12, 18 and 24 months, in cases Vs controls was: 57.1% Vs 51.9% ($p>0.05$); 55.5% Vs 67.8% ($p<0.05$); 54.2% Vs 70.9% ($p<0.05$); 57.1 Vs 70.9% ($p<0.05$).

CONCLUSION: Conclusion: IGB prior to LGB is a safe and effective temporary treatment for weight loss in super-obese patients, improving comorbidities, reducing anesthetic risk and operative time.

P1256 CHROMOENDOSCOPY WITH METHYLENE BLUE IS A USEFUL TOOL IN THE DIAGNOSIS OF ESOPHAGEAL CANDIDIASIS

P. Rogalski[1], J. Wasielica-Berger[1,*], E. Wroblewski[1], A. Swidnicka-Siergiejko[1], A. Kemona[2], D. Olszanska[3], K. Kaczynska[3], E. A. Tryniszewska[3], A. Dabrowski[1]. [1]*Department of Gastroenterology and Internal Medicine,* [2]*Department of Pathomorphology,* [3]*Department of Microbiological Diagnostics and Infectious Immunology, Medical University of Bialystok, Bialystok, Poland*

INTRODUCTION: *Candida* species are the most common cause of infective esophagitis. Currently, the diagnosis of esophageal candidiasis is based on the endoscopic examination combined with histopathological and/or direct microscopic examination of the specimens taken from pathologically changed areas. Aside from chromoendoscopy, staining with methylene blue (MB) is used to identify fungal structures on microscopic preparations. However, the usefulness of chromoendoscopy with MB in the diagnosis of esophageal candidiasis has not been determined yet.

AIMS&METHODS: Evaluation of the usefulness of endoscopy with MB staining in the diagnosis of esophageal candidiasis.

Patients with suspected candidiasis on the basis of endoscopic examination as well as patients with suspected oral candidiasis with accompanying dysphagia and odynophagia were recruited to the study. All patients underwent endoscopy with two biopsies (for histology and microbiology) taken from suspicious areas prior to staining and two additional biopsy samples obtained from sites positively stained with MB. Direct preparations were stained with Gram's method. Identification of cultured fungi and susceptibility tests were performed on the Vitek analyzer (bioMérieux). Histological preparations were stained using H&E and Grocott's method.

RESULTS: To date 21 eligible patients were enrolled to the study. Among 21 patients with endoscopic suspicion of candidiasis, esophageal candidiasis was confirmed by histology and microbiology in 14 patients (66%). Chromoendoscopy was positive in 19/21 patients. Methylene blue staining was positive in all patients with confirmed candidiasis. In patients with positive chromoendoscopy, in whom candidiasis was not confirmed by histopathology or on the basis of examination of direct microscopic preparations (5/19), *Candida* colonization was confirmed by isolation of fungi. In one patient, the presence of *Candida* colonies has been detected only by means of MB chromoendoscopy and subsequently confirmed by microbiology. In two patients with candidiasis suspected on the basis of classic endoscopy with a negative result of chromoendoscopy esophageal candidiasis was excluded. Fungi were isolated in 76% of cultures of biopsy material taken before staining and in 82% of cultures of biopsy samples taken from stained areas (NS).

CONCLUSION: The preliminary results of our study suggest that chromoendoscopy with MB is a quick and sensitive test confirming endoscopic diagnosis of *Candida* infection or colonization.

P1257 CARDIAC SAFETY OF RADIOFREQUENCY ABLATION IN THE ESOPHAGUS

P. Elbe[1,*], F. Baldaque Silva[1], S. Törnudd[2], T. Jernberg[1], A. Thorell[3], T. Franzén[2], M. Jensen-Urstad[1], L. Lundell[1], H.-U. Marschall[4]. [1]*KAROLINSKA INSTITUTE, Stockholm,* [2]*Vrinnevi Hospital, Norrköping,* [3]*Ersta Hospital, KAROLINSKA INSTITUTE, Stockholm,* [4]*Sahlgrenska University Hospital,, Gothenburg, Sweden*

INTRODUCTION: Radiofrequency ablation (RFA) can be a therapeutic option in the treatment of several medical conditions. It can be used for instance in the treatment of gastrointestinal neoplasia but also in the treatment of atrial fibrillation. RFA has proven to be an effective method for the treatment of neoplastic changes in the esophagus, mainly in Barrett's esophagus (BE), with low complications rate. Some patients may suffer chest pain after esophageal RFA, so the question naturally arises whether esophageal RFA can induce heart injury?

AIMS&METHODS: Consecutive patients who underwent esophageal RFA at 2 tertiary hospitals were included. Blood troponin T and proBNP levels were assessed before and 24 hours after RFA. The delivered energy in the ablations were either 10 or 12 Joule/cm2. Symptoms assessment was performed in each patient at the 24 hours control. Chest pain after treatment was graded as none, moderate or severe.

RESULTS: Twenty one patients were invited to paticipate, being 3 excluded due to incomplete sampling protocol. Eighteen patients were included (15 men), with avarage age of 64.4 years-old. Three patients had a previous history of myocardial infarct. After RFA, 5 patients suffered moderate pain and 1 severe pain. Three patients had a mild increase in the Troponin T level after treatment (5-12 units), being this increase not pathological and not related to chest pain nor to the delivered energy. None of the patients with elevated cardiac enzymes had a history of heart disease.

CONCLUSION: In this prospective study, esophageal RFA did not induce significant cardiac injury in any patient. This can be useful since some patients seek emergency with chest pain after RFA. Cardiac enzymes increase was not pathological in any patient and did not correlate to patients background. RFA in the esophagus seems a safe procedure in terms of cardiac injury.

P1258 THE USE OF TISSUE-ENGINEERED CELL SHEETS TO IMPROVE HEALING AFTER RADIOFREQUENCY ABLATION (RFA) IN THE ESOPHAGUS.

P. Elbe[1,*], E. Jonas[1], J. Enger[1], H. Pettersson[1], M. Kondo[2], S. Sjöqvist[1], N. Kanai[2], T. Ohki[2], M. Yamato[2], T. Okano[2], M. Egami[2], P. Blomberg[1], M. Löhr[1]. [1]*KAROLINSKA INSTITUTE, Stockholm, Sweden,* [2]*Department of Oral and Maxillofacial Surgery, Tokyo Women's Medical University, Tokyo, Japan*

INTRODUCTION: RFA has proven to be a safe method to eradicate Barretťs esophagus. However some patients do not heal properly with squamous cell epithelium after RFA. The patients, sometimes reffered to as "poor healers", are usually patients with long Barretts segments and hiatus hernias. Transplantation of tissue-engineered autologous oral mucosal epithelial cell sheets in the esophagus has shown to be able promotes re-epithelialization of the esophagus after ESD. We wanted to investigate if cellsheets could improve the healing RFA as well.

AIMS&METHODS: The first patient selected was a 71 year old male with a C8M10 Barretís esophagus according to the Prague classification. He had intestinal metaplasia but no dyplasia. 24 hour manometry and pH-metry showed a severe reflux with reduced clearance of the distal esophagus. The second patient was a 72 year old female with initially a 11 cm long Barretís esophagus with recurrent high grade dysplasia (HGD). The patient had previously been treated three times with endoscopic resection (ER) and six times with RFA but did still have four cm long, almost circumferential area with columnar lined epithelium containing HGD but no visible lesion. 24 hour manometry and pH-metry showed mild reflux but hypoperistaltic movements. We collected specimens of oral mucosal tissue from the patients and the epithelial cells were cultured for 16 days on temperature-responsive cell culture surfaces. At the day of the RFA a temperature reduction released the cellsheets that endoscopically transplanted to the raw surfaces. All patients were monitored by endoscopy and confocal microscopy once a week for a four week period.
RESULTS: During the four week period the first patient had complete re-epithelialization. He experienced no dysphagia nor any stricture or other complications. The second patient is just recently treated but so far there has been no complications.
CONCLUSION: Transplantation of tissue-engineered autologous oral mucosa-lepithelial cell sheets in the esophagus after RFA seems topromote re-epithelialization. Further studies are needed to show if this could be a procedure to treat patients with poor healing after RFA.

P1259 ENDOSCOPIC RESECTION OF DUODENAL ADENOMAS : EVOLUTION OF A HYBRID EMR-ESD TECHNIQUE IN 2 UK CENTRES

P. J. Basford[1,*], R. George[2], E. Nixon[2], T. Chaudhry[2], R. Bhattacharyya[1], P. Bhandari[1]. [1]*Gastroenterology, PORTSMOUTH HOSPITALS NHS TRUST, Portsmouth,* [2]*Gastroenterology, Pennine Acute NHT Trust, Rochdale, United Kingdom*

INTRODUCTION: Sporadic duodenal adenomas (SDAs) have traditionally been managed by radical or local surgical resection, but these techniques carry substantial mortality and morbidity risks. Recent series have shown EMR of SDAs to be an effective treatment but with a risk of delayed bleeding within 48 hours. ESD of SDAs carries very high risk of perforation (22-50%).
AIMS&METHODS: All ER procedures for SDAs at both centres for the period Jan 2005 – Dec 2012 were recorded in a prospective database which was analysed. Demographic data, histology, procedure success, long-term outcome and complications were assessed.
RESULTS: 34 patients were identified, of which 18 were male and 16 female. The mean age was 69 years (range 48-87). Mean adenoma size was 25mm (range 6-80mm). The majority of SDAs (71%) were located in the second part of the duodenum. Additional staging investigations (EUS/CT) were performed in 13 of the 34 cases. 21 cases were performed by traditional piecemeal-EMR, 1 by full ESD and 12 by a hybrid EMR-ESD technique combining circumferential mucosal incision by ESD, with en bloc or piecemeal snare resection. En bloc resection was achieved in 50% of cases and adjunctive use of APC was used in 68%. Successful resection was achieved in 97% of cases in a single ER session. Histology showed adenoma with low grade dysplasia in 22 cases and adenoma with high grade dysplasia in 12. There were no cases of invasive malignancy.
Mean duration of follow-up was 38 months. Recurrence of adenomatous tissue was detected in 10 (29%) of cases. This was successfully treated in 8 cases with APC or further ER. One patient is awaiting further treatment and one patient developed an unrelated malignancy and therefore no further treatment is planned.
No perforations occurred in these 2 series. There were 3 episodes (7.5% of ER procedures) of significant late bleeding occurring 1, 12 and 18 days respectively after ER. 2 of the 3 cases required endoscopic therapy to achieve haemostasis. The risk of delayed bleeding was significantly higher following resection of lesions of 30mm or larger compared to those under 30mm (33% vs 0%, P=0.003). Risk of delayed bleeding was not significantly related to ER technique used (EMR = 9.5%, ESD/Hybrid = 7.7%, P=0.855).
CONCLUSION: Endoscopic resection is an effective treatment for duodenal adenomas. Appropriate case selection can be made on the basis of endoscopic assessment without need for EUS/CT. Hybrid ESD-EMR technique is a promising new endoscopic treatment option. There is substantial risk of delayed bleeding which in contrast to other series can occur up to 2-3 weeks after the index procedure.

Demidov Yaroslavl State University,* [7]*Administration, Yaroslavl Regional Cancer Hospital, Yaroslavl, Russian Federation*

INTRODUCTION: HME combined with narrow-band imaging (NBI) provides effective detection and precise characterization of gastric lesions due to the ability of observing microvascular (MV) and microsurface (MS) patterns [1]. However, the diagnostic standards have not been established yet and their clinical application requires a high level experience of medical experts for making a correct diagnosis.
AIMS&METHODS: The aim was to evaluate the diagnostic accuracy of MV and MS criteria for differentiation of neoplastic and non-neoplastic gastric lesions and to create cancer risk assessment system. 128 gastric lesions in 106 patients (mean age 51.3 years, SD=12.1) were observed with HME-NBI (GIF-H190, Q260Z, Q160Z, Olympus endoscopes). MV and MS patterns were assessed independently: regular (RV, RS), irregular (IV, IS), absent (AV, AS) and compared with histology.
RESULTS: From 128 gastric lesions there were 69 with RV+RS, 7 with AV+RS, 11 with IV+IS and 33 with IV+AS. The data are summarized in the table. Combination of RV+RS and AV+RS was found as a low cancer risk group with sensitivity, specificity, positive predictive value and negative predictive value 91.6%, 100%, 100% and 86.5% respectively for non-neoplastic lesions. Combination of IV+IS, IV+AS and AV+IS was found as high-risk group with sensitivity, specificity, positive predictive value and negative predictive value 100%, 91.6%, 86.5%, 100% respectively for neoplastic lesions.
Table. Results of the study

	RV	IV	AV
RS	Benign – 64 (92.8%) LGD – 5 (7.2%)	n.i.	Benign – 4 (57.1%) LGD – 3 (42.9%)
IS	n.i.	LGD – 2 (18.2%) HGD – 3 (27.2%) AC – 6 (54.6%)	Benign – 2 (25%) HGD – 1 (12.5%) AC – 5 (62.5%)
AS	n.i.	Benign – 3 (9.1%) HGD – 2 (6.1%) AC – 28 (84.8%)	n.i.

n.i. – not identified;, benign conditions included chronic gastritis, intestinal metaplasia, hyperplasia; LGD – low-grade dysplasia; HGD – high-grade dysplasia; AC – adenocarcinoma
CONCLUSION: The results of the study showed good correlation of MV and MS criteria with histology. These criteria can be included into cancer risk assessment system for histology prediction and differentiation of non-neoplastic and neoplastic gastric lesions.

P1261 THE EFFICACY AND SAFETY OF 0.4% SODIUM HYALURONATE SOLUTION IN ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASM

S. Kim[1,*], Y. D. Kim[2], J. S. Jang[3], Y. K. Cho[1], J. Lee[2], S. R. Choi[3]. [1]*gastroenterology of internal medicine, Eulji General Hos, Eulji university, seoul,* [2]*gastroenterology of internal medicine, Medical School, Chosun Univerisity, Kwangju,* [3]*gastroenterology of internal medicine, Dong A University College of Medicine, Busan, Korea, Republic Of*

INTRODUCTION: Background: A sufficient amount of submucosal fluid cushion is one of the important requisites for endoscopic submucosal dissection. The ideal injection agent should provide a long lasting submucosal cushion. Sodium hyaluronate produces long lasting mucosal elevation.
AIMS&METHODS: To evaluate the efficacy and safety of sodium hyaluronate solution in endoscopic submucosal dissection for gastric neoplasm. A prospective multicenter randomized, double-blind, controlled trial was designed in this study. A total of 76 patients with 5~20mm sized gastric neoplasms were enrolled at three academic hospitals in Korea from June 2011 to October 2011. Patients were randomly assigned to the 0.4% sodium hyaluronate or control groups. All lesions underwent endoscopic submucosal dissection. Endoscopic submucosal dissection was performed with 0.4% sodium hyaluronate and normal saline solution for submucosal injection. The efficacy was assessed by en-bloc resection and the number of additional injections. The secondary evaluation variables were the

volume of injection material, steepness of mucosal elevation, bleeding rate, procedural time and operator satisfaction. The safety was assessed by analyzing adverse events during the study.
RESULTS: The usefulness rate in 0.4% sodium hyaluronate group and the controlled group was 90.90% and 61.11%, respectively, a statistically significant difference (p=0.0041). Depending upon the secondary evaluation variables, volume of injection material and operator satisfaction differed significantly between groups ($p < 0.05$). The safety of the solution did not differ between the groups (p=0.47).
CONCLUSION: 0.4% sodium hyaluronate solution gives gastric mucosa long lasting lifting compared to normal saline, thereby endoscopic submucosal dissection is more effective compared to the control group. The solution is safe when comparing adverse events to the normal saline group. 0.4% sodium hyaluronate is a useful agent for submucosal injection during endoscopic submucosal dissection.

P1262 RISK FACTORS FOR COMPLICATIONS ASSOCIATED WITH ENDOSCOPIC REMOVAL OF INGESTED FOREIGN BODY IN UPPER GI TRACT

W. S. Kang[1,*], S. W. Chun[1], J. H. Cho[1], H. M. Kim[1], J. S. Choi[1], E. T. Hwang[1]. [1]*Internal Medicine, Myongji Hospital, Goyang-si, Korea, Republic Of*

INTRODUCTION: There are few reports about ingested foreign bodies of upper GI(gastrointestinal) tract. We aimed to investigate the status of foreign bodies in upper GI tract and to determine the predictive risk factors associated with complications of endoscopic removal of foreign bodies.
AIMS&METHODS: Eighty-nine cases with endoscopically confirmed foreign bodies in the upper gastrointestinal tract were retrospectively investigated. A review of the medical records of the patients who underwent endoscopic foreign body removal at Myongji hospital between January 2004 and August 2012 was performed. Patients' demographic data including sex, age and presence of esophageal stricture were collected, and data about foreign body, such as, type, size, sharpness, location of impaction and radio-opacity were investigated. Values associated with endoscopic foreign body removal were duration of foreign body impaction, endoscopic removal duration time, removal method, the presence of complication, hospitalization after the procedure, operation related to endoscopic foreign body removal.
RESULTS: The types of upper gastrointestinal foreign bodies included fish bone (25.8%), food and drug (16.9%), metal (12.4%), stone (12.4%), shell (11.2%). The location of impaction was pharynx (4.5%), upper esophagus (40.4%), mid esophagus (32.6%), lower esophagus (3.4%), stomach (19.1%). The proportions of foreign body size were 42.7% (larger than 3cm) versus 57.3% (smaller than 3cm). Successful endoscopic foreign body removal without operation or endoscopy under general anesthesia was achieved in eighty-five patients. The development of complication after endoscopic removal was 37 cases (41.5%) including laceration with minor bleeding(20.2%), erosion and ulcer (19.1%), perforation (1.1%), abscess (1.1%). There was only one case of massive bleeding after foreign body removal. Cases of operation related to foreign body were 7 cases (7.9%). Multivariate analysis showed that age (HR 1.04, CI 1.01-1.07, p=0.013), size larger than 3cm (HR 3.83, CI 1.25-11.72, p=0.019), sharpness (HR 3.50, CI 1.07-11.40, p=0.038), and longer than 4 hours of duration of impaction (HR 4.61, CI 1.50-14.16, p=0.008) were significant independent risk factors associated with the development of complications in patients with upper gastrointestinal foreign bodies.
CONCLUSION: Fish bone was most common foreign body of upper gastrointestinal tract. Complication rate related to endoscopic foreign body removal was 41.5%, and the risk factor were increased with age, sharpness, larger size (larger than 3cm), and longer duration of impaction time (longer than 4 hours).

P1263 POSTBANDING ULCER HEMORRHAGE AFTER ENDOSCOPIC BAND LIGATION - PREDICTORS OF A RATHER STUDIED ENTITY

T. Pinto-Pais[1,*], S. Fernandes[1], L. Proença[1], C. Fernandes[1], I. Ribeiro[1], A. P. Silva[1], S. Leite[1], L. Alberto[1], J. Fraga[1]. [1]*Gastroenterology Department, CENTRO HOSPITALAR GAIA ESPINHO, Gaia, Portugal*

INTRODUCTION: The endoscopic band ligation (EBL) is the preferred treatment for acute variceal hemorrhage, and also used in primary and secondary prophylaxis. Complications after EBL include esophageal stricture, infection and recurrence of bleeding by postbanding ulcers. Postbanding ulcer hemorrhage (PBUH) is a significant cause of morbidity and mortality, which studies are limited to date.
AIMS&METHODS: AIM: To evaluate the incidence of PBUH in our institution, identify predictors of its occurrence and evaluate the treatment strategies to manage PBUH.
MATERIAL & METHODS: Retrospective analysis of all patients included in an EBL program in our department, for 3 consecutive years. Collected data: demographic, clinical, analytical (CBC, liver function tests, renal and coagulation - calculated scores MELD and Child-Pugh) and endoscopic (urgent/elective indication, number of ligation bands placed at each EBL session) and eventual complications. PBUH was confirmed endoscopically
RESULTS: Included 112 patients, a total of 505 primary prophylaxis sessions (n=37), secondary (n=430) and treatment (n=38) of variceal bleeding. EBL was performed in 40% (n=202), identifying PBUH in 13/202 (6.4%). PBUH occurred more frequently after urgent EBL for active bleeding (n=8) than after prophylactic EBL (n=5), with a mean time period of 9.2 days after the procedure. In comparative analysis, patients who suffered PBUH had lower platelet count and higher MELD and SCP scores, a statistically significant difference ($p < 0,05$). Endoscopic therapeutic performed: EBL (n=5), sclerosis (n=2) and conservative (n=6). There was no 30-day mortality in our patient sample.
CONCLUSION: In our study, postbanding ulcer hemorrhage occurred in 6.4% of cases, most often after EBL for variceal hemorrhage, in patients with advanced liver dysfunction (with higher MELD and Child-Pugh scores).

P1264 DUODENAL BIOPSIES FOR DIAGNOSIS OF COELIAC DISEASE – A 5-YEAR EXPERIENCE

V. Lam[1,*], A. Arnaout[2], S. Gupta[1]. [1]*Gastroenterology Department,* [2]*Histopathology Department, Croydon University Hospital, London, United Kingdom*

INTRODUCTION: Duodenal biopsies are indicated for patients having gastroscopies for anaemia, diarrhoea, weight loss and other autoimmune conditions to diagnose Coeliac Disease (CD). There is a low threshold for taking duodenal biopsies in patients as CD can present with a variety of symptoms and subtle endoscopic appearances. However, there are no large studies to show the efficacy of this practice for diagnosing CD.
AIMS&METHODS: Our study sought to evaluate the diagnostic yield of duodenal biopsies in patients having a gastroscopy and to calculate the cost of analysing tissue samples for diagnosis of CD.
A retrospective study was performed on patients who had endoscopic duodenal biopsies over a 5-year period between 2007 and 2011. Symptoms, serology, endoscopy and histology findings of the abnormal biopsies were collated. An estimate of the pathology cost for diagnosing a patient with CD on biopsy (not including endoscopy cost) was calculated.
RESULTS: Of 4410 duodenal biopsies, 4238 (96%) were normal and 162 (4%) were abnormal. 93 (58%) patients were males (mean age 64, range 18 - 95). Of the abnormal biopsies, 30% were from duodenal bulb and 70% from second part of duodenum. Only 11 (7%) patients were positive for anti-tissue transglutaminase (anti-TTG) and 4 (3%) were positive for anti-endomysial antibody (EMA). On endoscopy, 6 (4%) cases were suspected to have CD. Histology showed non-specific duodenitis in 85%, CD in 13% and ulceration in 3%.
In the CD group, there were 11 males and 10 females, (mean age 61, range 21 – 90). Presenting symptoms were abdominal pain in 9 (43%), diarrhoea in 7 (33%), unexplained gastrointestinal symptoms in 5 (24%), anaemia in 5 (24%), weight loss in 2 (10%) and prolonged fatigue in 1 patient. 6 (28%) were only anti-TTG positive, 5 (24%) were positive for both anti-TTG and EMA, neither test was performed in 4 (19%), 3 (14%) were negative for both and 1 patient was only EMA positive. On endoscopy, duodenum was normal in 9 (43%), 5 (24%) were suspected CD, 1 patient (5%) each had duodenitis and an ulcer, 5 (24%) reports could not be traced. On histology, 9 patients (43%) each were classified as Marsh IIIA, IIIB and 3 (14%) as Marsh IIIC. There was one case each of hypothyroidism and type 1 diabetes. Of the 4410 biopsies, only 21 cases (0.5%) were diagnosed with CD. The cost of analysing and reporting biopsies costs about £50 each thus totalling to £220,500 and averaging £10,500 for diagnosing each case of CD.
CONCLUSION: Taking routine duodenal biopsies at gastroscopy has a low diagnostic yield. It is not a cost effective way of diagnosing CD. Endoscopic duodenal biopsies should be taken if clinical suspicion is high with a negative serology or there are endoscopic findings suggestive of CD.

P1265 EFFICACY OF ENDOSCOPIC VARICEAL LIGATION FOR TREATMENT OF EARLY GASTRIC VARIX BLEEDING.

Y. J. Kim[1,*], K. A. Kwon[1], K. O. Kim[1], J. C. Park[1], Y. K. Jung[1], Y. S. Kim[1]. [1]*Departments of Internal Medicine, GACHON UNIVERSITY OF MEDICINE AND SCIENCE, Incheon, Korea, Republic Of*

INTRODUCTION: Gastric varix (GV) occurs in about 20% of patients with portal hypertension. GV are one of the most serious complications of portal hypertension. Endoscopic variceal obliteration (EVO) and endoscopic variceal ligation (EVL) are commonly used to manage gastric variceal bleeding. The aim of this study is to evaluate the efficacy of EVL compared to EVO for patients with early GV.
AIMS&METHODS: Sixty-nine patients with grade F1 or grade F2 GV were enrolled between June 2006 and May 2012. We retrospectively reviewed patient's medical records. Nineteen patients underwent EVO and fifty patients underwent EVL. Rebleeding was defined as newly-development hematemesis, hematochezia, melena, or endoscopically proven bleeding. Kaplan-Meier method and Cox regression analysis were used to examine the efficacy of EVL.
RESULTS: During follow-up period, rebleeding has occurred in eleven patients (4 EVO and 7 EVL) and twenty-five patients have died (5 EVO and 20 EVL). The median event-free survival for EVO and EVL were 248 (range 2~2105) and 458 (range 1~2179) days, respectively (p=0.332). The median overall survival were 368 (range 6~2195) and 647 (16~2179) days, respectively (p=0.360).

CONCLUSION: There were no differences in efficacy between EVO and EVL for treatment of grade F1 or F2 GV with bleeding. Further prospective, large-scale studies are needed.

P1266 DEVELOPMENT OF NEW TECHNIQUE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION USING CARBON DIOXIDE LASER

Y. Morita[1,*], H. Kutsumi[1], T. Azuma[1]. [1]*Kobe University, Kobe, Japan*

INTRODUCTION: Recently, endoscopic submucosal dissection (ESD) has increasingly been applied as a less-invasive treatment method for early gastrointestinal cancers. In ESD procedure, a solution such as saline and sodium hyaluronate solution is injected into the submucosa layer to lift the lesion and to avoid the risk of perforation. However, the process of ESD using electrosurgical knives is highly skilled and has a risk of perforation because of unexpected incision for muscularis propria. On the other hand, carbon dioxide (CO_2) laser with a wavelength of 10.6 μm is suitable for incision, coagulation, ablation, and hemostasis of soft tissues and has widely been used in clinical treatments. Furthermore, CO_2 laser has the character in which water is easy to be absorbed.
AIMS&METHODS: To assess the feasibility of ESD using CO_2 laser in porcine model.
A porcine stomach was used as a sample for an *in-vitro* experiment of safe ESD. A carbon dioxide laser (J. MORITA Mfg. Corp.) with a wavelength of 10.6 μm was delivered to the sample with a hollow optical fiber with an inner diameter of 700 μm. The carbon dioxide laser was operated in the continuous wave mode, and the output power from the hollow optical fiber was up to 15 W. The laser was irradiated normal to the surface of mucosa from a distance of 2 mm.
RESULTS: Although perforation was observed without submucosal injection, the muscle layer was not damaged when saline was injected into the submucosa in spite of the same laser irradiation condition.
CONCLUSION: In these studies, ESD using CO_2 laser with submucosal laser absorber may be feasible and safe methods for the treatment of early gastrointestinal tumors. Further results including *in-vitro* experiments of submucosal dissection and *in-vivo* laser ESD experiments will be presented at the conference.

P1267 THE FREQUENCY AND CLINICAL CHARACTERISTICS IN THE CARCINOMA DERIVED FROM SESSILE SERRATED ADENOMA/ POLYP (SSAP).

A. Chino[1,*], N. Yamamoto[2], T. Kishihara[1], N. Uragami[1], Y. Tamegai[1], M. Igarashi[1], Y. Kato[2]. [1]*division of gastroenterology,* [2]*pathology, Cancer institute hospital, Tokyo, Japan*

INTRODUCTION: New classification to sessile serrated adenoma/polyp (SSAP), traditional serrated adenoma (TSA), classical hyperplastic polyp (HP) was proposed in serrated polyps (SPs) from WHO 2010. SSAP come to be recognized as neoplasm having malignant potential such as serrated neoplastic pathway, more overe suspected as the prodromal lesion of MSI-H colon cancer so that it is concerned about having high malignant potential. However, since changing pathological classification there are few reports in the frequency of the carcinoma derived from SSAP.
AIMS&METHODS: This study is clinical examination about the frequency in the carcinoma derived from SPs and is going to compare with coexisted cancer with CAD. In our hospital during the period from March 2005 to December 2011 cases were removed by endoscopic resection and diagnosed SSAP or TSA or HP, there were 1,673 lesions. The indication of endoscopic treatment for colorectal tumors is the neoplastic lesion more than 5mm, in other words including the lesion in proximal or the large size lesion even if it is diagnosed classical HP by endoscopy. In the way of endoscopic resection we assumed polypectomy and mucosal resection (EMR) but deleted the case by hot biopsy or only biopsy forceps. The extracted lesion was reevaluated to of each SPs with new classification by one pathological leader. Characteristic histological features of SSA/P recognized the crypts showed dilation, serration, irreguraly branching and horizontally arranging(L-shaped, inverted T-shaped or anchor shaped) at the base. Moreover, the mixed lesion which included different SPs more than two kinds was omitted. And we examined the frequency of coexisted cancer with CAD into all of the CAD lesion resected during same period.
RESULTS: The total number of extracted lesion and coexisted early cancer is following that, in HP extracted lesions is 1,001 and coexisted cancer with HP is one (0.1%), in SSAP is 492 and coexisted cancer with SSAP is five (1%), in TSA is 180 and coexisted cancer with TSA is two (1%), in CAD is 18,683 and coexisted cancer with CAD is 1,146 (6%), respectively. In cancer coexisted with SSAP there was no significant difference about gender and age (average; 68-year-old), the median of the tumor diameter is 17 SD8mm (SD; standard deviation), all five cases recognized in proximal colon.
CONCLUSION: This examination in the malignancy such as progress speed was not included and it was only for early colorectal cancer, however, in practically resected lesion during the same period that frequency of coexistence cancers with SSAP was 1% it was lower than frequency for 6% of CAD and was rare with 0.1% in the HP.

P1268 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION FOR SUBMUCOSAL INVASIVE COLORECTAL CARCINOMA.

A. Ono[1,*], K. Ohata[1], Y. Tsuji[1], N. Matsuhashi[1]. [1]*NTT Medical Center Tokyo, Shinagawa-Ku, Japan*

INTRODUCTION: Endoscopic resection (ER) for early colorectal carcinoma has been recently performed more and more often. However, only little is known about treatment outcomes of ER for submucosal(SM) invasive colorectal carcinoma.
AIMS&METHODS: The aim of this study is to evaluate clinical outcomes of ER for SM invasive colorectal carcinoma(CRC). We checked electronic medical chart and extracted data on ER for SM CRC at NTT Medical Center Tokyo. Our treatment strategy followed Japanese colorectal cancer treatment guideline. Meeting all the following conditions means no need for additional operation after ER: SM invasion $< 1000\mu$m, budding grade 1 or 2, marginal involvement negative, and no lymphatic or vascular invasion. We collected data on patients' characteristics and pathological features of resected cancers, and investigated clinical courses.
RESULTS: From January 2000 through September 2012, ER was carried out for 138 SM cancers at our institution. 77 cases (55%) were followed up without additional treatment (44 males, 33 females, mean age 66.1yr), and 61 cases(45%) were performed additional treatment after ER. We next investigated 77 follow-up cases. 46 cancers were in colon and 31 were in rectum . macroscopic types were 38 protruded tumors and 39 laterally spreading tumors. Out of 77 cases without additional treatment after ER, 61 cases met guideline criteria, and as to the 61 cases there was no recurrence during follow-up period (47 ± 14.2 mths). 16 cases were outside the guideline criteria (13 lesions were $>$ SM 1000μm, 10 lesions were budding grade3, 3 lesions were positive margin, 5 lesions were lymphatic or vascular invasion, overlapped), but additional treatment was not performed. The reasons for not performing additional treatment were the risk of operation (4 cases), and patients' rejection (9 cases). Out of the 16 cases, 2 cases of recurrence (1 local recurrence/1 liver metastasis) occurred during follow-up period (42 ± 28.6 mths). 1 local recurrence subject developed multiple lymph node and liver metastasis rapidly, and 1 liver metastasis subject died 22month after ER.
CONCLUSION: In our study, as to SM CRC, outside the Japanese guideline criteria, recurrence occurred at a rate of 12.5 %. Once tumor recurrence happened, it is very difficult to control disease progress. So we must be careful when we choose not to perform additional treatment after ER for CRC with SM invasion $> 1000\mu$m.

P1269 PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY IN COLONOSCOPIC SURVEILLANCE OF PATIENTS WITH PSC-IBD.

A. Dlugosz[1,*], A. Barakat[1], A. Ost[2], A. Bergquist[1]. [1]*dept. of Gastroenterology and Hepatology, KAROLINSKA INSTITUTET,* [2]*dept. of Pathology, Karolinska University Hospital, Stockholm, Sweden*

INTRODUCTION: Primary sclerosing cholangitis related inflammatory bowel disease (PSC-IBD) represents a specific phenotype characterized by extensive colitis, low inflammatory activity, right-sided and patchy colonic inflammation and a high risk of cancer. Surveillance colonoscopies with targeted and random biopsies for detection of premalignant lesions have doubtful efficiency and are time-consuming
AIMS&METHODS: . The aim of the study is to evaluate the efficacy of probe-based Confocal Laser Endomicroscopy (pCLE) as a complement to high definition endoscopy (HDE) for the detection of colonic dysplasia in patients with PSC-IBD.
Methods: Twenty-five patients with PSC-IBD underwent colonoscopy in two steps. On the way from rectum to caecum the mucosa was evaluated with HDE with random biopsies taken according to the routine standards. On the way from caecum to rectum fluorescein-enhanced pCLE was performed and biopsies of all macroscopic and microscopic lesions were taken. All regions, where random biopsies were taken, were also examined with pCLE. Three investigators, blinded to histology and endoscopy, analyzed all pCLE videos.
RESULTS: PCLE revealed crypts irregularity in 70/243 biopsied regions and dysplasia suspected lesions in 13/70 biopsies. Histology confirmed the presence of low-grade dysplasia in 8/13 cases. Sensitivity, specificity and kappa index of pCLE versus histology in detecting dysplasia were 100%, 45% and 1.0 and in detecting crypts irregularity 90%, 100% and 0.922. The kappa index for HDE versus histology was 0.861 for dysplasia and 0.549 for crypts irregularity.
CONCLUSION: pCLE in PSC-IBD surveillance has high diagnostic accuracy that is superior to HDE alone. Future studies need to evaluate if real-time pCLE could replace random taken biopsies in PSC-IBD surveillance.

P1270 PATIENT-CONTROLLED SEDATION DURING COLONOSCOPY: RESULTS FROM A PROSPECTIVE RANDOMIZED CONTROLLED STUDY.

A. Ouakaa-Kchaou[1,*], D. Gargouri[1], H. Jaoua[1], D. Trad[1], H. Elloumi[1], N. Bibani[1], A. Kochlef[1], K. Ben Fadhel[1], J. Kharrat[1]. [1]*HABIB THAMEUR HOSPITAL, Tunis, Tunisia*

INTRODUCTION: Propofol is often associated with deep sedation and decreased maneuverability, so that, in Tunisia, sedation for colonoscopy is usually limited to intolerant patients. Patient-controlled sedation (PCS) with propofol has been advocated as a method for dealing with the narrow therapeutic window for moderate sedation, and is gaining increasing popularity for gastrointestinal endoscopy. This study was carried out to determine the feasibility, effectiveness and safety of PCS during colonoscopy.
AIMS&METHODS: Sixty American Society of Anesthesiologists (ASA) physical status class I to II adults, aged from 18 to 80, scheduled for elective colonoscopy were enrolled. Patients were prospectively randomized to receive either target-controlled infusion (TCI control group, n=30) or patient-controlled sedation (PCS group, n=30). Patients in the PCS group were connected to an infusion pump containing propofol and self-administered 10-mg boluses as often as they required. In the TCI group, sedation was initiated with propofol to obtain an effect-site concentration (Ce) of 1μg/ml. An anesthetist was present throughout the procedure. Primary endpoints included patient satisfaction and level of sedation according to the OAA/S scale. Other outcome measures assessed were clinician satisfaction, oxygen desaturation and patient recovery time.
RESULTS: During the study period, 234 patients underwent elective colonoscopy, 60 of them were eligible and were asked to participate in the study. All of them gave their informed consent and were prospectively randomized. The patients' mean satisfaction scores were not statistically different between the two groups. Clinician satisfaction was greater with PCS. Mean doses of propofol (0.072 vs. 0.128 mg/Kg/min; $p < 0.0001$), depth of sedation (4.58 vs. 3.97; $p < 0.001$) and time before discharge were significantly lower for patients in the PCS group. There were no statistically significant differences between the two groups regarding oxygen desaturation, duration of colonoscopy (26.46 min in the PCS group vs. 22.83 min in the control group) difficulty and therapeutic procedures (biopsy or polypectomy).
CONCLUSION: PCS with propofol is an effective and very well accepted form of sedation for coloscopy. However, combining patient-maintained sedation with target-controlled infusion could be the best technique.

P1271 COLD BIOPSY VS. COLD SNARE FOR THE RESECTION OF DIMINUTIVE AND SMALL COLORECTAL POLYPS: PRELIMINARY RESULTS

J. S. Kim[1], B.-I. Lee[1,*], H. Choi[1], E. S. Park[1], K.-M. Lee[2], S.-W. Kim[3], K. Y. Choi[3]. [1]*Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon,* [2]*St. Vincent Hospital, The Catholic University of Korea, Suwon,* [3]*Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of*

INTRODUCTION: There are several endoscopic techniques for treating diminutive and small polyps; however the optimal technique for removing these polyps is unknown.
AIMS&METHODS: This study was perfomed to compare the complete resection rate, complication rate, and tissue retrieval rate of cold biopsy polypectomy (CBP) versus cold snare polypectomy (CSP) for diminutive and small colorectal polyps. The patients with colorectal polyps 7 mm or smaller were randomly allocated to either CBP or CSP group. In CBP group, polyps were removed by the biopsy forceps until no residual tissue was observed. In CSP group, polyps were resected using the mini oval snare without electrocautery. Thereafter, in both groups, the base of the polypectomy site was excised with a 1-2 mm clear margin using EMR technique. After the EMR specimen was fixed on a plate, the most probable residual portion was marked with a pen under stereoscopy. Then the marked portion was cut into sections for histologic evaluation of incomplete resection.
RESULTS: A total of 101 polyps in 96 patients were removed by CBP (n=52) and CSP (n=49), and 85 (84.2%) of the polyps were adenomas. The incomplete resection rate of CBP and CSP for adenomas was 10.9% and 5.1%, respectively (P=0.445). In subgroup analysis, the incomplete resection rate of CBP and CSP for adenomas 5 mm or smaller was 2.8% and 3.4% (P=1.000) while the incomplete rate of CBP and CSP for adenomas 6-7 mm was 40.0% and 10.0%, respectively (P=0.303). A case of delayed bleeding occurred in each group; however the association between the bleeding and the polypectomy could not be concluded because additional EMR was performed for the polypectomy site. Tissue retrieval failure rate of CBP and CSP was 0.0% and 6.1%, respectively (P=0.111).
CONCLUSION: Cold snare tends to be superior to cold biopsy for complete resection of adenomas 6-7 mm in size. For adenomas 5 mm or smaller, complete resection rates of the two methods were comparable. Cold snare polypectomy may be associated with more tissue retrieval failure. Additional study results from more patients will be followed. (NCT01665898)

P1272 A META-ANALYSIS OF COLON CLEANSING WITH PEG COMPARED TO OTHER BOWEL PREPARATIONS.

C. Menard[1,*], A. Barkun[2,3], M. Martel[3], S. Restellini[4], O. Kherad[5]. [1]*Medicine, University of Sherbrooke, Sherbrooke,* [2]*Epidemiology and Biostatistics and Occupational Health, McGill University Health Center, McGill University,* [3]*Gastroenterology, McGill University, Montreal, Canada,* [4]*Internal Medicine and Rehabilitation and Geriatric, Geneva's University Hospitals and University of Geneva,* [5]*Internal Medicine, Tour Hospital and University of Geneva, Geneva, Switzerland*

INTRODUCTION: Different regimens of colon preparation are available for colonoscopy, they primarily include polyethylene glycol (PEG), sodium phosphate (NaP), picosulfate (PICO) or oral sulfate solution (OSS).
The objective of this meta-analysis is to evaluate the efficacy, safety and patient satisfaction of PEG versus any comparator, NaP, PICO, and OSS.
AIMS&METHODS: Systematic searches were completed querying MEDLINE, EMBASE, Scopus, CENTRAL and ISI Web of knowledge from January 1980 to September 2012. All fully published randomized controlled trials with colon preparation for colonoscopy were included. Populations including pediatric, sole inpatients or sole IBD patients were excluded. The primary outcome measure was the efficacy (excellent/good) of colon cleansing. Secondary outcomes included side effects or complications, procedural outcomes and patient satisfaction.
A meta-analysis was conducted with results reported as odd-ratios (OR) with 95% confidence intervals. Heterogeneity and publication bias were assessed and quantified.
RESULTS: From an initial 2033 citations, 68 trials fulfilled the inclusion criteria (15262 patients). When PEG was compared to all types of colon preparations, it did not show a significant difference in efficacy; OR(random)=1.15(0.92;1.44). Willingness to repeat was lower in the PEG group OR(random)=0.48 (0.29;0.22) as was fainting or dizziness OR(random)=0.76 (0.59;0.98), Headaches were increased with PEG; OR(fixed)=1.33 (1.01;1.74). Forty-seven trials included the comparison PEG versus NaP (10795 patients); PEG did not show a difference in efficacy; OR(random)=0.90(0.67; 1.20); willingness to repeat was decreased; OR(random)= 0.36(0.20; 0.64) as well as fainting or dizziness OR(fixed)=0.63(0.49;0.80). Six trials included the comparison PEG versus PICO (1208 patients). PEG did not show a difference in efficacy; OR(random)=1.03(0.43;2.48). Fainting or dizziness was decreased in the PEG group OR(fixed)=0.63(0.49;0.80). Two studies compared PEG to OSS. PEG was not different in efficacy; OR(random)= 0.74(0.47,1.15).
CONCLUSION: PEG provides similar bowel cleansing efficacy to different types of colon preparations. Willingness to repeat was significantly lower with PEG when compared to all types of preparation and NAP. With PEG, more patients reported headaches but less experienced fainting or dizziness compared to all types of preparations, NaP, and PICO.

P1273 A META-ANALYSIS OF SPLIT VERSUS NON-SPLIT COLON PREPARATIONS

M. Martel[1], A. Barkun[1,2], C. Menard[3,*], O. Kherad[4], S. Restellini[5]. [1]*Division of Gastroenterology,* [2]*Epidemiology and Biostatistics and Occupational Health, McGill University Health Center, McGill University, Montreal,* [3]*Medicine, University of Sherbrooke, Sherbrooke, Canada,* [4]*Internal Medicine, La Tour Hospital and University of Geneva,* [5]*Internal Medicine and Rehabilitation and Geriatric, Geneva's University Hospitals and University of Geneva, Geneva, Switzerland*

INTRODUCTION: Different regimens of colon preparation are available for colonoscopy, they primarily include polyethylene glycol (PEG), sodium phosphate (NaP), picosulfate (PICO) and oral sulfate solution (OSS).
The objective is to evaluate the efficacy, safety and patient satisfaction of split versus non-split regimens for the same comparator and across all preparation and amongst a same type; split versus non-split PEG, split versus non-split NaP, split versus non-split PICO, and split versus non-split OSS.
AIMS&METHODS: Systematic searches were completed querying MEDLINE, EMBASE, Scopus, CENTRAL and ISI Web of knowledge from January 1980 to September 2012. All fully published randomized controlled trials with colon preparation for colonoscopy were included. Populations including pediatric, sole inpatients or sole IBD patients were excluded. The primary outcome measure was the efficacy of colon cleansing. Secondary outcomes included side effects or complications, procedural outcomes and patient satisfaction.
A meta-analysis was conducted with results reported as odd-ratios (OR) with 95% confidence intervals. Heterogeneity and publication bias were assessed and quantified.
RESULTS: From an initial 2033 citations, 16 trials fulfilled the inclusion criteria for split dosing (4253). Compared to the latter, split-dose regimen significantly increased efficacy OR(random)= 4.08(2.86;5.82), willingness to repeat OR(random)=1.95(1.11;3.45), fainting or dizziness OR(fixed)=1.86(1.14; 3.03), and perianal irritation OR(fixed) = 2.39(1.35; 4.22). Eleven trials compared split versus non-split PEG (2971 patients). Efficacy was increased in the split PEG group OR(random)=3.88 (2.47;6.10), whereas nausea or vomiting was lower OR(random)=0.65 (0.52;0.81). Four trials compared split NaP versus NaP (1046 patients). Efficacy was significantly increased with split NaP OR(random)= 3.22(2.06;5.03); willingness to repeat was increased: OR=2.38(1.07,5.33) as well as fainting or dizziness OR=2.59(1.37,4.87), headache=2.49 (1.30,4.75) and perianal irritation OR=2.65(1.43,4.89). One trial

compared split versus non split PICO (236 patients), efficacy was increased with split PICO; OR=8.00(3.40,18.81). No trial with head-to-head comparison for split versus non-split OSS is currently published.
CONCLUSION: Split dosage regimen increase the quality of colon cleansing across all type of preparation with, in the case of PEG, improved symptoms and is the preferred method.

P1274 OPTIMAL TREATMENT OF PERFORATION DURING COLONOSCOPY : A REVIEW OF 46,138 PATIENTS

D. K. Shin[1,*], S. P. Hong[1], P. W. Park[1], K. H. Ko[1], C.-I. Kwon[1], W. H. Kim[1], Y. H. Cho[1]. [1]*Division of Gastroenterology, Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Korea, Republic Of*

INTRODUCTION: In the past, patients with colonoscopic perforation have been treated surgically, but surgery was associated with significant morbidity and mortality. These days, conservative treatment including endoscopic clip closure or laparoscopic repair has been used to treat colonoscopic perforations. Colonoscopic perforation represents one of the most frequent causes of malpractice claims for endoscopy. Choice of effective and less invasive treatment may reduce claims.
AIMS&METHODS: This study aimed to suggest the guideline for choosing optimal treatment of perforations that occurred during colonoscopy by analyzing our institutional data.
We conducted a retrospective review of medical records of patients who had been treated for colonoscopic perforation from January 2004 to March 2013 at Bundang CHA hospital in Korea.
RESULTS: A total of 46,138 patients underwent either a diagnostic or therapeutic colonoscopy procedure. A total of 35 (including 12 referred patients from outside institution) patients were treated due to colonoscopic perforation. The overall perforation rate was 0.05%. Most common perforation sites were sigmoid colon (40%) and rectum (17%). Twenty patients underwent surgery for perforation (13 laparotomy, 7 laparoscopic surgery) and fifteen patients underwent medical treatment (9 conservative, 6 endoscopic clip closure). Conservative treatment was safe in patients who had microperforation and were hemodynamically stable with or without peritoneal irritation sign on examination. Endoscopic clip closure was successful if perforation size was less than 10mm and patients had no aggravation of peritoneal irritation. Among the patients who underwent surgery, there were no significant differences in duration of fasting (4 vs. 6 mean days), perforation size (7 vs. 15 mean mm), the length of time from diagnosis to operation (3 vs. 4 mean hours) and mortality (0) between laparoscopic surgery group and laparotomy group. But, the length of hospital stay was significantly short at laparoscopic surgery group (8 vs. 14 mean days, p=0.006). No perforation-related major morbidity or mortality occurred in both conservative group and surgical group.
CONCLUSION: Conservative treatment including endoscopic clip closure may be effective if perforation size is small (microperforation or less than 10mm) and patients are hemodynamically stable regardless of peritoneal irritation sign. Otherwise, surgical treatment is recommended. Especially, laparoscopic surgery seems superior to laparotomy in hospital stay with non-inferior outcomes.

P1275 FACTORS AFFECTING THE CHARACTERISTICS OF COLORECTAL ADENOMA IN DIABETIC MELLITUS

D. W. Choi[1], S. C. Park[1], K. R. Lim[1,*], J. Kim[1], D. H. Choi[1], C. D. Kang[1], S. J. Lee[1]. [1]*Internal Medicine, Kangwon National University Hospital, Chuncheon, Korea, Republic Of*

INTRODUCTION: It has been reported that type 2 diabetes mellitus (DM) is associated with higher relative risk for colorectal cancers. Hyperinsulinemia associated with DM may lead to carcinogenesis through increased level of insulin-like growth factor-1.
AIMS&METHODS: The aim of this study is to evaluate the factors affecting the incidence of colorectal adenoma known as precancerous lesion in diabetic patients.
We retrospectively analyzed the data of patients who have type 2 DM and had a colonoscopy from august 2008 to august 2012. After having a colonoscopy, patients were divided into 2 groups with or without colorectal adenoma by pathologic findings and then the data from the both groups were analyzed by multivariate logistic regression analysis. The cases of incomplete study, familial polyposis, inflammatory bowel disease, prior colon cancer and other malignancy were excluded.
RESULTS: 72 patients were excluded in 383 enrolled patents from the study by exclusion criteria and the adenomas were found in 134 patents (43%). Higher incidence of adenoma was shown in the males (odds ratio=1.950, 95% CI 1.021-3.724, p=0.043) in multivariate analysis. Sulfonylurea was significantly related to the more than 10 mm sized adenoma (odds ratio=2.883, 95% CI 1.056-7.871, p=0.039). There was no relationship between the level of HbA1c and colorectal adenoma incidence.
CONCLUSION: The incidence of colorectal adenoma was higher in the male diabetic patients. The users of sulfonylurea showed a tendency to have a large colorectal adenoma. Further evaluation with more patients will be needed.

P1276 MULTICENTRIC AND PROSPECTIVE EVALUATION OF LARGE COLORECTAL ENDOSCOPIC MUCOSAL RESECTION (EMR) AND POLYPECTOMY FOR PATIENTS UNDER CHRONIC ASPIRIN THERAPY: THE "OPERA" STUDY

G. Vanbiervliet[1,*], T. Barrioz[2], P. Bulois[3], B. Nalet[4], C. Subtil[5], S. Chaussade[6], J. Filippi[7], M. Barthet[8], F. Cholet[9], M. LeRhun[10], G. Medinger[11], C. Boustière[12], B. Napoléon[13], J.-C. Saurin[14], T. Ponchon[14], OPERA Group study. [1]*Endoscopy, CHU NICE, Nice,* [2]*CHU Poitiers, Poitiers,* [3]*Hôpital Saint Philibert, Lille,* [4]*CH Montelimar, Montelimar,* [5]*CHU Bordeaux, Bordeaux,* [6]*AP-HP Cochin, Paris,* [7]*CHU NICE, Nice,* [8]*AP-HM Nord, Marseille,* [9]*CHU Brest, Brest,* [10]*CHU Nantes, Nantes,* [11]*CH Vendée, La Roche Sur Yon,* [12]*Hôpital Saint Joseph, Marseille,* [13]*Hôpital Mermoz,* [14]*Hospices Civils E. Herriot, Lyon, France*

INTRODUCTION: ESGE guidelines allow continuation of aspirin for polypectomy but not for EMR. The aim of the study was to evaluate the risk of bleeding after large colorectal EMR/polypectomy for patients under chronic aspirin therapy.
AIMS&METHODS: This was a multicentric and prospective study conducted from Jan 2010 to Oct 2012. Patients with high thrombotic risk under aspirin were included when colorectal EMR/polypectomy was scheduled. Patients using others anti platelets agents, anti coagulation, presenting disorders of coagulation/hemostasis, liver or renal insufficiency were excluded. The technique of resection was standardized. Preventive mechanical (loop, hemoclip) methods were allowed. Aspirin was also continued the day of procedure. The main objective was to determine the rate of delayed (DPB) and severe (SPB) colorectal post EMR/polypectomy bleeding. Secondary endpoints were to evaluate the incidence of immediate bleeding, the effectiveness of endoscopic hemostasis, the morbi/mortality induced and to identify predictive factors of bleeding. The follow-up was clinical during one month.
RESULTS: A total of 570 lesions were treated among 317 patients included in the study (248 men, mean age 68.8 ± 10.3 years [34-90]). Technique of resection was EMR (55%) or polypectomy (45%) using a piecemeal approach in 19% of cases. Mean size of polyps was 12.3 ± 10.2 mm [1-70] with 191 lesions (33.5%) ≥ 15 mm. Preventive mechanical techniques were used in 25% of cases. The immediate bleeding rate per patient was 9.7% (37/317) and per lesion 5.6% (37/570). The rate of DPB per patient was 1.9% (6/317) and per lesion 1% (6/570). The rate of SPB per patient was 5.6% (18/317) and per lesion 3.1% (18/570). In all cases of hemorrhage the endoscopic hemostasis was efficient except in an immediate one requiring surgery (technical success of 98%). Mean time of delayed bleeding occurence was 4.7 ± 3.8 days [1-10]. Blood transfusion and hospitalization (mean duration of 2.4 ± 2.3 days [1-10]) were required in 1.5% and 5% of cases respectively. No fatal evolution was recorded.
CONCLUSION: Immediate, delayed and severe bleeding risk after colorectal large EMR/polypectomy are low and acceptable.

P1277 HIGH DEFINITION PLUS COLONOSCOPY WITH I-SCAN VS STANDARD COLONOSCOPY: A RETROSPECTIVE STUDY OF A SINGLE CENTRE

G. De Roberto[1,*], G. Fiori[1], D. Tamayo[1], A. de Leone[1], D. Ravizza[1], C. Trovato[1], I. Bravi[1], C. Crosta[1]. [1]*Division of Endoscopy, EUROPEAN INSTITUTE OF ONCOLOGY, Milan, Italy*

INTRODUCTION: Colonoscopy is widely considered the gold standard for the detection of colorectal cancer and adenomatous lesions.
AIMS&METHODS: The aim of this retrospective study was to compare high-definition plus (HD+) colonoscopy (series EC-3890Fi, Pentax Ltd., Tokyo, Japan) with i-Scan functionality (electronic staining) vs. standard definition white-light colonoscopy (SDWL- series EC 380 FKp/EC 3885 FK/EC 3890 FK, Pentax Ltd., Tokyo, Japan). Adenoma detection rate was the primary endpoint, whereas the total number of polyps detected and number of patients with at least one hyperplastic lesion were the secondary endpoints. All the patients were referred for a screening colonoscopy within colon cancer screening program (based on Immunochemical Fecal Occult Blood Tests), for individual positive occult blood test and for individual prevention. All the colonoscopies were performed by five expert endoscopists.

RESULTS: A total of 2856 patients were included (1470 F/1386 M; median age 60 years) who underwent their first colonoscopy from January 2006 to December 2011; 1305 received HD+ colonoscopy and 1551 received SDWL colonoscopy. Number of procedures performed and proportion of each imaging technique used were not significantly different among endoscopists. Detected colorectal lesions were classified according to Paris classification and divided as follows: 0-5 mm, 6-9 mm, 10-19 mm, ≥20 mm. For each lesion, histological diagnosis was collected. The detection rate of any size adenoma and the total number of polyps detected were not significantly different between HD+ and SDWL, being 46 % vs 50% (p= 0.2) and 1799 vs 2731 (p= 0.9), respectively. However, the detection of IIb type lesions was higher with HD+ compared to SDWL (0.66% vs 0.14%, $p<0.05$); conversely the number of patients with at least one hyperplastic lesion was higher in the standard colonoscopy group (0.34% vs 0.27%, $p<0.05$).
CONCLUSION: The colonoscopy HD+ does not increase the adenoma detection rate in expert endoscopists with a adenoma detection rate already high, however it would improve the identification of completely flat lesions. The ability of endoscopists to accurately differentiate neoplastic from non-neoplastic lesions could explain the lower number of patients with at least one hyperplastic polyp removed in the HD+ group.

P1278 PRACTICABILITY OF BREATH MONITORING WITH A NEW RESPIRATORY RATE COUNTING DEVICE IN PATIENTS UNDERGOING ELECTIVE COLONOSCOPY UNDER PROPOFOL SEDATION

L. T. Heuss[1], G. W. Anand[1,*], K. Zdrnja[1]. [1]*Internal Medicine, SPITAL ZOLLIKERBERG, Zollikerberg, Switzerland*

INTRODUCTION: In many European countries (e.g. Switzreland) propofol is the most often used sedative in GI endoscopic procedures and is mostly used by the endoscopist or the endoscopy nurse without assistance of an aneasthesiologist. In some studies capnography has been suggested to increase detection of adverse respiratory events. However capnography is expensive and its use mainly relies on the observation of the breath curve.
AIMS&METHODS: Aim of this pilot study was to determine whether breath monitoring with a newly developed respiratory monitoring device could be a practical and accurate way of monitoring ventilatory response under sedation with propofol in addition to standard monitoring with pulse oximetry.
All patients (American Society of Anesthesiologists Classification (ASA) I-III) scheduled for elective colonoscopy under propofol sedation were monitored with a new monitoring device measuring respiratory rate based on humidity in expired air (respiR8™) in addition to standard monitoring with pulse oximetry. Detection of apnea longer than 30 seconds induced withholding propofol and stimulation of patients as loud speaking or chin lift maneuver. Apnea was defined as cessation of breathing for a minimum of 10 seconds . Significant apnea was defined as cessation of breathing for more than 30 seconds. Hypopnea was defined as reduction in respiratory rate below 6/Min. during a minimum of 10 seconds. The primary endpoint was detection of all respiratory events. Secondary end point included correlation of apnea or hypopnea with hypoxemia (measured as fall in oxygen saturation (SaO2) of at least 5% from baseline or less than 90%) or severe Hypoxemia (SaO2 <85%).
RESULTS: A total of 76 Patients (51 Female and 25 Male) were monitored with Respir8 during colonoscopy under propofol sedation. 37 patients (48.7%) developed at least one respiratory event. There were a total of 73 respiratory events ranging from one to 6 events in a single patient. Significant apnea > 30 sec occurred in 5 patients (6%). Only one apnea led to a relative SaO2 reduction (from 98 to 93%) after 50 seconds lag time. No event requiring immediate intervention such as assisted ventilation recorded.
CONCLUSION: Additional monitoring of ventilatory activity with Respir8 detects apnea or hypopnea earlier as compared to pulse oximetry and could therefore provide early warning of impending respiratory abnormality. The clinical impact of breath rate monitoring remains indetermined.

P1279 THE LEARNING CURVE OF ENDOSCOPIC SUBMUCOSAL DISSECTION IN THE COLORECTUM

H. Kashida[1,*], T. Adachi[1], T. Sakurai[1], Y. Asakuma[1], M. Kawasaki[1], T. Nagai[1], H. Mine[1], M. Takayama[1], S. Matsui[1], M. Kudo[1]. [1]*Kinki University, Osaka-sayama, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) for colorectal neoplasms is still a big challenge for most endoscopists even in Japan. The technique was introduced to and started in our institute in the year 2010. The aim of this study is to analyze the learning curve of colorectal ESD procedures for the first 3 years.
AIMS&METHODS: The aim of this study is to analyze the learning curve of colorectal ESD procedures for the first 3 years. The subjects are 121 consecutive lesions in 111 patients which were treated with ESD technique. The indications for ESD in our hospital are; 1. Neoplasms larger than 20mm but confined to the mucosa or invading minimally to the submucosal layer, 2. Those smaller than 20mm but unable to be lifted by injection due to fibrosis. The instruments used are PCF-Q260AZI or JI (Olympus), Short ST Hood and Flush Knife (Fujifilm) and VIO 400 or ICC200 (Erbe).
RESULTS: Male: female ratio was 56: 55 and the average age was 68.5 (44-90) years old. The final pathological diagnosis was SSA/P in 2, adenoma in 33, mucosal carcinoma in 69, minimally invasive (SM1) in 13 and deeply invasive (SM2) in 4. The average diameter was 35.5(7-80) mm and the gross appearance of the lesions was IIc in 2, Is in 3 and laterally spreading tumor (LST) in 116. The major site of each subgroup of LST was the cecum in 40 homogeneous granular-type (LST-GH), the rectum in 25 mixed-nodular type (LST-GM), the ascending colon in 23 flat-elevated type (LST-NGF), and the transverse colon in 28 pseudo-depressed type (LST-NGPD). The average size in LST-GH, LST-GM, LST-NG and LST-NGPD was 41.2mm, 42.8mm, 32.3mm and 25.7mm, respectively. The outcomes were evaluated after dividing the subjects into the first 50 lesions, the second 50 lesions and the following cases up to present. The en bloc resection rate was 78%, 88% and 95% in the 1st, 2nd and 3rd period. Post-procedure bleeding occurred in 1 case (0.9%) in the 1st period. Minor intra-procedure perforation was encountered in 6%, 2% and 0% of the cases in each period but emergency operation was not necessary. Delayed pneumoperitoneum was witnessed in one case of the 1st period, but it was attributable to the ileus caused by anal stricture. Two of the 4 cases with deep invasion were treated surgically afterwards. Local recurrence was witnessed in 3 cases where the ESD procedure had resulted in piecemeal resection, but the recurrent lesions were all treated endoscopically.
CONCLUSION: A learning curve was confirmed in the colorectal ESD procedures. The more cases are experienced, the higher the en bloc resection rate and the lower the complication rate got.

P1280 "PICO-BELLO-KLEAN STUDY": EFFECTIVENESS AND PATIENT TOLERABILITY OF BOWEL PREPARATION AGENTS PICOPREP® AND KLEANPREP® BEFORE COLONOSCOPY. A SINGLE-BLINDED RANDOMIZED TRIAL.

I. D. Munsterman[1,*], E. Cleeren[2], R. Brohet[2], T. Van der Ploeg[2], R. Van der Hulst[1]. [1]*Gastroenterology, [2]Linnaeus Institute, Kennemer Gasthuis, Haarlem, Netherlands*

INTRODUCTION: Adequate bowel preparation is an important condition for an effective colonoscopy. Polyethylene glycol solution (Kleanprep®) and sodium picosulphate solution (Picoprep®) are bowel cleansing agents both registered and available for this purpose. Reliable conclusions in the comparison of effectiveness between these agents can not be made based on previous research, due to the heterogeneity in study designs and subjective outcome assessments.
AIMS&METHODS: To compare the cleansing agents Kleanprep® and Picoprep®, primarily assessing effectiveness by degree of colon cleansing and secondarily determining patient tolerability.
In this single-blinded randomized controlled trial all patients referred for an outpatient colonoscopy received either Kleanprep® (n=88) or Picoprep® (n=85), stratified by two age groups: 18-64 and 65-80 years. Both Picoprep® and Kleanprep® were administered in a split-dose regimen, while fluid intake was monitored and registered. Effectiveness was measured by assessing bowel cleansing using the Boston Bowel Preparation Score. Patient tolerability was measured with a patient questionnaire. An intention-to-treat-analysis was performed.
RESULTS: There was no difference in level of bowel cleansing according to the Boston Bowel Preparation Score considering treatment arms. The overall cleansing score between Kleanprep® and Picoprep® was not significantly different (p=0,182). Reviewing segment scores, there were also no significant differences between Kleanprep® and Picoprep® (right colon p=0,051, transverse colon p=0,563 and left colon p=0,352). The minimum warranted level of cleansing (BBPS ≥ 6) is achieved with a percentage > 90% by both agents. Patients using Picoprep® scored significantly better on the aspects convenience and flavour of the preparation agent, compared to patients using Kleanprep® (p-value <0,001). Side effects like nausea, vomiting, headache and bloating were significantly less experienced by patients using Picoprep®. Side effects like abdominal pain and dizziness were similar between treatment arms.
CONCLUSION: The present study did not demonstrate a difference in effectiveness of bowel cleansing between Kleanprep® and Picoprep®. Both showed to be adequate bowel preparation agents, ensuring a good visibility of the colon during colonoscopy. Picoprep® was significantly better tolerated than Kleanprep®.

P1281 DOES THE ENDOSCOPIST FATIGUE PLAY ANY ROLE ON COLONOSCOPIST RESULTS?

J. J. Vila Costas[1,*], A. Borda Martín[1], J. Jiménez Pérez[1], F. Borda Celaya[1], I. Fernández-Urién[1], J. M. Zozaya Urmeneta[1]. [1]*Gastroenterology, COMPLEJO HOSPITALARIO DE NAVARRA A., Pamplona, Spain*

INTRODUCTION: Contradictory results have been published concerning the possible effect of endoscopist fatigue on colonoscopies findings, especially in relation to neoplastic polyp detection.
AIMS&METHODS: AIMS: To analysed possible differences in the diagnostic and therapeutic capacity of colonoscopies, depending if they were performed at the beginning or at the end of every working day.
METHODS: 1000 ambulatory and consecutive colonoscopies, sedated with propofol iv. were reviewed. The explorations were divided into 2 groups: A.- Early (The first 4 colonoscopies of each day, n = 569) and B.- Late (the rest of the session, n= 431). Possible differences between 2 groups concerning patients characteristics, incomplete colonoscopies, frequency, number, size of the bigger polyp, histology, and resection and recovery polyp rates were analysed.
RESULTS: Colonoscopies performed at the beginning and at the end of the working day were similar when comparing gender, age, colonoscopy indication, personal and familial history of colorectal polyps (p = n.s.). No significant differences were registered between both groups related to endoscopic findings: Incomplete colonoscopy: A (Early) = 1.3%, B (Late)= 1.2% (p = 0.99); Polyp detection rate: A = 46.2%, B = 42.4% (p = 0.97); Multiple polyps: A = 26%, B = 23.9% (p = 0.45); polyps <5mm: A = 26.7%, B = 22.9% (p = 0.18); Cases with all polyps resected: A = 95%, B = 95,6% (p = 0,79); cases with all polyps recovered: A = 86.9%, B = 91.7% (p = 0.12); Histology: hyperplastic polyps: A = 11.2%, B = 9.3% (p = 0.31); simple adenomas: A = 26.4%, B = 23.9% (p = 0.37); advanced adenoma: A = 7.7%, B = 9% (p = 0.46); carcinoma: A = 3.2%, B = 4.4% (p = 0.30).
CONCLUSION: 1.- Endoscopist fatigue at the end of the day does not influence on incomplete colonoscopies rate in our series.
2.- There are no differences in number of neoplastic detected lesions, macroscopic and histologic neoplasms characteristics or resection and recovery rates between colonoscopies performed at the beginning or at the end of the working day.

P1282 BLUE LASER IMAGING: APPLICATION FOR COLON POLYP CHARACTERIZATION

K. Togashi[1,*], D. Nemoto[1], N. Isohata[1], T. Otani[1], K. Utano[1], S. Endo[1], D. G. Hewett[2]. [1]*Coloproctology, AIZU MEDICAL CENTER, FUKUSHIMA MEDICAL UNIVERSITY, Aizuwakamatsu, Japan,* [2]*School of Medicine, University of Queensland, Brisbane, Australia*

INTRODUCTION: Lasers produce light through optical amplification based on the stimulated emission of photons. The emitted light is notable for its high degree of spatial and temporal coherence. Recently, a new image enhanced endoscopy system using laser light (now designated Blue Laser Imaging, BLI) is being used in Japan. In BLI, 2 monochromatic lasers (410nm and 450nm) are applied instead of xenon light. A 410nm laser visualizes small vessels on the mucosal surface because its wavelength represents the absorption spectra of vessels, and a 450nm laser provides white light by excitation. BLI is also equipped with a zoom apparatus for polyp characterization.
AIMS&METHODS: In this study, we aimed to evaluate the use of BLI for polyp characterization. Since November 2012 in our institution, colonoscopy has been primarily performed with BLI. Colorectal polyps were observed with BLI and resected/biopsied by experienced colonoscopists. With BLI, the polyp vascular pattern as well as surface pattern are clearly visualized, similar to narrow band imaging (NBI). Therefore, we applied the Sano classification frequently used in NBI.
RESULTS: BLI allowed clear visualization of vessel architecture even with a distant view, and without the need for dye application. To date, 381 lesions including 20 inflammatory polyps, 13 hyperplastic polyps, 307 adenomas, 23 mucosal cancers (adenomas with high grade dysplasia) and 18 submucosally invasive cancers were studied. Hyperplastic polyps revealed type 1 vascular pattern in 85%. Adenoma showed type II in 97%. 23 mucosal cancers showed type II in 52% and type IIIA in 48%. 18 submucosal cancers demonstrated type IIIA in 30% and type IIIB in 50%. These results are consistent with previous reports using NBI.
CONCLUSION: BLI provided useful information for polyp characterization, without dye application. Further prospective evaluation of the performance characteristics of the BLI system for polyp characterization is required.

P1283 COMPARISON OF ENDOSCOPIC SUBMUCOSAL DISSECTION AND ENDOSCOPIC MUCOSAL RESECTION TO LATERALLY SPREADING TUMORS

K. Kudo[1,*], S. kudo[1], T. hayashi[1], K. sudou[1], N. toyoshima[1], Y. yagawa[1], T. ishigaki[1], H. oikawa[1], T. hisayuki[1], K. wakamura[1], H. miyachi[1], N. ogata[1]. [1]*digestive disease center, showa university northern yokohama hospital, yokohama-shi, Japan*

INTRODUCTION: Laterally spreading tumors (LSTs) are usually benign in spite of their large diameter and therefore, good indication for endoscopic treatment.
On the other hand, Endoscopic submucosal dissection (ESD) enables en bloc resection for colorectal neoplasms regardless of their localization or diameter, and has been developed more popular as a treatment in Japan. However, the ESD procedures are difficult and associated with more risk of complications compared to conventional endoscopic mucosal resection or endoscopic piecemeal mucosal resection (EMR/EPMR).
AIMS&METHODS: The aim of this study is to evaluate the outcomes of treatment for LSTs, and to clarify indications for EMR/EPMR and ESD.
We retrospectively assessed all patients who underwent endoscopicaly or surgically treatment from April 2001 to December 2012. 17802 colorectal adenomas and early cancers were treated, and among them 2002 lesions were so-called LSTs. There are two subtypes of LSTs; non granular type (LST-NG) and granular-type (LST-G). We analyzed features of LST-NG and LST-G, and investigated the rate of en bloc resection, residual tumor/recurrence and complications between EMR/EPMR and ESD in LSTs.
RESULTS: The lesions which were treated by EMR/EPMR technique were 1437 in number and those treated by ESD technique were 485. The rate of submucosal invasion was significantly higher in LST-NG than in LST-G (15.7% vs 9.2%: $p<0.01$), and especially LST-NG over 20mm in diameter showed the very high rate of submucosal invasion (24.3%). The en bloc resection rate over 20mm in diameter of LSTs was 30.9% (197/637) in the EMR group(20 mm or more less than 30 mm LST-G was 40.8%, and LST-NG was 43.4%. LST-G of 30 mm or more was 10.4%, and LST-NG was 21.1%). 97.2% (432/444) in the ESD group. Residual tumor/recurrence was observed in 119 (8.3%) of the EMR group, but The prognosis of the residual tumor / recurrence of EPMR of mucosal carcinoma and an adenoma was not bad. there was no case with recurrence in the ESD group. With regards to complications over 20mm in diameter, there was no significant difference in the rates of post-treatment bleeding (2.6%vs.1.6%) and perforation (1.4%vs2.7%) between EMR/EPMR and ESD, In summary, LST-NG over 20mm in diameter should be removed en bloc with ESD technique because of its higher potential for submucosal invasion.
CONCLUSION: It is important to classify LSTs into LST-NG and LST-G in diagnosis.
ESD is feasible treatment for LST-NG especially more than 20 mm which is hard to be resected by EMR technique.

P1284 IS THE PROGNOSIS OF THE COLORECTAL CANCER IMPROVED WHEN THE OUTPATIENTS WITH NEGATIVE FIT UNDERGO COLONOSCOPY?

K. Wakamura[1,*], S.-E. Kudo[1], H. Miyachi[1], K. Kodama[1], T. Kudo[1], Y. Mori[1], M. Misawa[1], Y. Sugihara[1], S. Hayashi[1], H. Oikawa[1], K. Takeda[1], K. Ichimasa[1], T. Hayashi[1], S. Okoshi[1], E. Hidaka[1], F. Ishida[1]. [1]*Digestive Disease Center, SHOWA UNIVERSITY NORTHERN YOKOHAMA HOSPITAL, Yokohama, Japan*

INTRODUCTION: In Japan, the colorectal cancer morbidity has been increasing year by year. Therefore, screening examination is essential for early detection of the colorectal cancer (CRC). Fecal immunochemical test (FIT) is a simple, low cost and non-invasive method. Furthermore, there has been firm experimental evidence that FIT reduces the risk or CRC mortality. Therefore, FIT is recommended as a population-based CRC screening in Japan. However, some of CRC are negative for FIT. The endoscopic features of the CRC with false-negative FIT are not well known because colonoscopy is not generally performed in the FIT-negative examinees.
AIMS&METHODS: This follow-up study was designed to compare the prognosis of the FIT-negative CRC with the FIT-positive one. From January, 2007 to December, 2009, we performed 1-day FIT before endoscopy for 1592 outpatients who consented for the purpose of colonoscopy in our hospital. And we compared the FIT-negative group with the FIT-positive group about endoscopic findings and the three years overall survival (3ys OS).
RESULTS: Of 1592, 983 patients were in FIT-negative groups, and 609 were in the FIT-positive group. A significant difference was not seen in the sex between both groups. Of 983, 336 FIT-negative patients had neoplastic lesions, and the number of them was 566 (9: invasive cancer, 26: high grade dysplasia, 531: low grade dysplasia) while 690 (81: invasive cancer, 58: high grade dysplasia, 551: low grade dysplasia) in the FIT-positive group. The average age of the FIT-negative group was significantly younger than that of the FIT-positive group (58.3 ± 13.9 vs. 61.4 ± 13.8: $P<0.01$). The average tumor diameter in the FIT-negative group was significantly smaller than the FIT-negative group (4.72 ± 6.27 mm vs. 9.75 ± 12.1 mm: $P<0.01$). The detection rate of invasive cancer was lower in the FIT-negative group than the FIT-positive group (0.92% vs. 12.5%: $P<0.01$). As for advanced neoplasia, the detection rate was also lower in the FIT-negative group than the FIT-positive group, significantly (5.60% vs. 29.1%: $P<0.01$).

Furthermore, there were no distant metastasis cases in the FIT-negative group while 15 cases in the FIT-positive group. As for the 3ys OS of patients with invasive cancer, the FIT-negative group was 100% while the FIT-positive group was 92.4%.

CONCLUSION: The FIT is an excellent screening test, however the prognosis of CRC might be improved if the outpatients with negative FIT undergo colonoscopy.

P1285 IN VIVO TARGETING OF COLONIC NEOPLASIA BY MMP DIRECTED FLUORESCENCE ENDOSCOPY

L. Philipp[1,2,*], D. Bettenworth[1], K. Schwegmann[2], A. Faust[2], C. Poremba[3], M. Schäfers[2], D. Domagk[1]. [1]*Department of Medicine B,* [2]*European Institute for Molecular Imaging, University of Muenster, Muenster,* [3]*Center for Histology, Cytology and Molecular Diagnostics, Trier, Germany*

INTRODUCTION: Patients with ulcerative colitis are at increased risk for colorectal cancer (CRC). Therefore, endoscopic surveillance programs have been established, however their diagnostic yield is still not satisfying yet. Matrixmetalloproteinases (MMP)-2/-9 are key enzymes in metastatic processes of CRC and high expression levels can be observed in affected mucosa. Aim of this study was to evaluate molecular imaging by MMP-2/-9 guided fluorescence endoscopy (FE) for early tumor detection in a murine model of colitis associated CRC.

AIMS&METHODS: Colorectal cancer in C57Bl/6 WT mice (n=15) was induced by single i.p. injection of azoxymethane (AOM) and cyclic administration of dextran sodiumsulfate (DSS). A nonpeptidic, Cy5.5-labeled MMP-selective tracer (Cy5.5-AF443) was intravenously injected 24 hrs before endoscopic examination. Tumor development was assessed *in vivo* by white light endoscopy and FE applying a bandpass filter system. Murine colons were examined by fluorescence reflectance imaging (FRI) to measure tracer uptake *ex vivo*. *Ex vivo* tumors were enumerated stereomicroscopically and graded by HE staining and Ki67-immunhistochemistry. The expression and activity of MMP-9 in colorectal tumors was assessed by immunochemistry, western blot analysis and zymography.

RESULTS: By applying our MMP photoprobe a significant higher contrast of colonic adenomas as compared to the adjacent non-malignant mucosa could be achieved during fluorescence endoscopy (75.9 ± 8.7 vs. 66.5 ± 7.4, mean gray values, $P<0.001$). FRI detected significantly higher tracer uptake in colorectal adenoma as compared to healthy mucosa (Average Radiant Efficiency: 1.41 E+12 ± 0.75 E+12 vs. 0.62 E+12 ± 0.44 E+12 [p/s/cm≤/sr] / [μW/cm≤], $P < 0.001$) and revealed a tumor size dependent increase ($P < 0.05$). Proliferation rate in tumors was significantly increased as assessed by Ki67 positive cells per 10 high-power fields (25.7 ± 14.2 % vs. normal mucosa 11.8 ± 5.7 ($P < 0.01$). Standard histology revealed colorectal adenomas up to high-grade dysplasia and pT1 carcinomas.

Immunhistochemistry for MMP-9 proved markedly increased expression in high-grade dysplasia and pT1 tumors as compared to non-malignant mucosa and western blot analyses and zymography indicated higher levels of active MMP-2/-9 and its pro-enzymes in colorectal dysplasia.

CONCLUSION: Mucosal MMP-9 expression was significantly increased in colorectal high-grade dysplasia and pT1 tumors. Specific targeting of MMP was feasible to detect colonic dysplasia during fluorescence endoscopy and might facilitate the detection of human early colorectal cancer in the future.

P1286 ORAL SULFATE SOLUTION PROVIDES SUPERIOR BOWEL CLEANSING TO SPLIT-DOSE SODIUM PICOSULFATE AND MAGNESIUM CITRATE

J. Mcgowan[1], M. Cleveland[1,*], J. A. Di Palma[2], D. Rex[3]. [1]*Braintree Laboratories, Inc., Braintree,* [2]*University of South Alabama, Mobile,* [3]*Indiana University Medical Center, Indianapolis, United States*

INTRODUCTION: Split-dose bowel preparation has been shown to produce superior cleansing to evening only bowel preparation in patients undergoing colonoscopy. This study seeks to determine if differences in efficacy can be detected when an oral sulfate (OS) preparation and sodium picosulfate and magnesium citrate (P/MC) preparation are both given in a split-dose (PM/AM) administration.

AIMS&METHODS: Adult outpatients scheduled for colonoscopy were enrolled into this single-blind, multi-center study and were administered either an OS preparation (SUPREP®, Braintree Laboratories) or P/MC preparation (Prepopik™, Ferring Laboratories). Both preparations followed their approved labeling for a split dose (PM/AM) regimen. Colonoscopies were performed by investigators blinded to treatment assignment. Cleansing was graded using a 4 point scale (Excellent - no more than small bits of adherent feces/fluid, Good - small amounts of feces or fluid not interfering with exam, Fair - enough feces or fluid to prevent a completely reliable exam, Poor - large amounts of fecal residue, additional cleansing required) where scores of Good or Excellent were considered "successful". Patients with scores of Fair and Poor were considered failures, as well as those unable to undergo colonoscopy due to ineffective preparation.

RESULTS: Ninety-five percent of patients had successful preparation with OS, compared to 86% of P/MC patients ($p = 0.006$). Twice as many sulfate preparations (55%) were graded as Excellent by the colonoscopist, as compared to P/MC (26%, $p < 0.001$). All OS patients underwent colonoscopy. Five P/MC patients (3%) could not undergo colonoscopy after taking the preparation and needed to be rescheduled or receive an additional cleansing agent.

Preparation Success	Sulfate Solution (n=168)	Picosulfate (n=169)	p value
% Success	94.6	85.8	0.006
% Failure	5.4	14.2	
Cleansing by Grade	Sulfate Solution (n=168)	Picosulfate (n=164)	p value
% Excellent	54.8	26.0	< 0.001
% Good	39.9	59.8	
% Fair	3.6	7.7	
% Poor	1.8	3.6	

CONCLUSION: Oral sulfate solution provides superior bowel cleansing compared to sodium picosulfate and magnesium citrate when both are given as split-dose regimens. This result was seen in the global efficacy assessment, as well as in the proportion of Excellent preparations achieved. The high level of efficacy confirms results seen in prior studies, and adds greater support to the efficacy of split-dosing, especially when an oral sulfate solution is used.

P1287 CLINICAL IMPACT OF ENDOSCOPY POSITION DETECTING UNIT (UPD-3) FOR COLONOSCOPY IN NON-SEDATED PATIENT.

M. Fukuzawa[1,*], T. Gotoda[1], T. Sato[1], C. Kusano[1], K. Yamamoto[1], T. Kawai[2], F. Moriyasu[1]. [1]*Gastroenterology and Hepatology,* [2]*Endoscopy center, Tokyo Medical University, Tokyo, Japan*

INTRODUCTION: Achievement of high cecal intubation rate and patient's comfort depend on insertion shape of scope during examination. And insertion shape of scope during examination depends on experience.

AIMS&METHODS: This study aims to evaluate whether endoscopy position detecting unit (UPD-3) can improve cecal intubation rate regardless of experience of colonoscopy. A total of 240 patients enrolled from February 2012 through June 2012 were randomly divided into UPD-3 guided group or conventional group (no UPD-3 guidance). All colonoscopies were performed by experts (more than 500 colonoscopies) and trainees (less than 100 colonoscopies). Cecal intubation rate, procedure time, insertion methods (straight insertion: shortening the colonic fold through bending technique/ roping insertion: right turn shortening technique) and patient discomfort were assessed. Patient discomfort during scope insertion was scored by Visual analog scale (VAS) in 5-steps degree. CF-Q260DI (12.4mm in diameter) was used in UPD-3 guided group. CF-Q260AI (12.2mm) were used in conventional group. Patients with any abdominal operation in the past were excluded. CO2 insufflation was available in all procedures.

RESULTS: In conventional group (n=122), 77 and 45 procedures were performed by experts (E) and trainees (T), respectively. In UPD-3 guided group (n=118), 77 and 41 procedures were operaded by experts (UE) and trainees (UT), respectively. Intubation times were 8.1 minutes in E, 20.7 in T, 9.1 in UE and 19.5 in UT. It showed a significant difference between E and T ($p < 0.05$). The intubation time in UPD-3 guided group was not significantly shorter than that without UPD-3. As for straight insertion technique, its rate in UT (537%) was significantly improved rather than that in T (33.3%) ($p < 0.05$). VAS scale in UT was also getting better from 2.6 in T to 1.9 ($p < 0.05$).

CONCLUSION: Though UPD-3 could not contribute to shorten the intubation time both in expert and trainee, the rate of the straight insertion and the reduction of patients' pain during colonoscopy were significantly improved in trainees. Thus, this equipment should be clinically applied.

P1288 A RISK SCORE TO INDENTIFY SUBJECTS AT HIGH-AVERAGE RISK OF ADVANCED COLORECTAL NEOPLASIA

M. F. Kaminski[1,2,*], M. Polkowski[1,2], E. Kraszewska[1], M. Rupinski[1,2], E. Butruk[3], J. Regula[1,2]. [1]*Medical Centre for Postgraduate Education,* [2]*the Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology,* [3]*The Polish Foundation of Gastroenterology, Warsaw, Poland*

INTRODUCTION: The risk of advanced colorectal neoplasia is not evenly distributed throughout the screening population.

AIMS&METHODS: This study aimed to develop and validate a model to quantify the individual risk of advanced colorectal neoplasia in Caucasian subjects useful for health counselling.

We performed a cross-sectional analysis of database records for 40- to 66-year-old subjects who entered a national primary colonoscopy-based screening program for colorectal cancer in 73 centres in Poland in the single year of 2007. We used multivariate logistic regression to investigate the associations between clinical variables and the presence of advanced neoplasia in a randomly selected test set, and confirmed the associations in a validation set. We used model coefficients to develop a risk prediction score for advanced colorectal neoplasia.

Table: P1290

Variable	Pooled difference in means (95% CI)	p values
All polyps	0.132 (-0.064 to 0.328)	0.188
All adenomas	0.033 (-0.056 to 0.122)	0.468
Flat adenomas	0.077 (-0.099 to 0.254)	0.389
Hyperplastic polyps	0.104 (-0.072 to 0.280)	0.248

Polyps <10mm	91.3% (88.4 to 93.7)	74.7% (68.5 to 80.2)	3.86 (2.37 to 6.30)	0.115 (0.07 to 0.19)	37.08 (16.01 to 85.85)	0.902 +/- 0.08
All polyps	90.4% (88.3 to 92.2)	86.9% (83.8 to 89.5)	5.96 (2.32 to 15.32)	0.135 (0.08 to 0.225)	45.56 (15.13 to 137.15)	0.945 +/- 0.025

RESULTS: Advanced colorectal neoplasia was detected in 2,544 of the 35,918 included participants (7.1%). In the test set, a logistic-regression model showed that independent risk factors for advanced colorectal neoplasia were: age, sex, family history of colorectal cancer, cigarette smoking ($P<0.001$ for these four factors), and body mass index ($P=0.033$). The model was well calibrated in the validation set (ratio of expected to observed risk of advanced neoplasia: 1.00 (95% CI, 0.95-1.06)). The concordance statistics of the model were 0.64 for the test set and 0.62 for the validation set. We developed a risk score that quantified the risk of advanced neoplasia in the whole data set, from 2.49% for subjects scoring 0, to 19.44% for subjects scoring 7-8.
CONCLUSION: Developed and validated risk score consisting of simple clinical factors successfully quantifies the risk of advanced colorectal neoplasia in asymptomatic Caucasian subjects. This scoring system may be useful for counselling purposes or designing primary prevention studies.

P1289 THE MALIGNANT POTENTIAL OF NONPOLYPOID COLORECTAL LESIONS IN PATIENTS WITH LYNCH SYNDROME

N. Uragami[1,*], M. Arai[2], T. Kishihara[1], A. Chino[2], Y. Tamegai[1], M. Igarashi[1]. [1]*Endoscopy,* [2]*Gastoroennterology, Cancer Institute Hospital, Koto-ku, Japan*

INTRODUCTION: Patients with Lynch syndrome (LS) are at risk for developing colorectal cancer (CRC). Thus, an intensive colonoscopic surveillance program is recommended for them in order to reduce the mortality associated with CRC. However, there are still uncertainties about which type of lesion is more accurately detected and whether complete removal of all colorectal lesions should be considered during surveillance colonoscopy.
AIMS&METHODS: The aim of this study was to compare the endoscopic appearance and size of early colorectal lesions with 3 different mutations: MLH1, MSH2, and MSH6. The study included 88 Lynch syndrome patients with identified mutations in one of the DNA mismatch repair genes (MLH1, 29; MSH2, 52; MSH6, 7). For all LS patients who underwent at least one surveillance examination from January 2001 to March 2013 at the Cancer Institute Hospital, the colonoscopic finding of lesions and the histopathological diagnosis of the 3 different mutations were retrospectively analyzed. Advanced histology (AH) was defined as the presence of high-grade dysplasia or early cancer (invasion into the submucosa).
RESULTS: A total of 235 lesions were detected in the LS patients (49 MLH1 lesions, 166 MSH2 lesions, 20 MSH6 lesions); the average size of the lesions was 5.9 ± 4.0 mm (mean $\pm$ standard deviation, SD) and 51.5% of them were nonpolypoid. The histopathological diagnoses were low-grade dysplasia and serrated adenoma in 132 lesions (56%), high-grade dysplasia in 21 lesions (9%), and early cancer in 23 lesions (10%).
Among the nonpolypoid lesions of <10 mm in size, a significantly higher accuracy in detection of the adenoma was noted in MLH1 mutation carriers (87%) as compared to MSH2 mutation carriers (59%) ($p<0.05$). Among the nonpolypoid lesions of <5 mm in size, a significantly higher accuracy in detection of the adenoma was noted in MLH1 mutation carriers (83%) as compared to MSH2 mutation carriers (51%) ($p<0.05$). Among the lesions of <5 mm in size, the tendency of accurate detection of AH was higher in MLH1 mutation carriers (20.8%) than in MSH6 mutation carriers (9.6%).
CONCLUSION: Nonpolypoid lesions of <10 mm in size should be carefully evaluated, and complete removal of all colorectal lesions in patients with a MLH1 mutation is recommended. Nonpolypoid lesions in patients with a MLH1 mutation may have a high malignancy potential, despite a small size (<5 mm).

P1290 META-ANALYSIS OF FLEXIBLE SPECTRAL IMAGING COLOUR ENHANCEMENT (FICE) IN DETECTION AND CHARACTERIZATION OF COLORECTAL POLYPS.

C. Raychaudhuri[1], N. Mohammed[1,2,*], V. Subramanian[1,2]. [1]*Gastroenterology, Leeds Teaching Hospitals NHS Trust,* [2]*Gastroenterology, Leeds Institute of Molecular Medicine, Leeds, United Kingdom*

INTRODUCTION: Several endoscopic innovations have been developed recently to improve detection and characterization of colorectal polyps. Flexible spectral imaging colour enhancement (FICE) is a form of image enhanced endoscopy which enhances the visualization of mucosal structures and microcirculation by the selection of spectral transmission with a dedicated wavelength.
AIMS&METHODS: We aim to perform a meta-analysis to look at the effect of FICE on detection and characterisation of colorectal polyps.
Various electronic databases were searched for articles reporting on detection and characterization of colonic polyps comparing standard while light endoscopy and FICE. The pooled mean differences in total numbers of polyps, adenomatous polyps, flat adenomas, and hyperplastic polyps detected was calculated. Additionally, pooled sensitivity, specificity, positive and negative likelihood ratio, diagnostic odds ratio and pooled area under the receiver operating curve was calculated.
RESULTS: 5 studies/2150 patients and 11 studies/ 2425 patients were included in the analysis for detection of polyps and polyp characterization respectively. There were no differences between FICE and standard colonoscopy for the detection of all polyps, adenomatous polyps, flat adenoma or hyperplastic polyps. Pooled diagnostic accuracy for FICE is listed in table.
Table: Detection of Polyps
CONCLUSION: FICE does not seem to improve the detection rate of adenomatous polyps during screening colonoscopy. These results may partially be due to the small number of studies done so far using FICE. The pooled sensitivity and specificity of FICE does not meet the currently accepted criteria of the ASGE PIVI committee for use in routine clinical practice.

P1291 LOW-VOLUME ORAL SULFATE SOLUTION VERSUS HIGH-VOLUME POLYETHYLENE GLYCOL SOLUTION: ACHIEVING A CLEAR VIEW

N. Veloso[1], S. Pires[1], J. Dinis Silva[1], L. Gonçalves[1], R. Godinho[1], C. Viveiros[1], I. Medeiros[1,*]. [1]*Gastroenterology, Hospital Espírito Santo, Évora, Évora, Portugal*

INTRODUCTION: INTRODUCTION: The poor quality of bowel preparation remains one of the great difficulties of colonoscopy. We compared the adherence, tolerability and efficacy of a low-volume oral sulfate solution (LV-OSS) with a high-volume sulfate-free (standard 4-L polyethylene glycol) electrolyte lavage solution (HV-SFS) as bowel preparation for colonoscopy.
AIMS&METHODS: Aims & Methods: Prospective analysis in patients undergoing colonoscopy, in an outpatient setting, between January and December 2011. Patients were randomized to receive LV-OSS in equally divided doses, at 4pm and 10pm, the day before of colonoscopy versus (Vs) HV-SFS given the night before colonoscopy. The efficacy of the bowel preparation was assessed by the Ottawa bowel preparation scale. The scale is applied to each colon segment: right colon, mid colon and the rectosigmoid colon. The fluid quantity is a global value for the entire colon. The score is calculated by adding the 0 to 4 ratings for each colon segment and the 0 to 2 fluid quantity rating. The scale has a range from 0 (perfect) to 14 (solid stool in each colon segment and lots of fluid, completely unprepared colon). Preparations with ≥ 8 points were considered unsatisfactory.
RESULTS: Results: 416 patients were included (52.2% men; average age of 64,3years old. 209 patients received HV-SFS and 207 LV-OSS. 8.7% did not complete the intake of the preparation (77.8% HV-SFS Vs 22.2% LV-OSS; $p<0.001$). Incomplete progression occurred in 5.3% due to completely unprepared colon (54.5% LV-OSS Vs 45.5% HV-SFS; $p>0.05$), 31.8% did not complete the intake of the preparation. 35.6% revealed bad taste (77% HV-SFS Vs 23% LV-OSS; $p<0.001$). 21.9% had nausea (64.8% HV-SFS Vs 35.2% LV-OSS;

p<0.05). 7.9% had vomiting (63.6% HV-SFS Vs 36.4% LV-OSS; p<0.05). 42.1% had abdominal pain (50.3% HV-SFS Vs 49.7% LV-OSS; p>0.05). 14.4% had unsatisfactory bowel preparation (53.3% LV-OSS Vs 46.7% HV-SFS; p>0.05). The mean total score in the Ottawa scale to the LV-OSS Vs HV-SFS was 4.37±2.96 Vs 4.74±2.94 (p>0.05). Fluid quantity rating 1-2 occurred in 42.3% (52.6% HV-SFS Vs 47.4% LV-OSS; p>0.05).
CONCLUSION: Conclusion: The HV-SFS was associated with statistical significance of incomplete intake of the preparation, bad taste and the presence of nausea and vomiting, thus presenting lower adherence and tolerability. The LV-OSS was more effective, but without statistical significance.

P1292 CHARACTERISTICS OF THE ENDOSCOPISTS THAT INFLUENCE QUALITY OF COLONOSCOPY

R. Jover[1,*], COLONPREV STUDY INVESTIGATORS. [1]*Hospital General Univesitario de Alicante, ALICANTE, Spain*

INTRODUCTION: The main objective of screening colonoscopy is the detection of premalignant lesions. Several factors are directly related to colonoscopy quality, but scarce information exists about the characteristics of the endoscopists that influence detection of lesions
AIMS&METHODS: Fifty endoscopists participant in the study COLONPREV (a randomized trial aimed to compare screening by direct colonoscopy vs FIT) performed at least 20 procedures in the colonoscopy arm of this study, with a total of 3.838 colonoscopies. Evaluated factors related to colonoscopy quality were: adenoma detection rate (ADR), advanced ADR, proximal and distal ADR and adenoma rate. Evaluated characteristics of endoscopists were: age, sex, exclusive dedication to endoscopy, especialty, years as physician, years as especialist, total longlife number of colonocopies, number of colonoscopies last year, weekly hours dedicated to endoscopy and number of formative activities in the last year.
RESULTS: Mean age of endoscopists was 39.7 years. There were 31 men (62%). A 20.8% had exclusive dedication to endoscopy. All but one endoscopists were gastroenterologists. Age, sex, years as physician or as especialist did not show any relationship with the studied quality indicators. Endoscopists with exclusive dedication had a higher proximal ADR (19.3% vs 14.4%; p=0.04). Endoscopists with a total number of colonoscopies higher than 6.000 procedures showed a higher adenoma rate (0.66 vs 0.51; p=0.04). However, the weekly mean number of hours dedicated to endoscopy was not associated with any quality indicator. Performance of more than 300 yearly colonoscopies was associated with a better ADR (33.1% vs 27.5%; p=0.04) and adenoma rate (0.63 vs 0.41; p=0.0001). Finally, the endoscopists that assisted to at least 3 formative activities during the last year showed also higher ADR (35.2% vs 27.9%; p=0.02), adenoma rate (0.66 vs 0.49; p=0.03) and distal ADR (17.7% vs 13.6%; p=0.04).
CONCLUSION: The endoscopists characterisitics that are more associated to better quality indicators are the performance of more than 300 colonoscopies/year and the assitance to a higher number of formative activities.

P1293 SCREENING COLONOSCOPY WITH DYEING OF PROXIMAL COLON VERSUS TOTAL CHROMOCOLONOSCOPY USING INDIGO CARMINE: FIRST REPORT

S. Mouzyka[1,*]. [1]*Endoscopy, LISSOD, Kiev, Ukraine*

INTRODUCTION: The adenoma–carcinoma sequence developed is accepted in principle for colorectal cancer. The early detection and completely removal of colon adenoma is essential.
AIMS&METHODS: The aim of our study was to assess the detection rate of colorectal lesions by comparing total chromocolonoscopy and proximal chromocolonoscopy. In one institution, 183 asymptomatic patients (mean age 52,5) participated in study of screening video colonoscopy, performed by a single endoscopist. Informed consents were obtained in all cases. Patients were excluded if the bowel preparation was inadequate, if they had an earlier diagnosed colorectal neoplasia or inflammation, or if they were receiving anticoagulant medication. Patients received intravenous propofol prior to intubation of the colonoscope. Complete colonoscopy was performed in 183 (100%) cases. A total chromocolonoscopy using 0,2% indigo carmine solution was performed in 92 patients. A further 91 patients were examined with dyeing of cecum, ascending and transversal colon only. All lesions identified during screening colonoscopy in both groups were removed completely by cold forceps or snare polypectomy. The two groups were similar with regard to age, gender and rate of complete colonoscopy. Mann-Whitney U Tests were used to determine differences between groups.
RESULTS: There was not anything complications after colonoscopy. Results of colorectal lesions detection are shown in Table, the difference between two groups was insignificant (p value more than 0.05).

	Patients with colorectal adenoma	Patients with proximal adenoma	Patients with distal adenoma	Distal adenoma/patients
Total chromocolonoscopy	51,7%	37,4%	29,7%	0,53
Proximal chromocolonoscopy	53,8%	38,5%	31,9%	0,46

CONCLUSION: The results of our study show that proximal chromocolonoscopy can be recommended for improving adenoma detection rate instead of total chromocolonoscopy.

P1294 PREOPERATIVE EVALUATION WITH ENDOSCOPIC ULTRASONOGRAPHY AND ENDOSCOPIC SUBMUCOSAL DISSECTION FOR NEUROENDOCRINE TUMORS OF THE RECTUM

S. Shimaoka[1,*], A. Matsuda[1], T. Nioh[1], Y. Baba[1], S. Iifuku[1], T. Shamoto[1], M. Toyoda[1], K. Iwaki[1], N. Nishimata[1], K. Tsukasa[1], K. Tashiro[1], T. Niihara[1], Y. Nishimata[1], M. Hori[1], H. Nishimata[1], S. Tanaka[2]. [1]*Gastroenterology,* [2]*Pathology, Kagoshima Nanpuh Hospital, Kagoshima, Japan*

INTRODUCTION: Neuroendocrine tumors (NETs) of the Rectum are rare but are increasing in incidence as a result of increases in screening endoscopy of the colon and rectum. Eighty percent of rectal NETs are less than 1cm, limited to submucosa and have no metastasis; therefore endoscopic treatment is selected as minimal invasive therapy for small rectal NETs. However, incomplete resection of tumors sometimes occurs and in such cases, additional operation should be often required. Endoscopic submucosal dissection (ESD) is a developed EMR technique for reliable en bloc resection of large superficial lesions and is expected to enable expansion of the criteria for endoscopic treatment.
AIMS&METHODS: The objective of this study was to determine the efficacy and safety of ESD for rectal NETs. Thirty six patients (38 lesions) with rectal NETs treated endoscopically at Nanpuh Hospital between June 2002 and July 2012 were assessed. These patients were classified into two groups according to the endoscopic procedure ; EMR group (15 patients 15 lesions) and ESD group (21 patients 23 lesions). Endoscopic findings and Endoscopic ultrasonography (EUS) findings, rate of the en-bloc resection, rate of the complete resection, incidence of complications, length of hospitalization were evaluated.
RESULTS: There were no significant differences in age, gender, tumor size and location of the tumors. Macroscopically, all of the tumors appeared as dome-shaped or flat elevation and central depression was found in four lesions. Most of the lesions were detected as homogenous hypoechoic tumors with sharp border by EUS. However in three lesions the border was unclear and histological examination confirmed that tumor cells spread laterally in submucosal layer without mucosal elevation. The rates of en-bloc resection were 100% in both groups. The rate of complete resection of the ESD group was significantly higher than that of the EMR group (p=0.003). Perforations did not occur in either group. Postoperative bleeding occurred in one EMR case and one ESD case and these were endoscopically managed. The average hospitalization period after treatment was 3.3 days in EMR group and 5.1 days in ESD group (N.S.).
CONCLUSION: Endoscopic submucosal dissection appears to be safe and reliable treatment procedure for rectal NETs, especially when the border of the tumor is unclear by preoperative evaluation with EUS.

P1295 WHO SHOULD HAVE A COLONOSCOPY AMONG PATIENTS WITH INCIDENTAL COLON UPTAKE ON PET-CT?

S.-Y. Na[1,*], K.-J. Kim[2]. [1]*Internal Medicine, Jeju National University Hospital, Jeju-si,* [2]*Gastroenterology, Asan Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: It is a clinical dilemma whether patients with incidental colonic uptake (ICU) identified on positron emission and computed tomography (PET-CT) should undergo colonoscopy.
AIMS&METHODS: AIM: To identify the optimal cut-off value of maximum standard uptake value (SUVmax) for colorectal neoplasms and suggests for whom further colonoscopy is recommended in patients with ICU on PET-CT. METHODS: 691 consecutive patients who had a colonoscopy within 3 months after PET-CT between January, 2009, and December, 2009. Per-patient and per-lesion diagnostic performance measure of PET-CT for detecting colonic neoplasms were obtained in 306 patients. In addition, per-lesion sensitivity and positive predictive value (PPV) of various SUVmax criteria for detecting colorectal malignancy and high-grade dysplasia were determined. Receiver operating characteristic (ROC) analysis was used to identify the best positive likelihood ratio (PLR) for diagnosing malignancy and high-grade dysplasia.
RESULTS: Both per-patient and per-lesion PET-CT detection sensitivities for malignancy were 93.3% (28/30; 95% CI 76.5% to 98.9%) and 93.5% (29/31, 95% CI 77.2% to 98.9%) respectively and for high-grade dysplasia were 90.0% (9/10; 95% CI 54.1% to 99.5%). Per-patient negative predictive value (NPV) of malignancy and high-grade dysplasia were 99.1% (216/218; 95% CI 96.4% to

99.8%) and 99.5% (217/218; 97.1% to 99.9%). A SUVmax more than 2.5 as the criteria to specifically detect both malignancy and high-grade dysplasia yielded 92.3% per-lesion sensitivity and 42.9% per-lesion PPV. There is no missing malignancy or high-grade dysplasia among ICUs on PET-CT above the SUVmax=2.5. In the ROC curve analysis, a cut-off value of SUVmsx=5.8, at which the sensitivity, specificity, and PLR for diagnosing malignancy and high-grade dysplasia were 77.8%, 87.5%, and 6.2, respectively.

CONCLUSION: PET-CT is highly sensitive in detecting malignancy and high-grade dysplasia. In negative PET-CT, malignancy and high-grade dysplasia are highly excluded. In order not to miss the malignancy or high-grade dysplasia, it is preferable to perform the colonoscopy in all patients with ICU on PET-CT even in low SUVmax value. A cut-off value using ROC curve has limited capability in screening all malignancy and high-grade dysplasia, however this compromises best positive likelihood ratio with valuable predictive criteria for distinguishing from low-grade dysplasia or inflammatory process.

P1296 FEASIBLE INDICATION FOR COLORECTAL ESD: A PROPOSAL FROM TREATMENT OUTCOME IN A SINGLE CENTER ANALYSIS

T. Sato[1,*], M. Fukuzawa[1], T. Gotoda[1], C. Kusano[1], K. Yagi[1], M. Nonaka[1], K. Yamamoto[1], N. Yagi[1], Y. Tsuji[1], K. Iwatsuka[1], S. Kono[1], J. Uematsu[1], Y. Kishimoto[1], T. Kawai[2], F. Moriyasu[1]. [1]*Department of Gastroenterology and Hepatology,* [2]*Endoscopy Center, Tokyo Medical University, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is now covered by Japanese health insurance for the treatment of ''early colorectal cancers or adenomas with a maximum diameter of 2 to 5 cm'' regardless of tumour morphology and histological staging.

AIMS&METHODS: [Aim] This case-series study is aiming to reevaluate the clinical feasibility of colorectal ESD from the treatment results.

[Subjects & Methods]

Clinical records of 200 colorectal tumours which treated by ESD from June 2007 to March 2012 were reviewed. Tumours were classified into 3 groups according to the tumour size (<20, 20-50,51≦(mm)), then following clinical outcomes; tumour morphology, histology, procedure time, en-bloc resection rate and complications, were evaluated. ESD was indicated for the following lesions in accordance with the Working Group of ESD Standardization for Colorectal Tumors in Japan

RESULTS: Lesions <20mm (n=19) were macroscopically divided into IIa;2, LST-NG:8, LST-G:1, remnant tumour;8. As for histopathological assessment, 4 were adenoma (21%), 15 were cancer (79.0%), including 1 SM cancer (5.3%). Macroscopic type of lesions 20-50mm in size (n=161) were classified in to Is/Isp;10, IIa/IIa+IIc;3, LST-NG;67, LST-G;79, remnant tumour;2. 27 adenoma (16.8%), 124 cancer (77.0%), and 22 SM cancer (19.8%).

20 lesions which more than 50mm in size were classified in to LST-NG;1, LST-G;19. 15 intramucosal cancer (75%) and 5 SM cancer (25%).

The mean procedure time was 56.6 minutes, 96.2 and 171.5 each in 3 groups, respectively. Complete en-bloc resection rate was 94.7%, 88.8% and 90.0% in each group. By the location were C-T/D–S/R: 83.5 / 100 / 100,85.9 / 90.1 / 92.7, 85.9 / 90.1 / 92.7 respectively. There were no significant differences of en-bloc resection rate according to the tumours locations, but the mean procedure time was significant longer in large size tumor group.

Though postoperative bleeding and perforation was found in 4 (2%), in 5 (2.5%), all complications could be endoscopically managed. The rate of cacer becomes high as the tumor size becomes large. And SM cancer were included 25% in tumor size >50 mm..

CONCLUSION: Considering histological staging causing curability of the treatment, clinical indication of colorectal ESD should be feasible for the tumours less than 50mm.

P1297 COMPARISON OF CLINICAL OUTCOMES OF LOCAL EXCISION FOR LOWER RECTAL NEOPLASMS -ESD VS TRANSANAL RESECTION (TAR)-

T. Sakamoto[1,*], M. Yamada[1], Y. Otake[1], T. Nakajima[1], T. Matsuda[1], Y. Saito[1]. [1]*National Cancer Center Hospital, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection for lower rectal neoplasm is technically easy procedure comparing with other parts of colorectum. To elucidate the clinical outcomes of local excision for lower rectal neoplasms on using endoscopic submucosal dissection (ESD) and transanal resection (TAR).

AIMS&METHODS: We considered all patients who underwent ESD or TAR for lower rectal neoplasms from 1999 to 2012 at the National Cancer Center Hospital, Tokyo, for inclusion in this retrospective study. Patients were excluded if their lesions were histologically diagnosed as deep invasive submucosal cancer (≥1,000 μm) or if lymphovascular invasion was noted. In addition, patients who did not receive surveillance colonoscopy were excluded. Clinical outcomes, including the rate of complete en bloc resection and local luminal recurrence, were analyzed and compared between the ESD and TAR groups. Lesion size, macroscopic type, and extension to the dentate line were evaluated for association with the presence of local luminal recurrence in the TAR group.

RESULTS: A total of 96 lesions in 90 patients were eligible for the present study. ESD was performed on 77 lesions in 75 patients, and TAR was performed on 19 lesions in 15 patients. For the patients who underwent ESD, the median follow-up period was 11 months (range: 3–108 months) and the median lesion size was 3.8 cm (range: 2–12 cm). Macroscopically, 6 lesions were protruding (0–I), 63 lesions were laterally spreading tumors (LST), and 8 lesions were recurrent or residual tumor. In contrast, for the patients who underwent TAR, the median follow-up period was 22 months (range: 6–131 months) and the median lesion size was 3.7 cm (range: 1.2–10 cm). Macroscopically, 7 lesions were 0–I, 8 lesions were LST, and 4 lesions were recurrent or residual tumor. The rate of complete en bloc resection in the ESD and TAR groups were 88% and 53%, respectively ($p<0.001$). Local luminal recurrence was observed in 4% of patients in the ESD group and in 42% of patients in the TAR group ($p<0.001$). With regard to the parameters assessed in the TAR group, LST and recurrent lesions were relatively more frequent in cases of local luminal recurrence (75% and 45%, respectively); however, this difference was not statistically significant.

CONCLUSION: ESD is an excellent treatment option for lower rectal lesions indicated for topical treatment, considering the high success rate of en bloc resection and low rate of local luminal recurrence. Importantly, in cases of LST or recurrence in which it is difficult to recognize the lateral margin of the lesions, ESD should be performed.

INTRODUCTION: Confocal laser endomicroscopy (CLE) enables in vivo optical biopsies providing real-time diagnosis of colorectal lesions. It can differentiate between normal mucosa, neoplastic and inflammatory changes based on the examiner's interpretation of crypts architecture and vascular pattern during ongoing colonoscopy. Texture analysis has been used for interpreting and classifying medical images, with initial studies including radiology and ultrasound images.

AIMS&METHODS: Thus our aim was to determine if measurements resulting from gray level co-occurrence matrices can be employed as classifiers for colonic lesions imaged by CLE. Patients with neoplastic and inflammatory colonic lesions underwent CLE examination with a dedicated endomicroscopy system (EC-3870 CIFK, Pentax, Tokyo, Japan). Images of each lesion and corresponding normal mucosa were recorded for later analysis. A total of 472 images were analyzed as follows: 107 CLE images of colorectal cancer, 183 images of colitis, 30 images of colorectal polyps and 152 control images from normal mucosa. Analysis was performed using the public domain image processing tool ImageJ (Bethesda, USA) and the GLCM texture analyzer plug-in (Cabrera, USA). Five

texture parameters (contrast, entropy, correlation, angular second moment - ASM and inverse difference moment - IDM) were calculated for each image. We used these parameters in a support vector machine (SVM) for automatic classification of the lesions.
RESULTS: In a preliminary analysis, we found statistically significant differences between the mean values of all parameters (ANOVA test, $p<0.001$), while applying Bonferroni's multiple comparisons test we found that only ASM and IDM were different between all groups. We included these two parameters in the SVM as main classifiers, obtaining high classification rates for all pathologies (101/107 colorectal cancer, 170/183 colitis, 21/30 polyps and 148/151 control images).
CONCLUSION: This is, to our knowledge, the first attempt to use texture analysis for classifying colorectal lesions based on CLE imaging. Such computer aided analysis could enhance the diagnosis yield and reduce the intra- and interobserver variability of CLE examinations. Inclusion of automatic algorithms of diagnosis could thus offer support for evidence based clinical decisions in real-time while significantly decreasing the time for analysis of hundreds of images obtained during the examination.

P1299 OVER THE SCOPE FULL THICKNESS CLIP FOR THE CLOSURE OF ENTERO-CUTANEOUS FISTULAS

T. Emmanouil[1,*], S. Gavriel[2], A. Tachtaras[3], P. Evangelides[4], S. Baratsis[2]. *[1]Gastroenterology, [2]General Surgery, [3]Radiology, [4]Anaestesiology, Iaso General Hospital, Athens, Greece*

INTRODUCTION: Post surgery leakage of the gastrointestinal tract is a significant source of morbidity in clinical practice. It seems that Over-The-Scope Clip (OTSC) has been promising lately in the management of gastrointestinal complications such as bleeding, perforations, and fistulas closure where surgery has been traditionally the standard of care.
AIMS&METHODS: The aim of this study was to present the therapeutic results of OTSC in two cases with post surgical entero-cutaneous fistulas. The first case is a 37-year old female who presented with entero-cutaneous fistula after sigmoidectomy and the second is a 68-year old female with pouch-cutaneous fistula after total colectomy with IPAA for ulcerative colitis. They were investigated with endoscopy, CT- scan, pouchography, bowel contrast enema and treatment was planned according to the results and co-morbidities.
RESULTS: In both cases leakage and fistula formation was chronic (1 month and 22 years post operatively). Primary technical success was achieved in both cases. In the first case complete closure of the fistula was achieved in 6 weeks after clip placement in combination with external drainage and no additional surgery was needed. In the second case apart from external drainage and the clip, a loop ileostomy was performed and it came to complete closure after 4 weeks with no need of ileal pouch revision. Median follow up time was 4,2 months. No adverse events related to the use of clip were noted.
CONCLUSION: OTSC seems to be an effective and safe method for the management of post operative entero-cutaneous in combination with other methods especially in cases where major surgical procedures could be deleterious. Further experience and technical improvement is needed for better and permanent results.

P1300 CONDITIONS OF USE AND SAFETY OF SODIUM PHOSPHATE TABLETS FOR BOWEL PREPARATION IN FRANCE

T. Ponchon[1,*], H. Hagège[2], R. Laugier[3], S. Nahon[4], P. Coulom[5], C. ISNARD BAGNIS[6], A. ALBERT MARTY[7], F. HENRI[7]. *[1]HepatoGastroEnterology, Herriot University Hospital, LYON, [2]HepatoGastroEnterology, CHI, CRETEIL, [3]HepatoGastroEnterology, La Timone University Hospital, Marseille, [4]HepatoGastroEnterology, GHI Le Raincy, MONTFERMEIL, [5]Gastro Enterology, Clinique Saint Jean Languedoc, TOULOUSE, [6]Nephrology, La Pitie Salpetriere UMPC University Hospital, PARIS, [7]pharmaceutical company, CHATOU, France*

INTRODUCTION: The primary objective was to describe the conditions of use and safety of sodium phosphate (NaP) tablets in France.
AIMS&METHODS: Prospective, longitudinal observational study carried on by French private and public hospital gastroenterologists (GE) in routine medical practice. GE were randomly selected from a national database. Thousand consecutive patients likely to receive NaP tablets as bowel preparation should be included. The data collection was based on two questionnaires filled in by each GE and patient, focused on patient characteristics, use, safety, acceptability and quality of bowel preparation. This study was monitored throughout by an independent Safety Committee.
RESULTS: From September 2011 to March 2012, 1048 patients have been enrolled by 108 GE. Data were available for 996 patients. Both populations (GE and patients) were representative. The patients age ranged from 18 to 81 years (m±SD: 54.6 ±11.8), 20 were over 75 years. At baseline, 46% of patients had comorbidities, mainly cardiovascular, endocrine / metabolic and gastrointestinal conditions. Concomitant treatments were mainly cardiovascular drugs (39%). 55% of patients had a previous colonoscopy with PEG prep in 71% of them.98% of patients received appropriate and sufficient information on how to prepare. 84% of patients had a Boston BPS score ≥ 2 (preparation of good to excellent quality) in each colonic segment. Failure of colonoscopy was reported for 17 patients (1.7%) including only 7 for poor bowel cleansing. 310 patients (31%) reported an adverse event (AE). 6 patients stopped the study drug and only one patient had three serious AEs unrelated to the prep. The most common reported AE were bloating (26%), digestive discomfort (23%) and anal irritation (24%). Only 9.8% of patients experienced vomiting. Among the 360 upper GI endoscopies simultaneously performed, 201 showed superficial gastric lesions. The Safety Committee considered these lesions as likely NaP related in 19 patients (5%). Neither electrolytic disorders nor acute renal failure have been reported. Among the 520 patients who had previous colonoscopy, NaP tablets were preferred, designated as easier to take and more tolerable for 76%, 69%, 58% of patients, respectively and 72% of them were willing to take again the same preparation for a future colonoscopy.
CONCLUSION: The results of this observational study are consistent with those previously reported in controlled clinical studies and highlighted the safety, quality and acceptability of NaP tablets bowel prep in routine practice.

P1301 CAN ENDOSCOPIC SUBMUCOSAL DISSECTION OF COLORECTAL NEOPLASM GREATER THAN 50 MM SIZE BE SAFELY PERFORMED IN A GENERAL HOSPITAL?

Y. Minato[1,*], K. Ohata[1], K. Nonaka[1], Y. Misumi[1], T. Tashima[1], M. Shozushima[1], N. Matsuhashi[1]. *[1]Gastroenterology, NTT Medical Center Tokyo, Tokyo, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) is minimally invasive treatment and enables en-block resection for early colorectal neoplasm. However, it is not widely used in the large neoplasm lesions because of technical difficulty and complications. It has been reported that tumor size of 50 mm or larger was an independent risk factor for complications.
AIMS&METHODS: We aimed to examine the safety, efficacy and complications (perforation and delayed bleeding) of ESD for large colorectal neoplasm in a nonacademic hospital in Japan. All cases were carried out with 1 expert and/or 5 novice endoscopists who had performed under expert's supervision. We have treated 608 cases of colorectal neoplasms (size$\geq$20mm) from July 2007 to December 2012. We devided the cases into two groups by size :Group A (lesion size,20-49mm) and Group B (lesion size$\geq$50mm).
RESULTS: For the 608 cases, 511 cases (84.0%) were assigned to Group A and 97 cases (16.0%) were assigned to Group B. The average age, lesion size and procedure times were 67.4 years, 30.0 mm, 60.0 min in group A, and 67.1 years ($P=0.41$), 64.2mm, 119.6min ($p<0.001$), respectively, in Group B. En bloc resections rate ware 99.2% and 99.0% ($P=0.80$) and complication rate were 4.1% and 9.9% ($p=0.03$). Complications in Group A were 14 perforations, 6 bleeding and 1 ischemic colitis. In group B were 8 perforations and 1 bleeding. Emergency operations were performed two cases in Group A, but none in Group B.
CONCLUSION: ESD was expected to be more complicated for colorectal lesions greater than 50mm in size. However, if it is performed under expert's supervision even if it is a general hospital, ESD for colorectal neoplasm greater than 50 mm in size has become a safe therapeutic method.

P1302 COMPLEX ENDOSCOPIC RESECTION OF GIANT (>4CM) SESSILE/FLAT COLONIC POLYPS: TECHNIQUES AND OUTCOMES.

Z. P. Tsiamoulos[1,*], S. T. Peake[1], N. Suzuki[1], L. A. Bourikas[2], J. Warusavitarne[3], B. P. Saunders[1]. *[1]Wolfson Unit for Endoscopy, St Mark's Hospital/Academic Institute, London, United Kingdom, [2]Department of Gastroenterology, University of Crete, Crete, Greece, [3]Department of Colorectal Surgery, St Mark's Hospital/Academic Institute, London, United Kingdom*

INTRODUCTION: Giant, sessile/flat colon polyps (>4cm) are challenging to remove endoscopically and many lesions are still treated with laparoscopic or open segmental resection. However compared to surgery, complex endoscopic

resection can provide reduced procedure morbidity, significant lower cost and is generally preferred by patients.
AIMS&METHODS: We conducted a prospective analysis of all tertiary cases referred to our academic center for endoscopic assessment and complex resection of giant (>4cm) sessile/flat colon polyps over a 2½ year period (January 2010 - August 2012). Completion rates, adverse events and recurrence rates were recorded.
RESULTS: 107 consecutive patients [mean age 69 years) with 109 colon polyps underwent complex polypectomy. Mean polyp size was 52mm. 31% of polyps were proximally distributed and 69% distal. Primary reasons for referral were polyp size, submucosal fibrosis (SF) and difficult endoscopic access. ASA status of the patients were: ASA I/35%, ASA II/55% and ASA III/10%.
The majority of polyps (n=90) were resected by piecemeal Endoscopic Mucosal Resection (P-EMR). Endoscopic Mucosal Ablation(EMA)-assisted polypectomy (n=19) and Spiral-snare (n=29) were utilized in cases of moderate to severe SF. Supplementary techniques were employed to augment endoscopic access in 3 cases: two Endocuff-assisted polypectomy and one Laparoscopic-assisted polypectomy.
Complex polypectomy was successful in 94.5% in a single session with mean procedure time 43min. Immediate adverse events included controlled intra-procedural bleeding (13.7%), self-limiting vasovagal episodes (8.2%) and one deep submucosal tear (0.9%) treated with endoclips. Eight patients (7.4%) required hospitalization due to delayed post-polypectomy bleeding with one requiring emergency laparotomy. No mortality was noted.
92 patients attended for follow up at 3/6 months, with no recurrence in 45% of cases (n=41). <10mm recurrence (benign and easily treatable) was found in 42% (n=39) of cases and >10mm recurrence in 13% (n=12). One patient with large rectal recurrence had a TEMS procedure and two patients with histology showing malignancy had segmental resections. Further follow up at 9/15 months was performed in 40/92 patients with no recurrence in 70% (n=28), <10 mm benign recurrence in 28% (n=11) and one >10mm benign recurrence 3% (n=1).
CONCLUSION: Complex endoscopic resection of giant (>4cm) sessile/flat colon polyps demands a multi-modality approach, but good medium term outcomes can be achieved with most patients spared surgery. Minor recurrence occurs frequently but can be successfully managed with close surveillance.

P1303 EFFECT OF RECTAL INDOMETHACIN FOR PREVENTION OF POST-ERCP PANCREATITIS: A PROSPECTIVE, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED CLINICAL TRIAL

A. V. Patai[1,*], N. Solymosi[2], A. Patai[3]. [1]*2nd Department of Internal Medicine, Semmelweis University,* [2]*Faculty of Veterinary Science, Szent István University Budapest, Budapest,* [3]*Department of Gastroenterology, Sopron Elizabeth Teaching Hospital, Sopron, Hungary*

INTRODUCTION: Two problems of endoscopic retrograde cholangiopancreatography (ERCP) compromise the clinical benefits of endoscopic biliary therapy: failure of selective biliary cannulation and post-ERCP pancreatitis (PEP). Unsuccessful biliary cannulation may occur in up to 15 - 35% of cases. PEP remained the most common major complication of ERCP, its frequency was reported between 5 and 10 % generally, but it can increase at high risk procedures in high risk patients up to 42 %. On time interruption of unsuccessful attempts for cannulation seems to be important: after many unsuccessful attempts the risk of PEP rises and complete failure becomes inevitable.
AIMS&METHODS: To evaluate the efficacy of rectal indomethacin for prevention of PEP, while success rate of therapeutic ERCP was maximised. 539 patients selected for biliary endoscopic therapy were randomized in a prospective, double-blind clinical trial: 270 patients were given rectal 100 mg indomethacin and 269 patients received placebo within 1 hour before ERCP. Patients (with papillectomy, previous serious PEP, cannulation of minor papilla) receiving pancreatic stents were excluded. Wire-guide cannulation (WGC) was planned after 5 unsuccessful attempts, if 5 WGCs were unsuccessful, precut was performed.
RESULTS: The 2 groups were comparable in age, sex, analytical parameters, indications for ERCP, procedure and disease characteristics. Successful ERCP was performed in 529 patients (98.1%), ''simple'' diagnostic ERC was performed in 16 patients (2.6%), endoscopic biliary therapy was achieved successfully in 513 patients (95.2%). PEP occurred in 55 patients (10.2%), 18 patients (6.7%) in indomethacin group and in 37 patients (13.7%) in placebo group (p=0.007). Prophylactic effect of indomethacin was detected more definitely in patients having high risk procedure-related factors (13.8% in indomethacin group versus 28.3% in placebo group, p=0.028) and high risk patient-related factors (7% in indomethacin group versus 16.5 % in placebo group, p=0.004). No adverse event attributable to indomethacin was observed.
CONCLUSION: On time interruption of unsuccessful attempts for selective biliary cannulation and early implementation of precut can confer high success rate of biliary endoscopic therapy. Prophylactic 100 mg rectal indomethacin is effective for prevention of PEP, particularly in high risk patients and at high risk procedures.

P1304 NEEDLE-KNIFE SPHINCTEROTOMY OVER A PANCREATIC STENT (NKPS) IN DIFFICULT BILIARY CANNULATION BUT INCIDENTAL SELECTIVE PANCREATIC DUCT (PD) CANNULATION.

E. K. Choi[1,*], S. U. Jeong[1], S.-J. Boo[1], S.-Y. Na[1], B.-C. Song[1], Y.-K. Cho[1], H. J. Song[1], H. U. Kim[1]. [1]*Internal Medicine, Jeju National University Hospital, Jeju-Do, Korea, Republic Of*

INTRODUCTION: The rate of post-ERCP pancreatitis (PEP) increases when cannulation is difficult. Precut biliary endoscopic sphincterotomy (precut ES) has been used to improve the success rate of biliary cannulation; however, precut ES is an independent risk factor for PEP. There are a few reports that the pancreatic stent helps guide the precut ES improving the safety of the technique.
AIMS&METHODS: This was a prospective observational study of difficult biliary access and incidental selective PD cannulation that assessed effectiveness and safety of NKPS in this high risk situation for PEP. Between Jan. 2012 and Mar. 2013, consecutive patients who underwent ERCP with a clear indication for biliary access in Jeju National University Hospital were enrolled. All ERCP procedures were performed by one endoscopist. When bile duct cannulation was difficult and incidental PD cannulation was achieved, PD stent was placed using a 0.018 guidewire (Cook Endoscopy, Winston-Salem, NC) and 3F unflanged single pigtail plastic stent (4 to 8 cm, Zimmon; Cook Endoscopy). Using the PD stent as a guide, precut ES was performed by cutting cephalad in the 12-o'clock position beginning at the papillary orifice with needle-knife sphincterotome. Selective biliary cannulation was then attempted. The PD stent was left in place. This group of patients was classified as NKPS group and compared to the rest of patients, called routine group. ERCP-related complications were classified and graded according to consensus guidelines. Statistical analyses were performed by Fisher's exact test and Mann–Whitney U test using SPSS version 17.0 (SPSS, Inc., Chicago, IL).
RESULTS: Among 306 ERCP during this period, 175 patients with naïve papilla (M=89, F=86) for biliary indication were prospectively enrolled. Of those 175, 16 (M=9, F=7) were included in the NKPS group. The mean age was 64 in both groups. Successful biliary cannulation was achieved in all NKPS patients. PEP was developed in 8 of 159 (5%) in routine group and 2 of 16 (12.5%) in NKPS group (p=0.229). Bleeding was developed in 9 of 159 (5.7%), 1 of 16 (6.3%), respectively (p=1.000). Mean (SD) serum amylase levels after ERCP were 194.9 (377.5) U/L and 438.2 (474.6) U/L, respectively (p<0.001). All the PEP was mild in NKPS group. All PD stents were dislodged spontaneously within 7 days.
CONCLUSION: Even though NKPS group was high risk for PEP, the incidence of PEP was comparable to the routine group. If biliary cannulation is difficult and incidental PD cannulation is achieved, NKPS would be safe and feasible with a lower rate of post-procedure complications.

P1305 FEASIBILITY OF AN ENDOSCOPIC PORCINE MODEL OF BILIARY OBSTRUCTION USING OVER-THE-SCOPE CLIPS. EVALUATION OF ITS APPLICABILITY TO TRAINING IN EUS-GUIDED DRAINAGE PROCEDURES.

I. Peñas Herrero[1,*], N. Alcaide Suarez[1], S. Lorenzo Pelayo[1], A. Vargas García[1], C. de la Serna Higuera[1], M. Pérez Miranda[1]. [1]*Hospital Universitario Rio Hortega, Valladolid, Spain*

INTRODUCTION: There is a growing demand in clinical practice for EUS-guided drainage procedures. EUS-DP are technically challenging and carry morbidity. Porcine models of biliary obstruction by laparoscopic bile duct ligation have been used for training.
AIMS&METHODS: To develop a reproducible and affordable porcine model of biliary obstruction. To assess the potential use of such model for training in therapeutic EUS. After approval, the papilla of 16 swine was clipped using Over-the-scope (OTSC) clips (Ovesco, Tübingen, Germany). Variables used: a) Time to reach and identify the papilla with and without OTSC by the same operator at sequential intubations; b) Success rates at clipping the papilla by two novel & two experienced operators; c) Time to identify papilla Vs Time to place OTSC. Clinical, biochemical and imaging (abdominal ultrasound & laparoscopy) follow-up was performed at 3-4 and 8-10 days to assess efficacy & complications of OTSC placement. The feasibility of EUS-guided bilio-enteric anastomoses after OTSC clipping of the papilla was evaluated using both standard oblique-viewing (n=13) and prototype forward viewing lineal echoendoscopes (n=10) by non-expert (total career experience <25 EUS-DP) endosonographers under experienced operator supervision.
RESULTS: The OTSC clip was successfully deployed on the papilla of 15/16 animals (1 failure). No significant differences were found between time to identify the papilla (460 [158-892] seconds) and time to place OTSC clips (575 seconds). Two animals had post-procedure pain. One died at 48 hours and a gastric perforation was found at necropsy. Another one had a retroduodenal abscess found at necropsy at 10 day follow-up. At immediate follow-up, 14/15 animals had high serum bilirubin (mean value=3.55 mg/dL; mean increase over baseline=2.85 mg/dL). All 4 pigs in which ultrasound or laparoscopy had CBD (>4 mm), gallbladder and cystic duct dilation (but not intrahepatics). At second follow-up 8-10 days post clipping, all surviving animals exhibited at EUS massive CBD dilation (>15 mm). Only 3/14 had intrahepatic dilation. A total of 23 EUS-DP were attempted (16 by novel operators), including hepaticogastrostomy (n=3), choledochoduodenostomy (n=8) or cholecystgastrostomy (n=12). Although EUS-guided access and cholangiography were successful in 23/23, anastomoses were only accomplished in 30.5%

CONCLUSION: OTSC placement on the porcine papilla is a simple, effective model of biliary obstruction which appears to reflect the difficulty of EUS-DP. Its application for training purposes warrants further study.

P1306 LEARNING PHASE OF DIRECT PERORAL CHOLANGIOSCOPY USING ULTRA SLIM GASTROSCOPES

J. Weigt[1,*], A. Kandulski[1], P. Malfertheiner[1]. [1]*Gastroenterology, Hepatology & Infectious Diseases, UNIVERSTITY MAGDEBURG, Magdeburg, Germany*

INTRODUCTION: Direct peroral cholangioscopy (POCS) is an emerging technique complementing ERCP. Unless several data demonstrate the clinical relevance of POCS, only few data about the learning process of this technique are available.
AIMS&METHODS: Aim: To investigate the technical success rate and learning process of POCS in a tertiary center.
Methods:
All patients were investigated with standard ERCP and biliary sphincterotomy directly prior to cholangioscopy. After removal of the duodenoscope, an ultra slim gastroscope was directly advanced to the duodenum. The common bile duct was intubated using the balloon anchor technique. All POCS procedures were performed with water irrigation or carbon dioxide indufflation. Histology was taken from suspicious lesions. The investigation times and the success rates were calculated. Special caution was given to the time from oral intubation until visualization of the bile ducts that served as a key technical parameter.
RESULTS: A total of 36 POCS were performed. Intubation was successful in 31/36 (86%). Reasons for failed intubation were small caliber bile ducts, duodenal diverticulum and papillary adenoma. The mean intubation time was 9.2 min (3-23 min). The average intubation time did not change significantly over time (R^2= -0.03). The variance of intubation times changed over time and was 26.5 min in the first half of investigations and 19.2 min in the second half but did not reach significant levels. A minor bleeding caused by the anchor balloon was the only complication that was observed.
CONCLUSION: The technique of direct peroral cholangioscopy using the balloon anchor technique in combination with ultra-slim gastroscopes is technically demanding. Performance is safe after a short learning period at last in a tertiary center. Nevertheless, as POCS is not yet a standard technique, we suggest that POCS may only be performed by experienced endoscopists.

P1307 OUTCOME AND NATURAL COURSE OF CRITICALLY ILL PATIENTS WITH SCLEROSING CHOLANGITIS

K. Egger[1,*], F. Gesele[1], H. D. Allescher[1]. [1]*Zentrum für Innere Medizin, Klinikum Garmisch-Partenkirchen, Garmisch-Partenkirchen, Germany*

INTRODUCTION: Sclerosing cholangitis in critically ill patients (SC-CIP) is a severe biliary disease with a poor outcome. The mechanisms leading to this form of bile duct alterations are widely unknown. Data on outcome of a natural course are sparse.
AIMS&METHODS: In a period of 6 years (2005-2011) we includet 57 patients during or after the stay in a ICU in a large bavarian trauma and neurosurgical center from 2/2005 - 9/2009 retrospective and 12/2009 - 11/2011 prospective. All patients showed pathological endoscopic findings by ERCP. Characteristic findings were bile duct stenosis, vanishing bile ducts and biliary casts.
RESULTS: ERCP was performed usually (median) on day 53. 50/58 patients (88%) were followed by routine follow up, readmission, telefone contact or questionnaire with a follow up of 35,5 month. Underlying disorders were intracerebral bleeding (47%), severe poly trauma (29%), severe septic shock (17%), severe burning injuries (6%). Endoscopic therapy with papillotomy, balloon dilatation, cast removal if present was performed in all patients.
27 patients had a favourable (n=8) or stable course (n=19). 3 patients recieved LTX, 5 patients have being listed for LTX. 16 patients died during follow up, 4/16 patients in consequence of the SC-CIP.
CONCLUSION: In contrast to the literature, SC-CIP is not allways a rapidly progressive disease. The letality is 14,5% in a long term outcome of 2,6 years

P1308 ERCP PERFORATIONS IN THE NEW MILLENNIUM - RESULTS FROM 9000 ERCPS/ A LARGE TERTIARY REFERRAL CENTRE EXPERIENC

K. Monkemuller[1,*], J. Ramesh[1], S. Kodali[1], S. Varadarajulu[1], C. M. Wilcox[1]. [1]*University of Alabama at Birmingham, Birmingham, United States*

INTRODUCTION: Background: Although rare, perforations are one of the most dreaded complications of ERCP. The incidence of perforations during ERCP has been reported to range from 0.3 to 6%. However, this data stems mainly from older studies or retrospective databases. Current data is important, as ERCP has revolutionized to be mainly a therapeutic procedure. Data on outcomes and complications are essential to establish prevalence and incidence rates, standards, quality indicators and risk factors for perforations.
AIMS&METHODS: To assess the incidence of ERCP related perforations and outcomes at a large tertiary referral centre. A review of all patients undergoing ERCP at our institution from January 2003 to November 2012 was performed to assess the ERCP related perforations. All patients are routinely followed-up clinically or via telephone interview within 30 days after the procedure.
RESULTS: Out of a total of 9000 ERCPs that were performed (92% therapeutic interventions), a total of 12 iatrogenic perforations occurred, yielding an incidence of 0,0012%. The mean age of the patients was 58.8 years, range 23 to 79. Most perforations occurr3d in the second portion of duodenum (n = 10, 83%), all of these were related to sphincterotomy. One patient suffered from esophageal perforation and another patient with Billroth II anatomy suffered from a perforation of the afferent limb. Endoscopic closure of the perforation site was not performed in any patients as most of them were either diagnosed after the procedure or were not amenable to endoscopic intervention and needed surgery. Eight out of 12 (67%) patients were managed medically and four surgically. All patients improved and were discharged home. There were no deaths.
CONCLUSION: The perforation rate of ERCP was 0.0013%. Sphincterotomy-related perforations constituted the majority of iatrogenic damage. CT was the best method to detect perforation. Immediate endoscopic closure of the perforation was not done in any patients since most of them were diagnosed after the procedure or were not amenable to endoscopic therapy. Risk factors for perforation included altered surgical anatomy, female sex, sphincter of Oddi dysfunction.

P1309 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN ELDERLY PATIENTS.

L. C. Meireles[1,*], J. Canena[2], I. Marques[1], A. C. Lagos[1], A. P. Coutinho[1], B. Neves[1]. [1]*Gastrenterology, Centro Hospitalar Lisboa Norte,* [2]*Gastrenterology, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

INTRODUCTION: Old age is associated with biliary and pancreatic pathology with the consequent need to perform endoscopic retrograde cholangiopancreatography (ERCP). Some studies suggest that ERCP in very old patients is associated with an increasing number of complications and technical failure.
AIMS&METHODS: The aim of this study was to evaluate the clinical effectiveness and associate complications of ERCP in patients older than 85 years.
This was a retrospective review of 48 consecutive patients older than 85 years old, who underwent ERCP, in a 26-month period, in a single center. The data was collected to analyse demographic information, indications, technical and clinical success, ERCP procedures, ERCP diagnosis, complications and length of hospital stay.
RESULTS: Technical success was achieved in 98% of cases in the first attempt and 100% in the second. The median age was 89 years old (range: 86-102) and 68% women. The main indications were: gallbladder and pancreatic cancer (11 cases-23%), suspected choledocholithiasis (18 cases-38%). The main therapies associated with ERCP were: sphincterotomy (n = 36), biliary stent (n = 26); extraction of bile duct stones (n = 22), mechanical lithotripsy (n = 4). Complications occurred in 8% of patients: 2 patients had cholangitis (4%) and 2 pancreatitis (4%). No cases of: 1) need of mechanical ventilation after anesthesia, 2) hemorrhage requiring transfusion, 3) mortality associated with ERCP were recorded. The median length of hospital stay after examination was 2 days (range: 1-103)
CONCLUSION: Diagnostic and therapeutic ERCP is effective and safe in elderly patients who present similar outcomes as younger patients.

P1310 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN CHILDREN AND ADOLESCENTS: A UK SINGLE CENTER EXPERIENCE

M. Kumar[1,*], A. Koutsoumpos[1], G. Webster[1], S. Pereira[1]. [1]*Gastroenterology, University College London Hospital, London, United Kingdom*

INTRODUCTION: Endoscopic retograde cholangiopancreatography (ERCP) is a specialised endoscopic procedure associated with high risk of complications in adults. ERCP is not commonly performed in children and is mainly indicated for therapeutic interventions, however ERCP can also be a vital diagnostic tool in pancreatobiliary diseases where imaging is non-diagnostic. We report a UK tertiary center experience of ERCP in children and adolescents.
AIMS&METHODS: To prospectively evaluate our ERCP practice in children and adolescents and record technical success and complications. We also assessed correlation of radiological findings pre ERCP to cholangiopancreatography findings at ERCP.

Data was recorded prospectively from children and adolescents who underwent ERCP at University College London hospital between 2005 and 2012. Techincal success at ERCP and complication rates were analysed. We continue to collect data on long term outcomes of these patients.
RESULTS: 36 children underwent 40(n) ERCP procedures using a 11mm duodenoscope.22 patients were males. Median age was 11.5 years (range 3-17). Majority (67%) of ERCPs were performed as daycases. All ERCPs were performed under general anaesthesia by three experienced gastroenterologists. Common indications for ERCP were chronic recurrent pancreatitis needing pancreatic endotherapy (20), choledocholithiasis (10), abnormal liver function test (5), abnormal imaging(4). Majority were cotton grade 2(51%) and grade 3(36%) procedures. Therapeutic procedures performed included biliary sphincterotomy (12),CBD stones removal (10), pancreatic sphincterotomy (3), pancreatic stenting (8) and biliary stenting (2). Intended therapeutic success was achieved in 90% of procedures performed. In 10%of patients ERCP revealed new findings which were not reported on pre ERCP imaging. No major post ERCP complications were seen in our cohort apart from one patient who developed mild post ercp pancreatitis which was managed conservatively. No ERCP related mortality was reported.3 patients (7.5%) needed surgery as ERCP was unsuccessful in achieving intended therapeutic success.
CONCLUSION: ERCP in children and adolescents is safe and effective and can be performed as a daycase. Use of appropriate duodenoscope and accessories are key to success. Complication rates are minimal. ERCP can be a useful diagnostic tool where imaging is inconclusive. ERCP plays an important role in diagnosis and management of pancreatobiliary conditions in children and adolescents and can prevent complex pancreatobiliary surgery in selective cases.

P1311 WHEN AND TO WHOM SHOULD WE APPLY THE DOUBLE GUIDEWIRE CANNULATION METHOD DURING ENDOSCOPIC BILIARY INTERVENTION? -POST HOC ANALYSIS OF MULTICENTER RANDOMIZED CONTROLLED TRIAL-

N. Sasahira[1,*], H. Isayama[2], H. Kawakami[3], Y. Ito[4], S. Matsubara[5], H. Ishiwatari[6], M. Uebayashi[7], R. Uchino[8], H. Yagioka[9], O. Togawa[10], N. Toda[11], N. Sakamoto[3], J. Kato[6], K. Koike[2], EDUCATION study group. *[1]Gastroenterology, Sempo Tokyo Takanawa Hospital, [2]Gastroenterology, The University of Tokyo, Tokyo, [3]Gastroenterology, Hokkaido University, Sapporo, [4]Gastroenterology, Japan Red Cross Medical Center, [5]Gastroenterology, Tokyo Metropolitan Police Hospital, Tokyo, [6]Gastroenterology, Sapporo Medical University, Sapporo, [7]Gastroenterology, Japanese Red Cross Kitami Hospital, Hokkaido, [8]Gastroenterology, Kanto Central Hospital, [9]Gastroenterology, JR Tokyo General Hospital, Tokyo, [10]Gastroenterology, Saitama Medical University International Medical Center, Saitama, [11]Gastroenterology, Mitsui Memorial Hospital, Tokyo, Japan*

INTRODUCTION: Double guidewire cannulation technique (DGW) is one of the rescue techniques for wire-guided cannulation method (WGC) during ERC. Recent multicenter randomized controlled trial comparing early DGW and repeated WGC at the first unexpected insertion of guidewire into main pancreatic duct (MPD) showed no significant difference in either successful CBD cannulation or development of post ERCP pancreatitis (PEP) between the two groups (reported in DDW 2013). We performed post-hoc analyses to investigate the maximum use of DGW.
AIMS&METHODS: Among 707 consecutive patients with naiive papilla who were to undergo therapeutic biliary intervention with WGC, a total of 274 patients with unintentional insertion of guidewire into MPD on the first cannulation attempt were randomized into Repeated WGC group and Early DGW group. Main outcomes were the success rate of biliary cannulation within 10 attempts and 10 minutes from the randomization and the PEP rate.
RESULTS: Early DGW had a relative rate of successful CBD cannulation of 1.07 (95%CI 0.93-1.24) with a relative risk for PEP of 1.04 (CI 0.93-1.16). Subgroup analysis showed that Early DGW had an advantage in patients with biliary neoplasm (RR 1.36, CI 1.05-1.77) and with intra-/peri-diverticular ampulla (RR 1.24, CI 0.93-1.66). If the cannulation with the randomized way were limited in 5 attempts and 5 minutes, DGW had an increased RRof 1.16 (CI 0.91-1.49) for CBD cannulation with a decreased RR of 0.69 (CI 0.29-1.63) for PEP. Although the risk for PEP was not related to the number of attempts or the time for CBD cannulation in Repeated WGC group, it was significantly increased along with those in Early DGW group (11% in <5 attempts/minutes, 25% in 5-10 attempts/minutes, and 32% in >10 attempts/minutes, p=0.03).
CONCLUSION: In therapeutic ERC using WGC, early DGW neither facilitated CBD cannulation nor reduced PEP compared to repeated WGC. However, DGW might have an advantage in selected patients or by using it within 5 attempts and 5 minutes.

P1312 DISTINGUISHING BENIGN FROM MALIGNANT DOMINANT BILIARY STRICTURES IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS UTILIZING PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY (PCLE): A MULTI-CENTER, EXPERT CONSENSUS REVIEW

R. J. Shah[1], J. Chennat[2], P. Cesaro[3], A. Slivka[2], D. V. Sejpal[4], P. A. Jamidar[5], A. Sethi[6], S. I. Gan[7], M. H. Walter[8], M. Gaidhane[9], M. Kahaleh[9,*]. *[1]Gastroenterology, UNIVERSITY OF COLORADO, Aurora, [2]Gastroenterology, University of Pittsburgh Medical Center, Pittsburgh, United States, [3]Gastroenterology, Policlinico Agostino Gemelli / Univ. Cattolica Del Sacro Cuore, Rome, Italy, [4]Gastroenterology, Baylor College of Medicine Houston, Houston, [5]Gastroenterology, Yale University, New Haven, [6]Gastroenterology, Columbia University, New York, [7]Gastroenterology, Viriginia Mason Medical Center, Seattle, [8]Gastroenterology, Loma Linda University, Loma Linda, [9]Gastroenterology, Weill Cornell Medical Center, New York, United States*

INTRODUCTION: Probe-based confocal laser endomicroscopy (pCLE) enables subepithelial visualization of biliary strictures. Whether fibrosis and inflammation of PSC may alter pCLE interpretation or if expert consensus of findings can be achieved in PSC remains unknown.
AIMS&METHODS: Evaluate pCLE for dominant PSC stenosis by blinded consensus review of image sequences. Methods: 10 pCLE experts from 9 centers (8 US, 1 EU) had a consensus meeting. pCLE video sequences acquired during ERCP using the CholangioFlexTM confocal mini probe (Mauna Kea Tech. Paris, France) passed through a cholangioscope or catheter were reviewed. Investigators were blinded from clinical data. Normal and malignant Miami criteria and inflammatory Paris criteria were assessed. Patients with a minimum two of five malignant Miami criteria were "suspicious", one "reactive"; a normal reticular pattern was "benign". Tissue sampling results at time of ERCP was considered positive if malignant cytohistopathology. ROC curve analysis for pCLE performed. CI calculated.
RESULTS: pCLE sequences from 46 dominant PSC strictures were pooled from five centers. A presumptive diagnosis based on tissue sampling results and clinical follow-up was benign (n=39) and malignant (n=7). Combining pCLE and tissue sampling yielded sensitivity and NPV of 100%. See Table for operating characteristics. ROC of pCLE: AUC =.77 (CI.62-.88; p =0.006).

Operating Characteristics	pCLE	Tissue Sampling	pCLE + Tissue Sampling
Accuracy	80	98	85
Sensitivity	71	86	100
Specificity	82	100	82
NPV	94	98	100

CONCLUSION: The high operating characteristics of tissue sampling in our PSC patient cohort was related to selection bias. The combination of pCLE and tissue sampling in the evaluation of dominant PSC strictures has a high ability to exclude malignancy and may be helpful in determining surveillance intervals in this high-risk population. Operating characteristics of pCLE in the setting of PSC should further improve with increased experience of recognizing inflammatory criteria. A multi-center, international registry of pCLE in PSC patients is ongoing.

P1313 DOES REALLY DOUBLE BALLOON ENDOSCOPY INCREASES THE ERCP SUCCESS RATE IN PATIENTS HAVE ANATOMICALLY ALTERED GI TRACT?

S. Hülagu[1,*], G. Sirin[2], O. Sentürk[1], A. Celebi[1]. *[1]Gastroenterology Department, Kocaeli University, [2]Gastroenterology, Derince Education and Research Hospital, Kocaeli, Turkey*

INTRODUCTION: Endoscopic retrograde cholangiopancreatography (ERCP) success rate 85- 95% in patients with a normal gastrointestinal anatomy. But its success rate is lower in case of alternated anatomy (60% > 92%).
AIMS&METHODS: We aimed that to evaluate the effect of double balloon endoscope (DBE) on the endoscopic retrograde cholangiopancreatography (ERCP) success rate in patients with a history of Billroth II (BII) gastrectomy or hepaticojejunostomy with Roux-en-Y. The medical records of the patients who underwent ERCP at the Gastroenterology Department of Kocaeli University Medical Faculty Hospital, between December 2008 to September 2012 were examined. ERCP procedure was performed for 2254 patients. Of the 2254 patients, 61 patients (2.7%) have anatomically altered GI tract; 50 patients (26 men and 24 women) with a BII gastrectomy with Roux-en-Y underwent 56 ERCP attempts and 11 patients (6 men and 5 women) have hepaticojejunostomy with Roux-en-Y underwent 11 ERCP attempts before being referred to our center. The mean age of these 61 patients was 63 years (range 35-77 years). In all cases, the ERCP procedures were started using a side-viewing duodenoscope. If intubation of the afferent loop or reaching the papilla failed, we changed to DBE for the ERCP procedure (DBE-ERCP). The DBE-ERCP procedure was

performed using Fujinon EN-450 T5, Japan. We assessed the success rate of afferent loop intubation, reaching the major papilla, selective cannulation, possibility of therapeutic approaches, procedure-related complications, and the overall success rate.
RESULTS: Among the 61 patients have anatomically altered GI tract, the duodenoscope was successfully passed up to the papilla in 30 patients (% 49.2%), and cannulation was successfully performed in 27 patients (44.3%). Thirty-one patients (12 with failure in afferent loop intubation and 19 with failure in reaching the papilla) underwent DBE-ERCP. The DBE reached the papilla or enterobiliary anastamosis in 30 patients (96.8%) and selective canulation of choledocus could be achieved in all except 3 patients (90.3%). 18 patients (58.1%) who had common bile duct stones were successfully treated. In 3 patients with pancreatic head tumor and 2 patient with cholangiocarcinoma biliary stenting was performed. In 4 patients with benign biliary strictures balloon dilatation was performed. We observed perforation in one patient with Whipple, Roux-en-Y for Pancreatic Carsinoma due to procedure. The overall ERCP success rate increased from 44.2% (27/61) to 88.5 % (54/61).
CONCLUSION: The overall ERCP success rate increases with DBE in patients have anatomically altered GI tract.

P1314 PREDICTORS OF STENT DYSFUNCTION IN PALLIATIVE ENDOSCOPIC DRAINAGE OF MALIGNANT BILIARY OBSTRUCTION

S. Khorrami[1,*], E. Iyo[1], C. Paez[1], C. Garrido[1], A. Llompart[1]. [1]*Gastroenterology, Son Espases Hospital, Palma de Mallorca, Spain*

INTRODUCTION: The major disadvantage of endoscopic approach for the palliation of malignant biliary obstruction is the stent patency.
AIMS&METHODS: The aim of this study was to identify predictors of stent dysfunction in patients with malignant biliary obstruction caused by unresectable neoplasms. Medical records of consecutive patients who required placement of a biliary stent between August 2009 and August 2012 in a tertiary medical centre were retrospectively reviewed. Stent dysfunction was defined as relevant cholestasis worsening due to stent obstruction or migration, or as symptoms of cholangitis. Demographic data, comorbidity, performance status (ECOG), stricture location, neoplasm characteristics, presence of metastases, laboratory parameters (bilirubin, haemoglobin, albumin, CA 19.9), type of biliary stent, hospitalization time, complications, concomitant chemotherapy and overall survival were compiled. Univariate analysis and multivariate multinomial logistic regression were performed to identify independent predictors associated to stent dysfunction.
RESULTS: 51 of 64 patients with malignant biliary obstruction fulfilled the inclusion criteria and were included (56.9% females, 72.3 ± 13.6 year-old). Pancreatic cancer (49.1%) and cholangiocarcinoma (31.4%) were the most common indications for stent insertion. 17 self-expandable metal stents (15 one-step and 2 elective-exchanged) and 34 plastic stents were endoscopically placed. Twenty (39.2%) patients presented stent dysfunction (11.8% metal vs. 52.9% plastic stents, $p = 0.005$). Placement of metal stent was the only independent factor against dysfunction (OR: 0.045, 95%CI: 0.002-0.96), whereas concomitant chemotherapy (OR: 4.89, 95%CI: 11.16-20.71) was independently associated with the occurrence of stent dysfunction.
CONCLUSION: Concomitant chemotherapy is an independent risk factor for stent dysfunction in malignant biliary obstruction. Self-expandable metal stents must be preferred to plastic stents especially in those patients receiving palliative chemotherapy.

P1315 ENDOSCOPIC PANCREATIC STENTING IN THE TREATMENT OF ACUTE POST-ERCP PANCREATITIS

S. Shapovalianz[1], S. Budzinskiy[1,*], E. Fedorov[1], A. Mylnicov[1], A. Kotieva[1]. [1]*Department of Abdominal Surgery, Surgical Gastroenterology and Endoscopy, Russian National Research Medical University n/a N.I.Pirogov, Moscow, Russian Federation*

INTRODUCTION: The effectiveness of preventive pancreatic stenting for high risk post-ERCP pancreatitis (PEP) is proven, whereas rationality of the main pancreatic duct (MPD) stenting or the treatment of the PEP is disputable.
AIMS&METHODS: to evaluate retrospectively the results of endoscopic stenting of the MPD in the treatment of acute PEP, as a justification for prospective randomized trial.
From 01.01.2009 till 01.01.2013 we carried out 1948 retrograde endoscopic interventions on major duodenal papilla (MDP) and performed preventive pancreatic stenting in 52 (2.7%) cases. Acute PEP originated in 26 (1.33%) other cases (24 f. and 2 m.; mean age 57.9 ± 14.8; range: 34-85 years). The indication for primary endoscopic interventions was jaundice in all cases, caused by stenosis of the MPD and microlithiasis (14), choledocholithiasis (9), polyps of the MDP (2) and restenosis after previously performed EPT (1). Acute pancreatitis developed after failed ERCP in 1 (3.8%) pt.; after balloon papillodilation with extraction of bile stones in 1 (3.8%); after EPT in other 24 (92,4%) pts., including nonselective EPT in 6 cases, additional virsungotomy-in 3, extraction of bile duct stones-in 8.
RESULTS: We tried to perform stenting of the MPD in 21 pts. and succeeded in 19 (90.5%) cases. Pancreatic stents were removed in 5-12 days after their placement. Complications of pancreatic stenting have not been revealed; all patients recovered. The average length of hospitalization was 11.8 ± 3.7 days. Other 7 (26.9%) pts., including 2 pts. with failed attempts of stenting, underwent medical therapy and 2 of them - surgical intervention afterwards. There were 2 (28,6%) lethal outcomes in this subgroup. The average time of hospitalization was 23.8 ± 7.5 days.
CONCLUSION: Endoscopic stenting of the MPD is technically feasible in 90.5% of pts. with acute PEP and act as an effective and safe method of its treatment - after successful stenting there were no complications or progression of disease; all pts. have recovered. At the same time, in the subgroup of pts. where pancreatic stenting was not performed or failed, mortality reached 28.6% and the length of hospitalization was longer more than 2 times. Prospective randomized trial is needed to prove these initial promising results.

P1316 ERCP IN PATIENTS WITH PRIOR BILLROTH II GASTRECTOMY: REPORT OF A 30- YEAR EXPERIENCE

V. Bove[1,*], A. Tringali[1], I. Boškoski[1], G. Gigante[1], P. Familiari[1], V. Perri[1], C. Marmo[1], R. Landi[1], M. Mutignani[2], G. Costamagna[1]. [1]*Digestive Endoscopy Unit, Catholic University of Rome, Rome,* [2]*Ospedale Niguarda, Milano, Italy*

INTRODUCTION: ERCP in pts with Billroth II gastrectomy is difficult due to anatomy. Experience of a tertiary referral endoscopy centre is reported.
AIMS&METHODS: From Oct 1982 to Oct 2012, 713 pts with Billroth II reconstruction (567 M, mean age 69yrs) were retrospectively identified from a prospectively collected database. Main indications for ERCP were common bile duct stones (CBDS) (51.2%) and obstructive jaundice (24.3%).
Procedures were always started with a duodenoscope; in case of failure to reach the papilla the duodenoscope was changed with a gastroscope. Endoscopic sphincterotomy (ES) was performed using a long nose sigmoid inverted sphincterotome.
RESULTS: A total of 1050 ERCP were performed in 713 pts [1,47/patient (range 1-33)].
Results of duodenal intubation and bilio-pancreatic cannulation are summarized in ***table 1***.

Table 1. Results of duodenal intubation and bilio-pancreatic cannulation in 713 pts

	N	%
Successful duodenal intubation	**618**	**86.7**
Failed duodenal intubation	**95**	**13.3**
Long and angulated afferent loop	*73*	*76.8*
Jejunal loop perforation	*19*	*20*
Lack of collaboration	*3*	*3.2*
Successful cannulation/opacification	**580/618**	**93.8**
Overall success	**580/713**	**81.3**

In 14/618 pts (2.3%) the papilla was reached by a rendez-vous with a guidewire placed percutaneously.
Biliary and/or pancreatic ES were respectively performed in 490 (84.5%) and 23 pts (4%), including 5 minor papilla ES; 78 pts (13.4%) underwent diagnostic ERCP when MR cholangiography was not yet available; Plastic and metallic stents were inserted in 158 pts (27.2%). Extraction of CBDS and pancreatic stones were respectively performed in 318 (54.8%) and 12 pts (2.1%).
There were 45 complications (4.3%): peritoneal perforation 19 (1.8%); delayed post ES bleeding 11 (1.0%); ERCP related cholangitis 5 (0.5%); mild pancreatitis 5 (0.5%); retroperitoneal perforation 3 (0.3%); respiratory failure 2 (0.2%).
Retroperitoneal perforations were secondary to ES, balloon dilation of the papilla and laceration of a duodenal diverticulum (all managed conservatively). Peritoneal perforation, always required surgery. Two pts died after surgery (overall mortality 0.3%). The other complications resolved by conservative management or endoscopic re-intervention.
CONCLUSION: ERCP in Billroth II pts has comparable morbidity and mortality as in pts with normal anatomy. Main reasons of failure are related to inability to reach the papilla. Peritoneal perforations require prompt surgical approach. The use of a duodenoscope is recommended because it makes bilio-pancreatic cannulation and subsequent endotherapy.

P1317 MULTIDISCIPLINARY APPROACH FOR MEDIASTINAL NODAL STAGING OF LUNG CANCER WITH A COMBINED EBUS AND EUS PROCEDURE.

A. Velasco Guardado[1], A. Álvarez Delgado[1,*], R. Cordovilla Pérez[2], G. Varela Simó[3], A. M. Toracchi[2], M. C. García Macías[4], M. Lanchas Hernando[2], A. Rodríguez Pérez[1]. [1]*Gastroenterology,* [2]*Pneumology,* [3]*Thoracic Surgery,* [4]*Pathology., University Hospital of Salamanca, Salamanca, Spain*

INTRODUCTION: OBJECTIVE: To assess if the use of Endoscopic Ultrasound-Guided Fine-Needle Aspiration (EUS-FNA) improves mediastinal staging carried out by Endobronchial ultrasound–guided fine-needle aspiration (EBUS-FNA) of patients with lung cancer.
AIMS&METHODS: MATERIAL AND METHODS: We analyze all the punctures performed for mediastinal staging in patients with lung cancer following the criteria of the Spanish Society of Pneumology and Thoracic Surgery (SEPAR) since October 6, 2009 to April 2, 2013. Patients were divided into 2 groups according to the date of introduction of EUS-FNA in the unit: group 1 (G1) who underwent EBUS-FNA (October 2009 to July 2011), and group 2 (G2) in which EBUS-FNA was implemented with EUS-FNA (July 2011 to April 2013). Endoscopic examinations were performed by the same endoscopists: pulmonologist or thoracic surgeon in the case of EBUS-FNA and gastrointestinal endoscopist in EUS-FNA. All procedures were performed under moderate sedation We performed EBUS-FNA first and if it gives a negative result in the in situ histological analysis, EUS-FNA was performed. The presence of lymphocytes or presence of diagnostic cellularity was considered adequate sample. We didńt made histological confirmation in positive samples. Atypia, metaplasia and dysplasia were considered negative. Surgical confirmation (mediastinoscopy or surgery) was performed in all negative punctures. We had cytologist in the room.
RESULTS: We analyzed 150 patients for staging, 64 patients in G1 and 86 patients in G2, and there was no statistically significant difference in age, gender, rate of positive PET or average size of the lymph nodes between groups. The nodal regions punctured were 2R, 4R, 4L, 7, 10R, 11L, 8 and 9, and there was no difference between groups in terms of diagnostic performance. The invalid sample rate in G1 were higher than G2 but not significantly (10.2% vs 4.5%, $p = 0.18$). Comparing the groups (G1 and G2) we find differences with respect to: overall accuracy (93% vs 97%), sensitivity (86% vs 93%) and negative predictive value (88% vs 93%). In both groups, the specificity and PPV were 100%.
CONCLUSION: The combination of EUS-FNA and EBUS-TBNA obtain better results than single EBUS for mediastinal staging in lung cancer.
Disclosure of Interest: None Declared
Keywords: Endoscopic ultrasonography, lung cancer, staging

P1318 SINGLE-TIME COMBINED APPROACH OF TRANSBRONCHIAL ENDOSCOPIC NEEDLE ASPIRATION (TBNA) AND TRANSAESOPHAGEAL ECHOENDOSCOPIC ASPIRATION (EUS FNA) IN THE DIAGNOSIS OF MEDIASTINAL MASSES

D. Assisi[1,*], M. Filippetti[2], T. Federici[1], P. Visca[3], M. Anti[1]. [1]*Gastroenterology and Digestive Endoscopy Unit,* [2]*Thoracic Endoscopy Unit,* [3]*Pathology Unit, Regina Elena National Cancer Institute, Rome, Italy*

INTRODUCTION: Endoscopic techniques for the diagnosis of mediastinal masses are considered an excellent alternative to mediastinoscopy. TBNA is a safe and efficacy method to obtain tissue from anterior mediastinum. EUS FNA permits to obtain tissue for diagnosis from posterior and lower mediastinum with a good accuracy.
AIMS&METHODS: To evaluate the overall accuracy of TBNA and EUS FBNA performed as a single-time combined approach in the diagnosis of mediastinal masses.
RESULTS: 42 patients with mediastinal masses of uncertain diagnosis were submitted to TBNA and EUS FNA in one time combined approach under deep sedation in order to obtain tissue samples for cytological diagnosis. Cytology examination in ThinPrep was made by an expert pathologist no in site. In case of negativity or insufficient material patients underwent mediastinoscopy.
CONCLUSION: 31 out of 42 patients had a final diagnosis with the combined technique (27 lung cancer, 4 lymph- nodal metastasis by extra -thoracic cancer, 1 mesothelioma). 3 of 11 ''negative'' patients underwent mediastinoscopy that confirmed the absence of malignancy. The accuracy of lung cancer and extrathoracic metastasis diagnosis was respectively 84,8% and 77,7%. Overall accuracy of the combined approach was 83,3%. No complications occurred.
REFERENCES:
1. The combination of TBNA (when Endoscopic Bronchial Ultrasound is not available) and EUS FNA leads to a high rate of accuracy in the diagnosis of mediastinal masses, and the one-time approach has an important clinical impact on the diagnostic process of the disease

P1319 ULTRASONOGRAPHY AND PERIANAL INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE

D. G. Ferreira[1,*], T. Moreira[1], P. Lago[1], F. Castro-Poças[1], M. Salgado[1], C. Caetano[1], I. Pedroto[1]. [1]*gastroenterology, centro hospitalar do porto, Oporto, Portugal*

INTRODUCTION: INTRODUCTION: Ano-rectal ultrasonography (AR-EUS) is a simple and well tolerated method with a high diagnostic accuracy in the evaluation of perianal complications in the Inflammatory Bowel Disease (IBD).
AIMS&METHODS: AIM: Characterization of ano-rectal ultrasonography findings in patients with IBD. METHODS: We analyzed 236 patients with IBD with confirmed or suspected perianal involvement who were submitted to a US/EUS-AR in the period between January 2000 and December 2012. Demographic, clinical and ultrasonographic data were collected.
RESULTS: RESULTS: 398 US/EUS-AR were performed to 236 patients with IBD. Baseline characteristics: 220 patients with Crohn Disease (CD) and 16 with ulcerative colitis (UC). Average number of EUS-AR/patient: 1.69 (+-1.2). Female sex: 56%CD, 66%UC. Duration of IBD: 12.65 yrs in CD and 14.32 yrs in UC. Duration of perianal disease: 7.49 yrs in CD, 6.28 yrs in UC. AR-EUS was normal in 7.7% (n=17) patients with CD and in 18% (n=3) with UC. Disease localization of CD (Montreal Classification): L1=27.4%, L2=32.6%, L3=40%. CD Behavior (Montreal Classification): B1 44.5%, B2 31%, B3 24.5%. Previous perianal surgery: n=178. Medical treatment: Antibiotic 87%, Azathioprine/6MP 68%, MTX 11%, Biologic 45%. AR-EUS findings in UC: Intersphincteric fistula: n=7, transphincteric fistula: n=4, suprasphincteric fistula : n=3, anovaginal fistula: n=1, perianal abscesses: n=4, eco-structural changes: n=2. AR-EUS findings in CD: Fistulas: n=270 (Superficial=5, Intersphincteric: n=125,Transsphincteric: n=108, Supraspincteric: n=65, anovaginal: n=12, rectovaginal: n=3, anourethral: n=2), Abscesses: n=84, eco-structural changes: n=82, Internal anal sphincter lacerations: n=50, External anal sphincter lacerations: n=8, Anal fissure: n=24, Anal stenosis: n=3.
CONCLUSION: CONCLUSIONS: Most ultrasonography findings in patients with IBD represent supurative complications, although we have also find a high prevalence of echostructural changes and sphinteric lacerations, most due to prolonged supurative processes and surgical complications. AR-EUS plays a major role in the evaluation of the IBD patient with perianal involvement.

P1320 EUS ELASTOGRAPHY STRAIN RATIO IN DIFFERENTIATION OF PANCREATIC MASSES: CROATIAN EXPERIENCE

M. Opacic[1,*], N. Rustemovic[1], M. Premuzic[1], D. Opacic[2], Z. Ostojic[3], H. Ivekovic[1], P. Markos[1], K. Grubelic Ravic[1]. [1]*Department of Gastroenterology, University Hospital Center Zagreb,* [2]*University Hospital Center Zagreb,* [3]*Medical Faculty University of Zagreb, Zagreb, Croatia*

INTRODUCTION: EUS elastography has been proven as a promising method in differentiation of pancreatic tumors from the inflammatory masses, reducing the need for fine needle aspiration puncture[1]. Both quantitative elastography methods (strain ratio and histogram) show numeric values of tissue stiffnes. Technical details of the methods are described elsewhere[2,3].
AIMS&METHODS: Aims: to evaluate the diagnostic value of the strain ratio measurement in patients with the focal pancreatic masses, and to determine the cut–off value between inflammmatory focal changes and pancreatic cancer.
Methods: total of 149 patients were examined, 105 with focal pancreatic mases and 44 controls. Patients with history of chronic pancreatitis or presence of pancretic cysts were excluded. Strain values were recorded using Pentax EUS probe FG 38 UX (Pentax, Hamburg, Germany) in combination with hardware and software by Hitachi (Hitachi 8500, Hitachi medical systems). Tissue stifness were measured in the regions of interest before final diagnosis was achieved. Numerically expressed strain ratio between the mass and surrounding pancreatic tissue was automatically calculated by machine software. Finally patients with focal masses were divided in two groups after the diagnosis is established: pancreatic cancer group with positive cytology or histology after surgery (58 patients) and focal pancreatitis group with negative cytology and follow up after 3 and 6 months (47 patients).
RESULTS:

		Pancreatic cancer		
		Yes	No	
Strain ratio	Indicative ≥7.59	True positive 58/58	False positive 5/91	Positive predictive value 92% (87%>92%)
	Non indicative <7.59	False negative 0/58	True negative 86/91	Negative predictive value 100% (96%>100%)
		Sensitivity 100% (94%>100%)	Specificity 95% (91%>95%)	

CONCLUSION: Statistical analysis of our results showed that strain ratio with a cut-off value of 7.59 reaches 100% sensitivity and 95 % specificity in the differentiation of the patients with pancreatic cancer from the patients with the inflammatory pancreatic masses. These data are comparable with the results of other authors[2,4]. Future multicentric studies are needed, including comparison of strain ratio and histogram on the same groups of patients.

P1321 THE COMBINATION OF CONVENTIONAL ENDOSCOPIC AND ENDOSCOPIC ULTRASONOGRAPHIC FINDINGS CAN EFFICIENTLY PREDICT INVASION DEPTH OF EARLY GASTRIC CANCER.

M. Kato[1,*], Y. Tsujii[1], T. Inoue[1], T. Fujinaga[1], A. Maekawa[1], Y. Hayashi[1], T. Akasaka[1], S. Hiyama[1], T. Inoue[1], T. Yamada[1,2], S. Shinzaki[1], K. Watabe[1], T. Nishida[1], H. Iijima[1], M. Tsujii[1], T. Takehara[1]. [1]*Department of Gastroenterology and Hepatology, Osaka University Graduate School of Medicine, Suita,* [2]*Department of Gastroenterology, Osaka Medical Center, National Hospital Organization, Osaka, Japan*

INTRODUCTION: With development of endoscopic intervention for early gastric cancer (EGC), pre-therapeutic diagnosis of the invasion depth (T-staging) has become increasingly important. Recently some studies reported conventional endoscopy (CE) is comparable to endoscopic ultrasonography (EUS) for T-staging of EGC. However, for certain group of EGC, EUS would have additional diagnostic value because it directly provide tomographic image.
AIMS&METHODS: The aim of this study is to establish a diagnostic system for T-staging of EGC by combinating CE and EUS. A total of 233 consecutive EGC patients from April 2007 to March 2012 were included in this study. All patients underwent both CE and EUS for T-staging before treatment at Osaka University Hospital. Using CE, the criteria of massive submucosal invasion was defined as meeting at least one of following findings: 1) irregular surface, 2) submucosal tumor-like marginal prominence, 3) fusion of convergent folds in case of a lesion with fold convergence. Using EUS, massive submucosal invasion was defined as obvious irregular narrowing or budding into the sonographic layer 3. Three experienced endoscopists retrospectively reviewed the endoscopic imaging and made a diagnosis based on the criteria mentioned above. Diagnostic accuracy and inter-observer agreement was compared between CE and EUS.
RESULTS: According to pathological findings, 197 (85%) were mucosal and 36 (15%) were massively invading cancers. Overall accuracy ranged 71 to 79% in CE and 72 to 82% in EUS, respectively. There was no significant difference of diagnostic yield between CE and EUS. CE revealed fair inter-observer agreement ($\kappa = 0.56$ - 0.61). Kappa value of CE was higher than EUS ($\kappa = 0.47$ - 0.53). When diagnosed as mucosal cancer by CE, about 90% was predicted invasion depth accurately. On the other hand, when diagnosed as submucosal cancer by CE, 70% of pathological mucosal cancer was over-estimated invasion depth. EUS salvaged about 60% of these over-diagnosed cancers. Defining mucosal cancer as being diagnosed as mucosal cancer by either CE or EUS, diagnostic accuracy of combination of both modalities was more than 80% and significantly higher than CE alone ($p < 0.0001$, McNemar's test).
CONCLUSION: Using our simple diagnostic criteria, CE accurately picked up mucosal cancer with fair inter-observer agreements. However, CE over-estimates invasion depth of more than half of mucosal cancer, and EUS is useful in salvaging these lesions.

P1322 ESTIMATION OF THE MALIGNANT POTENTIAL OF GASTROINTESTINAL STROMAL TUMORS: THE VALUE OF CONTRAST-ENHANCED POWER DOPPLER EUS

N. Fukuta[1,*], T. Kato[1]. [1]*Department of Gastroenterology, Murakami Memorial Hospital, Asahi University, Gifu, Japan*

INTRODUCTION: The most important issue concerning Gastrointestinal stromal tumor (GIST) is that it is difficult to predict its prognosis. So far, the most important prognostic factors are tumor size, mitotic counts, metastasis to other sites and invasion. However, those factors are not sufficient to predict the malignant potential of such tumors because metastasis to other site sometimes occurs even when the tumor size is less than 5cm or the mitotic count is low. Recently, contrast agents for ultrasonography such as Sonazoid® have been introduced for routine clinical use. The contrast-enhanced power Doppler EUS (CE-PD EUS) with Sonazoid® permits evaluation of the intratumoral vascularity. The purpose of the present study was to evaluate whether vascularity is related to the diagnosis of submucosal tumors (SMTs) and to the malignant grade of the GISTs.
AIMS&METHODS: Eighty-four patients with SMTs were included in the present study. Tumors were observed in a real-time fashion of CE-PD EUS after the injection of Sonazoid® (0.015ml/kg). The vascular patterns were compared with tumor size, histological diagnosis and clinical findings such as metastasis.
RESULTS: The CE-PD EUS images of the SMTs were classified into 3 types according to the blood flow area of the tumors. The image pattern "Abscent" represented no vessels flowing inside of the tumor or only a few vessels around of the tumor, and "Poor" represented vessels flowing only in the peripheral part of the tumor, and "Rich" represented abundant vessels flowing from the periphery to the central part of the tumor. The details of esophagus SMTs were 18 leiomyomas, 2 lipomas and 1cyst. All SMTs were classified as "Abscent" image pattern. The details of stomach SMTs were 31 GISTs, 7 lipomas, 6 cysts, 5 leiomyomas, 1 glomus tumor, 2 schwannomas. GISTs were classified as "Poor" or "Rich" image patterns. In addition, malignant GISTs that diagnosed by histological findings or had metastasis were "Rich" pattern. And benign GIST that diagnosed by histological findings and had no metastasis were "Poor" pattern. The SMTs located in duodenum were 3 GISTs, 6 cysts, 1 lipoma, 1 paraganglioma. GISTs were classified as "Rich" image patterns. According to the CE-PD EUS images, GISTs were classified as "Poor" and the others as "Rich". Based on the final diagnosis, all tumors with "Poor" images were determined to be benign GISTs, and the rest tumors except one with "Rich" images were determined to be malignant GISTs.
CONCLUSION: It was indicated that the malignant GISTs had rich vascularity and the estimation of vascularity by CE-PD EUS offers additional and higher quality information on the malignant potency of GISTs than a histological diagnosis.

P1323 SERVE A JUICE PRIOR TO ENDOSCOPIC ULTRASOUND TO REVEAL THE CONCEALED DETAILS OF PANCREAS

A. Khaliq[1], S. Appasani[1,*], J. Basha[1], U. Dutta[1], K. Singh[1], R. Kochhar[1]. [1]*Gastroenterology, PGIMER, Chandigarh, India*

INTRODUCTION: Endoscopic ultrasound is useful to visualize pancreas. Sometimespancreatic ductal details are not fully appreciable during EUS. Secretin issecreted by intestinal epithelial cells and stimulates exocrine pancreas to producepancreatic juice causing temporary dilatation of pancreatic duct. Secretin isexpensive limiting clinical utility. The orange-lemon juice stimulates exocrinepancreas nearly similar to intravenous secretin.
AIMS&METHODS: ***Aim:*** To evaluate usefulness oforange-lemon juice prior to EUS for better visualization of pancreatic ductalchanges.
Methods: Prospective observational study. Patients with pancreaticdiseases including recurrent acute pancreatitis (RAP), chronic pancreatitis (CP)and pancreatic space occupying lesions (SOL's) and controls were enrolled. EUSwas done, pancreatic changes including ductal changes and the diameter ofpancreatic duct at a fixed point was noted. 200 ml of orange- lemon juice wasserved and EUS repeated after1 hour.
RESULTS: ***Results:*** Of 24 cases, 10 were RAP, 6 wereCP, 2 were pancreatic SOL's and 6 were controls. Mean diameter of MPD was2.092±1.912 mm and post juice increased to 3.108±2.29 mm. ($p < 0.001$). Onsub group analysis, the MPD increased from 1.26±0.21 mm to 1.84±0.33 mmin RAP ($p < 0.001$), 4.63±2.48 to 6.53±2.15 in CP ($p=0.002$). Side brancheswere better appreciated in 13/24(54.2%). In a case more number of intraductalstones appreciated. Diagnosis of incomplete divisum was made in a case afterjuice.
CONCLUSION: ***Conclusions:*** Orange- lemon juice facilitated EUS of pancreas increases thepancreatic ductal diameter significantly and is useful in better appreciation ofpancreatic ductal changes.

P1324 STUDY OF CHARACTERISTICS OF ESOPHAGEAL STRICTURES ON ENDOSCOPIC ULTRASOUND

A. Khaliq[1], S. Appasani[1,*], R. B. Thandassery[1], J. Basha[1], M. Manrai[1], U. Dutta[1], K. Singh[1], R. Kochhar[1]. [1]*Gastroenterology, PGIMER, Chandigarh, India*

INTRODUCTION: Endosonography helps in delineating the wall pattern of the esophagus. The nature and impact of EUS characteristics of corrosive strictures is not known.
AIMS&METHODS: Aim: To study endoscopic ultrasound features of esophageal strictures of corrosive and non-corrosive etiologies. To study the influence of EUS characteristics on the response to endoscopic dilatation.
Methods: Forty patients of esophageal strictures undergoing endoscopic dilatation were studied. Patients were dilated periodically with 15mm as end point. Need for repeat dilatation after achieving diameter of 15mm was classified as recurrence. All these patients were subjected to EUS(Pentax,Japan) after achieving dilatation to 15mm. On EUS maximal wall thickness, length of stricture, layered pattern of the wall (preserved or lost) was studied. The nature of the EUS characteristics of corrosive and non-corrosive strictures were compared. The role of these characteristics in predicting recurrence was assessed
RESULTS: 40 patients(19males) were analyzed. The etiology of strictures was corrosive in 17 and non-corrosive in 21(peptic(n=9), post radiotherapy (n=8) anastomotic (n=4) or due to drugs (n=2)). Mean age of study group was 48.5 years(36.4 years in corrosive group and 53 years in non-corrosive group). Mean number of dilatations to reach diameter 15mm was 5.5±3.9 in corrosive group and 1.9±0.9 in peptic group ($p=0.051$). The mean length of stricture in peptic group was 3.6+1.9 cm and in the peptic group it was 2.7+1.6cm ($p=0.177$). Differentiation of layered pattern of esophagus was lost in 13(85%)patients in corrosive group and 2(15%)patients in peptic group. Additional findings noted were tuberculous mediastinal lymphadenopathy in one and recurrence of tumor in 2 patients. Recurrence of symptoms occurred in 63% patients. Loss of layered pattern on EUS (85%vs.15%) was associated with higher recurrence($p=0.05$). The mean thickness of the esophagus was unable to predict (5.1+1.3mm vs. 5.2+2.7mm)($p=0.896$).
CONCLUSION: Patients with corrosive strictures had a loss of normal esophageal layered pattern on EUS in contrast to non-corrosive strictures. Loss of layered pattern predicted higher recurrence rates.

P1325 QUANTITATIVE ASSESSMENT OF TUMOUR PERFUSION OF COLORECTAL CANCER PATIENTS BY USING CONTRAST-ENHANCED ENDOSCOPIC ULTRASONOGRAPHY: A FEASIBILITY STUDY

T. Cartana[1,*], L. Brink[2], D. I. Gheonea[1], J. G. Karstensen[2], A. Ciocalteu[1], D. Pirici[3], C. V. Georgescu[4], M. L. Malmstrøm[2], A. Saftoiu[1,2], P. Vilmann[2], G. Gruionu[1,5]. [1]*Research Center of Gastroenterology and Hepatology, University of Medicine and Pharmacy of Craiova, Craiova, Romania,* [2]*Department of Endoscopy, Gastrointestinal Unit, Copenhagen University Hospital Herlev, Herlev, Denmark,* [3]*Department of Histology, University of Medicine and Pharmacy of Craiova,* [4]*Department of Pathology, Emergency County Hospital, Craiova, Romania,* [5]*Steele Laboratory of Tumor Biology, Department of Radiation Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, United States*

INTRODUCTION: Contrast enhanced endoscopic ultrasonography (CE-EUS) is a high resolution technique enabling minimally invasive assessment of tumour perfusion. Despite recent technology advancements, the use of CE-EUS in the evaluation of colorectal cancer (CRC) has not been previously reported.
AIMS&METHODS: Therefore the aim of our study was to evaluate tumour vascularity in CRC by using CE-EUS and time intensity curve analysis in correlation with pathology parameters of angiogenesis. We included 35 patients with CRC that were examined by low mechanical index CE-EUS prior to any therapy, using 4.8 ml of Sonovue (*Bracco, Italy*) administered in bolus injection as contrast agent. Time intensity curve (TIC) parameters were determined by offline analysis of recorded video sequences with specific software. Immunohistochemical assessment of tumour vascularisation included microvascular density calculation using CD31 and CD105 specific staining, which was available for 18 of the patients.
RESULTS: Most tumours were well vascularized at CE-EUS examination, demonstrating either homogenous uptake of the contrast agent or inhomogeneous enhancement, with stronger peripheral uptake and avascular areas towards the intestinal lumen. The mean values (± SD) for TIC parameters were: 10.08 ± 3.85 s for arrival time (AT), 24.03 ± 10.94 s for time to peak (TTP), 41.43 ± 19.24 a.u. for peak intensity (PI) and 5477.45 ± 2922.68 a.u.*s for the area under the curve (AUC). An inverse correlation was noted between AT and CD31 MVD, but without reaching statistical significance (*Spearman* $r = -0.55$, $p = 0.1328$) and also between TIC parameters Imax and AUC and lymph nodes involvement ($r = -0.439$, $p = 0.0683$).
CONCLUSION: CE-EUS using low mechanical index examination and TIC analysis is feasible for the assessment of intratumoral perfusion in colorectal cancer. Further studies on larger groups of patients are necessary to improve the examination technique and define its role in the evaluation of CRC patients.

P1326 ENDOSCOPIC ULTRASONOGRAPHIC STUDY OF SUBEPITHELIAL TUMORS – WHEN WE ARE SURPRISED WITH SIGNIFICANT PANCREATIC ALTERATIONS

T. Pinto-Pais[1,*], S. Fernandes[1], L. Proença[1], C. Fernandes[1], I. Ribeiro[1], J. Fraga[1]. [1]*Gastroenterology Department, CENTRO HOSPITALAR GAIA ESPINHO, Gaia, Portugal*

INTRODUCTION: Pancreatic disease is often misdiagnosed, not only by the nonspecific or scarce symptoms, but also by the difficulty in assessing the gland on routine tests such as abdominal ultrasound. Endoscopic ultrasonography (EUS) allows a detailed evaluation of the pancreas and, even when performed by other information, can be an opportunity to detect pancreatic disease so far unsuspected.
AIMS&METHODS: Objective: To evaluate the frequency of significant pancreatic alterations (SPA) in patients undergoing EUS for the study of subepithelial tumors (SETs) of the upper gastrointestinal tract (UGIT).
Material and Methods: Retrospective analysis of the EUS performed to study UGIT-SETs in our department, between 2009 and 2013. Patients with pancreatic-biliary pathology and neuroendocrine tumors of the gastrointestinal wall were excluded. Demographic, clinical and echoendoscopic (with SETs and SPA characterization) data were collected.
RESULTS: A total of 304 EUS were carried off to study UGIT-SETs. Significant alterations in the pancreas was detected in 3.3% (ten individuals), seven of which men, with a mean age of 63.9 years (47-78). Solid lesions were diagnosed in three individuals, cystic in three and significant changes in the echostructure of the gland in four. We conducted fine needle aspiration (FNA) in three patients, having diagnosed one adenocarcinoma, one neuroendocrine tumor and a mucinous cyst. Both patients with neoplastic disease underwent surgery. Patients with pancreatic echostructural changes were evaluated according to the Rosemont's criteria: two presented aspects suggestive of chronic pancreatitis, one indeterminate for chronic pancreatitis. Patients with small dimension lesions, FNA was not performed, remain under follow-up.
CONCLUSION: This study suggests an important role of endoscopic ultrasound in the early diagnosis of pancreatic lesions. In our sample, significant pancreatic alterations were diagnosed in 3.2% of patients undergoing endoscopic ultrasound to study sub-epithelial tumors of the upper gastrointestinal tract, 0.99% of neoplastic etiology.

P1327 ENDOSCOPIC ULTRASONOGRAPHY GUIDED PUNCTURE: DIAGNOSTIC VALIDITY IN SOLID PANCREATIC LESIONS

T. Correia[1,*], A. Oliveira[1], F. Portela[1], C. Sofia[1]. [1]*Gastrenterology department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: Fine needle aspiration biopsy guided by endoscopic ultrasound (EE-FNA) in pancreatic lesions overcomes some limitations of traditional puncture methods. However, there is no consensus regarding its usefulness and impact in resectable solid lesions.
AIMS&METHODS: Aim: Evaluation of diagnostic value and safety of EE-FNA in solid pancreatic lesions. Methods:Retrospective study of EE-FNA of solid pancreatic lesions performed between 2007 and 2011. The final diagnosis was obtained by: pathological examination of the surgical specimen, unequivocal cito and/or histology result of EE-FNA and by clinical and/or imaging follow-up. In diagnostic validity calculation, the results were considered suspicious malignant (true or false positives), and the samples insufficient for diagnosis were considered as true or false negatives.
RESULTS: There were 58 EE-PAAF and 53 patients, 27 were male and mean age was 59.6 ± 15.3 (24-81 years). The lesions were located mainly in the pancreatic head (72.5%), performing an average of 1.97 ± 0.95 passages (1-4). The average lesion size was 3.9 ± 1.5 cm. In the anatomo-pathological analysis: 17.2% of samples had no conclusive diagnosis (13.8% insufficient for diagnosis, 3.4% suspicious for malignancy), 60.3% positive for malignancy (including 44.8% ductal adenocarcinoma, 12.1% neuroendocrine tumors, and 3,4% mucinous tumors). It was not possible to get follow-up data of three patients. False negative rate was 9% and false positive rate was 1.8%. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy were 87.8%, 92.9%, 97.3%, 72.2% and 89.1%, respectively. Accuracy of repetitive punctures in patients with a first negative result was 66.7%. There were no major complications.
CONCLUSION: EE-FNA has a high diagnostic value in solid pancreatic lesions. The presence of inflammatory perilesional, changes can increase the false positive or negative results.

P1328 ENDOSONOGRAPHY IN THE DIAGNOSIS AND MANAGEMENT OF GISTS IN THE UPPER GASTROINTESTINAL TRACT – PRELIMINARY RESULTS

Y. Valerieva[1,*], B. Golemanov[1], P. Gecov[2], I. Terziev[3], B. Vladimirov[1]. [1]*Gastroenterology,* [2]*Clinic of Medical Imaging,* [3]*Department of Pathology, University Hospital "Queen Joanna -ISUL" Sofia, Bulgaria, Sofia, Bulgaria*

INTRODUCTION: Assessing the role of endosonography (EUS) in diagnosis and management of stromal tumors in the upper GI
AIMS&METHODS: For the period November 2011- March 2013 seventeen patients with submucosal lesions of the upper GI tract were evaluated in our centre (seven patients were female (41.2%), 10 patients were male (58.8%) at mean age 58±11). The anatomic sites of the lesions were as follows: esophagus in 4 patients (23.5%), stomach in 9 patients (52.9%) and duodenum in 4 patients (23.5%). All the patients had upper endoscopy findings of submucosal polypoid lesions with medium size of 31.53 ± 13.4 mm, some with surface ulceration. All patients were evaluated by linear endoscopic ultrasonography (EUS).
RESULTS: Endoscopic ultrasound evaluation revealed tumors originating from muscularis propria, and EUS diagnosis of gastrointestinal stromal tumors (GISTs) was assumed in all patients. EUS-FNA (EUS – guided fine needle aspiration) was performed in two of them, but obtained material was not enough for final diagnosis in both cases. Based on EUS features of tumors' malignant potential (size of lesion > 30mm, heterogeneity, cystic regions), tumor location and complications as uncontrolled bleeding, nine patients (53%) were treated in surgery. The rest of the patients (47%) underwent endoscopy treatment (conventional polypectomy, submucosal dissection, biliary stenting in a case with multiple liver metastases). No significant complications were present in both groups. Histology and immunohistochemistry analysis confirmed c-kit: CD 117 positive GIST in 82.4% of patients, correlating with preliminary EUS diagnosis. In 17.6% of cases EUS diagnosis was not confirmed.
CONCLUSION: Endoscopic ultrasonography is a reliable method for evaluation of gastrointestinal stromal tumors. EUS features of the stromal tumors (size, heterogeneity, borders, depth etc.) can predict their malignant potential and define GIST's management.

P1329 DOES FLEXIBLE SPECTRAL IMAGING COLOUR ENHANCEMENT (FICE) COMPARED TO WHITE LIGHT IMPROVE DETECTION OF SMALL BOWEL LESIONS DURING CAPSULE ENDOSCOPY?

A. Murino[1,*], E. J. Despott[1], M. Nakamura[1], A. O'Rourke[1], P. Bassett[1], C. Fraser[1]. [1]*Wolfson Unit for Endoscopy, St Mark's Hospital and Academic Institute, Imperial College, London, United Kingdom*

INTRODUCTION: Flexible spectral imaging colour enhancement (FICE) (Fujifilm, Saitama, Japan) reprocesses capsule endoscopic white light (WL) images producing virtual ones at specific optical wavelengths. The aim of this study was to examine the effect of FICE compared to WL on small bowel lesion detection during capsule endoscopy

AIMS&METHODS: Video clips of selected small bowel lesions were organised into 5 categories (angioectasias, ulcers, polyps, bleeding and 'normal') and viewed in 5 modes: WL, FICE-1, 2 and 3 and BM (blue-mode). In total, 25 video clips were examined in randomised order by 13 observers blinded to the content of each clip
RESULTS: There was a significant difference ($p<0.001$) between the 5 modes when all lesions were examined together. Sensitivity was highest for FICE-2 (+17% higher than WL). There was a significant difference in outcome between modes with angioectasias alone ($p<0.001$). FICE-2 had the highest sensitivity (+21% higher than WL). Differences between modes were observed for ulcers. Again, FICE-2 had the highest sensitivity value (+35% higher than WL). The positive predictive value (PPV) between different modes was then compared. There was no overall difference in PPV between the 5 modes when lesions were combined. Differences between modes were observed for angioectasias alone in that FICE-1, 2 & 3 and BM had a significantly lower PPV than WL ($p<0.008$). The number of false positives (NFPs) was significantly higher for FICE-1, 2 & 3 and BM compared to WL when all lesions were combined ($p<0.001$). The highest NFPs was observed for FICE-2 (2.9 times higher than WL). There were significant differences between modes for angioectasias alone ($p<0.001$): NFPs was greatest for FICE-2 (2.2 times higher than WL). A similar picture was observed for bleeding, with higher NFPs for FICE-1 & 2 and BM ($p<0.05$). FICE-3 had the highest NFPs for ulcers (over 3 times higher than WL) ($p<0.001$). For 'normal', FICE-2 had the highest NFPs (almost 5 times higher than WL) ($p<0.001$)
CONCLUSION: Our results suggest that while the sensitivity of specific FICE modes (particularly FICE-2) is higher than WL for SB lesions such as angioectasias and ulcers, FICE is associated with a lower PPV and higher false positive rate due to a tendency to overcall lesions when used in isolation. Applying FICE to interrogate uncertain lesions after WL detection may be a more appropriate use for this technology

P1330 SEGMENTAL GASTROINTESTINAL TRANSIT TIMES ASSESSED BY AMBULATORY TRACKING OF THREE ELECTRONIC MAGNETIC CAPSULES

A. Haase[1,*], T. Gregersen[1], S. M. Scott[2], V. Schlageter[3], M. Demierre[3], P. Kucera[4], K. Krogh[1]. [1]*Hepatology and Gastroenterology, Neurogastroenterology Unit, Aarhus University Hospital, Aarhus, Denmark,* [2]*Academic Surgical Unit & Neurogastroenterology Group, Queen Mary University, London, United Kingdom,* [3]*Motilis Medica SA, Motilis Medica SA, Lausanne, Switzerland,* [4]*Faculty of Bioengineering, Czech Institute of Technology, Prague, Czech Republic*

INTRODUCTION: Monitoring of transit abnormalities is important to the management of patients with gastrointestinal (GI) motility disorders. We present a novel ambulatory telemetric capsule system (3D-Transit) designed to evaluate total and segmental GI transit times (GITT) and GI contractile activity.
AIMS&METHODS: The aim of this study was to test the *in vivo* performance of the 3D-Transit (Motilis Medica SA) system. 3D-Transit is consisting of ingestible electronic capsules, an extracorporeal portable detector containing 4 sensors, and visualization software. The electromagnetic field emitted by each capsule is converted into space-time coordinates, relative to the distance and angular orientation of each capsule in relation to the sensors. Changes in position and orientation of the capsules reflect GI contractile activity and dynamic progression. Certain stereotypical movements of the capsule, allied to simultaneous changes in contraction frequencies are used for determining the entry into different gut segments. Twenty healthy volunteers (10 females, median age 32 (range 24-53); median BMI 22.7), with no history or current symptoms of GI disease, ingested three capsules (C1 – C3) at standardised times on consecutive days: C1 and C3 were ingested in the morning of days 1 and 2, and C2 was ingested in the evening on day 1. The subjects also had standardised meals, but were allowed to perform most of their normal daily activities.
RESULTS: The 3D-Transit system was well tolerated and the 3 capsules could be tracked simultaneously. Total and segmental GITT were obtained for all subjects. Median transit times (IQR) for C1 were: Total GITT 29 h (24-34), gastric emptying (GE) 4 h (3-4), small intestinal transit time (SITT) 5 h (4-6) and colorectal transit time (CRTT) 20 h (15-26). However, due to slower transit during the night, all values for C2, aside from CRTT, were longer than for C1: Total GITT 37 h (35-39; P=0.04), GE 7 h (4-8; P= 0.0005), SITT 8 h (5-12; P=0.04), and CRTT 21 h (17-25; P=0.53). Day-to-day variation (difference/mean) between C1 and C3 was 34% for GITT, 45% for GE, 47% for SITT, and 58% for CRTT.
CONCLUSION: The 3D-Transit system provides a safe and comprehensive evaluation of segmental GI transit in ambulatory subjects. Significant diurnal variations in gastric and small intestinal transit times indicate that timing of capsule intake must be standardised. However, day-to-day variation of transit times may be substantial. Nevertheless, the 3D-Transit system holds great promise for the future study of GI function in both health and disease.

P1331 A NOVEL TARGETED (LIMITED RADIATION) CT PROTOCOL PREDICTS SAFE CAPSULE ENDOSCOPY (CE) AFTER RETENTION OF THE AGILE PATENCY DEVICE.

A. Assadsangabi[1,*], K. Drew[1], T. Blakeborough[2], R. Sidhu[1], A. J. Lobo[1], M. E. McAlindon[1]. [1]*Gastroenterology,* [2]*Radiology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

INTRODUCTION: Capsule endoscopy (CE) is considered safe if the collapsible Agile patency device (Given Imaging Ltd) exits the patients within 30 hrs of ingestion as determined by the absence of a radiofrequency signal from the tag in the device. However, this fails to occur in this timeframe in up to 57%. These patients conventionally undergo plain abdominal X ray (AXR) to localise the device but half are further subjected to fluoroscopy, gastrograffin enemas or CT to clarify whether or not small bowel retention of the device has occurred[1]. This approach is organisationally difficult as it requires at least two further tests requiring expert interpretation including further intervention, irradiation and delays.
AIMS&METHODS: A novel protocol involving a single visit scout film and targeted (limited slice, low radiation exposure) CT to locate the patency device if it had not exited the patient at 30hrs was established, implemented prospectively and outcomes reviewed of consecutive studies between April 2010 – Sept 2012.
RESULTS: Calculated radiation exposures for the scout film, AXR and limited CT (mean of 18x5mm slices) were: 0.16mSv, 0.4mSv and between 0.8-1.4mSv respectively. Of 400 patients (including 102 patients known to have Crohn's disease), an absent radiofrequency signal denoted safe passage of the Agile device in 216 patients (54%). One patient could not swallow the capsule but all 215 remaining patients (100%) underwent CE without retention. Of184 patients with a positive signal undergoing the protocol, 172 (93.5%) were reported as having a patent small bowel (two patients on the basis of a scout film showing no patency device and 170 targeted CT scans identifying it in the colon). CE was performed without retention in 171 (99.4%) of these patients: one patient had a capsule retention after a targeted CT scan was incorrectly interpreted as showing the patency device immediately distal to an ileocolic anastamosis in a patient with Crohn's disease. In 12 patients in whom CT identified the device in the small bowel, further luminal radiology identified strictures in 7 (58%) and none proceeded to CE. Only one of the remaining five patients with normal small bowel radiology underwent CE, which was normal.
CONCLUSION: This is the largest series reporting outcomes of patency capsule small bowel assessment, following which further imaging was needed in as many as 46%. An absent radiofrequency signal predicted safe CE in all patients. Scout film and targeted CT offers a single visit, low radiation method to locate the Agile device and predicted safe CE in 99.4% of patients.

P1332 EMERGENCY VIDEO CAPSULE ENDOSCOPY IN PATIENTS WITH ACUTE GASTROINTESTINAL BLEEDING

C. Schlag[1,*], B. Neu[1], C. Menzel[1], S. Nennstiel[1], V. Phillip[1], R. M. Schmid[1], S. von Delius[1]. [1]*2nd Medical department, TECHNICAL UNIVERSITY MUNICH, Munich, Germany*

INTRODUCTION: Obscure gastrointestinal bleeding is a main indication for video capsule endoscopy. Its use in the emergency setting of acute gastrointestinal bleeding has been rarely analysed yet.
AIMS&METHODS: In this prospective study patients with clinical signs of upper/mid gastrointestinal bleeding (melena, dark or maroon-coloured stool) and hemodynamic instability and/or drop of haemoglobin ≥2g/dl/d and/or need of transfusion ≥2 red blood packed cells/d were included. If gastroscopy did not show the source of bleeding 0.5 l of PEG-solution and the capsule were placed endoscopically into the duodenum followed by drinking of 4l PEG-solution. Capsule recording was stopped after the capsule had reached the colon. The capsule-video was immediately analysed and depending on its result patients received further diagnostics or treatment.
RESULTS: 70 patients have been included in this study yet. In 55/70 patients (79%) gastroscopy showed the source of bleeding. The remaining 15/70 patients (21%) received an emergency video capsule endoscopy. 14/15 of these patients (93%) showed a complete examination of the small bowel. In 11/15 patients (73%) the source of bleeding was detected by capsule endoscopy (9/11 small bowel, 2/11 Caecum). In 2/15 patients the source of bleeding was detected by the subsequent colonoscopy, in 2/15 patients only after repeated gastroscopy.
CONCLUSION: In patients with signs of acute upper/mid gastrointestinal bleeding and negative gastroscopy emergency video capsule endoscopy is useful for the immediate detection of the bleeding site and allows guiding further therapy.

P1333 THE DIAGNOSTIC VALUE IN PAEDIATRIC SMALL BOWEL ASSESSMENT BY WIRELESS CAPSULE ENDOSCOPY: A TERTIARY CENTRE EXPERIENCE

E. Saliakellis[1,*], L. Fotis[1], S. Sider[1], M. Elawad[1], K. Lindley[1], F. Kiparissi[1]. [1]*GREAT ORMOND STREET HOSPITAL NHS FOUNDATION TRUST, LONDON, United Kingdom*

INTRODUCTION: Wireless capsule endoscopy (WCE) provides a method to assess small bowel pathology by filling the endoscopic gap between push-enteroscopy and ileocolonoscopy. The aim of this study was to assess the diagnostic value, tolerance and safety of WCE in paediatric patients referred to our unit.
AIMS&METHODS: This is a retrospective review of the WCE studies (PillCam SB, Given Imaging) that were performed during a 5.5-year period (May 2007-October 2012). Indications were confirmed/suspected IBD (n=114, 39%), obscure/occult GI bleeding (n=36, 12%), GI polyps syndromes/tumors (Peutz-Jegher's S., angiodysplasias, blue rubber bleb syndrome) (n=16, 5%), protein losing enteropathy(PLE) (n=15, 5%), recurrent abdominal pain (n=26, 9%), eosinophilic gastrointestinal disease (n=19, 7%), non-GI conditions with significant gut manifestations (autoimmune diseases, bone marrow transplantation, immunodeficiencies) (n=15, 5%) and other (coeliac disease, diarrhoea, failure to thrive etc.) (n=47, 16%).
RESULTS: 291 children (140 male, median age 10.8 years (range: 6.5 months to 19.0 years) swallowed 102 capsules(35%), 188 were placed endoscopically into the duodenum under
General anaesthesia using an acorn-like device (n= 179)/"Roth net". 72 patients (25%) were under the age of 8 years. In 220 cases (76%) the WCE was seen in the coecum at end of recording (8 hours). The swallowed capsule did not leave the stomach in 6 patients.2 patients retained the capsule, only one needing surgical removal of TI stricture with a normal contrast study pre WCE. Positive findings were observed in 184 (63%) of the studies of which 101 (34%) were diagnostic in terms of either establishing the diagnosis or altering the therapeutic approach of the patient. The diagnostic yield is highest in PLE (80%), polyposis syndromes/tumors (68%), Crohn's disease (39%) and bleeding (27%).
CONCLUSION: Our experience - which is based on the largest cohort of paediatric patients and the youngest child undergoing WCE - demonstrates that with careful selection of patients, WCE is a useful and safe diagnostic modality in children with suspected small-bowel diseases.

P1334 SMALL BOWEL CAPSULE ENDOSCOPY FOR ASSESSING EARLY POSTOPERATIVE RECURRENCE OF CROHN'S DISEASE: CORRELATION WITH THE ENDOSCOPIC SCORE AT 6 AND 12 MONTHS IN A PROSPECTIVE STUDY

G. Condino[1,*], E. Calabrese[1], S. Onali[1], E. Lolli[1], M. Ascolani[1], F. Zorzi[1], S. Giuseppe[2], C. Petruzziello[1], F. Pallone[1], L. Biancone[1]. [1]*Gastroenterology Unit, University of Rome Tor Vergata,* [2]*Surgery Unit, University of Rome Tor vergata, Rome, Italy*

INTRODUCTION: The role of Small Bowel Capsule Endoscopy (SBCE) for assessing early CD recurrence is undefined.
AIMS&METHODS: In a prospective longitudinal study, we aimed to compare the usefulness of SBCE for assessing early postoperative recurrence of CD, when using ileocolonoscopy (IC) as gold standard. We also aimed to assess whether SBCE visualizes the proximal small bowel (SB) lesions not detected by standard techniques and the interobserver agreement. From Febr. 2011 all consecutive patients (pts) undergoing ileo-colonic resection for CD were enrolled. Clinical assessment (CDAI) was performed at 3,6,12 months (mos). Recurrence was assessed by IC within 6mos (T6) and at 12mos (T12)(Rutgeerts' score:recurrence $\geq$1). Small Intestine Contrast Ultrasonography (SICUS) was performed at T6 followed, within 4wks, by SBCE in pts with no stenosis. CD lesions visualized by SBCE were blindly graded by 2 gastroenterologists (score 0-3, recurrence$\geq$1;Buchman AJG 2004). Results were expressed as median and range. Statistical analysis: Student's T test.
RESULTS: A total of 26 pts (17M, age 36, range 19-74) were enrolled. SBCE was not performed in 15 pts, due to strictures (n=3), impact risk (n=3), low compliance to perform SBCE (n=7) or IC (n=2). At T6, among the 11 pts performing all the 3 procedures, 1 showed clinical recurrence (CDAI > 150) and 9 endoscopic recurrence (grades: 1:n=2; 2:n=4; 3:n=3). At T6, findings compatible with recurrence were detected by SICUS in 7 (7TP;2TN;2FN) and by SBCE in 10 pts (both observers: grade 3:n=10; grade 0:n=1; 9TP,1TN,1FP). In 4/11 pts, SBCE showed multiple aphtoid ulcers in the proximal SB not detected by standard imaging. No SBCE retention and a 100% interobserver agreement was observed. At 12mos, 8/11 pts already performed IC, with recurrence graded in 6 (score: 2:n=4; 3:n=1; 0:n=1). When the analysis was restricted to the 6 pts already performing both SBCE and IC at T6 and IC at T12, clinical recurrence was observed in 1 pt at T6 and in 2 pts at T12. The SBCE score at T6 was not correlated with the endoscopic score of recurrence at T6 (p=0.26; r=0.53). Differently, the SBCE score at T6 was significantly correlated with the endoscopic score of recurrence at T12 (p=0.011; r=0.91).
CONCLUSION: Early after surgery for CD, SBCE may visualize superficial lesions of the proximal SB not detected by standard techniques. A significant correlation was observed between the severity of CD lesions assessed by SBCE early after surgery and the endoscopic score of recurrence at 1 year.

P1335 PROKINETICS IN VIDEO CAPSULE ENDOSCOPY: A SYSTEMATIC REVIEW AND META-ANALYSIS

I. M. Vicente[1,*], J. Ong[1], M. A. De Lusong[1]. [1]*Section of Gastroenterology, Philippine General Hospital, Manila, Philippines*

INTRODUCTION: About 20% of patients undergoing video capsule endoscopy (VCE) fails to complete the examination. This review assessed if prokinetics can result in an improved VCE completion rate, gastric transit time, and small bowel transit time.
AIMS&METHODS: A search of randomized trials until November 2012 was obtained, using MEDLINE and PubMed databases, and the Cochrane Central Register of Controlled Trials. The keywords used were 'video capsule endoscopy' and 'prokinetics'. Randomized controlled trials comparing prokinetics with placebo or no intervention were included. Each study was appraised by two independent reviewers using the Jadad Score. Meta-analysis was performed using the forest plot review. For outcome measures where forest plot was not feasible, a narrative review was done.
RESULTS: Two RCTs on erythromycin and five on metoclopramide involving 485 patients were included in the study. Metoclopramide improves VCE completion rate when compared to control (OR 1.93 [1.22, 3.06], p = 0.005), but not erythromycin (OR 1.13 [0.38, 3.33], p = 0.83). The two studies on erythromycin reported conflicting results with regards to gastric transit time. On the other hand, four out of the five studies on metoclopramide demonstrated significant improvement of gastric transit times among patients given metoclopramide. Metoclopramide and erythromycin were noted to have no effects on small bowel transit time.
CONCLUSION: Metoclopramide may improve VCE completion rate. Such trend was not observed in erythromycin. However, due to moderate heterogeneity, more research is needed to confirm the benefit of giving metoclopramide in VCE.

P1336 FINDINGS AND LONG TERM OUTCOMES FOR PATIENTS FOLLOWING VIDEO CAPSULE ENDOSCOPY TO INVESTIGATE IRON DEFICIENCY ANAEMIA

J. Patel[1,*], A. Jenkins[1]. [1]*Gastroenterology, NHS, London, United Kingdom*

INTRODUCTION: It is unclear whether there is a benefit in performing capsule endoscopy (CE) in all patients with iron deficiency anaemia (IDA) after negative upper and lower GI endoscopy. British Society of Gastroenterology (BSG) guidelines suggest that CE should be reserved for patients with rapidly recurring anaemia, transfusion dependent anaemia and when there are symptoms to suggest small bowel disease. There is little information about long term outcomes in patients who have undergone CE to investigate IDA.
AIMS&METHODS: This retrospective study analysed findings and long term outcome of 115 patients (median age of 68, 56% female) investigated for IDA by CE after negative upper and lower GI endoscopy between April 2005 and December 2011.
RESULTS: 62 patients (54%) had positive findings on CE. 51 patients (44%) had small bowel pathology: active bleeding (8), angiodysplasia (17), small intestinal erosions and ulcers (21), tumour (3), small bowel mucosal atrophy (2). Six patients had gastric pathology (active bleeding, erosions or gastric antral vascular ectasia). Four patients had colonic pathology (active bleeding or angiodysplasia). There were follow up data for up to six years and the findings at CE resulted in active treatment of the underlying pathology in 16 patients (14% of total cohort). For the remaining 46 patients with positive findings, symptomatic treatment with iron replacement therapy was sufficient. Positive CE findings were detected in 41 of 80 (51%) patients whose anaemia resolved after iron therapy or treatment of underlying pathology versus 21 of 35 (60%) patients with refractory or recurrent anaemia.
For 53 patients with negative CE subsequent follow up revealed a cause in six: Meckel's diverticulum, angiodysplasia, ulcerative colitis, coeliac disease, pernicious anaemia and endometrial cancer. The other patients with negative CE were successfully treated symptomatically with iron replacement therapy.
CONCLUSION: There were relevant findings in over 50% of patients undergoing CE to investigate unexplained IDA and a significant number of these were actively treated. Selection for performing CE based on the presence of recurrent or refractory anaemia did not improve diagnostic outcome.

P1337 FRENCH MUTICENTRIC EXPERIENCE OF COLON CAPSULE ENDOSCOPY IN REAL PRACTICE : PRIMARY RESULTS OF THE COLON CAPSULE ENDOSCOPY OBSERVATORY "ONECC"

J.-C. Saurin[1,*], T. Ponchon[2], G. Gay[3], J.-C. Letard[4], K. Vahedi[5], R. Benamouzig[6]. [1]*Gastroenterology, E. Herriot Hospital. Hospices Civils de Lyon,* [2]*Gastroenterology, Hospices Civils de Lyon, Lyon,* [3]*Gastroenterology, CHU Strasbourg, Strasbourg,* [4]*Gastroenterology, Clinique Poitiers, Poitiers,* [5]*Gastroenterology, Clinique Trocadero, Paris,* [6]*Gastroenterology, CHU Avicennes, Avicennes, France*

INTRODUCTION: Most colon capsule endoscopy (CCE) studies are from expert centers following a research protocol. Very few data are available regarding colon capsule performance in usual clinical practice. Colon capsule endoscopy has been implemented in France through a national observatory (ONECC) directed by the French Society of Digestive Endoscopy (SFED) and the French Private Gastroenterology Association (CREGG). The aim of this observatory is to evaluate the feasibility of colon capsule use in general practice and in specific indications.
AIMS&METHODS: Capsule was available for 161 users in 116 centers. Physicians were included in the observatory after accepting a national chart. Indications for capsule were : i) failure or ii) contra-indication to colonoscopy, or iii) well informed refusal of colonoscopy. All users accepted to fill in an e-CRF including indication for colonoscopy and for CCE, preparation (on a 4 level scale : excellent, good, fair, bad), results of CCE, indication for colonoscopy, and one year follow-up including the result of a possible secondary colonoscopy.
RESULTS: Two years after initiation of the observatory, 662 CCE has been registered with 585 e-CRF filled. The indication for CCE was identified in 97.3 % of CRF and corresponded to on third each of the 3 accepted above indications. CCE detected polyps in 253 pts (44 %), with significant polyps in 125 (28.0 %). Significant polyps were detected in 20.4, 23.1 and 14.5 % of patients with an indication for CCE of failure, contraindication, and refusal of colonoscopy respectively. Preparation were performed with classical PEG (4 liters) in 313 pts (50.7 %), with 2 l PEG and sodium ascorbat (PEG/SA) in 133 (21.5 %), with a different preparation in 171 (17.7 %). Preparation results were excellent/good in 79 %, 80 % and 81 % of patients with 4 l PEG, 2 l PEG/SA, and other preparations respectively. Quality of preparation did not impact on the rate of significant polyps (18.5 % of patients with excellent/good versus 22 % of those with fair/bad preparation). The mean colon capsule reading time was of 46 mn. Results of secondary colonoscopy are awaited from the one year follow-up data.
CONCLUSION: Preliminary experience of a national colon capsule endoscopy network and observatory shows the feasibility in real clinical practice, the excellent respect of nationally validated indications for CCE, a 28 % yield of significant polyps, and a satisfying preparation result with different preparation regimens

P1338 IS UPPER AND LOWER ENDOSCOPY TO BE REPETEAD BEFORE PERFORMING CAPSULE ENDOSCOPY IN PATIENTS REFERRED TO TERTIALY CENTER FOR OBSCURE GASTROINTESTINAL BLEEDING ?

M. E. Riccioni[1,*], R. Urgesi[1], C. Marmo[1], V. Bove[1], G. Costamagna[1]. [1]*Gastrointestinal Endoscopy Unit, università cattolica del sacro cuore policlinico agostino gemelli, roma, Italy*

INTRODUCTION: CE rapidly became in the last ten years first line examination after negative upper and lower GI endoscopy for obscure gastrointestinal bleeding. Approximately two thirds of patients undergoing capsule endoscopy (CE) for obscure GI bleeding (OGIB) will have an abnormality found in the small bowel. Despite this, many other patients that underwent CE for OGIB, had the source of their blood loss only in the stomach or the colon
AIMS&METHODS: To evaluate the indication to repeat a new complete endoscopic work-up in subjects related to a tertiary center for obscure bleeding before CE.
A review was made of a prospective database of 637 out of 1008 consecutive patients undergoing capsule endoscopy for obscure GI bleeding at our tertiary center.
RESULTS: One hundred seventy nine patients out of 637 (28.1%) had lesions in the upper or lower digestive tract (stomach, duodenum or proximal colon) without small bowel lesions. Specifically, 138 out of 637 (21.6%) patients had lesions in the upper digestive tract as the probable cause of the bleeding missed by esophagogastroduodenoscopy: 11 gastric angiodysplasias; 13 gastric antral vascular ectasia (GAVE), 1 gastric cancer, 1 gastric peri-anastomotic cancer in B-II gastric resection, 3 gastric ulcers and 3 cases of multiple gastroduodenal erosions. Forty one out of 637 (9.5%) patients had lesions in lower gastrointestinal tract missed at previous colonoscopies. In particular, 24 angiodysplasias, 8 ulcers/erosions, 8 active bleeding without a clear source, 2 cecal carcinoma, 1 diverticular disease and 3 cases of erosive colitis. The identification of these lesions was aided by the suspected blood indicator. All patients underwent endoscopic therapy or surgery for their non-small-bowel lesions.
CONCLUSION: About 30% of patients submitted to CE for obscure bleeding had missed lesions in upper or lower GI tract. The reasons why these lesions have been missed are unclear. In this setting a cost analysis evaluation could be warranted in order to understand if it could be "economically" more appropriate to repeat a conventional endoscopic work up before CE.

P1339 DOES BOWEL PREPARATION IMPROVE SMALL BOWEL IMAGE QUALITY AND READER CONFIDENCE LEVELS WHEN EXCLUDING SIGNIFICANT FINDINGS AT CAPSULE ENDOSCOPY?

R. Rameshshanker[1,*], A. O'Rourke[1], J. Butcher[1], C. Fraser[1]. [1]*Wolfson Endoscopy Unit, St Mark's Hospital, Harrow, United Kingdom*

INTRODUCTION: Capsule endoscopy (CE) is the first line of investigation for examining the small bowel (SB) mucosa. While standard preparation (SP) is more convenient for patients, mucosal visibility may deteriorate within the distal SB. Recent meta-analyses suggest that bowel-cleansing agents (BCA) can improve small bowel image quality (IQ). The influence of BCA compared to SP on reader confidence levels (RCL) when excluding clinically significant findings (CSF) has not been examined.
AIMS&METHODS: To compare RCL when excluding CSF and assessing IQ during reading following SP or BCA prior to CE.
We performed a retrospective analysis of SB capsule images of 100 consecutive patients who underwent a complete CE examination at our institution from Oct 2012 - Mar 2013. Patients had SP (intake of clear liquids for 18 hours & 12 hour fasting prior to the procedure without BCA) or BCA (2l of polyethylene glycol (PEG) or magnesium citrate (MC) in addition to SP). The participants' demographic and clinical data were collected and SB transit time (SBTT) calculated. A four-point scale was used to assess IQ (grade 1 = $<80\%$ of mucosa visible $\pm$ excessive debris $\pm$ severely reduced brightness to grade 4 = $\geq$ 90% of mucosa visible $\pm$ mild debris$\pm$ mildly reduced brightness). The SBTT was divided into quartiles (Q1-Q4) by time and the IQ score, RCL and number of CSF for each quartile were determined by a gastroenterologist experienced in CE, blinded to the preparation. Procedures were examined in randomised order.
RESULTS: 49 (49%) patients had SP (group A) while 51 (51%) had one of the BCA (39% had PEG and 61% had MC, group B). There was no significant difference in age (p=0.87), sex (p=0.57), indication (p=0.25) and SBTT (group A: 264±112 mins vs. group B: 233±100mins, p=0.14) between groups. For each quartile, IQ scores were significantly higher for group B than A except in Q1 (Q1: 3.7±0.7 vs 3.5±0.6, p=0.06; Q2: 3.6±0.5 vs 3.1±0.6, $p<0.0001$; Q3: 3.2±0.6 vs 2.3±0.7, $p<0.0001$; Q4: 2.8±0.5 vs 1.9±0.8, $p<0.0001$). There was no difference in detection of CSF between group A and B (41% vs 51%, p=0.33, respectively). For each quartile, RCL for excluding significant findings were significantly higher for group B than A except in Q1 (Q1: 100% vs 96%, p=0.06; Q2: 96% vs 73%, $p<0.0001$; Q3: 88% vs 33%, $p<0.0001$; Q4: 77% vs 20%, $p<0.0001$). There was no significant difference in IQ or RCL between PEG or MC. 3 procedures (all SP) were considered unsatisfactory for IQ with recommendation to repeat after BCA.
CONCLUSION: BCA pre-CE significantly improve small bowel IQ and RCL when excluding CSF. BCA appear to be an important parameter for optimising the qualitive aspects of CE reading.

P1340 HOW USEFUL IS SMALL BOWEL CAPSULE ENDOSCOPY FOR THE INVESTIGATION OF IRON DEFICIENCY ANAEMIA AND CAN CLINICAL PHENOTYPE PREDICTS FINDINGS?

R. Rameshshanker[1,*], A. O'Rourke[1], J. Butcher[1], C. Fraser[1]. [1]*Wolfson Endoscopy Unit, St Mark's Hospital, Harrow, United Kingdom*

INTRODUCTION: Small bowel capsule endoscopy (SBCE) is a useful diagnostic tool for the evaluation of small bowel (SB) disorders. Iron deficiency anaemia (IDA) is one of the most common indications for SBCE.
AIMS&METHODS: Our aim was to evaluate the presence or absence of influencing factors that predispose to a positive or negative SBCE in an IDA setting. We carried out a retrospective review of our tertiary referral centre's SBCE procedures performed between Oct 2011-Mar 2013. All non-vegan patients with a history of IDA with complete SB examinations were included. Demographic and clinical data were collected and SBCE reports evaluated.
RESULTS: A total of 250 patients had SBCE for IDA (56% females, mean age 61yrs). Clinically significant SB findings (CSFs) were found in 32% (79/250) of patients, including vascular lesions (33%), inflammatory lesions (33%), coeliac (13%), active bleeding/altered blood (15%) and others (5%). 193 (77%) patients presented with IDA alone (Group A), while the remaining patients had an additional history of overt GI bleeding (OGB) (Group B). No significant difference for CSFs between groups was identified (30% vs. 37% for Group A and B, respectively, p=0.34). 112 (45%) patients had a history of usage of pro-haemorrhagic medication (aspirin, clopidogrel, NSAIDS or warfarin). CSFs were significantly higher in patients who had taken these medications than those who had not (42% vs. 22%, p=0.0017). The difference was even more significant when considering OGB as an additional risk factor (40% vs. 20% respectively, p=0.0009). In order to identify a CSF for patients without a history of pro-

haemorrhagic medication use or OGB, an additional 8 SBCE's were needed (number needed to treat = 9). 120 patients (48%) had no GI cause for IDA found (negative gastroscopy, colonoscopy and SBCE). 56 patients had a SB radiological investigation (RI) (CT enterography/MR enterography/barium follow through) prior to SBCE. CSFs were found in 9% and 95% of patients, respectively, who had an RI vs. SBCE ($p < 0.0001$).

CONCLUSION: SBCE is a useful diagnostic tool for the investigation of IDA when a history of OGB, antiplatelet therapy, NSAIDs or warfarin usage is present, since the likelihood of CSFs is significantly increased. The benefit of SBCE in IDA when these factors are absent is potentially debatable. Almost half of patients with IDA have a normal GI tract, indicating that non-GI causes need to be considered, while RI is of low value for the investigation of IDA.

P1341 COMPARISON OF VIDEO CAPSULE ENDOSCOPY AND FAECAL CALPROTECTIN AS DIAGNOSTIC TOOLS IN PATIENTS WITH ABDOMINAL SYMPTOMS SUGGESTIVE OF SMALL BOWEL CROHN'S DISEASE

S. Zaman[1], K. Patel[1,*], R. Goel[1], D.-M. Borrow[1], S. H. Anderson[1]. [1]*Gastroenterology Department, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom*

INTRODUCTION: Faecal calprotectin (FC) is a widely agreed non-invasive marker of gastrointestinal (GI) inflammation. There is a dearth of evidence comparing FC levels to findings of video capsule endoscopy (VCE). Particularly, there is a scarcity of data investigating the suitability of FC as a screening tool to select individuals requiring VCE in the investigation of patients with abdominal symptoms suggestive of small bowel Crohn's Disease (CD). We studied the correlation between FC levels and VCE findings and analysed their combined utility in detecting small bowel CD.

AIMS&METHODS: We retrospectively compared VCE findings and FC levels in adult patients referred with GI symptoms (abdominal pain, diarrhoea, weight loss, anaemia and bloating). Where multiple FC were measured, the value closest to the date of VCE was used. History of non-steroidal anti-inflammatory drugs, aspirin, clopidogrel and prednisolone use in the six weeks prior to VCE were identified. Findings of relevant investigations (GI endoscopy, MRI, CT, coeliac serology, histology, haemoglobin, C-reactive protein and platelet count) were also reviewed. FC and VCE findings were analysed against final diagnosis.

RESULTS: 62 patients were studied (21 males, mean age 41). One study was excluded due to capsule retention in the stomach. The median time between FC and VCE was 92 days. 29 had a normal FC ($\leq$60mg/g, mean 18mg/g) of whom 5 had abnormal VCE findings (17.2%). 32 had a raised FC ($>$60mg/g, mean 263mg/g) of whom 7 had abnormal VCE findings (21.9%). Two-tailed Fisher's exact test revealed that the difference between the two groups was not statistically significant ($p=0.75$).

In the normal FC/abnormal VCE group 3 out of 5 patients were diagnosed with CD (one had CD confirmed on colonoscopy). One case had mild patchy terminal ileal (TI) erythema. Another had non-specific TI aphthous ulcers. In the raised FC/abnormal VCE group 3 out of 7 patients were diagnosed with CD (all 3 had active CD on colonoscopy). Two cases had jejunal apthous ulcers, and there was one case each of mild patchy TI erythema and TI apthous ulcers. Two-tailed Fisher's exact test revealed that the difference between these two groups was also not statistically significant ($p=1$).

CONCLUSION: The utility of FC to diagnose small bowel CD remains debatable, with previous studies showing differing outcomes.[1,2] In our cohort, FC levels did not reliably correlate with VCE findings. The correlation of FC level with the diagnosis of small bowel CD by VCE was also not statistically significant. Based on our findings, the decision to proceed to VCE should be based on clinical symptoms, and not on abnormal FC levels.

P1342 THE EFFICIENCY OF COLONIC CAPSULE ENDOSCOPY IN DETECTION OF COLORECTAL POLYPS AND CANCERS COMPARING TO COLONOSCOPY: MULTICENTER, PROSPECTIVE CROSSES OVER STUDY

M. Voska[1], S. Suchanek[1,*], O. Majek[2], G. Vojtechova[1], M. Zavoral[1], M. Benes[3], J. Spicak[4], J. Bures[5]. INTRODUCTION: To assess the feasibility, accuracy, and safety of second-generation of colon capsule (CCE-2) in screening population in a head-to-head comparison with colonoscopy. The interim analysis of results is presented.

AIMS&METHODS: In this multicentre (four centers) feasibility study, second generation of colon capsule endoscopy has been prospectively compared with conventional colonoscopy (standard method) in a cohort of colorectal neoplasia low risk patients (screening population). The efficiency in detection of colorectal polyps ($\geq$ 6 mm and $\geq$ 10 mm) and cancers has been assessed. Colonoscopy was independently performed within 10 hours after capsule ingestion. Capsule-positive but colonoscopy-negative cases were counted as false positive. Level of bowel preparation, rate of adverse events and patient preferences were assessed.

RESULTS: From January 2011 until April 2013, 139 patients (mean age 60 years) has been enrolled; data from 119 patients has been analyzed. The capsule has been excreted within 10 hours after ingestion and before the end of the battery lifetime in 85% of patients. Patient rate for polyps of any size was 50%; in 49% of these patients adenomas have been found. The capsule sensitivity for detection of patients with polyps of size $\geq$ 6mmas 67 % and for those with polyps $\geq$ 10mm it was also 67 %, with specificities of 64 % and 93 %, respectively. One invasive carcinoma has been detected by CCE-2 and colonoscopy. For all lesions, the sensitivity of capsule endoscopy was higher in patients with good or excellent bowel preparation (on four grade scale). Overall colon cleanliness for capsule endoscopy has been adequate in 81% of patients. Four mild adverse events related to both procedures have been reported. 56% of patients would prefer CCE-2 as a primary screening method.

CONCLUSION: Second generation of colon capsule has appeared to have a high sensitivity for the detection of clinically relevant colorectal neoplasia in screening population. This method might be considered as an adequate tool for colorectal cancer screening.

P1343 EFFICACY OF DOUBLE PIGTAIL STENT AS CONSERVATIVE TREATMENT OF GRADE B PANCREATIC FISTULA AFTER PANCREATODUODENECTOMY WITH PANCREATOGASTRIC ANASTOMOSIS.

E. Bartoli[1,*], L. Rebibo[2], B. Robert[3], M. Fumery[1], R. Delcenserie[1], J.-M. Regimbeau[2]. [1]*Gastro-enterology,* [2]*Digestive surgery,* [3]*Radiology, Amiens North Hospital, Amiens, France*

INTRODUCTION: Despite improvements in surgical techniques and immediate postoperative care, the morbidity rate associated with pancreatoduodenectomy (PD) is still high - notably due to a pancreatic fistula (PF) rate of between 2% and 30%. Pancreatic fistula is diagnosed when the amylase level in abdominal drain fluid on postoperative day 3 is three times higher than the normal serum amylase level. Grade B PF is defined as a symptomatic pancreatic fistula and requires a specific combination of radiologically guided external drainage, drug treatment and nutritional support. This treatment is effective but requires prolonged hospitalization and the maintenance of external drainage. The objective of the present study was to evaluate the feasibility and efficacy of endoscopically guided internal drainage (with a double-pigtail stent (DPS)) of grade B PF after PD with pancreatogastric anastomosis.

AIMS&METHODS: Between January 2008 and October 2011, all patients presenting grade B PF after endoscopic PD (n=6) were included in the study. The PF was diagnosed according to the International Study Group on Pancreatic Fistula's criteria. Endoscopic treatment was standardized with a DPS and a nasocystic drain. The primary efficacy endpoint was the feasibility and efficacy of DPS placement. Secondary endpoints included data on the PF, the DPS placement procedure and the long-term outcome.

RESULTS: Endoscopic DPS placement was achieved in all patients and there were no complications. The median (range) time to onset of PF after PD was 14 days (3–18). The median time to DPS placement after discovery of the PF was 6 days (0–37). Closure of the external PF was obtained 7 days (median) after implementation of DPS (range: 7–26). The median time to external drain removal was 7 days (7–27) after DPS placement. Median time to oral refeeding was achieved 7 days after the DPS placement for all patients. The median time to DPS removal was 60 days (49–120). The median length of hospital stay after DPS placement was 10 days (7–28). During a median follow-up period of 21 months (16-49), there was no recurrence of peri-anastomotic collection after removal of the DPS.

CONCLUSION: Endoscopic treatment of grade B PF after PD appears to be effective and safe and is associated with shorter hospitalization. These encouraging results need to be confirmed in a larger series.

P1344 STENT AND VENT: DUAL TRANSGASTRIC AND TRANSPAPILLARY APPROACH FOR THE MANAGEMENT OF PANCREATIC PSEUDOCYSTS WITH PANCREATIC DUCT DISRUPTION

H. Winter[1,2,*], S. Kadirkamanathan[2], R. Shidrawi[1]. [1]*Gastroenterology, Homerton University Hospital, London,* [2]*Upper GI Surgery, Broomfield Hospital, Chelmsford, Chelmsford, United Kingdom*

INTRODUCTION: Management of pancreatic pseudocysts remains controversial and complex with few studies describing a multimodality approach. With increasing experience with endoscopic techniques, surgical intervention is reducing. We review outcomes of single-operator management of symptomatic pseudocysts within a single centre with an interest in pancreatic endotherapy.

AIMS&METHODS: Retrospective analysis of patients with symptomatic pseudocysts between 2002-2012 was performed. All patients underwent ERCP,

sphincterotomy and bile duct trawl. Where possible, pancreatic duct stenting with papillotomy was performed, bridging any rupture or stricture with a 7 or 10Fr straight Teflon stent. All patients underwent curvilinear endoscopic ultrasound (EUS)-guided drainage of the pseudocyst if the cyst wall bordered the gastric wall. The cyst was punctured with a 19G needle, followed by diathermy or balloon dilatation of the tract using a 10F cystotome (Wilson-Cook, Ireland) or Hurricane RX biliary dilatation balloon catheter (Boston Scientific, Ireland). A 10F double pigtail Teflon stent was then inserted. Where not possible, alternative methods of drainage were explored. Pancreatic stents were retrieved within 8 weeks. Cystgastrostomy stents were removed once patients were convalescent and resolution of cyst confirmed. Successful therapy was defined as resolution of pseudocyst.

RESULTS: 24 patients were referred (17 male) with a median age of 44yrs (21-81). Notes were available for 22. 1 was lost to follow up and 2 (8%) did not survive due to multiorgan failure. Of the remaining 19, 18 (95%) demonstrated resolution of pseudocyst. At ERCP, 20 (91%) had successful pancreatic duct cannulation and transpapillary stenting and 19 of these (95%) demonstrated complete healing of pancreatic duct disruption. Complications included stent migration (2), fracture (1). At EUS, 16 pseudocysts (73%) were amenable to drainage. The remainder underwent percutaneous drainage (2), surgery (1), or resolved spontaneously (3). Of those drained via cystgastrostomy, 1 patient died and 1 was lost to follow up. 12 (86%) of the remaining cysts resolved. 1 required surgical drainage due to early migration of stent and 1 has persistent small pseudocyst. Complications included bleeding (1), stent migration (2), gastric perforation (1). Cystgastrostomy stents were retrieved at a median of 9.5 months (2-36).

CONCLUSION: Dual transgastric and transpapillary management of symptomatic pancreatic pseudocysts with pancreatic duct disruption is safe and effective. Our data suggests that this approach can limit surgical intervention, potentially reducing associated morbidity and mortality.

P1345 DIFFICULTIES ENCOUNTERED FOR REMOVING FULLY COVERED SELF-EXPANDING METAL STENTS INSERTED IN BENIGN BILIARY CONDITIONS

J. García-Cano[1,*], L. Álvarez-Burneo[2], L. Taberna-Arana[2]. [1]*Department of Digestive Diseases, Hospital Virgen de la Luz,* [2]*Family Practice, Health District of Cuenca, Cuenca, Spain*

INTRODUCTION: Use of fully-covered self expanding metal stents (FCSEMSs) for benign biliary conditions is increasing. They have been used to manage benign biliary strictures, refractory leaks, to tamponade biliary sphincterotomy bleeding, to close biliary sphincterotomy perforations, to remove uncovered SEMS with a stent-in-stent technique and even for complex and difficult common bile duct stones. Apart from the larger diameter they offered compared with a single plastic stent, easy extraction is of major importance when they are used in such benign conditions. Metal materials, although fully covered with different coating membranes, appear to produce always some tissue hyperplasia that can lead to bury the FCSEMSs duodenal end, without excluding some inward migration.

AIMS&METHODS: Retrospective, single centre study of problems found at FCSEMSs removal when the duodenal stent part was buried in the papillary area.

RESULTS: Extraction of biliary Wallflex FCSEMSs (Boston Scientific, Natick, USA) inserted for bening biliary conditions was attempted in 49 ocassions. The duodenal stent part was found buried in nine (9/49 or 18.4%). In three occasions, a guidewire was passed beyond the stent and a 15 mm dilation balloon inflated inside the stent followed by pulling manoeuvres. All FCSEMSs were removed but in one circumstance the duodenoscope slipped back and perforated the duodenum. This patient was operated but unfortunally died postoperatively. The technique was abandoned and replaced in the remaining six occasions for pulling from inside the stent with a 15 mm common bile duct stones extraction balloon. ERCPs were time-consuming but successful. All FCSEMSs could be removed. Nine buried stents had remained for a mean of 301 days (range 240-360) whereas 40 visible stents in the papillary area and easily extracted with a foreign bodies forceps, were in place for a mean of 145.6 days (range 30-273) ($p < 0.05$).

CONCLUSION: In this single centre and relatively small series, all FCSEMSs inserted for benign conditions could be removed. Brusque manoeuvres have to be avoided. In our opinion and in a certain subjective figure, FCSEMSs should not remain in place for more than six months if an easy extraction wants to be anticipated.

P1346 EFFICACY AND LIMITATION OF PANCREATIC STENTING FOR PATIENTS WITH CHRONIC PANCREATITIS

N. Sueyoshi[1,*], M. Takata[1], S. Tanaka[1], R. Yamamoto[1], R. Yoshida[1], A. Nishio[1], H. Takenaka[1], S. Miura[1], S. Sasaki[1], N. Indo[1], Y. Yano[1], Y. Yamaoka[1], Y. Hiroyoshi[1], S. Tochitani[1], K. Fujita[1], N. Matsuki[1], T. Anami[1], E. Anami[1], S. Matsui[1], E. Sugahara[1], T. Fujita[1], A. Watanabe[1], A. Sugahara[1], H. Mukai[1]. [1]*Digestive disease center, Department of gastroenterology, Yodogawa Christian Hospital, Osaka, Japan, Osaka, Japan*

INTRODUCTION: To evaluate the efficacy of pancreatic stenting in patients with chronic pancreatitis with intraductal stones as short-term stenting, and inserting ENPD at the time of stent removal.

AIMS&METHODS: From 1998 to 2013, 98 patients of chronic pancreatitis with intraductal stones were performed lithotripsy. The population consisted of 87 males and 11 females with mean age 54.8. The etiology of chronic pancreatitis was alcohol abuse in 70, idiopathic in 21, and pancreas divisum in seven. 76 patients succeeded in lithotripsy, and 67 of them remained upstream ductal dilation after lithotripsy. In the 67, we performed pancreatic stenting. 52 patients were performed through the major papilla, and 15 through the minor papilla. As short-term stenting, we inserted 10-Fr stent and removed it within 6 weeks. We also inserted 5Fr ENPD at the time of 10-Fr stent removal, and removed it in one or two days after.

RESULTS: We succeeded stenting in 79.1% (53 patients, 231 stents). Stents were advanced across the stricture of the MPD through the major papilla (39 patients, 191 stents) or minor papilla (14 patients, 40 stents). Over 6 months after stent removal, we could follow 49 patients (major papilla 36 patients, minor papilla 13) who were able to abstain from drinking alcohol. 26 patients (53.1%) presented with recurrence of intraductal stones. The patients of whom the diameter of the upstream MPD after 10-Fr stent removal was less than 7mm, were named the dilation improved group. Their recurrence rate was 41.2% (14/34 patients)(major papilla 37.0%, minor papilla 57.1%). The recurrence rate of the dilation non-improved group; the diameter of the upstream MPD 7mm and above; was 80.0% (12/15 patients) (major papilla 66.7%, minor papilla 100%). The non-improved group had a significantly higher recurrence rate. Median time to recurrence of the dilation improved group was 380 days, and significantly longer than of the non-improved group 266 days. Inserting 5Fr ENPD at the time of 10-Fr stent removal had no effect on recurrence rate of intraductal stones, but could prolong the time to recurrence on the dilation non-improved group. Median time to recurrence of the non-improved group was 199 days when we didn't insert ENPD, but 510 days when we inserted.

CONCLUSION: On the dilation improved group, we confirmed the efficacy of pancreatic stenting. And on the dilation non-improved group, inserting ENPD might prolong the time to recurrence.

P1347 LONG TERM MANAGEMENT OF IRRETRACTABLE COMMON BILE DUCT STONES: ELECTIVE STENT EXCHANGES OR EXPECTANT APPROACH? A TERTIARY CENTRE EXPERIENCE OF 6 YEAR FOLLOW UP.

N. Mohammed[1,*], M. Pinders[2], K. Harris[3], S. M. Everett[2]. [1]*Gastroenterology, Leeds Institute of Molecular Medicine,* [2]*Gastroenterology,* [3]*Radiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

INTRODUCTION: Long term management of difficult Common bile duct stones (CBDS) is either 'elective stent exchange' (ESE) 6-12 monthly or 'permanent stent insertion' (PSI) in selected cases with biliary stenting as sole management option.

AIMS&METHODS: The aim of our study was to evaluate the clinical outcomes of ESE and PSI for irretractable CBDS in our centre.

A retrospective review of all patients who underwent plastic stent insertion for biliary access in difficult CBDS from January 2006 to December 2011. Electronic patient records were used to gather data. Patients who had plastic stents inserted for irretractable CBDS were included in the study. Patients with biliary strictures/leak, hepato-biliary cancer and those who had metallic stents inserted during their follow up period were excluded. Patients in ESE group underwent planned exchange of biliary stents every 12 months whereas in PSI group patients had biliary stents inserted with an intention to replace only if blocked or if patients represented with biliary complications. The decision as to which group patients were in was based on individual clinician and patient preferences.

RESULTS: 674 patients underwent 1769 stent related procedures in the study period. 165 patients met the inclusion criteria among which 119 patients had temporary plastic stent insertions and subsequent duct clearance. 18 patients were identified as in PSI group and 28 in ESE group. Mean age of patients in each group was similar (ESE-Mean 84.6, range 70-95, PSI- Mean 83.1, range 57-95) but patients in PSI group had multiple co-morbidities represented by high American Society of Anaesthesiologists (ASA) score (PSI-3.0, ESE-2.7). Although number of procedures performed in PSI group were lesser than ESE group but biliary complications were significantly higher. Characteristics of each group are given in Table 1.

	ESE group	PSI group
Total number of procedures	45 (mean 1.95)	9 (Mean: 0.52)
Blocked stent	1/28 (3.5%)	9/18 (50%)
Procedure related complications	2 Minor bleeds 2 Desaturations	3 Minor bleeds 2 Desaturations 1 Bradycardia 1 pancreatitis
Ducts cleared	4 (14%)	1 (5%)
Follow up	736 months (mean 27.25 months)	603 months (mean 33.5)
Deaths (within 30 days of procedure)	2 (non-biliary)	2 (1 biliary sepsis, 1 non-biliary)

CONCLUSION: In our series, patients selected for expectant management (PSI) had higher comorbidity; 50% re-presented acutely with stent blockage. Whilst this is not a randomised comparison, it suggests that expectant management option may be suitable only for patients with limited life expectancy.

P1348 THE PREDICTORS OF COMPLICATIONS AND LONG-TERM OUTCOME AFTER ENDOSCOPIC TREATMENT IN PATIENTS WITH PANCREATIC PSEUDOCYSTS

O. Kushniruk[1,*], V. Kolomijtsev[2], I. Tumak[1]. [1]*Dept. of postgraduate surgery and endoscopy, Lviv National Medical University,* [2]*Dept. of Surgery, Lviv Medical University, Lviv, Ukraine*

INTRODUCTION: To estimate the pancreatic pseudocysts (PP) features and technique of endoscopic drainage (ED) as potential predictors of complications and late recurrence rate (RR).
AIMS&METHODS: 94 patients with PP have been evaluated, included 20 (21.3%) after acute pancreatitis and 74 (78.7%) with chronic pancreatitis. In 83 from them (88,0%) diagnosed communication with main pancreatic duct. Multiple cysts (not more than 3 in one patient) were determined in 8 (9.0%) and septaited in 2 (2.2%) patients. Among these 20 patients underwent transpapillary ED. In 74 patients was performed transmural ED, included 30 cases with endosonography assistance. Combination of methods was used in 13 (13.8%) patients.
RESULTS: minor complications occurred in 15 (15.95%) patients. 3 (3.3%) during the procedure and 12 (13.5%) in early postoperative period): cyst leakage, stent dislocation, secondary infection and hemorrhage. All of them but two were treated endoscopically. One patient died (1.06%) from cause, not related to ED procedure.
Higher level of septic complication after ED of ''younger'' PP (8-12 weeks) was found ($p=0.089$). CR was higher after introduction of straight stents ($p=0.037$). EUS-guided drainages completely prevented bleeding.
