Remote surveillance was performed in 71 patients. Cyst recurrence revealed in 8 (11.3%) cases. ''Free of relapse survival'' analysis showed better prognosis in alcohol PP vs. biliary ($p=0.01$ Cox's F-test), cystostomy balloon dilation ($p<0.001$), stents *in situ* more than 3 months. There were no recurrence in pancreatic body cysts, but 17.9% in head and 21.4% in tail cysts ($p=0.02$ and $p=0.03$). Better results were in patients with more than 2 stents (0 vs 13%) and with pseudocyst without PD communication (0 vs 11,3%).
CONCLUSION: The prevention of stent dislocation for the decreasing of CR and prophylaxis of recurrence is important. Pig-tail stent fits the best for these purposes. Balloon dilation and setting of more than 2 stents is necessary for diminishing of RR especially of pancreatic head and tail cysts in biliary pancreatitis.

P1349 PERCUTANEOUS AND ENDOSCOPIC TREATMENT OF BILIARY STRICTURES AFTER LIVER TRANSPLANTATION IN CHILDREN – MANAGEMENT, OUTCOME AND RISK FACTORS

P. Czubkowski[1,*], M. Markiewicz-Kijewska[2], J. Pertkiewicz[3], P. Kaliciński[2], K. Janiszewski[3], M. Rurarz[1], J. Pawłowska[1]. [1]*Department of Gastroenterology, Hepatology and Eating Disorders,* [2]*Department of Pediatric Surgery and Organ Transplantation, The Children's Memorial Health Institute,* [3]*Endotherapy, Warsaw, Poland*

INTRODUCTION: Biliary stricutres (BS) are common complication in paediatric liver transplantation and in spite of the overall progress they remain a significant cause of graft loses.
AIMS&METHODS: We performed the retrospective chart review of 50 liver transplantations (48 patients: 29 male/19 female and 34 cadaveric/16 living - related) presenting with biliary strictures. In regard to biliary anastomosis, patients were referred to endoscopic retrograde cholangiopancreatography (ERCP) or percutaneous transhepatic biliary drainage (PTBD) with balloon dilatation and biliary stent or catheter interposition. The aim of the study was to analyze our experience in the treatment of BS after liver transplantation.
RESULTS: Anastomotic BS were diagnosed in 37 (74%) cases and multilevel in 13 (26%). Most BS developed in the first year after LTx – 32 (64%). At the moment of first non-surgical intervention 29 patients had hepaticojejunal anastomosis and 21 had choledochocholedochal anastomosis. Sixty-two ERCP procedures were performed in 21 patients (mean 2,9 per patient). They were successful in 15 (71,4%). The total median duration of ERCP treatment was 1,23 (0,72-2,43). In 34 patients 86 PTC procedures were performed (mean 2,5 per patient). PTBD was successful in 22 patients (64,7%). The interventions were complicated in 19% (ERCP) and 10% (PTBD). 8 patients underwent surgery after failed PTBD, successful in 4 cases. 9 patients were either re-transplanted or listed for ReLTx (19%). The overall good outcome of treatment without need for ReLTx was achieved in 41 (82%) patients. Non-surgical interventions were successful in 37 (74%). Median age at first percutaneous or endoscopic intervention was 13.5 years (0,9-1,9) and time from LTx to first ERCP or PTC 0,68 years (0,08-11,4). Total median follow up after transplantation was 5,6 years (1,13-16,1) and after last biliary intervention 3,72(0,6-8,3) years. The only risk factors of poor outcome were presence of multilevel BS and period of treatment before 2008.
CONCLUSION: Non-surgical approach is effective and safe in biliary strictures after liver transplantation. The majority of patients require repeatedly performed interventions. Surgical approach should be considered in selected cases with poor response to primary treatment.

P1350 ENDOSCOPIC TREATMENT OF PANCREATIC PSEUDOCYST BY USING DIABOLO STENT IN 16 PATIENTS

R. Delcenserie[1,*], M. Bourgeois[1], E. Bartoli[1], F. brazier[1], T. Yzet[2], M. Eoche[1], M. Khan[1], D. Fuks[3], J.-M. Regimbeau[3]. [1]*Gastroenterology,* [2]*Radiology,* [3]*Visceral Surgery, Amiens University Hospital, Amiens, France*

INTRODUCTION: Diabolo stent, because of its wide diameter (10 or 16mm), permits either an adequate drainage of pancreatic cystic liquids towards the digestive tube or endoscopic access to the cystic cavity.
AIMS&METHODS: Between September 2011 and September 2012 we placed 24 Diabolo stents (Cousin Endosurg; Taewong medical) in 16 patients of symptomatic or complicated pancreatic pseudocysts (9 males, 7 females aged 32 to 84). Among these 16 patients, 10 patients had pancreatic pseudocysts (6 to 17cm) with clear or colored liquid. The duration of stenting was for one month in our first patient and then it was from 4 to 6 months for the rest of our group. In the second group there were 6 patients with necrotic and infected pancreatic pseudocysts after an acute pancreatitis. In this group we performed N. O.T.E.S (Natural Orifice Transluminal Endoscopic Surgery).
RESULTS: No major per procedure complications occured. Early response (<1month) in our first group of 10 patients with clear liquid pseudocysts shows significant decrease in the cyst size in 2 patients, disappearance of cyst in 7 patients and removal of the stent in 1 patient on day 18 because of direct contact of the stent with splenic vein. Intermediate response (6 months) shows spontaneous migration of the stent without cystic recurrence in 1 patient, stent in place without cystic recurrence in 5 patients and backward movement of stent without cystic recurrence in 3 patients. In our second group with infected and necrotic pseudocysts, we placed from 1 to 3 stents for each patient with early removal to perform the N.O.T.E.S for necrosectomy. In this group the early and intermediate term response was favorable in 3 patients by regression of the pseudocyst size and disappearance of the symptoms, 3 patients had to be operated on, one preciously because of rupture the pseudocyst after opacification, 2 because of inadequate endoscopic drainage with early favorable response and one unfavorable response because of sepsis and multiple organ failure.
CONCLUSION: Endoscopic treatment of pancreatic pseudocysts by placing Diabolo Stent is not a complicated procedure; in case of pseudocyst with clear liquids there is a favorable clinical and radiological early and intermediate term response. We will know about the long-term response by our patients' follow up. As to the infected and necrotic pseudocyst the Diabolo stent is theoretically interesting, easy to place and has a very low complication rate of this procedure, though the efficiency has to be determined.

INTRODUCTION: We previously reported a longer time to recurrent biliary obstruction with less stent migration using a partially-covered nitinol self-expandable metallic stent (Wallflex™ Biliary RX Partially Covered Stent; Boston Scientific Corp, Natick, Mass) in a multicenter prospective study: WATCH study (Gastrointest Endosc. 2012;76:84-92). A fully-covered type of this SEMS (Wallflex™ FCSEMS) is commercially available but there is a concern about the increased risk of stent migration in FCSEMS.
AIMS&METHODS: The aim of this study is to evaluate the safety and efficacy of a new, commercially available FCSEMS. Between September 2011 and July 2012, 156 patients (64 males, a median age of 75 years old, and median survival time of 198 days) with unresectable distal malignant biliary obstruction underwent FCSEMS placement in sixteen Japanese referral centers. Data on baseline characteristics, survival, stent patency, stent-

related complications and removability were prospectively collected. Primary endpoint was recurrent biliary obstruction (RBO) and secondary endpoints were technical success rate, stent-related complications and stent removal.
RESULTS: Stent placement was technically successful in all patients. The rate of RBO was 29% (stent occlusion, 15% and stent migration, 14%). The cause of stent occlusion was biliary sludge (6%), food impaction (3%), tumor overgrowth (2%) and others (5%). Tumor ingrowth was not observed. Median cumulative time to RBO was 318 (interquartile range: 157-NA) days. Other stent-related complications included pancreatitis (6%; mild in 5% and moderate in 1%), cholecystitis (4% of 150 patients with gallbladder in situ) and cholangitis without stent occlusion (4%). Stent removal was successful without complications in all 25 attempted cases (100%) after a median of 120 (range, 3-471) days from stent placement.
CONCLUSION: Wallflex™ FCSEMS appeared comparable to PCSEMS in terms of RBO, but stent migration rate was relatively high. Endoscopic removal is easily and safely accomplished in all 25 attempted cases. (Clinical trial registration number: UMIN000007131)

P1352 RISK FACTORS FOR PANCREATITIS FOLLOWING METAL STENT PLACEMENT FOR UNRESECTABLE MALIGNANT MIDDLE-, LOWER- COMMON BILE DUCT OBSTRUCTION

T. Ban[1,*], H. Kanie[1], T. Yamada[1], K. Hayashi[1], E. Orito[1]. [1]*Gastroenterology, Nagoya Daini Dedcross Hospital, Nagoya, Japan*

INTRODUCTION: Transpapillary metal stent (MS) placement is a useful strategy for patients with malignant biliary obstruction (MBO) but can be associated with post-procedure pancreatitis.
AIMS&METHODS: The objective of the present study was to identify risk factors for the occurrence of pancreatitis following this procedure. Eighty consecutive patients who underwent MS placement were studied. The rate of pancreatitis after MS placement and risk factors for pancreatitis were investigated. The following variables were assessed: gender; sex; etiology of MBO (pancreatic cancer vs. non-pancreatic cancer); timing of MS placement (one-step vs. two-steps or more); type of stent (covered vs. uncovered); EST; pancreatic duct injection; diameter of pancreatic body; and pancreatic duct diameter at the pancreatic body.
RESULTS: Pancreatitis after MS placement was identified in 10 of 80 patients (12.5%). In univariate analysis, the frequency of pancreatitis was significantly higher (p=0.001) in patients with non-pancreatic cancer (32.0%, 8/25) than in those with pancreatic cancer (3.6%, 2/55). Pancreatitis occurred more frequently (p=0.031) in patients whose pancreatic duct diameter at the pancreatic body was $<$3 mm (25.0%, 7/28) when compared with patients whose pancreatic duct diameter was $>$3 mm (6.1%, 3/49). Multivariate logistic regression analysis showed that the etiology of MBO (non-pancreatic cancer) was the only strong risk factor for pancreatitis (adjusted OR, 19.52; 95% CI, 2.07-184.03; p=0.009).
CONCLUSION: Non-pancreatic cancer was the only strong risk factor for pancreatitis after MS placement for MBO.

P1353 INTERIM ANALYSIS OF A PILOT STUDY OF NEW COVERED METALLIC STENTS WITH A LARGE BORE SIZE (NITI-S SUPREMO-12 STENT) FOR UNRESECTABLE DISTAL BILIARY MALIGNANCIES

T. Mukai[1,*], I. Yasuda[2], H. Isayama[3], H. Kawakami[4], T. Itoi[5], Y. Nakai[3], H. Kogure[3]. [1]*Department of Gastroenterology, Gifu Municipal Hospital,* [2]*First Department of Internal Medicine, Gifu University Hospital, Gifu,* [3]*Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo, Tokyo,* [4]*Department of Gastroenterology, Hokkaido University Graduate School of Medicine, Sapporo,* [5]*Department of Gastroenterology and Hepatology, Tokyo Medical University, Tokyo, Japan*

INTRODUCTION: Self-expandable metallic stents (SEMSs) have a significantly longer patency than plastic tube stents because of their larger dimensions. Moreover, covered SEMSs might have longer patency than uncovered SEMSs because they can prevent tumor ingrowth through the stent mesh. However, a new concern regarding covered SEMSs is an increased risk of stent migration. Theoretically, SEMS with larger dimensions might increase patency and reduce the risk of migration. Therefore, we have invented a novel, fully covered SEMS (FCSEMS), Niti-S SUPREMO-12 (SUPREMO-12), with a diameter of 12 mm. In addition to its larger bore, its flared ends prevent migration, and the knitting structure comprises large and small cells that alternately increase and decrease the amount of radial force, such that the stent fits into the bile duct.
AIMS&METHODS: To investigate the clinical safety, efficacy, and complication rates associated with Niti-S SUPREMO-12 stent for malignant distal biliary obstructions (Clinical trial registration number: UMIN000007061). Outcome Measurements: The primary outcomes were (1) stent occlusion and dysfunction rates at 180 days after stent placement, (2) stent patency duration, (3) time to recurrent biliary obstruction (TRBO), and (4) overall stent patency and function rates; secondary outcomes included (1) the median survival time, and (2) the stent-related complication rate.
RESULTS: Thirty-eight consecutive patients were enrolled into this prospective pilot study between June 2011 and November 2012. The median observation period was 238 days (range, 13–680 days). Among the 38 patients, 12 (32%) survived. Stent dysfunction was observed in 9 patients (24%). Stent occlusion, because of food impaction, was observed in 3 patients and tumor ingrowth was observed in 2 patients; stent migration was observed in 3 patients (1 proximal and 2 distal migration). Furthermore, mild cholecystitis and mild pancreatitis developed in 1 patient. Stent patency rate and the TRBO at 6 months were 89% and 82%, respectively. Mean stent patency and TRBO were 270 ± 13 and 264 ± 16 days, respectively. Stent removal was attempted in 6 patients and was successful in all of them.
CONCLUSION: The preliminary results suggest that this stent may be safe to use, with acceptable complication rates. Randomized controlled trials with conventional FCSEMSs will be necessary for evaluating the usefulness of this stent.

P1354 LONGER LENGTH TO THE STRICTURE FROM THE PAPILLA WAS RISK FACTOR FOR DYSFUNCTION OF COVERED METAL STENT IN PATIENTS WITH DISTAL MALIGNANT BILIARY OBSTRUCTION.

Y. Abe[1,*], K. Kawakubo[1], H. Kawakami[1], M. Kuwatani[1], T. Kudo[1], K. Kubo[1], N. Sakamoto[1]. [1]*Department of Gastroenterology and Hepatology, Hokkaido University Graduate School of Medicine, Sapporo, Japan*

INTRODUCTION: Placement of covered self-expandable metal stent (CSEMS) has been reported to be effective for palliation of distal malignant biliary obstruction. However, the risk factors for their dysfunction remained unclear.
AIMS&METHODS: The aim of this study was to identify the risk factors for dysfunction of CSEMS. One hundred forty patients (median age 66, male/female 84/56, pancreatic carcinoma/cholangiocarcinoma/others 105/17/18) who underwent CSEMS placement for distal malignant obstruction between October 2005 to April 2013 in a tertiary care center were included. Distal end of CSEMS was located in the duodenum. The median length to the stricture from the papilla was 30.8mm. Wallstent and ComVi stent were classified as the previous CSEMS group (n=35), while Wallflex and Supremo stent were the latest CSEMS group (n=105). We retrospectively examine the stent patency by using Cox proportional hazard analysis.
RESULTS: Stent dysfunction was observed in 26 (18.5%) patients. The rate of dysfunction was 42.9 and 10.8% in patients with the previous CSEMS group and the latest CSEMS group respectively. The cause of dysfunction was as follows; food impaction in 8, tumor overgrowth in 8, biliary sludge in 4, nonocclusion cholangitis in 3, and stent migration in 3. The median time to stent dysfunction was 535 days. Multivariate analysis by Cox proportional hazard model revealed that patients in the previous CSEMS group (Hazard ratio 3.36 [95%CI: 1.53-7.58], p=0.003) and with longer length to the stricture from the papilla (2.30 [1.02-5.51] p=0.045) were significant risk factors for stent dysfunction.
CONCLUSION: The latest CSEMS had longer stent patency than the previous CSEMS. The longer length to the stricture from the papilla was the significant risk factor for dysfunction of CSEMS in patients with malignant distal biliary obstruction.

P1355 PANCREATIC CYSTIC LESIONS: COULD DIAGNOSTIC STRATEGY BE OPTIMIZED?

A. I. Fernandes[1,*], N. Almeida[1], N. Dias[2], M. A. Cipriano[2], F. Portela[1], A. M. Ferreira[1], M. R. Silva[2], F. X. Cunha[2], C. Sofia[1]. [1]*Gastroenterology,* [2]*Pathology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: Pancreatic cystic lesions (PCL) are relatively common in our clinical practice but its diagnostic approach is complex. A correct diagnosis of the type of cystic lesion is essential to avoid unnecessary surgeries.
AIMS&METHODS: To establish diagnostic accuracy of preoperative laboratory and imaging methods when compared with gold-standard – definitive histological diagnosis following surgical resection. This was a retrospective study that included all patients submitted to surgical excision of PCL between 1998 and 2012. Clinical parameters and pre-operative diagnostic procedures were analyzed and compared with definitive histological diagnosis. Statistical analysis performed with SPSS v20.0.
RESULTS: The study included 38 patients (female–22; mean age–55.7±15.3 years). *Clinical presentation*: abdominal pain–65.8%; nausea/vomiting–36.8%; jaundice–18.4 %; diarrhea/steatorrhea–15.8%, abdominal mass–5.3%; 5 patients (13.2%) were asymptomatic. *Elevated serum tumour markers*: CA19.9–23.7%; CA125–7.8%; CA72.4–2.6%; CEA–2.6%. *Imaging methods used in the diagnosis*: abdominal ultrasound–81.6%; abdominal CT–97.4%; abdominal MRI–39.5%. *Imaging characteristics of the lesions*: average size–51±27mm; location in the head of pancreas–55.3%; 3 patients had multiple lesions. *Radiological diagnosis*: Mucinous Cystic Neoplasm (MCN)–13.2%; Intraductal Papillary Mucinous Neoplasm (IPMN)–10.5%; Pseudocyst–5.3%; Neuroendocrine tumor–2.6%; Cystadenocarcinoma–2.6%; Solid pseudopapillary neoplasm (SPN)–2.6%; Indefinite–63.2%. Endoscopic ultrasonography (EUS) evaluation was made in 14 patients, and it was complemented with fine needle aspiration (EUS-FNA) in 12. The liquid CEA was $>$192ng/ml in 3 of the 5 patients in which it was determined. *Diagnosis made by EUS* (14 patients): MCN–28.6%;

Adenocarcinoma–7.1%; Indefinite–64.3%. *Diagnosis made by EUS-FNA* (12 patients): MCN–41.7%; Cystadenocarcinoma–25%; Pseudocyst–16.7%; Serous Cystadenoma–8.3%; IPMN–8.3%. *Definitive histological diagnosis*: Serous Cystadenoma–31.6%; IPMN–23.7%; MCN–21.1%; Pseudocyst–13.2%, MCN with associated carcinoma–5.3%; SPN–2.6%; Lymphoepithelial Cyst–2.6%. *Preoperative diagnostic accuracy*: Radiological methods – 5/38 patients (13.2%); EUS – 3/14 (21.4%); EUS-FNA – 7/12 (58.3%). The false negatives of EUS-FNA were associated with the cytology and not with the determination of CEA.

CONCLUSION: Radiological methods and EUS have limited diagnostic accuracy to correctly identify the type of PCL. EUS-FNA, particularly with CEA determination, is the technique with greater sensitivity and should play a greater role in the diagnostic strategy of PCL.

P1356 LAPAROSCOPIC RESECTION OF BENIGN LIVER CYSTS HAS A HIGH SUCCES RATE

C. Noerregaard[1,*], A. P. Ainsworth[1]. [1]*Department of Surgery, Odense University Hospital, Odense, Denmark*

INTRODUCTION: Large benign liver cysts often tend to be symptomatic with the most common symptoms being pain, abdominal discomfort or nausea.

AIMS&METHODS: The aim of this study was to evaluate the outcome of laparoscopic resection of benign liver cysts.

We did a retrospective study of the records of patients who had surgery for liver cysts between December 2007 and December 2012 at our institution. In addition, patients were contacted by telephone in March 2013 with a questionnaire regarding present symptoms.

RESULTS: 31 patients underwent laparoscopic surgery for benign liver cysts (27 women, 4 men). Median age was 61 years (range 27 to 81 years). Main indication for surgery was upper abdominal pain (n= 27 (87%)) followed by abdominal discomfort (n= 11 (35%)). In 19 patients (59 %) the indication for surgery was based on the findings at CT, in 15 patients (48%) on the findings at ultrasonography, and in 4 patients (13%) both procedures were performed preoperatively. In one case (3%) MRI was the only preoperative diagnostic imaging procedure performed. The laparoscopic approach was successful in 29 patients (94%). Thus, two conversions (6%) to open surgery were necessary due to intraperitoneal adherences from previous surgery and cyst puncture(s). Mean postoperative hospital stay was one day (range 1 to 14 days). Histological evaluation revealed 29 non-neoplastic cysts (94%) and two cyst adenomas (6%). Two minor postoperative complications occurred: one patient suffered minor bleeding into the cyst cavity and one patient had bile leakage into the cyst cavity. None of these had however had need for re-operation. There was no 30-day mortality. Mean follow-up time was 28 months (range 1 to 60 months). At follow up, nine patients (28%) have had reoccurrence of cysts that had been verified by imaging procedures. In five patients (16%) the reoccurring cysts gave symptoms (i.e. pain) and all these patients were offered re-operation. However, only three had wanted this and undergone new laparoscopic operation. Three patients (10%) have had ultrasonically guided cyst puncture during follow-up, and one patient have had both surgery and external cyst puncture. Two patients were lost to follow up.

CONCLUSION: Laparoscopic resection of benign liver cysts has a high success rate in terms of pain relief and it is a safe procedure with a short postoperative hospital stay. However, some patients suffer from recurrent symptoms and need re-therapy. It is not known whether this re-occurrence of symptoms is because of recurrence of the cyst or because of development of a new one.

P1357 CORRELATION BETWEEN FECAL ELASTASE-1 AND PANCREATIC VOLUME IN PATIENTS WITH PANCREATIC DISORDERS OR AFTER PANCREATIC RESECTION

F. Carestiato[1,*], P. Campagnola[1], A. Amodio[1], C. Sozzi[2], N. Cardobi[2], G. Marchegiani[3], O. Messina[1], A. Gabbrielli[1], R. Manfredi[2], T. Tumelero[1], G. Vettori[1], L. Frulloni[1], L. Benini[1]. [1]*Medicine,* [2]*Radiology,* [3]*Surgery, University of Verona, Verona, Italy*

INTRODUCTION: Ideally, pancreatic function tests should allow a quantification of the amount of functioning pancreatic parenchyma. This assumption is widely accepted when considering duodenal output of pancreatic enzymes after maximal hormonal stimulation. No data are available to confirm this assumption considering the concentration of an enzyme, elastase-1 (FE-1), on a spot fecal sample, after physiologic stimulation by meals.

AIMS&METHODS: Aim of our study was to confirm the efficacy of FE-1 in the evaluation of pancreatic volume.

FE-1 and pancreatic volume were studied in patients with three different pancreatic disorders: asymptomatic chronic hyperenzymemia (CH; our control group); previous duodeno-cefalo-pancreatectomy (DCP); chronic pancreatitis (CP). These patients were studied over the last five years by both magnetic resonance and FE-1 tests, with a maximum time interval of 6 months between each other. Mean ±1 SEM are reported. ANOVA, Student's t test and the linear Pearson's test were used for statistical analysis. $P<0.05$ was accepted as the limit for significance. FE-1 was measured by an ELISA test on a spot fecal sample. Pancreatic volume was obtained using VIBE T1-depending sequences after contrast-enhanced MR.

RESULTS: We studied 154 patients (64 CH; 32 DCP; 58 CP). A significant difference was found among the three groups both for FE-1 (CH 468.6± 11.0 μg/g; DCP 83.8± 19.4; CP 285±23.6) both for pancreatic volume (CH 112.4±3.7 ml; DCP 30.5±2.7; CP 53.0±3.6) ($p<0.001$, ANOVA; $p<0.001$, Student's t test, for all contrasts). All CH had a volume >50 ml and FE-1 >200. A significant linear correlation was found between FE-1 and pancreatic volume for all patients ($r=0.655$, $p<0.001$). A correlation was confirmed considering separately DCP ($r=0.58$, $p<0.001$) and CP patients ($r= 0.34$, $p=0.009$) but not CH ($r=-0.03$; NS).

CONCLUSION: Fecal elastase-1 is well correlated with pancreatic volume, measured by magnetic resonance. The correlation is found only in patients with a reduction in residual pancreatic parenchyma, either due to chronic pancreatitis or to pancreatic resection. In patients with benign asymptomatic hyperenzymemia (our control group) no correlation could be demonstrated. The dispersion of data might be due to the spot fecal collection (rather than to total output) and to a submassimal pancreatic stimulation provided by meals.

P1358 SIGNIFICANCE OF EN BLOC RESECTION WITH THE ANTERIOR RENAL FASCIA FOR ADENOCARCINOMA OF THE LEFT PANCREAS

H. Kitagawa[1,*], H. Tajima[1], H. Nakagawara[1], I. Makino[1], T. Miyashita[1], S. Nakanuma[1], H. Hayashi[1], H. Takamura[1], T. Ohta[1]. [1]*Gastroenterologic Surgery, Kanazawa University, Kanazawa, Japan*

INTRODUCTION: The radical antegrade modular pancreatosplenectomy (RAMPS) has logically advantage for curative resection of the adenocarcinoma of the left pancreas. The anterior renal fascia is a key structure and resection planes should set behind this fascia. But it is difficult to find out this fascia and set appropriate plane accurately. We developed a modified technique to set the dissection plane easy and accurately.

AIMS&METHODS: Excision of the anterior surface of the IVC at the level of the 3rd portion of the duodenum is a first step to approach the posterior dissection plane behind the anterior renal fascia after clamping the splenic artery. This dissection plane proceeds along the left renal vein toward the hilum of the kidney. After that this plane proceeds cranial to the upper edge of the pancreas.

RESULTS: Between July 2007 and December 2012, 25 patients with pancreatic adenocarcinoma underwent the modified RAMPS. The mean age was 67 years, the mean tumor diameter was 35 mm, mean operating time was 385 minutes, and mean blood loss was 349 ml. No postoperative deaths occurred. Invasion to the retropancreatic tissues and lymph node metastases were detected in 17 and 13 cases, respectively. The surgical margins were histologically clear (R0 resection) in 21 patients (84%). Median survival was 29 months and 5-year overall survival rate was 45%. There are 5 patients who live over 5 years without recurrence.

CONCLUSION: This modified RAMPS has advantage for en bloc resection including the anterior renal fascia and contribute to improve the survival of the distal pancreatic carcinoma.

P1359 MAJOR HEPATIC RESECTION IN HEPATIC HYDATIDOSIS,MAJOR HEPATIC RESECTION IN HEPATIC HYDATIDOSIS

I. Abdelkader Salama[1,*], M. A. aboushady[1]. [1]*Department of Hepatobiliary and Liver transplant Surgery, National Liver Institute,Menophyia University, Shiben Elkom, Egypt*

INTRODUCTION: Ecchinococcal disease is still a serious problem in certain parts of the world, with liver as the most affected organ. Surgery remains the mainstay of treatment of hydatidosis, but the optimal surgical procedure remains unsettled

AIMS&METHODS: Objective: Safety and efficacy of major hepatic resection in multiple and giant hepatic hydatidosis.

Patients& Methods: 63 patients had hepatic hydatidosis associated with spleen, lung, and suprarenal hydatidosis were managed by major hepatic resection between April 2005 to April 2011. 43 (68%) males and 20(32%) females, age range 8-56 years. Cysts were found in the liver only in 51 (81%) patients, liver with spleen in 5 (8%), liver, spleen with lung in 2 (3.1%), liver and lung in 4 (6.3%), liver and suprarenal in one patient (1.6%).

RESULTS: Multiple cysts were found in 38 (60%) and solitary cyst in 25 (40%) with Cysts diameter ≤ 5 cm in 22 (35%), 5-10 cm in 16 (25%), and 10-38 in 25 (40%). Right hepatectomy in 24 (38%),Right trisectionectomy in 2(3.2%), right hepatectomy with Segment III in 4 (6.3%), right hepatectomy with Segment I in 2 (3.2%), left hepatectomy in 12 (19%), left lateral Sectionectomy in 6 (9.5%), left hepatectomy with Segment VI in 3 (4.8%), left lateral sectionectomy with Right posterior sectionectomy in 2 (3.2%), right hepatectomy with splenectomy in 7 (11%) and right hepatectomy with right suprarenal in one (1.6%) patient were performed. Hospital stay was 4.2 (3-13 days) There was one mortality and 12(19%) morbidities. No recurrence on follow up period (8-60 months) was observed.

CONCLUSION: : Radical procedure is safe and effective option for hepatic hydatidosis and should be performed when the entire lobe is diffusely involved by huge or multiple hydatidosis with little healthy liver tissue.

INTRODUCTION: The pancreaticoduodenectomy (PD) is the efficient treatment to obtain long-term survival for adenocarcinoma of the pancreatic head (APH). The presence of cirrhosis is usually considered as a contraindication for surgery based on old data. The objective of this study was to evaluate the results of PD for APH in cirrhotic patients compared to non-cirrhotic

AIMS&METHODS: This was a French retrospective multicenter study in patients with APH with cirrhosis between January 2004 to March 2012. A matching in 2: 1 with patients with APH but non-cirrhotic from the Surgical French Association report 2010 was conducted among a selection of 1886 patients. The matching was performed on demographic criteria and operative data. The primary endpoint of the study was the morbidity and mortality of the PD for APH in cirrhotic patients. Secondary endpoints were operative data, morbidity specific to pancreatic surgery and cirrhosis and follow-up data

RESULTS: 32 patients were matched with 64 non-cirrhotic patients. There was 27 male (84%) with a mean age of 62.1 years. The mean percentage of weight loss was 6.5%. 68% of cirrhotic patients were Child A while the other were Child B. 35% had portal hypertension. Alcohol was the cause of cirrhosis in 60%. The overall complication rate was 84.3% vs. 40.6% ($p \leq 0.05$) with 50% vs. 22% major complication ($p \leq 0.05$). Pancreatic fistula rate was 12.5% vs. 6.2% (NS). Post-operative mortality rate was 15% vs. 4.7% (NS). In the cirrhosis group, 46.8% had post-operative ascites and 15.6% had liver failure. There was no difference in tumoral, lymph node staging and R1 resection between the two groups. Major complication rate in Child A group was 33%, with 9% of pancreatic fistula and 4.5% of post-operative mortality. Post-operative mortality of Child B cirrhosis was 40%. Access to adjuvant therapy rate was 57% in Child A, 25% in Child B and 65% in control group. Recurrence rate was 43.5% in Child A vs. 51.5% in control group. Mean overall survival was 24 months in cirrhosis group vs. 23 months in control group

CONCLUSION: The PD for adenocarcinoma of the pancreatic head in cirrhotic patients is feasible, but with an increased risk of complications not specific to pancreatic surgery, but to cirrhosis. Presence of Child B cirrhosis must consindicate surgery.

P1361 IMPACT OF TECHNICAL MODIFICATION OF EUS-GUIDED ENDOSCOPIC PAPILLECTOMY FOR AMPULLARY NEOPLASM ON THE RATE OF POST-RESECTION ACUTE PANCREATITIS

J. C. Ardengh[1,*], M. V. Silva-Ney[2], T. Baron[3], E. T. Orsini[1], G. Motta[1], R. Kemp[1], J. S. Santos[1]. [1]*Surgery and Anatomy of HCFMRP-USP, Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto,* [2]*Surgery da Faculdade de Medicina da Universidade Federal de Goiás, Hospital das Clínicas da Universidade Federal de Goiás, Goiânia, Brazil,* [3]*Gastroenterology, Mayo Clinic, Rochester, United States*

INTRODUCTION: The insertion of a temporary pancreatic duct (PD) stent seems to prevent acute pancreatitis (AP) after endoscopic papillectomy (EP).
AIMS&METHODS: The aim of this study was evaluate the usefulness of a modified technique of endoscopic papillectomy (EP) is decreasing the rate of AP. Indications for EP: tumor confined to the papilla (T1) without tumor spread into the bile/pancreatic duct. EUS tumor staging was done to determine main PD (MPD) diameter before EP in all patients. After staging 14/41 patients underwent endoscopic snare papillectomy with the echoendoscope. A PD stent was placed in patients without MPD dilatation (30 and 35 mm) determined by EUS measure. 25 (group A [GA]) underwent EP without insertion of a PD stent. 16 (B-Control [GB]) underwent EP with insertion of a PD stent. The occurrence of adverse events (AEs) was compared between the groups in relation to the MPD diameter as determined by EUS.
RESULTS: 18 patients had adenomas, 12 adenocarcinomas, 4 hyperplastic lesion, 3 neuroendocrine tumor, 2 lipoma, 1 gastrointestinal stromal tumor and one hamartoma. The average size of the lesion removed in Group A and B was 18 mm (10-43) and 13 mm (5-16), respectively (p=0.04). The average MPD diameter in GA was 45 + sd (0.09) and GB 36 mm + sd (0.1) with p=0.11. AEs occurred in 43.9% (AP (10), bleeding (6), cholangitis (1) and cholecystitis (1)). There was a difference between groups A and B (36% vs. 56.2%, odds ratio [OR] 0.44, 95% [CI], 0.12 to 1.58). The frequency of early AEs in GA was lower than in GB (28% vs. 50% [OR] 0.37, 95% [CI], 0.10 – 1.34). AP occurred in 24.3%. There was significant difference between GA and GB (8% vs 50%; $p<0.001$). Late AEs occurred in 7.3%. There was no significant difference between groups (8% vs 6.2% [OR] 1.3, 95% [CI] 0.11 to 15.7). Local recurrence occurred in 9.7%.
CONCLUSION: The use of EUS before endoscopic papillectomy allows proper staging (T1) and MPD measurement. With a MPD > 36 mm and wide excision during EP obviate the need for MPD stent placement. In expert hands, complications are infrequent and can't be avoided by routine placement of a pancreatic duct stent. Further studies are needed to confirm these findings.

P1362 PROGRAMED EUS-GUIDED NECROSECTOMY (EUS-N) VERSUS OPEN SURGICAL TREATMENT (SUR-N) OF INFECTED WALLED OFF PANCREATIC NECROSIS (WOPN)

J. C. Ardengh[1,*], T. Baron[2], E. Taglieri[1], O. Micelli-Neto[1], E. T. Orsini[1], G. Motta[1], R. Kemp[1], J. S. dos Santos[1]. [1]*Surgery and Anatomy of HCFMRP-USP, Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil,* [2]*Gastroenterology, Mayo Clinic, Rochester, United States*

INTRODUCTION: The surgical approach in patients with infected WOPN there is a significant risk of complications and mortality. This approach consists in open surgical necrosectomy (SUR-N) or video-assisted retroperitoneal debridement. An alternative treatment is an endoscopic or EUS-guided step-up approach consisting of endoscopic transluminal necrosectomy.
AIMS&METHODS: The primary endpoint of this study is to compare the results of SUR-N versus programmed EUS-N in relation to adverse events, clinical and technical success, morbidity and mortality. In this study, we assigned 52 patients with necrotizing pancreatitis and suspected or confirmed infected necrotic tissue to undergo primary open SUR-N or a programmed EUS-N with a step-up approach to treatment. The step-up approach consisted of programmed EUS-N every 7 days followed, if necessary, by open necrosectomy in case of severe adverse events.
RESULTS: The primary end point occurred in 35 of 52 (67%) assigned to open necrosectomy and in 17 of 52 patients (33%) assigned to the EUS-N step-up approach. The average hospital stay for patients undergoing EUS-N [20 (6-48d)] and SUR-N [16 (3-105d)]. The clinical insuccess rate was 11.8% vs. 37.2% (p = 0.254) for patients undergoing EUS-N and SUR-N, respectively. New-onset adverse events occurred less often in patients assigned to the EUS-N than in those assigned to SUR-N (23% vs. 54%, P=0.279). The rate of death did not differ significantly between groups (12% vs. 0%, P=0,119). Patients assigned to the EUS-N had a lower rate of new-onset diabetes (5.8% vs. 17.1%, P=0.422).
CONCLUSION: A EUS-N, as compared with open necrosectomy, reduced the rate of the adverse events composite end point of major complications among patients with necrotizing pancreatitis and infected necrotic tissue.

P1363 PATIENT-SPECIFIC 3D ORGAN MANUFACTURING BY MULTI-MATERIAL 3D PRINTER FOR SURGICAL SIMULATION OF LIVER TRANSPLANTATION AND HEPATECTOMY

M. Sugimoto[1,*]. [1]*Gastroenterology, Kobe University, KOBE HYOGO, Japan*

INTRODUCTION: Our new technology of Bio-Texture Modeling by multi-material 3D printing system enabled manufacturing patient-specific 3D organ models by simultaneous jetting of different types of model materials and compounding the PVA, which is a water-soluble synthetic resin. We have used 3D personalized models of patients' organs for surgical simulation and navigation purposes. We evaluated its feasibility for liver transplantation and hepatectomy in five clinical cases.
AIMS&METHODS: Based on MDCT data, after generating its surface polygons using OsiriX application, the inkjet 3D printer created 3D liver and abdominal cavity models. This system enabled the simultaneous use of two different materials to shape and color the models in different ways, such as transparent colors or changing their firmness, textures and structures. We created life-size copies of the liver and abdomen of patients using two different kinds of plastics injected in layers, with each layer measuring 0.016 millimeters in thickness. We programed a printer to create clear models made from acrylic resins that allowed them to visualize and understand the liver's complex internal structures, such as bile duct and blood vessels or the exact location of a tumor.
Then, we printed liver models in part from polyvinyl alcohol to mimic the wetness and texture of a human liver, and to make the model a realistic stand-in for surgical practice.
RESULTS: Before a liver transplant surgery begins, we have used 3D replicas of a child's abdominal cavity and an adult-sized donor's graft liver to determine where and how to best trim. We took a knife to a 3D donor's liver replica, the models helped us figure out where to carve it. So that it would fit into the smaller space while preserving the organ's key functions, leading to a successful living-related liver transplant. For the liver cancer surgeries, the actual size transparent liver model with vessels and tumor could be manufactured and be handled. All hepatic cancers were successfully resected including multiple liver metastases. The elastic liver models were useful for surgical simulation and educational aspects.
CONCLUSION: Surgeons usually faced a dilemma before transplanting a parent's liver into a child: How exactly to trim the organ to fit the space in the child's smaller cavity while preserving its functions. We believe that the technology could help younger, less experienced surgeons practice with accurate copies before surgery.

P1364 DISORDERS OF CARBOHYDRATE METABOLISM IN PATIENTS WITH CHRONIC PANCREATITIS BEFORE SURGERY

A. Khrunyk[1], Prof G. Shabat[2,*], Dr Igor Shevtchuk, Myroslav Debenko. [1]*Abdominal surgery, Ivano-Frankivsk Regional Clinical Hospital,* [2]*Surgery, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*

INTRODUCTION: Violation of endocrine pancreatic function occurs in 30-83% of patients with chronic pancreatitis [2]. The progressive pancreas parenchyma fibrosis with inflammatory and degenerative changes leading to reduction in β-cells of islets of Langerhans and decreased insulin secretion [1]. Violation of insulin secretion may run, in the form of glucose intolerance and pancreatic diabetes [2]. According to the literature, the incidence of pancreatic diabetes is extremely difficult to establish because of the difficulty of diagnosis of chronic pancreatitis and high compensatory potential endocrine organ function [3]. Few data on the role of C-peptide in the early diagnosis of disorders endocrine pathology software tool [4].
AIMS&METHODS: Aim – examine the nature of software changes endocrine function in patients with Chronic Pancreatitis in the preoperative period.
The study is based on the analysis of patients with Chronic Pancreatitis, operated in the surgical department of the Ivano-Frankivsk Regional Clinical Hospital from 2006 to 2011. Inclusion criteria: Patients with Chronic Pancreatitis diagnosed according to the Shalimov's classification (1997), which performed surgery on the pancreas. Condition endocrine functions investigated by determination of plasma glucose, glucose tolerance and C-peptide by ELISA (normal 0.5-3.2 ng/ml).
RESULTS: Analyzed 90 patients: 72 (80%) – the operation carbohydrate metabolism was not in the 10 – (11.1%) was observed glucose intolerance, diabetes mellitus was found in 8 (8.9%) patients. In 30 пациентс investigated C-peptide. Level was normal in 21 (70%) patients, 9 (30%) – reduced, including in 4 (13.3%)

cases of diabetes occurred in 2 (6.7%) – was marked glucose intolerance and in 3 (10%) is observed violations. Attention is drawn to the general downward trend in C-peptide in the group with no carbohydrate metabolism, indicating a gradual depletion of insular apparatus of the pancreas and the possible risk of diabetes, indicating lack informative determine the glucose levels in the early diagnosis of disorders endocrine function of pancreas.

CONCLUSION: C-peptide can be considered a marker of early changes endocrine pancreas functions in Chronic Pancreatitis in conjunction with the study of glycemic profile.

P1365 A PROSPECTIVE SINGLE CENTER RANDOMIZED DOUBLE-BLIND PARALLEL GROUP COMPARATIVE TRIAL TO DETERMINE THE EFFICACY OF PROPHYLACTIC SINGLE DOSE CEFAZOLIN VERSUS PLACEBO REDUCING SURGICAL SITE INFECTION IN GENERAL LAPAROSCOPIC CHOLECYSTECTOMY PATIENTS

S. Ruangsin[1,*], S. Laohawiriyakamol[1], S. Mahattanobon[1], S. Chewatanagonkul[1]. [1]*Department of Surgery, Faculty of Medicine, Prince of Songkla University, Had Yai, Songkhla, Thailand*

INTRODUCTION: Laparoscopic cholecystectomy (LC) is the safest procedure for patients who have gallbladder disease, especially gallstones(1). The average rate of surgical site infection (SSI) of LC is occured between 0.4% and 3.8%(2-6) especially in high risk patients. The prophylactic antibiotic for LC has been questioned, however, as recent meta-analyses have concluded that prophylactic antibiotics for elective laparoscopic cholecystectomies in low risk patients is not useful(7-9). Given this current controversy concerning the efficacy of prophylactic antibiotics in LC.

AIMS&METHODS: The aim of this study was to determine whether the use of prophylactic antibiotics was associated with a lower rate of surgical site infection in elective laparoscopic cholecystectomy in patients with low and high risk factors of surgical infection.

Patients who met the inclusion criteria were randomized into two double-blinded groups, one of which received an isotonic sodium chloride solution of 10 mL (group A=placebo) and the other of which was given cefazolin 1 g (group B=study drug) via slow intravenous injection 30-60 minutes before the initial skin incision. The 4-port laparoscopic cholecystectomy technique was used in all procedures. The patient risk of infections was recorded and patients were monitored at least 30 days postoperatively for development of surgical site infections.

RESULTS: A Total of 299 cholecystectomy patients were randomized (149 in group A and 150 in group B). Surgical site infection occurred in seven patients (2.34%), 5 patients (1.67%) in the placebo group and 2 patients (0.67%) in the cefazolin group, which was not a statistically significant difference (p-value=0.248). No specific risk factors for surgical site infection such as diabetes mellitus, bupivacaine injection at surgical wound, postoperative intra-abdominal drainage, American Society of Anesthesiologists class 3, age more than 60 years, liver cirrhosis, continuous prednisolone use, obesity and conversion to open cholecystectomy were identified.

CONCLUSION: A single dose of preoperative prophylactic cefazolin had no benefit in reducing the incidence of surgical site infection in laparoscopic cholecystectomy, in patients with either low risk or high risk of infections.

P1366 DOES DISTAL PANCREATECTOMY WITH CELIAC AXIS RESECTION REALLY IMPROVE THE SURVIVAL OF PATIENTS WITH PANCREATIC BODY CANCER?

T. Sugiura[1,*], K. Uesaka[1], H. Kanemoto[1], Y. Okamura[1], T. Ito[1]. [1]*Division of Hepato-Biliary-Pancreatic Surgery, Shizuoka Cancer Center, Sunto-Nagaizumi, Japan*

INTRODUCTION: The survival impact of the distal pancreatectomy with en-bloc celiac axis resection for locally advanced pancreatic body cancer remains controversial. The aim of this study was to analyze the role of distal pancreatectomy with celiac axis resection (DP-CAR) for carcinoma of body of the pancreas.

AIMS&METHODS: Between 2002 and 2012, a total of 14 patients underwent DP-CAR, whereas 52 underwent standard distal pancreatectomy (DP). The indication of DP-CAR is a) tumor invasion of either celiac axis or common hepatic artery or both (CA/CHA (+)), b) tumor invasion of the root of splenic artery which is difficult to dissect without secure the enough surgical margin (CA/CHA (-)). Among the patients with DP-CAR, CA/CHA (-) and CA/CHA (+) were detected in seven patients each. The short and long-term surgical results were compared between DP and DP-CAR, and CA/CHA (-) and CA/CHA (+).

RESULTS: DP-CAR was associated with significantly longer operation time compared to DP (334min vs 257 min, p=0.001), greater blood loss (941ml vs 498ml, p=0.013), and higher incidence of positive surgical margin (43% vs 15%, p=0.014). Combined portal vein resection and reconstruction tended to be performed more frequently in DP-CAR compared to DP (29% vs 10%, p=0.087). However, morbidity was almost identical (86% vs 69%, p=0.318). There was no hospital death in both groups. The median disease-free survival time was 15.1 months in DP and 8.2 months in DP-CAR (p=0.022). The median overall survival time was 28.3 months in DP and 26.2 months in DP-CAR (p=0.347). In patients who underwent DP-CAR, there was no significant difference regarding the short-term results between CA/CHA (-) and CA/CHA (+) groups. The R1 resection rate of CA/CHA (+) was twice compared to that of CA/CHA (-) (57% vs 28%, p=0.592). The median disease-free survival was 14.3 months in CA/CHA (-) and 3.8 months in CA/CHA (+) (p=0.013). All patients with CA/CHA (+) had recurrence within 12 months after resection. The median overall survival time was 31.2 months in CA/CHA (-) and 13.3 months in CA/CHA (+) (p=0.002).

CONCLUSION: The indication of DP-CAR were classified into two; CA/CHA (-) and CA/CHA (+) according to postoperative survival. Patients with CA/CHA (-) are good candidates of DP-CAR. However, DP-CAR does not improve the survival of patients with CA/CHA (+), therefore these patients might be considered as having borderline resectable cancer.

P1367 PATENCY OF THE MAIN PANCREATIC DUCT AFTER PANCREATICODUODENECTOMY WITH INVAGINATION ANASTOMOSIS.

Y. Senda[1,*], T. Sano[1], Y. Shimizu[1]. [1]*Department of Gastroenterological Surgery, Aichi Cancer Center, Nagoya, Japan*

INTRODUCTION: Invagination technique is one of the most widely used methods to accomplish a pancreaticojejunostomy (PJ) after pancreaticoduodenectomy.
However, patency of the main pancreatic duct after pancreatoduodenectomy with invagination anastomosis is unclear.
AIMS&METHODS: The purpose of this study was to determine whether patency of the main pancreatic duct after pancreatoduodenectomy with invagination PJ is lower than duct to mucosa PJ.
Thirty patients underwent pancreatoduodenectomy in Aichi Cancer Center between January 2011 and December 2011. Their medical records were reviewed to evaluate the patency of the main pancreatic duct after surgery. Invagination anastomosis was performed in 18 patients, while duct to mucosa anastomosis was performed in 12 patients.
The diameter of main pancreatic duct, the thickness of pancreas and the fatty liver which are evaluated by CT after pancreatoduodenectomy are compared between invagination PJ group (IV) and duct to mucosa group (DM).
RESULTS: Patients with soft pancreatic texture were 20 (67%), narrow main pancreatic duct were 17 (57%). The overall pancreatic fistula rate was 33.3%.
The median observation period was 369.5 days (121-675) and there were no significant differences between two groups.
The number of patients with soft pancreas texture were significantly higher in IV group (p=0.045).
There were no significant differences between two groups in both preoperative (DM=3.5±1.7mm versus IV=2.4±1.0mm) and postoperative (DM=1.1±0.3mm versus IV=1.1±0.2mm) diameter of the main pancreatic ducts.
There were no significant differences in the pancreas texture (DM=9.5±1.4mm versus IV=10.3±1.0mm).
There were no significant differences in CT value of the liver between two groups both before and after surgery (DM=60.7±3.6HU versus IV=60.5±2.7HU).
Postoperative CT value of the liver was lower than preoperative CT value in both groups, but the difference of CT value between before and after surgery did not reveal significant differences.
CONCLUSION: There was no evidence of lower patency of the main pancreatic duct after pancreatoduodenectomy with invagination anastomosis.

P1368 LAPARO-ENDOSCOPIC MANAGEMENT FOR CHOLELITHIASIS AND COMMON BILE DUCT STONES

C. Rizzetto[1,*], G. Munegato[1], D. Da Ros[1], M. Schiano di Visconte[1], R. Bonadio[1]. [1]*General Surgery, Azienda Ospedaliera ULSS7, Conegliano, Italy*

INTRODUCTION: The ideal management of cholelithiasis and common bile duct stones (CBDS) is still a matter of debate. A single stage option based on laparoscopic cholecystectomy (LC) followed by an intraoperative endoscopic retrograde cholangio-pancreatography (ERCP) seems to offer some advantages. The aims of the study is to investigate the feasibility, results and procedure-related complications.
AIMS&METHODS: A retrospective chart review was done from all consecutive patients undergone to LC and ERCP between 2003 and 2012 at our surgical unit. We reviewed patients' characteristics, indication for surgery, conversion rate to open procedure, post-operative complications and hospital stay
RESULTS: During the study period, 184 patients (male 76; female 108) were identified with a median age of 69 years (IQR 55.5-77.5). 159 patients underwent an urgent procedure (86.5%), while 25 patients were operated electively. Laparoscopic procedure was attempted in all patients and a conversion to open procedure was necessary in 9 (4.9%). The endoscopic cannulation technique was successful in all patients. The primary stone clearance rate was 98.4% (181/184). There was no mortality. A complication was recorded in 12 patients (6.5%): pancreatitis in eight, small bleeding in two, cholangitis in one, bile leakage from the cystic duct in one. The median hospital stay was 7 days (IQR 10-15).
CONCLUSION: Laparo-endoscopic management of CBDS is feasible, safe and has a high stone clearance rate. Obviously, the technique requires logistics to perform LC and ERCP in the operating room, but is a single stage option that may reduce the hospital charges.

P1369 SHOULD LAPAROSCOPIC CHOLECYSTECTOMY BE PERFORMED REGARDLESS OF AGE?

C. Rizzetto[1,*], G. Munegato[1], D. Da Ros[1], M. Schiano di Visconte[1], R. Bonadio[1]. [1]*General Surgery, Azienda Ospedaliera ULSS7, Conegliano, Italy*

INTRODUCTION: Since elderly patients become a growing part of the population and advanced age is associated with an increase in post-operative complications, this study was conducted to evaluate the outcomes of laparoscopic cholecystectomy (LC) in patients aged 80 years or older.
AIMS&METHODS: A retrospective chart review was done of LC performed in a consecutive series of elderly patients between 2003 and 2012 at our surgical unit. We reviewed patient' characteristics, indication for surgery, comorbid conditions, conversion to open procedure, postoperative complications and hospital stay.
RESULTS: During the study period, 102 patients (male 39; female 63) underwent LC with a median age of 83 years (IQR 80.5-86). Of these, a comorbid condition was present in 45 patients (44%). Seventy patients (68.5%) underwent an urgent procedure, while 32 patients (33%) were operated electively. A conversion to open procedure was necessary in 5 (4.9%). An intraoperative endoscopic retrograde cholangio-pancreatography was necessary in 23 patients (22.5%) for associated common bile duct stone presence. Mortality was nihil and morbidity rate was 18.6%. No bile duct injury occurred. The median hospital stay was 9 days (IQR 7-14).
CONCLUSION: LC in extremely elderly is feasible and well tolerated, that can be accomplished with acceptable low morbidity even as an emergency procedure.

P1370 FEASIBILITY AND SAFETY OF TOTALLY LAPAROSCOPIC RESTORATIVE PROCTOCOLECTOMY FOR ULCERATIVE COLITIS IN THE ELDERLY. A PROSPECTIVE COHORT STUDY.

F. Colombo[1,*], G. Sampietro[1], A. Frontali[1], S. Casiraghi[1], A. Cassinotti[1], S. Ardizzone[1], F. Corsi[1], D. Foschi[1]. [1]*Department of Surgery, Gastroenterology and Oncology, L.Sacco University Hospital, Milano, Italy*

INTRODUCTION: Since its introduction in the early 1980s, very few data are available on the ileo-pouch-anal anastomosis (IPAA) performed in elderly patients. Laparoscopy seems to reduce morbidity in many surgical fields. Aim of the present study is to prospectively evaluate the feasibility and safety of laparoscopic IPAA for Ulcerative Colitis (UC) in patients over 65 years of age.
AIMS&METHODS: Starting from January 2007, all the consecutive, unselected patients with UC admitted in our Department and treated with a restorative proctocolectomy procedure were inserted in a prospective database. All surgical procedures, both proctocolectomy and abdominal colectomy followed by proctectomy and IPAA (staged surgery), were performed videolaparoscopically. Patients >65 years were compared to younger patients in terms of clinical characteristics, surgical procedure, and perioperative outcome. Analysis of data was performed using Student's t test, Fisher exact test, and Chi-square where appropriate.
RESULTS: From January 2007 to June 2012, 99 patients entered the study. 77 completed all the surgical steps up to the ileostomy closure. Of these, sixty-three (39 males) patients were <65 yrs and 14 (9 males) >65 yrs. The elderly group had a mean age of 69 yrs (compared to 45 yrs), duration of disease of 13 yrs (compared to 11 yrs; p = 0.04), higher ASA score (p = 0.002), dysplasia or cancer rate of 29% (compared to 18%, ns), emergency setting of 28% (compared to 26%, ns), conversion rate of 7% (compared to nil, ns), a one or two versus three steps procedure of 71% (compared to 52%, ns), stapled IPAA of 93% (compared to 89%, ns), overall major and minor complication rate of 28% and 7% (compared to 19% and 28%, ns), overall readmission and reoperation rate of 7% and 14% (compared to 28% and 17%, ns). No significant differences were found in preoperative medication with steroids, immunomodulators (thiopurine, cyclosporine and anti-TNF) or combined therapy. Operative data were similar for both groups.
CONCLUSION: Totally laparoscopic proctocolectomy with IPAA for UC in elderly patients over 65 yrs of age is a safe and effective procedure. Minimally invasive approach seems to maintain its advantages in older patients, reducing the surgical impact in patients with high comorbid conditions. Age and comorbidities do not seem to be a contraindication to totally laparoscopic IPAA surgery.

P1371 LAPAROSCOPIC LAVAGE IN HINCHEY III ACUTE SIGMOID DIVERTICULITIS (ASD)

J. Grosek[1,*], M. Omejc[1], F. Jelenc[1], A. Tomažič[1], M. Djokic[1]. [1]*Abdominal Surgery, University Medical Centre Ljubljana, Ljubljana, Slovenia*

INTRODUCTION: Hartman's procedure is conventionally considered the gold standard for patients with generalized peritonitis (Hinchey III, IV). Colectomy is an effective means of controlling peritonitis, yet it carries considerable risks of short-term and long-term morbidity and mortality. Therefore there has recently been a trend toward a more conservative approach, i.e. laparascopic lavage without colonic resection.
AIMS&METHODS: Retrospectively we analyzed patients, treated for acute sigmoid diverticulitis at our institution (two departments) between 2008 and 2012.
In our secondary surgical centre 70 patients were treated every year for ASD. Average age and average time of hospitalization were 64 years and 6 days, respectively. In our tertiary surgical centre 12 patients on average were treated every year. Average age and average time of hospitalization were 63 years and 13 days, respectively. Hinchey stage, type of operation and the rate of postoperative morbidity and mortality were analyzed retrospectively for both departments.
RESULTS: Secondary surgical centre: 82% of patients had Hinchey I ASD, 5% Hinchey II, 5% Hinchey III and 3% Hinchey IV. 13% of patients were operated on. In 2/3 of patients a colectomy was made (2/3 with anastomosis, 1/3 Hartman's procedure), in 1/3 a laparoscopic lavage only was done. The rate of postoperative morbidity and mortality were 20% and 10%, respectively.

Tertiary surgical centre: 30% of patients had Hinchey I ASD, 46% Hinchey II, 12% Hinchey III and 12% Hinchey IV. 67% of patients were operated on and in 85% a colectomy was made (½ Hartman's procedure, ½ anastomosis). In 15% a laparoscopic lavage only was done. The rate of postoperative morbidity and mortality were 18% and 11%, respectively.
CONCLUSION: Prospective, randomised, well prepared studies with adequate follow up are needed to further our understanding of the (potential) role of laparoscopic lavage in the treatment of ASD. Currently, 4 European groups are conducting such trials. The results are eagerly awaited.

P1372 SUCCESSFUL TREATMENT OF SUPERFICIAL DUODENUL NEOPLASMS BY LAPAROSCOPIC WEDGE DUODENECTOMY WITH ENDOSCOPIC TRANSMURAL MARGINATION: A SINGLE-CENTER STUDY

K. Ohata[1,*], M. Murakami[2], K. Yamazaki[2], N. Misumi[1], T. Tashima[1], Y. Minato[1], M. Shozushima[1], K. Nonaka[1], N. Matsuhashi[1]. [1]*Gastroenterology, NTT MEDICAL CENTER, TOKYO,* [2]*Gastroenterological and General Surgery, Showa Universtiy Hospital, Tokyo, Japan*

INTRODUCTION: Superficial duodenal neoplasm (SDN) is a rare disease for which there is no established treatment method. Endoscopic resection is technically difficult, surgical approach is difficult to decide the borderline of the lesion precisely. We invent the new approach to remove SDN that involves a combination of endoscopic and laparascopic technics: laparoscopic wedge duodenectomy with endoscopic transmural margination (LWDETM).
AIMS&METHODS: The aim of this study was to investigate the results of a single center experience and assess the validity of LWDETM for SDN. Between January 2011 and April 2013, 35 patients with SDN (a total of 38 lesions) underwent LWDETM. All cases were assessed for their age, sex, location, en-bloc resection rate, R0 resection rate, lesion size, sample size, procedure time, length of hospital stay after LWDETM, complication, and histpathological report. LWDETM procedure: Under general anesthesia, the duodenum was first mobilized laparoscopically. Then the tumor location was confirmed by endoscopy. The peripheral margin was marked around the tumor endoscopically and each marking was perforated intentionally using a needle knife in the coagulation mode under laparoscopic observation. Subsequently, the seromuscular layer was laparoscopically dissected along the marking circumferentially using an ultrasonically activated device. After sero-muscular layer incision, submucosa-mucosal layer was dissected along sero-muscular layer incision with ultrasonically activated device. The closure of the defect in the duodenal wall was performed by the laparoscopic hand-suturing technique.
RESULTS: 35 patients (27 males and 8 females, mean age 63.3) were treated by LWDETM. In 3 patients, because 2 lesions were located quite closely, we resected them at the same time. 24 lesions were located at the second portion, 12 at the bulb and 2 at the third portion of the duodenum. En-bloc and R0 resection was achieved for 97.4 % (37/38), too. The mean resected lesion size was 11.6 mm, and the mean resected specimen size was 26.1 mm. The mean procedure time was 128 minutes. The mean length of hospital stay after LWDETM was 12.6 days. There were no severe complications. Histopathological examination confirmed that 19 were adenomas, 8 adenocarcinomas 6 neuroendcrine tumors and 5 hyperplastic polyps.
CONCLUSION: In our experience of LWDETM for SDN, successful en-bloc and R0 resection was achieved without severe complications. We believe that in treatment of SDN this method will be considered as one of the powerful options.

P1373 BASIC LAPAROSCOPIC SKILLS ACQUIRED IN INTENSIVE VIRTUAL REALITY TRAINING MODULE IN PRE-GRADUATE EDUCATION - ARE THEY TRANSFERABLE INTO REALISTIC ENVIRONMENT? PROSPECTIVE EXPERIMENTAL STUDY

M. Soltes[1,*]. [1]*1st Department of Surgery, UNIVERSITY OF PAVOL JOZEF SAFARIK IN KOSICE, Kosice, Slovakia*

INTRODUCTION: Although virtual reality simulation has been suggested to be an effective tool in basic laparoscopic skills training, limited data is available concerning the structure of effective training modules and their application in pre-graduate education.
AIMS&METHODS: Aim of the study was to assess transferability of basic laparoscopic skills acquired during intensive virtual reality training module in pre-graduate education into realistic environment. Medical students included in this prospective experimental study practiced well defined simple complex task (peg transfer) on virtual reality trainer (15 repetitions). Identical task was performed prior and after virtual reality training in realistic conditions (box trainer) with time to complete task recorded. Results achieved were tested for statistically significant differences.
RESULTS: 100 trainees participated in the study (65 males, 35 females; mean age 24.05±1.39 years). Mean duration of training module was 122.5±13.5 minutes. Time needed to perform task on box trainer prior virtual reality training was 420.2±143.8 seconds. Performance time after virtual reality training was shortened by 31.4±12.5 % to 278.9±81.6 seconds. This difference was proven to be statistically significant ($p < 0.001$).
CONCLUSION: Basic laparoscopic skills acquired during pre-graduate virtual reality training on the level of simple complex tasks in intensive training module appear to be transferable into realistic environment. As a result, virtual reality training carries potential for utilization not only in post-graduate but also in pre-graduate education and training. Retention of such skills should be further investigated to allow for optimal timing in pre-graduate curriculum.

P1374 COMPLEXITY OF LAPAROSCOPIC PROCEDURES AND FREQUENCY OF ELECTRIC EQUIPMENT FAILURE - PROSPECTIVE OBSERVATIONAL STUDY

M. Soltes[1,*]. [1]*1st Department of Surgery, UNIVERSITY OF PAVOL JOZEF SAFARIK IN KOSICE, Kosice, Slovakia*

INTRODUCTION: Although electric equipment extensively used in laparoscopic surgery is supposed to be reliable and safe, several studies reported relatively high incidence of its failure. Nevertheless, the influence of complexity of surgery on frequency of failures was not described yet.
AIMS&METHODS: Prospective observational study was carried out in a single university centre setting with cart based operating room setup. Laparoscopic procedures observed were categorized according to their complexity: basic (laparoscopic cholecystectomy, TAPP hernioplasty, laparoscopic appendectomy) and advanced (laparoscopic Nissen fundoplication, splenectomy, adrenalectomy, colorectal resections, bariatric procedures). Electric equipment failure was defined as a situation when it was not functioning at all or had impaired function at the time it was needed. To detect and assess failures, laparoscopic procedures were observed by an independent researcher.
RESULTS: 153 consecutive basic procedures (group I.) were compared to 78 advanced ones (group II.). Overall, 133 (57.6 %) surgeries were disturbed by troubles with electric equipment – 218 incidents were recorded, ranging from 0 to 4 per procedure, with mode value 1 failure per surgery. No clinically relevant adverse consequences were noticed. 128 failures (58.7 %) were due to malposition (equipment missing or missplaced) and 90 (41.3 %) due to malfunction. In case of malfunction, defect was a cause only in 4 cases (1.8 %) and reason remained unclear 15 times (6.9 %), while remaining failures (91.3 %) were related to faulty connection or improper equipment setup. Mean time to solve the problem was 1.88 minutes with range from 0.5 to 10 minutes. No statistically significant difference was detected between groups concerning number of procedures disturbed by failure, number of incidents, type and reason of failures and time to repair (p=ns). Operating time was significantly prolonged in advanced procedures group (group I. 59.18±21.26 min, group II. 163.27±36.11 min) ($p < 0.001$).
CONCLUSION: Although electric equipment is used significantly longer during advanced laparoscopic procedures due to prolonged operating time, increased complexity of surgery does not seem to influence number of failures. This result can be explained by observation that majority of incidents is related to equipment positioning and setting. Even though these failures rarely achieve clinical significance, any incident prolongs operating time, disturbs surgical team and carries potential risk for adverse event. As more than 90% of incidents are easily preventable by definition, every effort should be made to prevent them.

INTRODUCTION: In many natural orifice transluminal endoscopic surgery (NOTES) interventions the peritoneal cavity is accessed through the gastrointestinal wall. Thus, severe bleeding from intraabdominal vessels or accidentally damaged organs is a likely complication. Successfull termination of intraabdominal hemorrhage by endoscopic means is an important issue. Several techniques are established, but there are no data available that directly compare the suitability and complication rate of the different methods.
AIMS&METHODS: Aim: To prospectively examine the efficacy and safety of 3 endoscopic prototype devices for the treatment of acute bleeding of lacerations in liver and spleen.
Method: 12 pigs (30-37kg) were randomised for transgastric (TGA, n=6) and transvaginal (TVA) access. After gastric or vaginal full-thickness wall incision the endoscope was introduced into the peritoneal cavity. Three lacerations of liver and spleen of approximately 2.5cm were created laparoscopically in each animal. After randomisation 3 haemostatic techniques were used: i) endoscopic suturing with t-bars (EST); ii) prototype monopolar forceps (MF); iii) experimental Forced Argon Plasma Coagulation (FAPC). Intraabdominal pressure and pulmonary arterial pressure (PAP) were monitored continuously during the procedures. Autopsy and histology were carried out 6 weeks after the procedure.
RESULTS: In liver and spleen hemorrhage EST failed to control the bleeding quickly enough before vision was inhibited. MF achieved liver hemostasis in 50% of cases after a mean time of 40.0±4.1min. Using FAPC it took 21.4±2.9min to entirely control liver hemorrhage ($p < 0.0001$ compared to MF). Splenic hemorrhage could neither be controlled nor stopped in any of the cases using the MF device. FAPC achieved control of the splenic bleeding in 100% of cases in

30.6±3.1min. Intraabdominal pressure was limited to 12 mmHg in all cases (mean 9.6±0.6mmHg). PAP was 21.6±0.9mmHg before the procedure and 21.8±1.1mmHg after the procedure ($p > 0.05$). There was no difference in PAP between MF and FAPC ($p > 0.05$).

CONCLUSION: FAPC is a valuable technique to control severe bleeding from liver and spleen even when other techniques fail. FAPC can be safely applied when the intraabdominal pressure is limited to 12mmHg without an increase in PAP excluding pulmonary embolism. Further studies in humans are needed to prove these data.

P1376 MUCOSAL VS. SEROSAL OTSC CLOSURE IN NOTES: A RANDOMIZED CONTROLLED STUDY

T. Hucl[1,*], M. Kocik[2], M. Benes[1], J. Maluskova[3], E. Kieslichova[4], M. Oliverius[2], J. Spicak[1]. *[1]Gastroenterology and Hepatology, [2]Surgery, [3]Pathology, [4]Anesthesiology, INSTITUTE FOR CLINICAL AND EXPERIMENTAL MEDICINE, Prague, Czech Republic*

INTRODUCTION: Efficient and safe closure is critical for clinical application of natural orifice transluminal endoscopic sugery (NOTES). Over the scope clip (OTSC) has become a widely accepted technique of transluminal closure. However, the usual clip application is based on mucosa approximation and does not fulfill the surgical principle of serosa-to-serosa approximation in hollow organ closures.

AIMS&METHODS: The aim of the study was to evaluate the feasibility, safety and efficiency of serosal OTSC closure in comparison to the standard mucosal OTSC closure in a porcine survival model.

After performing a gastric incision with a needle knife followed by 18 mm balloon dilation, twenty female pigs (25-45kg) were randomized to receive either mucosal (10 animals) or serosal (10 animals) OTSC closure. In mucosal closure, the mucosal portions of the incision edges were approximated by a double grasper and pulled into the clip's cap, whereas in serosal closure, the serosal portions of the incision edge were grasped, approximated and pulled into the cap. Laparoscopic assistance with a 5mm camera was used to ensure serosal approximation. Immediate air leak tests were performed and the animals were closely observed for a period of two weeks when they were sacrificed for postmortem examination.

RESULTS: All OTSCs were applied successfully in a mean time of 5.3 min (range 2-7 min) in the mucosal group and in a mean time of 8.8 min (range 4-12 min) in the serosal group ($p=0.001$). Air leak tests were negative in all closures. All animals survived without complications. The clip was in place at 14 days in 6 animals in the mucosal group and in 7 animals in the serosal group, respectively ($p > 0.01$). Minor adhesions were present in half of the animals in both groups. Necropsy demonstrated patent full-thickness gastric closure with no macroscopic signs of infection in all animals. However, 4 animals in the mucosal group and 5 animals in the serosal group had microscopic signs of mucosal inflammation, which was in 2 animals in the mucosal group and 3 animals in the serosal group positive for Gram staining ($p > 0.01$). Histologically, the mucosal closure was characterized by an end to end apposition of the gastric wall layers, whereas the serosal closure was characterized by a side to side apposition of the layers.

CONCLUSION: Serosal OTSC closure was feasible, safe and efficient. It required a longer time to perform due to increased technical difficulty. Serosal OTSC closure does not seem to add any benefit to the standard mucosal OTSC closure.

P1377 THE FAECAL FLORA DOES NOT REFLECT THE COLONIC MUCOSAL FLORA, A 454 PYROSEQUENCING STUDY OF A POPULATION-BASED COHORT OF HEALTHY INDIVIDUALS

A. Carstens[1,2,*], A. Fahlen[3], D. Lundin[4], A. Nixon[5], L. Agréus[5], L. Engstrand[3,6], J. Halfvarson[2,7]. *[1]Dep of Internal Medicine, Ersta Hospital, Stockholm, [2]School of Health and Medical Sciences, Örebro University, Örebro, [3]Dep of Microbiology, Tumor and Cellbiology, Karolinska Institute, [4]SciLifeLab, KTH, [5]Department of Neurobiology, Care Sciences and Society, [6]SciLifeLab, Karolinska Institute, Stockholm, [7]Div of Gastroenterology, Örebro University Hospital, Örebro, Sweden*

INTRODUCTION: The introduction of non-cultured based methods has revolutionized our understanding of microbiota. Yet, there are still surprising gaps in the characterization of this ecosystem and data on the microbial composition in Crohn's disease are inconsistent. Due to its simplicity in collection, faecal samples are often used for characterization and comparisons of gut microbiota. However, the degree to which faecal microbiota reflects the mucosal flora remains uncertain and previous data are contradictory.

AIMS&METHODS: We aimed to characterize the agreement in diversity in faecal flora and colonic mucosal flora in a population-based cohort of healthy individuals, using culture-independent high-throughput 454 pyrosequencing of the 16S rRNA gene.

Faecal samples and biopsies were selected randomly from 33 individuals, who were not treated with antibiotics within the last three months, within the population-based randomised colonoscopy (Popcol) study.(1) Biopsies were collected from the caecal region of colon during endoscopy, after standard bowel cleansing (Phosphoral, CCS Healthcare). Faecal samples were posted by mail and collection of faecal samples within two days before colonoscopy was an inclusion criteria. The microbiotic composition was analyzed by 454- pyrosequencing according to previous described methods.(2) Shannon index of diversity was used to assess the diversity of the microbial community. Differences in continuous data were analysed by paired t-test.

RESULTS: In 32/33 subjects, fecal samples and biopsies meeting the inclusion criteria were available. The median age of enrolled subjects was 46 (24-70) years. Analysis of OTUs showed a trend towards higher overall diversity in biopsies compared with faecal samples ($p=0.06$).

CONCLUSION: Our data suggest that the microbiotic profile in faeces does not mirror the mucosal bacterial composition in the proximal colon accurately. Further studies are needed to characterize the possible differences in faecal- and mucosal flora in more detail.

P1378 BIOGEOGRAPHY OF THE COLONIC MICROBIOTA DEMONSTRATES CONSERVED STRUCTURE IN HEALTH WITH ALTERATIONS IN INFLAMMATION

A. Lavelle[1,*], G. Lennon[1], A. Balfe[1], O. O'Sullivan[2], N. Docherty[3], H. Mulcahy[4], G. Doherty[4], K. Sheahan[4], J. C. Coffey[5], P. Cotter[2], F. Shanahan[6], D. Winter[4], P. R. O'Connell[4]. *[1]School of Medicine and Medical Science, University College Dublin, Dublin, [2]Food Research Centre, Teagasc, Cork, [3]Department of Physiology, Trinity College Dublin, [4]Centre for Colorectal Disease, St Vincent's University Hospital, Dublin, [5]4i Centre for Interventions in Infection, Inflammation and Immunity, University of Limerick, Limerick, [6]Alimentary Pharmabiotic Centre, University College Cork, Cork, Ireland*

INTRODUCTION: Large sequencing projects based on stool sampling have related diet, host phenotype, geography and age in the search for functional and phylogenetic cores which may explain the complexity and interindividual variability characteristic of the human lower gastrointestinal tract microbiota. While the Human Microbiome Project has sought to incorporate spatial structuring of community assembly through biogeographic characterisation of multiple body sites, more subtle ecological landscapes may be apparent within host niches in the human colon.

AIMS&METHODS: Protected specimen brush (PSB) sampling was used in conjunction with biopsy sampling and laser capture microdissection to sample across four regions of the colon in four healthy volunteers undergoing colonoscopy and two patients with ulcerative colitis undergoing colonic resection. The regional microbiota was extensively sequenced in these individuals using amplicon pyrosequencing comparing whole mucosal biopsy with luminal brush samples and laser capture microdissection-retrieved samples from the mucus gel layer.

RESULTS: There was a statistically significant reduction in the proportion of Bacteroidetes in samples of adherent mucous when compared to both whole mucosal biopsies and luminal brush samples. There was a corresponding increase in the proportion of Firmicutes and Actinobacteria in the mucosa-associated mucous gel compared to both whole biopsies and luminal samples. Within individuals, samples separated according to luminal or mucus-gel layer origin by unweighted UniFrac. When two patients with ulcerative colitis were added, increased mucosa-associated levels of Clostridiaceae and Peptostreptococcaceae were noted as well as a breakdown in the luminal and mucosal segregation in areas of severe inflammation.

CONCLUSION: Within the context of inter-individual variability in the colonic microbiota, certain patterns of spatial organisation are apparent. As glycan foraging is an important mechanism for endurance of bacterial species within the gut microbiota, it is possible that the mucus gel layer provides a platform for the stable preservation of key microbial lineages in health, while luminal communities are more closely involved in the commerce of dietary metabolism. The breakdown of such a structure and the expansion and perseverance of certain OTUs in inflammation may contribute to chronicity in inflammatory bowel disease.

P1379 APPENDICEAL DENDRITIC CELLS ARE PRO-INFLAMMATORY, DRIVE GUT-SPECIFIC T-CELL RESPONSES AND ARE ALTERED IN ULCERATIVE COLITIS

E. R. Mann[1,2,*], D. Bernardo[1], H. O. Al-Hassi[1], G.-H. Lee[1], N. Yassin[1], S. Sarkar[1], A. Baird[3], A. Hart[1], R. Phillips[3], S. Knight[1]. *[1]Imperial College London, Harrow, United Kingdom, [2]Johns Hopkins Medicine, Baltimore, United States, [3]St. Mark's Hospital, Harrow, United Kingdom*

INTRODUCTION: Appendicectomy is associated with reduced risk of developing ulcerative colitis (UC). UC develops from a disruption of intestinal immune homeostasis and inflammatory T-cell infiltrates. It is unclear whether the appendix is an immunologically active organ. Gut dendritic cells (DC) determine mucosal immune homeostasis, governed by their ability to drive effector T-cell responses, and determine whether T-cell responses generated are immunogenic

or tolerogenic. However, gut DC are poorly characterised in humans and *bona fide* DC from the human appendix had previously not been characterised.
AIMS&METHODS: We aimed to identify DC from the human appendix from UC patients and non-inflammatory controls. The appendix, with caecal/ileal samples were removed from surgical resection specimens from patients with active UC or familial adenomatous polyposis patients (pre-malignancy; control samples) undergoing colectomy. DC were identified by flow cytometry and used for *in vitro* T-cell stimulation assays.
RESULTS: Human appendiceal DC were identified; the majority expressed lymph-node homing marker CCR7. Appendiceal DC exhibited an activated/inflammatory profile compared to their caecal/ileal counterparts with enhanced expression of DC activation marker CD40 and enhanced production of pro-inflammatory cytokines IL-1β and IL-23. T-cells from the appendix expressed gut-homing marker β7 integrin; furthermore, appendiceal DC generated dose-dependent stimulation of T-cells expressing β7. However, despite appendiceal ability to drive gut-specific T-cell responses, their stimulatory capacity was lower than caecal or ileal DC. In UC, appendiceal DC exhibited similar changes to those found in colonic DC i.e. restricted expression of DC activation marker CD40 and an enhanced proportion of non-myeloid ($CD11c^-$) DC compared to control DC.
CONCLUSION: The appendix is immunologically active. The lymph-node homing potential of appendiceal DC, taken with their ability to drive gut-specific T-cell responses strongly suggests a role for the appendix in mucosal immune homeostasis. These data provide a mechanism for appendiceal DC involvement in generating immune responses affecting the rest of the GI tract. The antigen-sampling role of DC and the inflammatory profile of appendiceal DC may be indicative of a separate reservoir of enteric bacteria within the appendix. The loss of DC function observed in colonic DC in UC also applies to DC within the appendix and provides an explanation for appendicectomy being associated with reduced risk of UC.

P1380 TNBS-INDUCED CHRONIC COLITIS IS ASSOCIATED WITH FIBROSIS AND MODULATES TGF-B1 AND AKT SIGNALING IN RATS.

E. Loeuillard[1,*], J. Bertrand[1], A. Herranen[1], C. Guérin[1], M. Coëffier[1], M. Aziz[2], P. Déchelotte[3], G. Savoye[4], R. Marion-Letellier[1]. [1]*INSERM Unit UMR1073,* [2]*Laboratory of Anatomo-pathology,* [3]*Nutrition unit,* [4]*Gastroenterology, Rouen university, rouen, France*

INTRODUCTION: Fibrosis is a major complication in Crohn's disease and no specific treatment except surgery is available. To better understand mechanisms underlying intestinal fibrosis, a chronic model of intestinal inflammation has been developed.
AIMS&METHODS: We aimed to explore signaling pathways involved in fibrosis, including TGF-β pathway during chronic experimental colitis. As proteasome inhibition by bortezomib exhibits antifibrotic properties in other organs, we tested its potential antifibrotic effect in this model.
Chronic colitis was induced at D0 in male Sprague-Dawley rats by weekly intrarectal injection of increasing doses of 2,4,6 trinitrobenzene sulfonic acid (TNBS, n=8) for 6 weeks while the control received the vehicle (Control, n=10). To test the effect of bortezomib, rats received intraperitoneal injections of bortezomib ($25mg.kg^{-1}.d^{-1}$ twice a week, TNBS+BTZ, n=8) from D37 to D44 or vehicle. Fibrosis and inflammation were assessed macroscopically and histologically. We studied TGF-β production by ELISA and TGF-β signaling pathway, i.e. phospho-SMAD2/3, phospho-ERK2/ERK2, phospho-p38/p38, and Akt by western blot. Proteasome inhibition was assessed by chymotrypsin-like activity measurement.
RESULTS: TNBS rats had a colon higher inflammatory and fibrosis score than controls (2 versus 0, $p<0.01$; 2 versus 0, $p<0.01$) and tended to have a higher production of colon TGFβ (5500 versus 3700 $pg.mg^{-1}$, p=0.06). TNBS rats had a higher expression of TGF-β-related proteins such as phospho-SMAD2/3, phospho-ERK2/ERK2, phospho-p38/p38, and Akt (1.97 versus 1.12, $p<0.05$; 0.79 versus 0.264, $p<0.05$; 2.79 versus 0.06, $p<0.05$; 1.17 versus 0.05, $p<0.001$ respectively). While bortezomib significantly decreased, as expected, chymotrypsin-like activity (20357 versus 6912, $p<0,05$), bortezomib had no statistically significant effect on fibrosis score and fibrosis related proteins.
CONCLUSION: Rats with TNBS-induced chronic colitis exhibited colon fibrosis associated with high expression of TGFβ signaling especially in the Akt pathway. Proteasome inhibition by bortezomib had no effect on fibrosis in our experimental conditions. As Akt seems to be involved in this model, targeting this pathway may be considered in intestinal models of fibrosis.

P1381 IMPACT OF DIAGNOSTIC DELAY ON CLINICAL OUTCOME OF CROHN'S DISEASE

G. Maconi[1,*], M. Monteleone[1], F. Furfaro[1], C. Bezzio[1], R. Sciurti[1], A. Dell'Era[1], S. Ardizzone[1], R. de Franchis[1]. [1]*Gastroenterology Unit, Department of Biomedical and Clinical Sciences, L. Sacco University Hospital, Milan, Milan, Italy*

INTRODUCTION: The diagnosis of Crohn's disease (CD) may be difficult due to unspecific symptoms and limited test accuracies and is frequently associated with a variable diagnostic delay. The impact of delay in diagnosis on outcome of CD patients is still unknown. This study aimed at determining if the diagnostic delay affects the clinical outcome of CD patients.
AIMS&METHODS: This is a retrospective cohort study including a 250 consecutive patients (Mean age: 49,6 yrs; male: 146 pts) regularly followed at IBD unit of our Hospital. For each patient the following data, directly obtained by a patient questionnaire and checked in the clinical charts, were recruited: sex, age, time of onset of the symptoms, exact date of definitive diagnosis of Crohn's disease, smoking habit, active perianal disease, current or past medical therapy for CD, including the use of immunosuppressants, biological and steroid therapy, history of perianal and abdominal conservative or resective surgery for CD. The need of surgery, immunosuppressive or biological therapy was considered as clinical variable of bad outcome of CD. Influence of diagnostic delay and other possible predictors on outcome of CD was evaluated by univariate and multivariate binary logistic regression analysis.
RESULTS: Diagnostic delay in CD patients varied from 0 to 298.30 months (mean: 27.22 mths). 68 patients were treated with immunosuppressants and biological therapy and 80 patients underwent surgery for perianal (n=7) or abdominal complications of CD (n=73) and 34 patients in immunosuppressant therapy underwent resective surgery. The delay of diagnosis was significantly associated with need resective surgery (p 0.043) but not with other clinical variables such as the use of biologics, steroids and immunosuppressants. With univariate regression analysis we found a significant association between longer diagnostic delay and resective surgery (OR 1.005; 95% CI 1.00-1.012; p 0.043) and period of diagnosis (OR 3.0; 95%CI 1.5-6.3). Diagnostic delay and period of diagnosis were independent predictors of increased risk of surgery. No parameters were associated to increased need of conservative surgery and perianal surgery.
CONCLUSION: Diagnostic delay and period of diagnosis of CD are independent predictors of increased need for resective surgery. The conformation of this preliminary finding in a wider series of patients may have significant impact on the work up of patients with suspected CD.

P1382 ENTEROCOCCUS FAECALIS LIPOPROTEINS CONTRIBUTE TO VIRULENCE BOTH IN CHRONIC INFLAMMATION AND IN INFECTION MODELS

I. G. Sava[1,*], S. Ocvirk[1], Y. Bao[2], J. Huebner[2], B. R. Sartor[3], D. Haller[1,4]. [1]*Biofunctionality Unit (ZIEL), Chair of Nutrition and Immunology, Technische Universität München, Freising,* [2]*Department of Medicine, University Medical Center, Freiburg, Germany,* [3]*Department of Medicine, Division of Gastroenterology and Hepatology, University of North Carolina, Chapel Hill, United States,* [4]*ZIEL – Research Centre for Nutrition and Food Science, Biofunctionality Unit, Technische Universität München, Freising, Germany*

INTRODUCTION: *Enterococcus faecalis* is an ubiquitous bacterium occurring both as member of the core microbiota and as nosocomial pathogen and it has been shown that IL10-/- mice are susceptible to *Enterococcus faecalis*, developing chronic colitis after monocolonization with this microorganism (1).
AIMS&METHODS: We investigated the role of *Enterococcus faecalis* lipoproteins (highly conserved bacterial structures recognized by Toll-like receptor 2 (TLR2)) by deleting the *lgt* gene encoding a prolipoprotein diacylglyceryl transferase involved in bacterial lipoproteins synthesis (2). Wild type and mutant bacteria (Δlgt) were compared regarding development of colitis in IL10-/- mice and virulence in two invertebrate models - *Galleria mellonella* and *Caenorhabditis elegans*. Additionally, the impact of *lgt* deletion on the innate immune response was investigated *in vitro* using bone marrow-derived dendritic cells and mouse embryonic fibroblasts stimulated with bacterial lysates of the two bacterial strains.
RESULTS: Monoassociation of germ-free IL10-/- mice with Δlgt mutant resulted in significant reduction of inflammation in the distal colon, which was associated with decreased spleens and mesenteric lymph nodes weights. Additionally, increased infiltration of CD3-positive cells could be observed by immunofluorescence in the mice monoassociated with the wild type bacteria. These effects were not due to differences in bacterial colonization, as both wild type and the mutant bacteria were recovered in similar numbers from the cecum of the monoassociated mice. Deletion of *lgt* gene resulted in decreased dendritic cells maturation and significantly lower capability to induce secretion of interleukin-6 and TNF in bone marrow-derived dendritic cells and in mouse embryonic fibroblasts after stimulation with bacterial lysates. Using bone marrow-derived dendritic cells isolated from mice lacking TLR2, secretion of the above-mentioned pro-inflammatory cytokines was highly reduced, independently from the bacterial strain used to stimulate the cells. These effects confirm the role of lipoproteins as ligands for TLR2. Both in an insect (*Galleria mellonella*) and a nematode (*Caenorhabditis elegans*) model of infection, *lgt* deletion resulted in attenuated invertebrate mortality.
CONCLUSION: *Enterococcus faecalis* lipoproteins are involved in innate immune recognition and are relevant structures both in infections and in chronic inflammation models.

P1383 PERI-ANAL DISEASE AS A PREDICTIVE FACTOR OF DISABLING CROHN'S DISEASE

J. Santos-Antunes[1,*], F. Magro[2], R. Coelho[2], P. Andrade[2], E. Rodrigues-Pinto[2], S. Lopes[2], G. Macedo[2]. [1]*Gastroenterology,* [2]*Centro Hospitalar S. João, Porto, Porto, Portugal*

INTRODUCTION: Peri-anal disease is considered a predictive factor for disabling Crohn's disease. However, its real impact in the global prognosis is not well known.
AIMS&METHODS: Evaluate peri-anal disease as a prognostic factor for intra-abdominal Crohn's disease, in a cross-sectional study in patients with Crohn's Disease followed in our Inflammatory Bowel Disease outpatient clinic.
RESULTS: Six hundred and eighty three patients were identified, 49.9% females, with mean age of 41±14 years. Mean age at diagnosis was 29±12 years, with a mean duration of the disease of 146±99 months. Forty-six percent had ileal, 39% ileo-colic and 15% colic disease, with upper digestive tract involvement in 11%. Twenty-eight percent had peri-anal disease. No differences between patients with or without peri-anal disease were found regarding steroids the need to use steroids (p=0,724) or hospitalization (p=0.180) at diagnosis, as regarding the mean number of intra-abdominal surgeries (0.48 vs 0.40, p=0.153), or time to anti-TNF therapy (93 vs 87 months, p=0,732). Peri-anal disease was not a risk factor for intra-abdominal surgery (RR=1.277, CI 95% 0.877-1.861), and patients without peri-anal disease had the first abdominal surgery earlier (33 vs 54 meses, p=0.011). In the other hand, patients with peri-anal disease needed more cycles of steroids (2.95 vs 2.23, p<0,001), more number of hospitalizations (2.48 vs 1.33, p<0,001) and immunosuppression with azathioprine earlier (58 vs 43 months, p=0,042). All the results showing no statistical significant differences had a statistical power greater than 99%.
CONCLUSION: Patients with peri-anal disease did not have worse prognosis in terms of intra-abdominal disease. However, they needed more hospitalizations, more steroids and earlier immunosuppression.

P1384 THE ROLE OF HUMAN NEUTROPHIL ELASTASE AND ITS INHIBITOR ELAFIN IN ULCERATIVE COLITIS

K. Kok[1,*], P. Giuffrida[1], R. Curciarello[1], L. langmead[2], T. MacDonald[1]. [1]*Centre for Immunology and Infectious Disease, Barts and The London School of Medicine and Dentistry,* [2]*ROYAL LONDON HOSPITAL, London, United Kingdom*

INTRODUCTION: Mucosal inflammation in ulcerative colitis (UC) is characterised by an influx of neutrophils which secrete large amounts of human neutrophil elastase (HNE), causing matrix degradation. They also produce the elastase-specific inhibitor, elafin.
AIMS&METHODS: The aim of this study is to evaluate the relative production of elastase and elafin in active UC, and to investigate the modulatory effect of elafin on mucosal proteolytic activity *ex vivo*.
We utilised intestinal biopsies from 18 patients with active UC and 12 non-UC healthy controls. Biopsies were homogenised and lysed to extract mucosal proteins. Proteolytic activity, using elastin as a substrate, was determined. Concentrations of elafin were measured using ELISA. The effect of protease inhibitors on proteolytic activity were determined *in vitro* using elafin, marimastat (matrix metalloproteinase inhibitor) and the synthetic elastase inhibitor, AAPV [N-(Methoxysuccinyl)-Ala-Ala-Pro-Val Chloromethyl Ketone]. The effect of elafin on proteolytic activity *ex vivo* was assessed by 24 hour organ culture in the presence and absence of elafin.
RESULTS: Mucosal protein homogenates from patients with active UC displayed higher proteolytic activity in comparison to healthy controls (p=0.002). Elafin levels were increased in mucosal homogenates from active UC (p=0.007). The addition of elafin, marimastat or AAPV, *in vitro*, each diminished proteolytic activity. Organ culture of UC biopsies in the presence of elafin reduces the proteolytic activity of active UC *ex vivo*.
CONCLUSION: Colonic mucosal tissue from UC patients displays significantly higher elastinolytic activity in comparison to healthy controls. The addition of elafin has a restorative effect on the elastinolytic activity of UC mucosal homogenates, with the most notable effect in those tissues that had highest proteolytic activity. This occurs in the presence of significantly higher quantities of elafin in active UC mucosa. These data also show a beneficial modulatory effect of elafin on human gut tissue, suggesting a possible role for supplementary elafin in the treatment of UC.

P1385 THE NEUROTROPHIC AGENT SR 57746A PROMOTES MUCOSAL HEALING AND PREVENTS MUCOSAL INJURY IN THE INTESTINE

M. Porzner[1,*], J. Walldorf[2], M. Hermann[2], G. Joodi[2], J. H. Niess[3], G. von Boyen[4], K. Mäder[5], S. Pratsch[2], J. Weissbach[6], A. Kleger[1], T. Seufferlein[1]. [1]*Department of Internal Medicine I, University of Ulm, Ulm,* [2]*Department of Internal Medicine I, University of Halle, Halle, Germany,* [3]*Department of Visceral Surgery and Medicine, Bern University Hospital, Bern, Switzerland,* [4]*Department of Internal Medicine, Hospital of Sigmaringen, Sigmaringen,* [5]*Department of Pharmacy,* [6]*Department of Biochemistry, University of Halle, Halle, Germany*

INTRODUCTION: Neurotrophic growth factors are likely to play a major role in maintaining the integrity of the gut epithelium by promoting mucosal healing and thereby stabilizing the intestinal barrier. At the molecular level these compounds prevent apoptosis of enterocytes that otherwise leads to increased mucosal permeability. SR 57746A is a selective agonist at 5-HT1A receptors which has neurotrophic and neuroprotective properties.
AIMS&METHODS: The aim of this study was to evaluate if SR 57746A could have therapeutic potential in model systems of experimental colitis and could hence qualify as a novel therapeutic strategy for IBD patients.
Cell proliferation, apoptosis and migratory capacity were assessed in transformed and non-transformed colonic epithelial cells along with the apoptotic response in primary rat enteric glial cells upon treatment with SR 57746A. Furthermore, enema application of SR 57746A and i.p. infliximab were investigated in a therapeutic as well as a prophylactic setting in the DSS- and CD4-transfer colitis models. The effect of both agents was determined by endoscopy and immunohistochemistry.
RESULTS: SR 57746A potently prevented Apo-1- or TRAIL-induced apoptosis by an ERK- and AKT- dependent mechanism without inducing proliferation or migration in intestinal epithelial cells. In addition, SR 57746A prevented cytokine-induced apoptosis of enteric glial cells. *In vivo* SR 57746A treatment promoted mucosal healing by both, clinical and histological assessment in the experimental colitis models. Interestingly, SR 57746A also prevented mucosal injury in a prophylactic setting. Surprisingly, topical application of SR 57746A was as efficient as i.p. application of infliximab in both settings.
CONCLUSION: SR 57746A prevents colonic epithelial and enteric glial cells from apoptosis by a ERK-/AKT- signalling dependent mechanism. Enema application of SR 57746A showed promising results in two independent mouse models of experimental colitis in the therapeutic and prophylactic setting. Clinical trials are now warranted to test the efficacy of this strategy in patients.

P1386 IL-9 AND IL-9R ARE OVEREXPRESSED BY ULCERATIVE COLITIS PERIPHERAL BLOOD CELLS

M. T. Chiriac[1,*], N. Nalleweg[1], G. Hundorfean[1], M. F. Neurath[1], J. Mudter[1]. [1]*Medical Clinic 1, University of Erlangen-Nuremberg, Erlangen, Germany*

INTRODUCTION: Many of the functions that have been historically linked to the Th1/Th2 paradigm are increasingly becoming associated with Th17- and more recently with Th9-type responses. Whereas the contribution of Th17 cells has been extensively explored, the role of IL-9 and its receptor in ulcerative colitis, a disease characterized by dense neutrophilic infiltration of the gut resulting in crypt abscess, has not been addressed so far.
AIMS&METHODS: We investigated the role of leukocyte-expressed IL-9 and its receptor in ulcerative colitis. Whole blood or fractionated leukocyte populations were investigated for the presence of the IL-9 receptor using western blot, immunofluorescence and flow cytometry. Interleukin production by peripheral blood mononuclear cells was assessed under anti-CD3/anti-CD28 and/or PMA-ionomycin stimulation using sandwich ELISA and flow cytometry. IL-9-dependent modulation of neutrophils' life-span was addressed by flow cytometry with Annexin V and 7-AAD. Additionally, the presence of the IL-9 receptor in gut biopsies was investigated by double immunofluorescence stainings using confocal microscopy.
RESULTS: Peripheral blood mononuclear cells from ulcerative colitis patients produced significantly more IL-9 compared to cells from healthy controls whereas non-stimulated cells produced solely negligible levels of IL-9. There was a high degree of correlation between IL-9 levels and the general inflammatory status of patients as measured by the C reactive protein values. Neutrophils from ulcerative colitis patients expressed significantly more IL-9 receptor compared to control cells. Functionally, IL-9 on its own had little influence on the cultured neutrophils but significantly prolonged the life-span of GM-CSF-stimulated granulocytes from ulcerative colitis patients. Additionally, neutrophils found in biopsies form ulcerative colitis patients also stained positive for the IL-9 receptor indicating their possible *in situ* implication in the pathogenesis of ulcerative colitis.
CONCLUSION: Our present study provides the first data on the implication of leukocyte-expressed IL-9 and IL-9 receptor in the pathogenesis of ulcerative colitis. By producing more IL-9 and/or better responding to its pro-inflammatory actions, leukocytes from ulcerative colitis patients may be critically involved in the outcome of disease. Furthermore, the study suggests that IL-9 and its receptor could become useful disease markers or targets for specific therapies.

P1387 ANTIBIOTIC-INDUCED ALTERATION OF THE GUT MICROBIOTA PROTECTS TNFDELTAARE MICE FROM CROHN'S DISEASE-LIKE ILEITIS

M. Weiher[1,*], T. Clavel[2], M. Schmid[1], A. Walker[3], I. Martinez[4], J. Walter[4], P. Schmitt-Kopplin[3], G. Kollias[5], D. Haller[1,2]. [1]*Nutrition and Immunology, TU Munich,* [2]*Junior Research Group Intestinal Microbiome, ZIEL – Research Centre for Nutrition and Food Science, Biofunctionality Unit, Technische Universität München, Freising,* [3]*Institute of Ecological Chemistry, Helmholtz Zentrum München, Neuherberg, Germany,* [4]*University of Nebraska, Department of Food Science and Technology, Food Industry Complex, Lincoln, United States,* [5]*Institute of Immunology, Biomedical Sciences Research Center Alexander Fleming, Vari, Greece*

INTRODUCTION: Crohn's disease is associated with dysbiosis of the gut microbiota. To test the causative role of intestinal microorganisms in the development of genetically-driven chronic inflammation and to identify bacterial taxa

associated with disease, we used the TNF^{deltaARE} mouse model of Crohńs disease-like ileitis.
AIMS&METHODS: To modify the intestinal microbial composition, two antibiotics (Van/Met: vancomycin (0.25 g/l), and metronidazole (1 g/l)) were administered to TNF^{deltaARE} and wild-type mice (each n = 6) in drinking water for 4 weeks. Inflammation was scored by microscopic observation of distal ileal, caecum tip and proximal colon sections directly after antibiotic therapy or after a recurrence phase of two, four, or six weeks. Bacterial composition was analyzed by high-throughput 16S rRNA gene sequencing and bacterial spatial distribution was shown by Fluorescence *in situ* hybridization. Metabolomic analysis of caecal content via FT-ICR/MS allowed mapping of gut metabolic networks associated with inflammation.
RESULTS: Antibiotics substantially reduced ileitis in TNF^{deltaARE} mice (histopathology of 1.6 ± 1.2 *vs*. 4.9 ± 0.8 in the antibiotic *vs*. control group; n = 5-6; p < 0.001), but had no effect on tissue pathology in the caecum and proximal colon. Four weeks after antibiotic treatment, recurrence of ileitis was observed (score of 4.1 ± 1.5). 16S rRNA gene sequencing showed marked changes in bacterial diversity and composition in the caecal lumen and the ileal mucosa. Total bacterial counts were not affected. In control mice, *Firmicutes* and *Bacteroidetes* were the dominant phyla (> 82 % total sequences). Antibiotics increased the occurrence of lactobacilli in the ileal mucosa (19.6 ± 27.6% *vs*. 76.3 ± 19.8%), whereas the proportion of *Bacteroidetes* was reduced (7.2 ± 10% *vs*. 15.0 ± 6.0%). Fluorescence *in situ* hybridization (EUB-338 probe) showed changes in the spatial distribution of ileal bacteria in TNF^{deltaARE} mice, relative to the epithelial layer. Metabolite profiling of caecal content by FT/ICR-MS indicated changes in bile acid and carnitine metabolism. Mono-association and caecal microbiota transplant experiments are currently underway to address the causative role of gut bacteria in experimental ileitis.
CONCLUSION: Our findings indicate an essential role of intestinal bacteria in the development of Crohn's disease-like ileitis.

P1388 TOLL-LIKE RECEPTORS 2 AND 4 ARE EXPRESSED ON DENDRITIC CELLS IN CROHN'S AND IDIOPATHIC PERIANAL FISTULAE.

N. A. Yassin[1,2,*], S. Sarker[2], G. Lee[2], G. Malietzis[2], E. Mann[2], D. Bernardo[2], R. Phillips[1], S. Knight[2], A. Hart[1], H. Al-Hassi[2]. [1]*St Mark's Academic Institute, St Mark's Hospital,* [2]*APRG, Imperial College London, London, United Kingdom*

INTRODUCTION: Genetic, microbiological and immunological factors play a role in the aetiology of Crohn's disease (CD). However, the aetiology of fistulating perianal Crohn's disease remains unclear and the disease a challenge to treat due to poor healing and high recurrence rates. Dendritic cells play major roles in the pathogenesis of Crohn's disease and express Toll-Like receptors (TLR) which are pattern recognition receptors that are activated by bacterial ligands. Previous studies have shown increased expression of TLR 2 and 4 in colonic Crohn's biopsies as compared to normal. Data on the characterisation of dendritic cells from perianal Crohn's and idiopathic fistulae are sparse.
AIMS&METHODS: We aimed to determine alterations in TLR 2 and 4 expression on dendritic cells from Crohn's and idiopathic perianal fistulae.
Biopsies were taken from anal fistula tracts of 20 Crohn's and 20 idiopathic patients. Samples were incubated in complete medium overnight and 'Walk out' cells isolated from the cell culture supernatant. Dendritic cells were identified and characterized by flow cytometry as HLA-DR positive and lineage (CD3, CD14, CD16, CD19, CD34 and CD56) negative. The expression of TLR 2 and 4 was determined. Unpaired student t-test was used for comparisons and $p < 0.05$ was considered as significant.
RESULTS: TLR 2 and 4 were expressed on dendritic cells from both Crohn's and idiopathic perianal fistulae. There was no significant difference in the expression of TLR 2 between Crohn's and idiopathic fistulae (p=0.27). TLR 4 expression was equally expressed on dendritic cells from both Crohn's and idiopathic fistulae (p=0.45)
CONCLUSION: Toll-like receptors 2 and 4 are expressed on dendritic cells from Crohn's and Idiopathic perianal fistulae. Although a direct comparison can not be made, it is interesting to note that the expression of TLR 2 and 4 in luminal disease (Hart et al 2005) differs to that in perianal fistulae. Similar levels of expression of TLR 2 and 4 have been noted in Crohn's disease in contrast to perianal Crohn's where the upregulation of TLR 4 seems to be more marked than TLR 2. This may suggest the important role that bacterial products play in the immunopathogenisis of both Crohn's and idiopathic perianal fistula disease

P1389 THE ROLE OF THE GUT HOMING MARKER (B7) IN THE IMMUNOPATHOGENISIS OF PERIANAL CROHN'S FISTULAE – INCREASED EXPRESSION ON DENDRITIC CELLS

N. A. Yassin[1,2,*], E. Mann[2], G. Lee[2], S. Sarker[2], G. Malietzis[2], D. Bernardo[2], S. Knight[2], R. Phillips[1], A. Hart[1], H. Al-Hassi[2]. [1]*St Mark's Academic Institute, St Mark's Hospital,* [2]*APRG, Imperial College London, London, United Kingdom*

INTRODUCTION: The aetiology of fistulating perianal Crohn's disease remains unclear and the disease a challenge to treat due to poor healing and high recurrence rates. Dendritic cells play major roles in the pathogenesis of Crohn's disease and express tissue-specific homing markers. Data on the characterisation of dendritic cells from perianal Crohn's and idiopathic fistulae are sparse. We aimed to determine alterations in homing marker expression on dendritic cells from Crohn's and idiopathic perianal fistulae.
AIMS&METHODS: Biopsies were taken from anal fistula tracts of 23 Crohn's and 21 idiopathic patients. Dendritic cells were identified as HLA-DR positive and lineage (CD3, CD14, CD16, CD19, CD34 and CD56) negative, and were characterized by flow cytometry. The expression of the skin-homing marker CLA, and the gut-homing marker $\beta7$ was determined. Unpaired student t-test was used for comparisons and $p < 0.05$ was considered as significant.
RESULTS: Percentage expression of b7 on dendritic cells was significantly higher in Crohn's compared with idiopathic perianal fistulae (p=0.017). There was no significant difference in CLA expression, which was low in both groups. When comparing the proportion of Dendritic cells that are double positive for both $\beta7$ and CLA between the Crohn's and idiopathic groups, we found that these cells are significantly lower in Crohn's (p=0.002).
CONCLUSION: Increased expression of $\beta7$ on dendritic cells of Crohn's perianal fistulae may lead to increased gut dendritic cells infiltrates contributing to impairment in healing. Anti-$\beta7$ therapies may aid healing when applied to perianal Crohn's fistulae.

P1390 THE PRESENCE OF ENDOTOXINS IN CROHN'S AND IDIOPATHIC PERIANAL FISTULA TRACKS

N. A. Yassin[1,2,*], D. Bernardo[2], S. Mallappa[1], S. Sarker[2], P. Tozer[1], S. Knight[2], H. Al-Hassi[2], R. Phillips[1], A. Hart[1]. [1]*St Mark's Academic Institute, St Mark's Hospital,* [2]*APRG, Imperial College London, London, United Kingdom*

INTRODUCTION: Theories on the aetiology of idiopathic perianal fistulae suggest that fistulas occur following a cryptoglandular infection. It has been suggested that persistence of an infective agent or the type and virulence of the infective agent may be involved in pathogenesis. However, studies assessing microbiological changes in Crohn's fistulas are sparse. Recent studies in our laboratory did not identify any live bacteria in fistula tracks of both idiopathic and Crohn's fistulae. In case that bacteria have a role in the pathogenesis of perianal fistulae, it is possible that bacterial products may be responsible for the inflammation and not live bacteria. Endotoxins are bacterial products which are not secreted but released when cells are disrupted. They are heat-stable toxins which are associated with the outer membranes of gram-negative bacteria. There is currently no published literature regarding the presence of endotoxins in perianal fistula tracks.
AIMS&METHODS: We aimed to assess for the presence of endotoxins in samples taken from Crohn's and idiopathic perianal fistula tracks.
Biopsy samples were taken from anal fistula tracks of 20 Crohn's and 23 idiopathic patients. Samples were taken from the top of the track (as close to the internal opening as possible), the middle of the track and the bottom of the track (as close to the external opening as possible). Samples were incubated separately in medium overnight. After centrifugation, the supernatant was recovered and frozen at -80°C and stored for bulk analyses. The Limulus Amebocyte Lysate (LAL) test kit was used for endotoxin (lipopolysaccharide) analysis.
RESULTS: Endotoxins were found to be present in some of the samples but not in all. This displays both an intra- and inter-individual variability. However, when the differences between the different parts of the fistula track were analysed, there was no statistically significant difference between the percentage positive expression of endotoxins at the top of the fistula track (p=0.45), the middle of the fistula track (p=0.73) and the bottom of the fistula track (p=0.74).
CONCLUSION: Endotoxins are present in both idiopathic and crohn's perianal fistula tracks. A non-statistically significant trend has been observed in percentage positive expression of endotoxins at the top of the fistula track as compared with the middle and the bottom. These results improve our understanding of the aetiology of perianal fistulae and may provide a therapeutic target in the future.

P1391 INTRACELLULAR KILLING OF BACTERIA IS NOT IMPAIRED IN CROHN'S DISEASE MONOCYTE-DERIVED MACROPHAGES

P. K. Flanagan[1,*], B. J. Campbell[1], S. Subramanian[2], J. M. Rhodes[1]. [1]*Gastroenterology, University of Liverpool,* [2]*Gastroenterology, Royal Liverpool University Hospital, Liverpool, United Kingdom*

INTRODUCTION: Patients with Crohn's disease exhibit an attenuated inflammatory response after trauma or *Escherichia coli* infection and have delayed clearance of subcutaneous bacteria compared to healthy controls. Adherent, invasive *E. coli*, increased in Crohn's disease, replicate within macrophages and may have a primary pathogenic role. Crohn's disease patients' macrophages may have a primary defect in bacterial killing, allowing survival of AIEC
AIMS&METHODS: We aimed to assess the relative ability of monocyte-derived macrophages from Crohn's patients to kill intracellular *E. coli* and *Staphylococcus aureus* compared to healthy controls. Peripheral blood monocytes were obtained from consenting adults by centrifugation over Lymphoprep™ followed by 2h adherence to plastic NuncÒ tissue culture dishes and subsequent differentiation into macrophages by 5d culture (as per Smith *et al*, J.Exp.Med. 2009, 206: 1883-97). Macrophages were infected with an adherent, invasive *E. coli*

HM605, *E. coli* K12 or *Staph. aureus* Oxford strain. Intramacrophage killing was assessed using the gentamicin protection assay. Cytokine release to the culture medium was also determined by sandwich ELISA. Macrophage-mediated chemotaxis of human neutrophils, obtained from healthy controls by centrifugation over Polymorphoprep™, was quantified in Boyden chambers
RESULTS: No significant difference in the relative killing of *E.coli* K12 (-14±11% vs -45±9%) and *Staph. aureus* (-52±4% vs -63±5%) nor in the relative survival of AIEC HM605 (+50±26% vs +8±22%) within monocyte-derived macrophages was seen (healthy controls vs Crohn's disease respectively; n=10 each group, ANOVA). TNFα, IL-6 and IL-8 production were not significantly different between the two groups and neutrophil chemotaxis was equivalent. Smoking status did not affect bacterial survival, with no differences observed in killing between current smokers, ex-smokers and non-smokers
CONCLUSION: Macrophages from patients with Crohn's disease do not appear to have an inherent defect in killing and exhibit normal pro-inflammatory responses. We postulate that local environmental factors may inhibit macrophage function *in vivo*. AIEC evade killing and possess the ability to replicate within macrophages from both healthy controls and Crohn's disease patients

P1392 DIFFERENTIAL EXPRESSION OF AQUAPORINS IN HUMAN INTESTINAL MUCOSA DURING EARLY STAGE INFLAMMATORY BOWEL DISEASE

P. Ricanek[1,2,*], L. K. Lunde[3], S. A. Frye[1], M. Støen[1], K. Helmersen[4], S. Nygård[5], J. P. Morth[6], A. Rydning[2], M. H. Vatn[4], M. Amiry-Moghaddam[3], T. Tønjum[1]. *[1]Centre for Molecular Biology and Neuroscience and Department of Microbiology, Oslo University Hospital, Rikshospitalet, Oslo, [2]Department of Gastroenterology, Akershus University Hospital, Lørenskog, [3]Centre for Molecular Biology and Neuroscience and Department of Anatomy, Institute of Basic Medical Sciences, University of Oslo, Oslo, [4]EpiGen Institute, Campus Ahus, Institute of Clinical Medicine, Lørenskog, [5]Bioinformatics Core Facility, Institute for Medical Informatics, Oslo University Hospital and University of Oslo, [6]Centre for Molecular Medicine, Nordic EMBL Partnership, University of Oslo, Oslo, Norway*

INTRODUCTION: Aquaporins (AQPs) are a family of pore-forming proteins that efficiently and selectively mediate transport of water and small solutes across biological membranes. AQPs belong to a distinct family of membrane transport proteins that are selective for water molecules. Studies of AQPs have provided important insight into mechanisms that mediate water homeostasis and their role in human health and disease.
AIMS&METHODS: Here, we characterize the tissue-specific expression of selected AQPs using biopsies from the terminal ileum and colon of patients with newly diagnosed Crohn's disease (CD) or ulcerative colitis (UC). The goal was to investigate the relationship between AQP expression and the pathological features of inflammatory bowel disease (IBD) in humans. AQP1, 3, 4, 5, 7, 8 and 9 gene expression was quantified in biopsies from distal ileum and proximal and distal colon by quantitative real-time polymerase chain reaction (qRT-PCR). Protein expression of selected AQPs was also assessed by confocal microscopy with immunofluorescence (IF). Through multiple alignments of the deduced amino acid sequences, the putative 3D structure of AQP1, 3, 7, and 8 were modelled.
RESULTS: The qRT-PCR data indicated that AQP1, 3, 7 and 8 genes are expressed in all parts of the intestinal mucosa examined in this study. Notably, expression of AQP1 and AQP3 was downregulated in the ileum of CD patients and expression of AQP7 and AQP8 was downregulated in the ileum and the colon of UC patients. The findings were confirmed by confocal IF which also indicated a loss of apical immunolabeling for AQP3 and AQP8 in colonic surface epithelium and crypts of the IBD samples.
CONCLUSION: AQPs 1 and 8 and the aquaglyceroproteins 3 and 7 are the predominant aquaporins expressed in the human lower intestinal tract, their expression is significantly reduced in patients with IBD and they are differentially expressed in specific bowel segments in patients with CD and UC. These data represent a new link between gut inflammation and water/solute homeostasis and suggest that AQPs may play an important role in IBD pathophysiology.

P1393 NEUTRALIZING ANTIBODIES AGAINST PLACENTAL GROWTH AS A NOVEL TREATMENT MODALITY IN EXPERIMENTAL CROHN'S DISEASE.

P. Hindryckx[1,*], P. Jacques[2], L. Devisscher[1], D. Laukens[1], L. Ferdinande[3], B. Jonckx[4], D. Elewaut[2], M. De Vos[1]. *[1]Gastroenterology, [2]Rheumatology, [3]Pathology, Ghent University Hospital, Ghent, [4]ThromboGenics NV, Leuven, Belgium*

INTRODUCTION: In contrast to vascular endothelial growth factor-A (VEGF-A), placental growth factor (PlGF) is exclusively involved in pathological angiogenesis. Therefore, PlGF is an attractive target for the treatment of diseases associated with increased angiogenesis, like inflammatory bowel disease (IBD).
AIMS&METHODS: The aim of this study was to analyze the potential of neutralizing PlGF antibodies in a mouse model of Crohn's disease (CD).
Intestinal mucosal VEGF-A and PlGF levels were assessed by ELISA during the course of chronic ileitis in the murine TNFDARE model of Crohn's disease. To analyze the effect of PlGF inhibition in this model, mice were treated with neutralizing anti-PLGF antibodies (50mg/kg, 2x/week intraperitoneally, N=8) or an equal dose of the corresponding control IgG (N=8), starting at an advanced stage of disease (week 9). The mice were clinically monitored and finally sacrificed for histological analysis and quantification of myeloperoxidase levels, inflammatory cytokines and leukocyte adhesion molecules. A subgroup of the mice was scanned with deoxy-2-[18F]fluoro-d-glucose (FDG) micro-positron emission tomography (μPET)/computed tomography (CT) before sacrification.
RESULTS: In contrast to VEGF-A, intestinal PlGF levels showed a linear increase with the progression of experimental chronic ileitis. Anti-PLGF reduced PlGF activity in the terminal ileum without affecting the VEGF-A levels. PlGF inhibition resulted in progressive weight gain of diseased TNFDARE mice ($P<0.01$ versus IgG-treated mice). Compared to IgG-treated mice, anti-PLGF-treated mice showed less histological inflammation, reduced levels of MPO and inflammatory cytokines ($P<0.05$ for all parameters) and lowered inflammation-induced terminal ileal FDG-uptake on μPET-CT after three weeks of treatment.
CONCLUSION: Placental growth factor is highly involved in chronic intestinal inflammation and its suppression with neutralizing monoclonal antibodies dampens the inflammatory process in a mouse model of CD-like chronic terminal ileitis. These results warrant a clinical trial with anti-PLGF in human CD.

P1394 ENTERIC GLIAL CELLS FROM CROHN'S DISEASE PATIENTS HAVE ALTERED FUNCTION ON INTESTINAL EPITHELIAL BARRIER: TOWARD THE IDENTIFICATION OF NOVEL ESSENTIAL LIPIDIC GLIOMEDIATORS.

S. Coquenlorge[1,*], N. Cenac[2], M. Biraud[3], J. Jaulin[4], N. Vergnolle[2], M. Neunlist[5], M. Derkinderen[5]. *[1]Inserm UMR-913, Nantes University, Nantes, [2]Centre de Pathophysiologie de Toulouse Purpan, INSERM UMR-1043 CNRS UMR-5282, Toulouse, [3]Inserm UMR-913, [4]Inserm UMR-913, CHU Hotel-Dieu, [5]Inserm UMR-913, IMAD, CRNH, CHU Hotel-Dieu, Nantes, France*

INTRODUCTION: Evidence have identified enteric glial cells (EGC), the major constituent of the enteric nervous system, as key regulators of intestinal epithelial barrier (IEB) functions. Under physiological conditions, EGC enhance IEB repair, reduce its permeability, and increase its resistance to pathogens. These mechanisms are altered during inflammatory bowel disease (IBD) such as Crohn's Disease (CD) and Ulcerative Colitis (UC). EGC lesions have also been observed in IBD, but there is a lack of information about pathophysiological processes that could link IBD EGC to IEB dysfunctions.
AIMS&METHODS: To address this question, we have characterised EGC isolated from CD, UC, and cancer patients (considered as control EGC). We have compared their phenotype by measuring glial marker expression (GFAP, S100beta, Sox10) and have analysed their production for EGC-derived soluble factors (IL6, TGFbeta, proEGF, GSNO) but also for 31 lipidic mediators. In parallel we have studied EGC functional impact on IEB in a co-culture model using the human intestinal epithelial cells (IEC; Caco-2). In this model we have measured IEB transepithelial resistance (EVOM) and paracellular permeability (sulfonic acid-FITC flux). We have also analysed Caco-2 spreading (ZO1 immunostaining and cell area measurement), and proliferation (Ki67 immunostaining).
RESULTS: EGC from CD, UC or control patients expressed the same level of GFAP, Sox10, S100beta and did not present significant variations in their proliferation rate. In the same manner, their expression/production of IL6 and TGFbeta mediators and their impact on IEB permeability were comparable. But whereas control EGC increased significantly IEC transepithelial resistance and spreading, CD EGC had no effect. Analysis of the lipid profile of EGC supernatants revealed that CD EGC produced significantly less 5- and 15-HETE compared to control or UC EGC.
CONCLUSION: All together, these results show that human EGC from CD patients have lost their protective property on IEB that are IEC spreading and IEB resistance. These defects could be due to a lack of lipidic mediator production by CD EGC.

P1395 PPARGAMMA IMPROVES INTESTINAL FIBROSIS BY TARGETING THE EMT-ACTIVATOR ZEB1

S. Speca[1,*], V. Flati[2], C. Dubuquoy[3], C. Rousseaux[3], A. Langlois[1], L. Dubuquoy[1], B. Bertin[1], S. Bellinvia[4], P. Desreumaux[1], G. Latella[2]. *[1]INSERM U995, Université Lille-Nord de France, Lille, France, [2]University of L'Aquila, L'Aquila, Italy, [3]Intestinal Biotech Development, Lille, France, [4]GiulianiSpA, Milano, Italy*

INTRODUCTION: Intestinal fibrosis is a common consequence of Inflammatory Bowel Disease (IBD), in which excessive extracellular matrix (ECM) components deposition causes obstruction and loss of function. Our previous data show inhibition of TGF-β1/Smad pathway mediated by a new transrepressive PPARγ modulator, GED-0507-34 Levo, and relative improvement of fibrotic disease in a DSS model of chronic colitis. TGF-β1/Smad is

the prototypical pathway regulating epithelial to mesenchymal transition (EMT) in fibrosis. PPARγ is highly expressed in intestinal epithelial cells (IEC) and its GED-mediated activation may inhibit TGF-β induced phenotypic EMT and in particular the over-expression of Zinc finger E-box-binding homeobox 1 (ZEB1), a pivotal epithelial markers transcriptional repressor.

AIMS&METHODS: Aim: To evaluate the role of GED-induced PPARγ activation to reverse the progression of TGF-β induced EMT, and to determine its ability to downregulate ZEB1 expression in intestinal epithelial cells.

Methods: Intestinal epithelial cells (HT29) differentiated by a 4 day treatment with TGF-β1 (10 ng/ml) were stimulated with GED 1mM. A PPARγ knockdown HT29 (ShPPARγ HT29) cell line was included in the study to confirm the PPARγ-dependence of GED effect. After 4 day of combined treatments EMT was determined by quantitative real-time PCR analysis of A33 and Cytokeratin 20 (two specific intestinal epithelial markers) aSMA, Collagen, Fibronectin and ZEB1. Collagen deposition was evaluated by Picrosirius red staining.

RESULTS: TGF-β1 induced phenotypic EMT in cultured HT29 and ShPPARg HT29 cell line via significantly reduced A33 and Cytokeratin 20 expression ($p<0.05$) and significantly increased expression of mesenchymal differentiation markers, α-SMA and Fibronectin ($p<0.01$) in association with the loss of epithelial morphology. GED reduced αSMA and Fibronectin mRNA expression (1.2 fold and 2.5 fold vs TGF-β, respectively. $p<0.05$) and restored specific IECs markers. GED determined a 65% reduction of TGFβ-induced collagen deposition ($p<0.05$). ZEB1 mRNA expression was downregulated by GED in TGF-b treated IEC by 2.2 fold ($p<0.05$) compared to TGF-β treated cells. Significant effects of GED treatment were not observed in ShPPARγ HT29.

CONCLUSION: GED reversed all EMT markers in a PPARγ-dependent manner. The present study could represent a useful start point to better highlight the action spectrum of PPARg in prevention and care of intestinal fibrosis and to identify new specific molecular target to develop efficient therapeutic strategies.

Haller[1,4]. *[1]Chair of Nutrition and Immunology, Technische Universität München, Freising-Weihenstephan, Germany, [2]Division of Infectious Diseases, Department of Internal Medicine, University of Texas, Houston, [3]Center for Gastrointestinal Biology and Disease, Department of Medicine, University of North Carolina, Chapel Hill, United States, [4]ZIEL - Research Centre for Nutrition and Food Science, Biofunctionality Unit, Technische Universität München, Freising-Weihenstephan, Germany*

INTRODUCTION: *Enterococcus faecalis* – a commensal of the human intestinal microbiota - was shown to induce intestinal inflammation in the IL-10-/- mouse model of experimental colitis making this an exemplary model to analyze structure-function relationships for microbe-host interactions. The enterococcal polysaccharide antigen (Epa) was previously described to affect *E. faecalis* virulence.

AIMS&METHODS: In this study, we characterized enterococcal virulence using a newly generated epaB deletion mutant (TX5692).

RESULTS: *E. faecalis* Δ*epaB* mutant showed reduced virulence in *Galleria mellonella* and *Caenorhabditis elegans* infection models. A deletion of epaB resulted in diminished biofilm generation including attenuated formation of microcolonies and impaired adhesion to epithelial cells *in vitro*. To further analyze microbe-host interaction, germ-free *Manduca sexta* larvae, a natural host to *E. faecalis*, were mono-associated with *E. faecalis* mutant and wild-type strains. Compared to wild-type OG1RF, the Δ*epaB* mutant showed impaired midgut colonization and altered adhesion to larval intestinal epithelium. In a mono-association experiment, IL-10-/- mice associated with Δ*epaB* mutant strain showed significantly diminished intestinal pathology and reduced chronic inflammation markers, such as lower spleen weight and less increased colon length, compared to OG1RF-associated mice.

CONCLUSION: Our experiments show an impact of epaB on *E. faecalis* virulence and intestinal pathogenesis in a colitis mouse model. This indicates to mechanisms related to altered adhesion of *E. faecalis* to mucosal surfaces and may unravel a track of how epaB-mediated adhesion contributes to *E. faecalis*-host interaction.

P1397 SERUM METABOLOME IN MILD-MODERATE ACTIVE ULCERATIVE COLITIS AND CELIAC DISEASE

S. Sitkin[1,2,*], E. Tkachenko[2], T. Vakhitov[1], L. Oreshko[2], T. Zhigalova[2]. *[1]State Research Institute of Highly Pure Biopreparations, [2]I.I. Mechnikov North-Western State Medical University, St. Petersburg, Russian Federation*

INTRODUCTION: Ulcerative colitis (UC) is a chronic autoimmune inflammatory bowel disease whose pathogenesis is not fully understood. Celiac disease (CD) is a disorder that caused by an abnormal immune reaction to the dietary gluten and primarily affects the small intestine. Gas chromatography-mass spectrometry (GC-MS) of serum generates comprehensive metabolic profiles, reflecting integrated human (systemic) and gut microbial metabolism which may be altered in disease states.

AIMS&METHODS: The aim of this study was to investigate GC-MS-based serum metabolomic profiles in UC patients, CD patients and healthy controls, potentially to provide insights into disordered integrated metabolism and underlying mechanisms.

Serum metabolic profiles and fecal samples were collected from 75 individuals (20 patients with mild-moderate active UC, 35 CD patients, and 20 healthy controls). The multivariate analysis techniques such as principal components analysis (PCA) and other methods were used to assess differences between groups.

RESULTS: We characterized 84 serum metabolites by use GC-MS and multivariate analysis to differentiate between diseased and non-diseased individuals, as well as between the UC and CD cohorts. 18 metabolites at least have a combined (human + microbial) origin. In serum of UC patients, phenylacetic acid (PAA), 4-hydroxyphenylacetic acid (4-HPAA), 3-indolylacetic acid (IAA), succinic acid (SA) and fumaric acid (FA) were the metabolites most prominently increased, whereas 3-phenylpropionic acid (PPA) was significantly decreased. Serum of CD patients showed significant increases in IAA, 3-indolepropionic acid (IPA), SA and FA. Differences in serum metabolite levels of UC patients, CD patients and controls may indicate the difference in the metabolic activity of gut microbiota (some *Clostridia* and *Bacteroides* spp.) involved in phenylalanine and tyrosine metabolism. Increased serum levels of succinic acid, produced abundantly by some *Bacteroides* spp., suggest its possible damaging effect on intestinal mucosa especially in ulcerative colitis. Orally administered butyrate + inulin (Zacofalk NMX, Dr. Falk Pharma GmbH, 3 tablets per day for 4 weeks) as supplement to mesalazine in UC or gluten free diet (GFD) in CD was effective in reducing disease activity, with a marked improvement of gut microbiota and serum metabolic profiles in both diseases.

CONCLUSION: Quantitative metabolomic profiling of serum using GC-MS discriminates between UC patients, CD patients and healthy controls. Metabiotic consisting of butyric acid and inulin can be effectively used in UC, as well as in CD, improving symptoms and metabolic profiles.

P1398 DIRECT ROLE OF IFX ON INTESTINAL MUCOSA SUSTAINS MUCOSAL HEALING: EXPLORING NEW MECHANISMS OF ACTION

V. Petito[1], F. Scaldaferri[1,*], L. R. Lopetuso[1], E. Stigliano[2], V. Arena[2], S. Bibò[1], A. Amato[1], G. Cammarota[1], A. Sgambato[2], A. Gasbarrini[1]. *[1]Department of Internal Medicine, Gastroenterology Divison, [2]Department of Pathology, CATHOLIC UNIVERSITY OF SACRED HEART, ROME, Italy*

INTRODUCTION: Infliximab (IFX), the first born chimeric antibody anti-TNF-a in IBD, is effective in IBD through several mechanisms of actions, including an action on both immune and no immune intestinal cells. Although clinical studies demonstrated clear efficacy of IFX in inducing and maintaining IBD remission, it is still not clear whether IFX really acts at mucosal levels.

AIMS&METHODS: Aim of this study is to verify mechanisms of action of IFX at intestinal mucosal level and whether these pathways contribute in mucosal healing. The direct effect of IFX was assessed on human colonic mucosa biopsies, taken from IFX naïve patients in active state of disease. Biopsies were washed, weighted and incubated for 12 hours in 24-well plate, with or without IFX (50 µg/ml). Supernatants were assessed for multiplex cytokines evaluation (Bio-Plex®, BIO-RAD). Moreover, cultured biopsies were included for histological evaluation and then stained to evaluate CD68, CD3, E-cadherin expression and apoptosis by the terminal deoxynucleotidyl transferase (dUTP) nick end labeling assay.

RESULTS: IFX- treated biopsies displayed reduced inflammatory infiltrate with a reduction in total counts of CD68 and, particularly, for CD3 positive cells when compared to untreated biopsies, with an increase of E-cadherin expression and apoptosis at Tunel assay. Cytokines evaluation on supernatants of biopsies treated with IFX showed lower TNF-α, IL-17, IL-6 and IL-8 concentration, with an increase in INF-γ, FGF and IL-1β. Biopsies from active IBD patients exposed to a direct incubation with IFX for 12 hour showed a better and more conserved histology aspect then that of IFX-untreated biopsies.

CONCLUSION: These data suggest that IFX acts directly on intestinal mucosal level and that it could contribute to slower loss of glandular epithelium, probably because of the decrease in the pro-inflammatory cytokines activity and an increase in genes involved in repair function, like basic FGF.

P1399 IN VITRO EVIDENCE ON POTENTIATION IMMUNE REGULATORY PROPERTIES OF A UNIQUE SUBPOPULATION OF HUMAN MSC

Z. han[1], X. Cao[2,*]. [1]*The State Key Laboratory of Experimental Hematology, Institute of Hematology and Hospital of Blood Diseases, Chinese Academy of Medical Sciences and Peking Union of Medical College,* [2]*gastroenterology, tianjin medical university general hospital, tianjin, China*

INTRODUCTION: MSCs have been found to have significant immunosuppressive capacities which make it as a potential treatment for various immune disorders including IBD. MSCs pretreated by proinflammatory cytokines such as INFr and TNFa obtain intensive immunoregulatory effect, thus far the qualification of activated MSCs is still unclear, especially for human cell as the effect molecule seems different between the cell of human and mice.
AIMS&METHODS: The hMSChireg, a subpopulation of human mesenchymal stem cells with character of CD106+, has just been defined by us. Subpopulations of MSCs were separated using EasySepH PEPositive Selection Kit. LC3-II was detected by Western Blot. Monocytes transfected with LC3-GFP were treated in different co-cultured system respectively and then LC3+ spots were quantified by fluorescent microscopy. The Microarray was done by CapitalBio Corporation.
RESULTS: The hMSChireg induce an almost complete inhibition of IFN-r secretion of PHA stimulated PBMCs whereas the residual ones induce only partial inhibition (5% vs 39%). Also, hMSChireg can suppress TNF-a production to a much lower level than their counterpoint (41% vs 79%). hMSChireg decrease the expression of IFN-r and TNF-a more effectively (2% vs 19%, 5% vs 19%). In addition, hMSChireg can induce Treg more effectively than the other part of MSCs (5.4% vs 3.3%), hMSChireg treated monocytes up-regulate their LC3-II gene expression while the effect of their counterpoint is weaker. hMSChireg more significantly enhance autophagy of macrophage (4.20 vs. 1.56). gene expression profiles are generated from both hMSChireg and residual MSCs which show that the levels of COX-2, IL-1a, IL-1b, IL-6, IL-8 and IDO1 are significantly up-regulated in hMSChireg with an increased ability to secrete PGE2.
CONCLUSION: MSChireg, as a unique subpopulation of MSC, more effectively suppress Th1 polarization of CD4+ T cells and induce Treg and at same time more significantly enhance autophagy. This indicates that MSChireg may not only contribute to inhibit excess inflammatory but also ameliorate the defective innate immunity in IBD. However, even under inflammatory conditions only a proportion of MSC can be detected in the intestine, suggesting that additional mechanisms of immune suppression may be active. In addition, enhancing binding of MSChireg enhances their migration to the inflamed colon and in turn may also be expected to potentiate their immunosuppressive effects in vivo. So we hypothesize that MSChireg could lead to a more rapid clinical response and a dose reduction of cells, which could have profound effects on current treatment development programs.

P1400 CHARACTERIZATION OF PERIANAL CROHŃS DISEASE - RETROSPECTIVE COHORT STUDY

D. G. Ferreira[1,*], P. Lago[1], M. Salgado[1], C. Caetano[1], I. Pedroto[1]. [1]*gastroenterology, centro hospitalar do porto, Oporto, Portugal*

INTRODUCTION: Perianal manifestations of Crohńs Disease (PMCD) are multiple and may be a therapeutic challenge. Its prevalence is variable with differing results depending on the type of study, length of follow up and the kind of considered perianal lesions. Most studies focus only on fistulas and abscesses and are of an era prior to the introduction of anti-TNF.
AIMS&METHODS: AIM: Characterization of the perianal manifestations in a cohort of patients with Crohńs Disease (CD).
METHODS: Retrospective cohort study with 921 patients with CD. Five PMCD were analyzed: fistulas, abscesses, anal stenosis, ulcers of the anal canal and anal fissures. Other variables: sex, current classification of CD (Montreal Classification), time of follow up, type of PMCD, past and current medical-surgical treatment and response to medical-surgical treatment.
RESULTS: 249/921 (26.3%) patients have at least one PMCD. Baseline characteristics: Average age of diagnosis: 31,2yrs. Male sex: 46%. Average time of follow up: 15,2yrs. Current Montreal Classification: B1 39.1% B2 36.6% B3 24.3% L1 39.1% L2 29.0% L3 31.9% (+L4 3.4%). Rectal involvement: 46.4%. In 41.6% of cases the PMCD preceded the diagnosis of CD. Average number of perianal manifestations: 2.5/patient. PMCD characterization: 9.1% fissures; 9.1% ulcers of the anal canal; 43% fistulas (complex fistulas in 74% of cases); 36.8% abscesses: 2% anal stenosis (4 post-hemorrhoidectomy). Medical therapy in the diagnosis: 71.9% isolated thiopurine, 2.3% anti-TNF: 0.89% combined therapy. Present medical therapy: Anti-TNF: 9.4%; Anti-TNF + thiopurine 25.1%; Thiopurine: 43.5%; MTX; 2.6%; MTX + anti-TNF 4.3%. Surgical/endoscopic approach: anorectal stenosis dilation (n=8). Fistuletomy (n=70). Protectomy (n=10, 8 with previous ulcers of the anal canal), advancement flap (n=9). Response to medical-surgical treatment: none 6.4%, partial response 13.2%, complete response 70.2%, in evaluation 9.9%.
CONCLUSION: In this cohort 26.3% of the patients with CD have at least one of the 5 PMCD studied. The suppurative complications are the most common, although a high number of ulcers of the anal canal have been documented. The fistulas are mainly complex requiring a medical/surgical approach. Presently the majority of the patients are undergoing treatment with thiopurines or combination therapy with anti-TNF. This is one of the largest studies of characterization of perianal Crohńs Disease.

P1401 PATIENTS' PERCEPTIONS OF PSYCHOLOGICAL SURVEYS IN INFLAMMATORY BOWEL DISEASE.

E. McDermott[1,*], J. Moloney[2], K. Byrne[1], K. Malone[1], H. Mulcahy[1]. [1]*St Vincent's University Hospital, Dublin,* [2]*St Luke's Hospital, Kilkenny, Ireland*

INTRODUCTION: With treatment advances, life expectancy in inflammatory bowel disease (IBD) is normalising and thus there is an increasing focus on disability and quality of life (Qol). This has resulted in a multitude of tools to measure patient reported outcomes. Despite this, little is known about patients' perceptions regarding QoL research and which aspects they consider most important
AIMS&METHODS: To explore patient perceptions of IBD QoL research.
387 IBD patients were approached, of whom 341 (88%) (median age 36 years; 175 male) completed a comprehensive questionnaire that included validated instruments to assess depression, anxiety, quality of life, self-esteem, body image and sexual satisfaction. Patients were asked to provide feedback regarding the study, specifically questions they did or did not like and the introduction of such questions at routine clinic visits. Free text boxes were provided for comments. Statistical analysis was performed in SPSS vs 20 and using grounded theory coding of qualitative responses.
RESULTS: 83% of patients reported liking the study. Reasons for liking the study included, 'to express feelings', that 'it covered all aspects of daily life both physically and emotionally' and that it 'might help others'. Additional recurring themes included; the survey made them feel 'less alone', and being 'easier to express emotions in a survey'. 17% disliked the questionnaire. The majority reported that is was 'too long' while others commented that it was 'repetitive', 'too personal' or that they 'don't like doing surveys'. When asked if they would like any of these questions asked at regular clinic, 75% reported yes and 25% reported no. When given an option of which questions they would like asked, the most popular related to work/daily activities in 54%, mood and feelings in 54%, body image in 27% and sexual health in 16%. There was little correlation between liking the study and wanting questions asked at clinic, (r, 0.14, p=0.02). Linear regression identified education as being associated with liking the questionnaire, (p=0.03), while older age, body image disturbance and disability were associated with wanting questions asked at clinics, ($p<0.001$, $p<0.001$, p=0.009).
CONCLUSION: Most patients are interested in participating in QoL research. Patients appreciate the opportunity to address psychosocial concerns and to help others, indicating a high degree of altruism among IBD patients. Areas of particular interest were activities of daily living and mood. This highlights the importance of QoL research in care for patients with IBD, and also suggests that there are few predictable variables to identify patients who are more invested in QoL issues than others.

P1402 PSORIASIS PHENOTYPE IN INFLAMMATORY BOWEL DISEASE: A CASE-CONTROL PROSPECTIVE LONGITUDINAL STUDY

E. Lolli[1,*], R. Saraceno[2], G. Condino[1], C. Petruzziello[1], S. Onali[1], E. Calabrese[1], S. Chimenti[2], F. Pallone[1], L. Biancone[1]. [1]*Gastroenterology Unit, University of Rome Tor Vergata,* [2]*DermatologyUnit, University of Rome Tor Vergata, Rome, Italy*

INTRODUCTION: Psoriasis has been associated with Inflammatory Bowel Disease (IBD). However, whether IBD is associated with specific phenotypes of psoriasis is unknown.
AIMS&METHODS: In a case-control prospective longitudinal study, we aimed to assess the psoriasis phenotype in patients with IBD, when compared with non-IBD control patients (non-IBD C). At this purpose, from January 2011 to April 2013, dermatological assessment was performed in 188 consecutive IBD patients under follow up. Dermatological assessment was focused in detecting the presence of psoriasis (present/absent) and in defining characteristics of psoriasis (localization, phenotype) including severity (mild/moderate/severe). In order to define psoriasis phenotype, each IBD patient with psoriasis was matched for gender, ethnicity and age (±5 years) with one non-IBD patient with psoriasis, referring to the same University/Hospital. Data were expressed as median and range and differences between groups assessed by the T test.
RESULTS: Dermatological assessment was performed in 188 IBD patients (85 F, age 45.5 yrs, range 18-85; IBD duration 9 yrs, range 1-46). Among these 188 patients, there were 72 UC (35 M, age 47, range 23-85; UC duration 6 yrs, range 1-40; UC extent: distal 26, left-sided 11, pancolitis 31, ileal pouch 3, ileostomy 1) and 116 CD (69 M, age 44, range 18-80; CD duration 10 yrs, range 1-46; CD colitis 8, ileo-colitis 24, ileitis 34, neo-terminal ileum 45, ileostomy 2, jejunum 1,

distal ileum + jejunum 2). Non-IBD C included 50 patients (31 M, age 47, range 18-75). Among the 188 IBD patients, psoriasis was detected in 48 (26 %; 28 CD, 20 UC). In the IBD group, the median age and IBD duration were comparable in patients with or without psoriasis (age 50.5 range 23-72 vs 44 range 18-85; IBD duration 8 yrs range 1-45 vs 9 yrs range 1-41; p=ns for both). Mild psoriasis was detected in a higher proportion of IBD patients (40/48; 83%) than non-IBD C (28/50; 56%;$p < 0.001$). Scalp psoriasis and sebopsoriasis were the more common psoriasis phenotype in IBD (16/48; 33%), followed by inverse psoriasis (7/48; 15%) and by palmo-plantar psoriasis (5/48;10%). Psoriatic arthritis was detected in 9/50 (18%) non-IBD-C and in 4/48 (8%) IBD patients (p=n.s.). In 4/48 (12%) IBD patients, psoriasis developed after anti-TNFs (palmo-palmar 3, sebopsoriasis 1).
CONCLUSION: Results from a cohort of IBD patients matched with non-IBD control patients suggest that specific phenotypes of psoriasis may be associated with IBD.

P1403 SCREENING FOR MELANOMA AND NON MELANOMA SKIN CANCER IN IBD PATIENTS BEFORE TREATMENT WITH THIOPURINES AND ANTI-TNFS: A PROSPECTIVE COHORT STUDY.

E. Lolli[1,*], R. Saraceno[2], C. Petruzziello[1], G. Condino[1], M. Ascolani[1], A. Capanna[1], P. Scarozza[1], S. Onali[1], E. Calabrese[1], S. Chimenti[2], F. Pallone[1], L. Biancone[1]. [1]*Gastroenterology Unit, University of Rome Tor Vergata,* [2]*Dermatology Unit, University of Rome Tor Vergata, Rome, Italy*

INTRODUCTION: Recent evidences suggest an increased risk of Non Melanoma Skin Cancer (NMSC) using thiopurines in IBD and preliminary observations suggest an increased melanoma risk by using anti-TNFs.
AIMS&METHODS: In a prospective study, we aimed to assess the frequency of NMSC and melanoma in a cohort of IBD patients screened for skin cancer before thiopurines or anti-TNFs. From January 2012 to April 2013, consecutive IBD patients in follow up, with clinical indication to use thiopurines or anti-TNFs were screened by one experienced dermatologist. Dermatological assessment was performed before (T0), 6 (T6) and 12 mos (T12) after immunomodulators (IMM). Dermatological assessment was focused in detecting NMSC or melanoma. Results were expressed as median and range.
RESULTS: Dermatological assessment has currently been performed in 61 IBD patients (32M, age42, range 20-70; IBD duration 7yrs, range 1-30). IBD group included 15 UC (9M, age39, range 23-70; duration 6 yrs, range 1-17; UC distal 2, left 2, extensive11) and 46 CD (23M, age 42, range 20-67; duration 8,5yrs, range 1-30; CD colitis 2, ileo-colitis 10, ileitis 13, neo-terminal ileum 21). Combined therapy (1 azathioprine, AZA+Infliximab, IFX; 2 AZA+adalimumab, ADA) was initiated by 3/61(5%) patients. Monotherapy included AZA in 26/61(43%) IBD(7 UC,19 CD), 6-mercaptopurine in 2/61 (3%) IBD(1UC,1CD) and anti-TNFs in 36/61 (59%) patients (8 UC,28CD), including IFX in 18/61 (29%)(6UC,12 CD), ADA in 18/61(29%) patients (2UC,16CD). Before IMM, 1/61(1.6%) patients showed NMSC, while no melanotic cancers were detected. At T0, all patients were treated with local photolyase aimed to prevent skin cancer. At T6, dermatological assessment has been performed in 19/61 (31%) patients, as 8 (13%) discontinued therapy (intolerance in 7: AZA 5, ADA 1, IFX 1; pregnancy in 1, IFX); 2 (3%) were lost to follow up; 2 (3%) died (cirrhosis or sepsis), while 30 (49%) patients are continuing the follow up. At T12, 45/61(74%) patients are therefore in follow up; in 1(2%) patient no lesions were detected, while 4/61(7%) patients discontinued IMM due to intolerance (1AZA,2ADA,1IFX). No cases of NMSC or melanoma were detected at 6 or 12 mos (1NMSC detected only at T0).
CONCLUSION: In a cohort of IBD patients from a Mediterranean area, dermatologic screening before immunomodulators showed a low frequency of NMSC and no melanoma. Dermatologic screening and photoprotection are however reccomended during IMM in IBD patients already showing a higher risk of skin cancer.

P1404 FREQUENCY AND PREDICTORS OF NEGATIVE CALPROTECTIN IN IBD IN TERTIARY CENTER

J. Letkovsky[1,*], J. Toth[1], T. Koller[1], Z. Zelinkova[1], A. Krajcovicova[1], S. Oravcova[1], M. Huorka[1], T. Hlavaty[1]. [1]*Fifth Internal Department, University Hospital Bratislava, Bratislava, Slovakia*

INTRODUCTION: Fecal calprotectin (f-cal) is a sensitive marker of intestinal mucosal inflammation. It might be a more sensitive predictor for disease activity and risk of relapse than mucosal healing
AIMS&METHODS: The aim of this study was to analyze the f-cal levels in IBD patients in a tertiary IBD center. Furthermore, we analyzed predictive factors of negative f-cal. cohort consisted of 134 IBD patients, 83 with Crohn's disease (CD) and 51 with Ulcerative colitis (UC). Demographic and clinical characteristics of the disease and concomitant medication were determined in every patient. F-cal levels were measured using cut-off value for negative f-cal < 50ug/g. We also analyzed the prevalence of undetectable f-cal levels using cut-off value $< 7,8$ug/g. Predictors of negative f-cal were analyzed.
RESULTS: Negative f-cal was detected in 54/134 (40,2%) IBD patients, 35/83 (42,2%) CD patients, 19/51 (37,3%) UC patients. Undetectable f-cal was present in 36/134 (26,4%) of IBD patients, in 23/83 (27,7%) of CD patients and in 13/51 (25,5%) UC patients. In IBD patients on biologics (n=77), those on concomitant AZA had negative f-cal in 21/41 (51,2%) as compared to those without AZA 10/36 (27,8%); p=0,036. Undetectable levels of calprotectin were present in 16/41 (39,0%) patients trated with biologics on AZA and in 5/36 (13,9%) patients without AZA; p=0,013. Amongst CD patients treated with biologics (n=54), the concomitant AZA therapy was associated with negative f-cal in 16/27 (59,3%) patients compared to 7/27 (25,9%) patients; p=0,013. Inflammatory behaviour was associated with significantly lower rate of negative f-cal 7/27 (25%) in comparison to stricturing and fistulising CD 28/56 (50%);p=0,03.
CONCLUSION: The results of this study indicate a rather low frequency of negative f-cal in IBD patients. Biological therapy with concomitant AZA shows the highest rate.

P1405 THE RISK OF COLITIS-ASSOCIATED CANCER IN ULCERATIVE COLITIS PATIENTS – A SINGLE CENTER STUDY

M. Ross[1], T. M. Nowacki[1], M. Eveslage[2], P. R. Tepasse[1], F. Pott[1], N. H. Thoennissen[3], M. Brückner[1,*], D. Bettenworth[1]. [1]*Department of Medicine B, University Hospital of Münster,* [2]*Institute of Biostatistics and Clinical Research, University of Münster,* [3]*Department of Medicine A, University Hospital of Münster, Münster, Germany*

INTRODUCTION: Epidemiological data and molecular insights hint at an increased risk for colitis associated cancer (CAC) in patients suffering from ulcerative colitis (UC) [Eaden Gut 2001]. However, since recent studies propose decreasing time-trends for CAC [Söderlund Gastroenterology 2009], the aim of our study was to determine the prevalence of CAC in a German referral center, as well as to characterize the risk profil of affected UC patients.
AIMS&METHODS: A cohort with a total of n=434 UC patients visiting our clinic between the years 2002 and 2013 was evaluated. Data analysis was performed by univariate logistic regression. Impact of clinical parameter was evaluated by Odds ratios (OR) and 95% confindence intervals (CI), significance was assessed by Wald-test.
RESULTS: Mean patient age at UC diagnosis was 45.7 ± 15.1 with manifestation profile 47.2% pancolitis, 44.4% left-sided colitis and 8.4% proctitis. Disease duration in 56.6% of patients was between 0-8 years, in 21.1% between 9-15 years and in 22.2% more than 15 years. Overall, CAC was detected in ten patients (2.3% of the total cohort). Of these, six patients suffered from pancolitis and eight suffered from UC longer than 15 years. Thus, UC disease duration was strongly associated with the risk for CAC (P=0.004); disease duration between 9-15 years: OR of 2.5 (95% CI 0.1-41.1), more than 15 years: OR of 21.1 (95% CI 2.5-171.3). Furthermore, the risk of dysplastic polyps was also significantly related to disease duration (P=0.02); disease duration between 9-15 years: OR of 1.6 (95% KI 0.5-4.8), more than 15 years: OR of 4.1 (95% KI 1.7-10.1). Established antiinflammatory medication (e.g. 5-ASA, anti-TNF-a) significantly reduced the risk for dysplastic polyps and CAC (P=0.03, OR of 0.3, 95% CI 0.1-0.8; and $P < 0.05$, OR 0.2, 95% CI 0.07-0.9).
CONCLUSION: The rate for CAC found in our relatively large, retrospective, single-institution cohort study contradicts the findings of recent studies and confirms historical data [Eaden 2001]. The risk for dysplastic polyps and CAC is strongly associated with longer disease duration and the extent of colitis. Furthermore, antiinflammatory therapy led to a significant risk reduction for dysplastic polyps and CAC.

INTRODUCTION: Even though the negative impact of tobacco smoking on Crohn's disease (CD) phenotype and complications is well established, the clinical usefulness of smoking cessation in ameliorating disease activity has been evaluated by one single prospective study that took place before the era of widespread and early use of anti-TNF and immunosuppressant drugs. Our aim was to evaluate the current clinical benefit of quitting smoking in CD patients prospectively followed after a complete smoking cessation.
AIMS&METHODS: 1170 patients from 14 IBD centers were included. The subjects presented various smoking status and were followed every 3 months. All included smokers were advised to quit smoking and different smoking cessation strategies were proposed according to the clinical practice of each

participating center. Patients not exposed to tobacco before inclusion (non- and former smokers), current smokers and quitters were prospectively compared regarding differences in their disease outcomes.
RESULTS: Subjects with complete data regarding their disease outcomes along with a study follow-up larger than 1 year were included in the present analysis (134 current smokers, 326 non-smokers and 67 quitters). At present, this cohort has 39 months (interquatile range of 18-42) of global study follow-up with a median of 18 months of smoking-free time for the quitters. In comparison with non-smokers, current smokers presented more disease activity (43% vs. 32%, $p<0.05$), more severe disease flare-ups with subsequent hospitalization (15.6% vs. 7.4%, $p<0.05$) and a trend towards an increased need for anti-TNF drugs (16.5% vs. 8.8%, p=0.06). Surprisingly, no differences with respect to disease activity, complications and different therapeutic requirements were found between current smokers and patients who achieved a complete smoking cessation.
CONCLUSION: In this multicenter prospective study, current smokers present a more severe disease course when compared to patients not exposed to tobacco. With the present follow-up, no differences in disease activity, complications and treatment were found between ongoing smokers and patients who quit.

P1407 A 7 YEARS STUDY ON EPIDEMIOLOGIC ASPECTS OF INFLAMMATORY BOWEL DISEASE IN THE NORTH EAST OF ITALY.

T. Slongo[1,*], F. Ferrara[1], R. Marcello[1], H. Heras Salvat[1], G. Guarnieri[1], G. Battistella[2], A. Caroli[1], N. Dal Bo[1], A. Schiavinato[1], A. Furlanetto[3], A. P. Dei Tos[3], F. Di Mario[1]. *[1]Department of Specialist Medicine, Gastroenterology Unit, Treviso General Hospital, [2]Department of Epidemiology, Treviso General Hospital, [3]Department of Clinical Pathology, Pathology Unit, Treviso General Hospital, Treviso, Italy*

INTRODUCTION: Several studies confirm that the incidence and prevalence of inflammatory bowel disease (IBD) are increasing with time. Moreover the distribution of these results is extremely heterogeneous according to different geographic areas considered. Great interest causes this evaluation since the IBD are chronic diseases that require continuing therapy and assistance. It is not clear if the trend is justified by environmental risk factors or if it is secondary to a greater diagnostic accuracy.
AIMS&METHODS: The aim of this study was to determine the change of prevalence of IBD, ulcerative colitis (UC) and Crohn's disease (CD), in the residing population in our Sanitary District 9 Veneto in the last seven years. A retrospective study of prevalence was performed in an area on 500,000 inhabitants from 2005 to 2011 evaluating the IBD registry of the National Health System and considering all new registered exemptions.
RESULTS: 353 new exemption for IBD have been reported during the observation period. The prevalence of IBD detected in 2005 was 100,36/100.000 inhabitants of which 25,46/100.000 CD and 74,89/100.000 UC; no statistically significant difference between males and females (p=ns). In 2011, however, the prevalence of IBD was 179.13/100.000 inhabitants of which 59,63/100.000 CD and 119,5/100.000 UC, being the male population higher than the female one (p=0,028). In a cohort of 398 cases followed for 5 years no difference in the average age of death in comparison to the general population was found (IBD men 72,1±16,6 yrs, women 79,3±10,2 yrs vs general population men 74,2±16 yrs, women 81,2±15 yrs, p=ns). The most frequent cause of death is represented by cardiovascular disease (8 cases), followed by cancers not related to IBD (6 cases), other (3 cases). One patient died of complications related to UC diagnosed in late age.
CONCLUSION: The prevalence rate of IBD in the studied district corresponds to the data detected in the countries of northern Europe. A progressive increase in the diagnosis of IBD in the last years has been demonstrated, namely 179/100.000 inhabitants in 2011 opposite to 100/100.000 at baseline (2005). At the same time, leasting the years CD increased from 25/100.000 to 56/1000.000. The life expectancy in IBD is similar to that of the general population and the causes of death are not related to IBD.

P1408 THE DIAGNOSTIC ACCURACY OF FECAL CALPROTECTIN IN POUCHITIS

A. Bálint[1,*], I. Földesi[1], K. Farkas[1], G. Lázár[2], L. Tiszlavicz[3], M. Szűcs[4], F. Nagy[1], Z. Szepes[1], R. Bor[1], T. Wittmann[1], T. Molnár[1]. *[1]First Department of Medicine, [2]Department of Surgery, [3]Department of Pathology, [4]Department of Science and Informatics, University of Szeged, Szeged, Hungary*

INTRODUCTION: Total proctocolectomy with ileal pouch-anal anastomosis (IPAA) represents the most common surgical procedure for intractable ulcerative colitis (UC), although up to 50% of the patients undergoing surgery will develop pouchitis. The diagnosis of pouchitis requires both pouch endoscopy and biopsy. Searching for non invasive markers which correlate with the degree of the mucosal inflammation is becoming more and more important.
AIMS&METHODS: The aim of our prospective study was to compare fecal calprotectin and matrix metalloproteinase (MMP)-9 in patients with and without pouchitis assessed by clinical, endoscopic and histological scores and to evaluate the diagnostic accuracy of fecal calprotectin and MMP-9 in pouchitis. Stool and blood samples were collected in 27 IPAA patients before control endoscopy. Pouchoscopy was performed and biopsies from the reservoir were taken for histology. Pouchitis was defined as Pouchitis Disease Activity Index (PDAI) > 7 points. The presence of cuffitis was evaluated by endoscopy. Demographics, pouch wear time, inflammatory laboratory parameters and medications used at the time of the study were recorded. Calprotectin and MMP-9 were quantified by use of enzyme-linked immunosorbent assay.
RESULTS: Pouchitis was detected in 22% of the patients. Cuffitis was presented in 8 cases. Fecal calprotectin and MMP-9 was significantly higher in patients with vs. without pouchitis (616.4 vs. 118.5, p=0.02 and 23.5 vs. 3.95, p=0.04), but none of them correlated with cuffitis. The cut-off value for fecal calprotectin and MMP-9 in the diagnosis of pouchitis revealed to be 370 μg/g and 5 ng/ml respectively. None of the examined inflammatory laboratory markers correlated significantly with pouchitis. The pouch wear time did not influence the development of the pouch inflammation.
CONCLUSION: Fecal calprotectin and MMP-9 proved to be reliable markers for the determination of pouch inflammation which may be helpful in the diagnosis of pouchitis and in the differentiation between pouchitis and cuffitis.

P1409 FEASIBILITY OF ENDOSCOPIC ASSESSMENT AND TREATING TO TARGET TO ACHIEVE MUCOSAL HEALING IN CROHN'S DISEASE

G. Bouguen[1], B. Levesque[1,*], S. Pola[1], E. Evans[1], W. Sandborn[1]. *[1]Division of Gastroenterology, University of California San Diego, La Jolla, United States*

INTRODUCTION: Current evidence suggests that treatment strategies focused on controlling symptoms do not alter the course of Crohn's disease (CD). Mucosal healing (MH) as a treatment target is of growing interest because it is associated with improved outcomes. We therefore evaluated utility of "treating to target" according to endoscopic findings to reach MH.
AIMS&METHODS: The medical records of 199 patients with CD followed in a single inflammatory bowel disease unit from 2011 to 2012 were reviewed through April 2013. After an initial assessment, endoscopic outcomes were reviewed in all patients with baseline endoscopic lesion. Cumulative incidence of MH (disappearance of all baseline ulcerations) and endoscopic improvement (disappearance of deep ulceration) were estimated using a Kaplan-Meier method. Independent predictors and factors associated with MH were identified using a Cox proportional hazards model.
RESULTS: At baseline, the median age was 38 (IQR75 25-52) and median disease duration was 6.8 years (IQR75 1.5-18.5). Previous treatment included immunosuppressives, TNF antagonists, and surgery for 58 (52.7%), 58 (52.7%) and 42 (38.1%) of patients, respectively. A total of 68 patients (out of 174 patients) underwent repeat endoscopic assessment, representing a total of 163 procedures (including baseline assessments). The median time between two procedures was 26 weeks (IQR75 18.1-38). Second and subsequent assessments were a priori planned to assess response to adjusting therapy and 56 patients were asymptomatic at the time of assessment. After a median follow up of 62 weeks, 34 patients (50%) achieved MH and 41 (60.3%) patients had endoscopic improvement. The cumulative probabilities of endoscopic improvement were 11%, 38% and 61% at 24, 52 and 76 weeks respectively and cumulative probabilities of mucosal healing were 16%, 47%, and 70% at 24, 52 and 76 weeks respectively. None of baseline factors were independently predictive of mucosal healing including prior or current use of immunosuppressives and TNF antagonists. Importantly, independent factors associated with mucosal healing were a median time between endoscopy under 26 weeks (HR=2.13;95%IC 1.04-4.47, p=0.038) and any therapeutic change in case of absence of MH (including biologics introduction/optimization/switch or immunosuppressive introduction/switch)(HR=3.2; 95%IC 1.46-8.04, p=0.003).
CONCLUSION: We demonstrate that repeated objective measurement of disease activity and adjusting therapy to the target of MH is feasible and highly effective. Randomized trials that evaluate treat-to-target algorithms are needed to determine if this treatment strategy can change the course of the disease.

P1410 A SCORE USING TISSUE EOSINOPHIL COUNT AND IMMUNOHISTOCHEMICAL MARKER OF CD30 MAY DISCRIMINATE CROHN'S DISEASE FROM ULCERATIVE COLITIS

C. Flores[1,*], C. D. M. Francesconi[1], L. Meurer[2]. *[1]Gastroenterology, [2]Pathology, Hospital de Clínicas de Porto Alegre, PORTO ALEGRE, Brazil*

INTRODUCTION: Routine histopathological examination from colonoscopic biopsies sometimes are not useful to differential diagnosis of colonic involvement by Inflammatory Bowel Diseases (IBD). The development of new immunohistochemical tools may be helpful to overcome this limitation.
AIMS&METHODS: To evaluate the relevance of CD30 expression by Immunohistochemistry, eosinophil count and histopathological features in differential diagnosis of IBD.
185 IBD patients (105 CD/ 80 UC), were evaluated at a specialized center in a university hospital. Diagnosed according to Lennard-Jones criteria, reviewed by a gastroenterologist expert and corroborated by five years follow up. Patients were all treatment naïve at the time of collection of the biopsies. The samples were taken from affected areas in the colon and examined by an experienced gastrointestinal pathologist. Study approved by the local IRB.
RESULTS:

	CD (105)	UC (80)	p
Eosinophils – median (P25 – P75) most altered segment	42 (25,5 – 63,5)	107 (67 – 123)	<0,001
CD30 – median (P25 - P75)	3 (2 – 6)	33 (24 – 52)	<0,001

Using standard pathological criteria, the accuracy was 69.1% in the differential diagnosis between CD and UC. Assessing the most altered segment the median of eosinophils was 42 (25.5 – 63.5) in CD and 107 (67 – 123) in UC ($p < 0.001$). Assuming a cutoff ≥ 70 eosinophils, the sensitivity was 78.3% and specificity of 71% favoring the UC diagnosis, the area under the ROC curve was 0,767 (CI 95%: 0,696–0,838). After total count of $CD30^+$ cells in 10 high-power fields a median of 3 cells (2-6) in CD and 33 cells (24-52) in UC ($p < 0,001$). The cutoff determined by ROC curve was 15 (S = 97.5%, E = 94.3%, LR + = 17.1;-RV = 0.03, area under the curve: 0.967, 95% CI: 0.941 - 0.993). A value was assigned to each variable based on the statistical power of each, making a total sum of 10 points to build a histopathological score for the CD diagnosis. If the sum of the variables is ≥ 5 achieved 100% specificity and a sensitivity of 86.8%. Considering the cutoff of 4 points the score comes to a sensitivity of 95.3%, and reduces the specificity of 100% to 94.9%.

CONCLUSION: The use of routine assessment of the histopathological features in association with the $CD30^+$ cells count provides a high accuracy for CD and UC differential diagnosis. All parameters assessed here are easily performed, of low cost and accessible by most pathological laboratories. Further studies are warranted to validate our findings.

P1411 MOTIVATIONAL INTERVIEWING IN THE OUTPATIENT VISIT: A USEFUL TOOL IN INFLAMMATORY BOWEL DISEASE

F. Mocciaro[1,*], R. Di Mitri[1], G. Russo[1], I. Bravatà[1], S. Leone[2].
[1]*Gastroenterology and Endoscopy Unit, ARNAS Civico-Di Cristina-Benfratelli Hospital,* [2]*CEO, AMICI, Italian National Association of Patients with IBD, Palermo, Italy*

INTRODUCTION: Motivational interviewing (MI) is a patient-centered counselling style developed for eliciting behaviour change by helping patients (pts) to modify their lifestyle. MI was applied for substance/alcohol abuse, smoking cessation, weight loss, management of chronic pain. The strategy at the base of this approach is comprised of some basic skills: the ability to ask open ended questions, the ability to provide affirmations, the capacity for reflective listening, and the ability to periodically provide summary statements to the pts.

AIMS&METHODS: We report data on MI applied to inflammatory bowel disease (IBD) pts at their first outpatient visit (June '12-February '13). We decided, also, to supplement MI counselling using the aid of explanatory pictures. We evaluated all consecutive IBD pts referred for the first time to our outpatient clinic. At the end of visit pts filled out a questionnaire, anonymously and in a separate room, comparing the visit with their prior experience.

RESULTS: 45 pts (23 males [51%]), with a mean age of 36.1±15.2 yrs and a median disease duration of 12 months (range 1-120), were evaluated. Twenty-one pts were affected by Crohn's disease (47%), 19 by ulcerative colitis (42%), and 5 by indeterminate colitis (11%). Sixty-seven percent of pts (30/45) were previously evaluated by a gastroenterologist while the remaining 33% (15/45) only by their general practitioner (GP). At final analysis a high rate of pts (60%, 27/45) reported a good overall satisfaction but when we analyzed pts previously evaluated by a gastroenterologist 11/30 (37%) reported a complete dissatisfaction. This rate increased to 47% (7/15) in pts evaluated only by GP. Twenty-seven/45 pts (60%) reported a unsatisfactory communication skills of the physician or physicians lack of empathy (30% marked "zero empathy"). Younger pts (<40 yrs) had a significant dissatisfaction rate compared to older pts (p=0.017, OR 5.4;95% CI 1.26-22.9); no differences were found considering level of education or employment status. After MI all pts (100%) reported a good satisfaction rate without lack of empathy (32/45 pts [71%] marked "excellent empathy") due to the fact that they felt they had complete answers to their questions. All pts, also, liking the use of explanatory pictures. The mean duration of the visit was 41.5±8.7 minutes.

CONCLUSION: Our experience showed as MI can be very well appreciated by IBD pts. It is a quite time-consuming technique but considerably useful at the first visit and in younger pts. Explanatory pictures help pts to better understand their clinical condition. MI can help physicians, especially gastroenterologists, to move from "cure" to "care" with their IBD pts.

P1412 MICRORNA MIR-UP1 SERVES AS A BIOMARKER FOR THE COURSE OF INFLAMMATION IN EXPERIMENTAL COLITIS AS WELL AS IN CROHNS DISEASE.

F. Pott[1,*], C. Cichon[2], H. Sabharwal[2], A. Schmidt[2], D. Bettenworth[1].
[1]*Department of Medicine B,* [2]*Infectiology, Centre for Molecular Biology of Inflammation, University of Münster, Muenster, Germany*

INTRODUCTION: Crohns disease is a chronic-remittent disease with the risk of disabling complications due to uncontrolled inflammation. A patient-tailored use of anti-inflammatory therapy is needed. However, overtreatment of patients bears the risk of severe side-effects such as opportunistic infections. Sensitive markers to non-invasively follow the course of the disease are still missing. Recent studies demonstrated a specific expression pattern of micro-RNAs (miRNA), involved in many biological processes, in Crohns disease. Aim of our study was to evaluate miR-up1 to monitor the course of inflammation in experimental colitis as well as in Crohns disease patients and to investigate its potential role as a biomarker for disease activity.

AIMS&METHODS: Experimental Colitis was induced in C57BL/6 WT mice by administration of 3% dextran sodium sulphate (DSS) in drinking water for 7 or 10 days, respectively, with daily measurement of body weight. On day 14, mice were sacrificed and histological damage was assessed according to the Dielemann Score. Expression of miR-up1 was determined by qRT-PCR in murine colonic samples and murine peripheral blood as well as in human blood from Crohns disease patients with acute flare and healthy controls (n=4 per group).

RESULTS: On day 14, DSS-treated mice revealed a significant loss of body weight as compared to control mice (20.8 g ± 2.9 vs. 27.6 g ± 1.6; P=0.006). Moreover, histological damage in DSS treated mice was markedly increased as compared to controls and still partially elevated in recovering mice (0.50 ± 0.19 (controls) vs. 21.71 ± 8.16 (colitis) vs. 14.54 ± 2.81 (recovery)). Most severe inflammation was located in the distal colon. Accordingly, mucosal expression of miR-up1 in the distal colon of colitic mice was significantly increased as compared to healthy controls (0.51 ± 0.08 vs. 0.38 ± 0.01; P=0.04). Furthermore, miR-up1 expression in the whole colonic tissue correlated strongly with the severity of histological damage ($r^2 = 0.73$; $P < 0.05$). In human blood from Crohns disease patients with acute flare, miR-up1 expression was significantly increased as compared to healthy controls (0.25 ± 0.17 vs. 1.9 ± 1.15; P=0.03).

CONCLUSION: We demonstrate that miR-up1 expression in colonic tissue monitors the course of DSS-colitis with a positive correlation to the histological damage. In addition, our preliminary data proofs a markedly increase of miR-up1 expression in peripheral blood of Crohns disease patients with acute flare. Therefore, miR-up1 might serve as a bio-marker to follow the course of inflammation in DSS-colitis as well as in Crohns disease patients.

P1413 ACCURACY OF FECAL CALPROTECTIN IN THE ASSESSMENT OF POST-OPERATIVE ENDOSCOPIC RECURRENCE IN PATIENTS WITH CROHN'S DISEASE

G. Boschetti[1,*], G. Phelip[1], D. Moussata[1], A.-L. Charlois[1], B. Flourié[1], S. Nancey[1]. [1]*Gastroenterology, Lyon-Sud Hospital, Lyon, France*

INTRODUCTION: Endoscopic post-operative recurrence is frequent in Crohn's disease (CD) and is highly predictive of further clinical recurrence. AIMS: i) to assess the performance of fecal calprotectin (fCal) to discriminate in CD patients who had undergone an ileo-colonic resection those who experienced an endoscopic recurrence from those who did not; ii) to determine the best threshold of fCal capable to distinguish between CD patients with or without a post-operative endoscopic recurrence.

AIMS&METHODS: At least one ileo-colonoscopy was performed in 28 consecutive patients with CD who had undergone a curative resection of the distal ileum and proximal colon (2 colonoscopies were performed in 5 of them) during the previous year. Post-operative endoscopic recurrence was defined as a Rutgeerts endoscopic severity index $\geq$i2. Just before the beginning of the colon cleansing, a fecal sample was collected in the patients for routine fCal measurement by ELISA (Bühlmann, Suisse). Concentrations of fCal were compared in patients who experienced an endoscopic recurrence and in those who did not using the Mann-Whitney test. The accuracy of fCal to discriminate between patients in endoscopic remission (i0, i1) from those in endoscopic recurrence (i2, i3, i4) was determined by constructing a ROC curve and sensitivities, specificities, positive (PPV) and negative predictive values (NPV) were also calculated using various fCal levels as cut-off points.

RESULTS: Among the 33 ileo-colonoscopies performed, a postoperative endoscopic recurrence was assessed in 10 patients (all in clinical remission) with a Rutgeerts score i2 (n=3), i3 (n=3), i4 (n=4). FCal concentrations were significantly higher in patients with an endoscopic recurrence compared with those without (368 ± 333 mg/g *vs* 106 ± 79 mg/g ; $p < 0.001$). The AUC of fCal to discriminate between patients with or without a post-operative endoscopic recurrence was 83 %. The respective accuracies of fCal to diagnosis post-operative endoscopic recurrence according to fCal threshold are summarized in the Table.

Accuracies Cut-off	Sens	Spec	PPV	NPV
[fCal]=100 mg/g	89 %	50%	60%	92 %
[fCal]=150 mg/g	66%	87 %	66 %	87 %
[fCal]=200 mg/g	55 %	87 %	62 %	84 %
[fCal]=250 mg/g	33 %	87 %	50 %	78 %

CONCLUSION: FCal using a cut-off of 100 mg/g had the best sensitivity and NPV to distinguish CD patients in clinical remission who experienced a post-operative recurrence from those who did not. If these results are confirmed in a larger population sample size, finding a fCal concentration above this cut-off might allow to avoid performing some ileo-colonoscopies in the CD post-operative setting.

P1414 POPULATION PHARMACOKINETIC EVALUATION OF INFLIXIMAB REVEALS PATIENT FACTORS THAT INCREASE INFLIXIMAB CLEARANCE AND SHORTEN HALF-LIFE IN INFLAMMATORY BOWEL DISEASE PATIENTS

I. Dotan[1,2,*], Y. Ron[1,2], H. Yanai[1,2], S. Becker[1], S. Fishman[1,2], L. Yahav[1], M. Ben Yehoyada[1], D. Mould[3]. *[1]IBD Center, Gastroenterology and Liver Diseases, TEL AVIV SOURASKY MEDICAL CENTER, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Projections Research Inc, Phoenixville, United States*

INTRODUCTION: Infliximab (IFX) is an effective therapy for inflammatory bowel diseases (IBD: ulcerative colitis (UC) and Crohn's disease (CD)), but may be associated with significant side effects as well as loss of response (LOR). One mechanism of LOR is increased IFX clearance (CL), resulting in short half-life and decreased troughs. Few evaluations of the pharmacokinetics (PK) of IFX in IBD are published.

AIMS&METHODS: Aim: To investigate factors affecting IFX PK variability in IBD.

Methods: IBD patients were prospectively recruited and IFX serum concentrations as well as antibodies toward IFX (ATI) were measured by ELISA during therapeutic drug monitoring (TDM). Demographic, clinical and laboratory data were recorded. Disease activity was defined according to clinical activity scores. IFX data were evaluated using population modeling (Nonmem Version 7.2 Icon Development).

RESULTS: IFX concentrations (n=75) from 38 patients (CD: 12, UC 17, IBD-undetermined: 9) were evaluated. Baseline (mean ± SD) demographics were: weight 69.4±13 kg, age 37±12.2 yrs., Males: 29, BMI 22.8±4.2 kg/cm, CRP 19.4±3 mg/L, albumin 4±0.6 g/dL. Positive ATI at baseline were present in 1 patient, and developed in 14. Disease activity was moderate in 22 and severe in 10 patients. Patient factors significantly associated with high IFX CL were: low albumin, high body weight, and the presence of ATI ($p \leq 0.001$). IBD type did not affect IFX CL. Typical (ATI negative, weight 70 kg, ALB 4 g/dL) CL was 0.617 L/day. Over the range of albumin (2.4-5 g/dL), CL would be 1.12-0.47 L/day. Over the range of weights (45-112 kg), CL would be 0.22-0.40 L/day. ATI formation was associated with a 25% increase in IFX CL. The estimated median effective half-life was 9.8±2.2 days. Simulations investigating alternative dose strategies suggested more reliable measurable concentrations over the dose interval were achieved when the dose interval was shortened than increasing administered dose. After induction, IFX concentrations declined during maintenance with 8 week dosing.

CONCLUSION: IFX CL is significantly influenced by patient factors (albumin, weight, ATI). Decreasing the dose interval for IFX is the suggested dose adjustment strategy, particularly for low albumin patients. Higher starting doses may benefit low weight patients. PK models and TDM may ensure patients have measurable concentrations over entire dose interval. Thus, individualized rather than fixed dosing may improve outcomes for IBD patients treated with IFX.

P1415 DIFFERENTIAL DIAGNOSIS BETWEEN INTESTINAL TUBERCULOSIS AND CROHN'S DISEASE BY ILEOCOLONOSCOPIC FINDINGS

J. J. Park[1,*], S. J. Park[2], S. P. Hong[2], T. I. Kim[2], W. H. Kim[2], J. H. Cheon[2]. *[1]Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, [2]Internal Medicine, Severance Hospital, Yonsei University, Seoul, Korea, Republic Of*

INTRODUCTION: Proper differential diagnosis between intestinal tuberculosis (ITB) and Crohn's disease (CD) remains challenging problem.

AIMS&METHODS: The aim of this study was to develop simple and valuable models for distinguishing these diseases based on the ileocolonoscopic findings. Between January 2003 and January 2010, 202 consecutive patients with ulcers on ileocolonoscopy (106 ITB, 96 CD) were enrolled. Ileocolonoscopic features of these patients were retrospectively reviewed following predetermined criteria. Patients were randomly allocated to a training or a validation set at 2: 1 ratio. Parameters which were significant on univariate analysis were subsequently tested by a classification and regression tree (CART) analysis and logistic regression analysis.

RESULTS: On univariate analysis of the training set, transverse shape ulcer, scars, pseudodiverticulum, patulous ileocecal valve, focal distributions, and ascending colon involvement were more frequently observed in patients with ITB than in patients with CD. Whereas, longitudinal shape ulcer, skip lesion, aphthous lesion, cobblestone appearance, pseudopolyp, segmental or diffuse distributions, and involvement of terminal ileum, transverse colon, descending colon, sigmoid colon, or anorectum were more common in patients with CD than ITB. The CART generated a tree model algorithms which are constructed with three variables including anorectal involvement, presence of aphthous lesion, and patulous ileocecal valve. The CART model made correct diagnosis for ITB or CD in 56 of 68 patients (82.4%). Whereas, stepwise multiple logistic regression analysis identified four independent predictive factors for discriminating ITB or CD : aphthous lesion, pseudopolyp, ascending colon involvement, anorectal involvement. The calculation formula (1.4 - [2.92 × aphthous lesion] - [1.89 × pseudopolyp] + [2.10 × ascending colon involvement] - [3.59 × anorectal involvement] < 0) predict CD with an accuracy of 88.2% (60/68).

CONCLUSION: The novel calculation formula and the decision tree model may be useful for initial differentiation between ITB and CD.

P1416 PERIANAL ADENOCARCINOMA AND SQUAMOUS CELL CARCINOMA IN CROHN'S DISEASE

J. Dreanic[1,*], J. Cosnes[2], D. Laharie[3], C. Baudry[1], V. Abitbol[4], Y. Bouhnik[5], P. Marteau[6], M. Nachury[7], L. Abramowitz[8], L. Siproudhis[9], M. Allez[1], The GETAID. *[1]Gastroenterology, Saint Louis, [2]Gastroenterology, Saint Antoine, Paris, [3]Gastroenterology, CHU Bordeaux, Bordeaux, [4]Gastroenterology, Cochin, Paris, [5]Gastroenterology, Beaujon, Clichy, [6]Gastroenterology, Lariboisière, Paris, [7]Gastroenterology, CHRU Lille, Lille, [8]Gastroenterology, Bichat, Paris, [9]Gastroenterology, CHU Rennes, Rennes, France*

INTRODUCTION: Adenocarcinoma (ADK) and squamous cell carcinoma (SCC) of the anus and/or low rectum can occur in Crohn's disease (CD) patients with perianal lesions.

AIMS&METHODS: To describe characteristics of ano-rectal cancers in CD patients with perianal lesions, to estimate the incidence in a single center cohort and to identify risk factors. Cases of anal/low rectal cancers were collected in GETAID centers and the CESAME cohort, and retrospectively analyzed. Inclusion criteria were diagnosis of CD and histologically proven cancer located in anus or low rectum. The following characteristics were registered: age, sex, disease duration, smoking status, perianal lesions duration and type, histopathology, treatment and outcome. Disease-free and overall survival (OS) was analyzed. Actuarial rate of ano-rectal cancer was calculated in a single center cohort (MICISTA). The link between variables and cancer was assessed by log rank analysis.

RESULTS: 40 cases (26F/14M) were identified: ADK (n=29,72%), SCC (n=7,18%), high-grade dysplasia (n=2), neuroendocrine carcinoma (n=1) and rectal lymphoma (n=1). Median age at cancer diagnosis was 42 years (21-74). Median delay between diagnosis of CD and cancer was 19 years (3-37). Median delay between perianal lesions occurrence and cancer was 10 years (0-37). The median delay between diagnosis of stenosis and cancer was 3 years (0-18); it was significantly shorter in SCC (0.4 years) as compared to ADK (4 years). Diagnosis was often difficult and made on the specimen of proctectomy in 8 cases (20%). Mean follow-up was 1.2 years (0-13) for the all population. At the time of analysis, 19 patients had recurrence after treatment with a median disease-free survival of 32 months (5-131) and 13 patients died with a median OS of 52 months (18-180). In the single center cohort (20 cases out of 4908 patients), the actuarial rate of ano-rectal cancer was 0.8% at 20 years and 1.8% at 30 years. In univariate analysis, rectal and colon location, perianal lesions and no tobacco were identified as risk factors. Only rectal location and perianal lesions were significant in multivariate analysis.

CONCLUSION: Perianal ADK and SCC in CD have a poor prognosis and occur more frequently in patients with perianal lesions and rectal involvement. Patients with stenosis may be at a higher risk of ADK. Strategy of surveillance should be considered in high-risk patients.

P1417 DEVELOPMENT OF A NEW IMMUNOASSAY FOR THE ACCURATE DETERMINATION OF ANTI-INFLIXIMAB ANTIBODIES IN INFLAMMATORY BOWEL DISEASE

J. Semmler[1,*], A. Pilch[1], F. P. Armbruster[1], A. Dignass[2], J. Stein[3]. *[1]Immundiagnostik, AG, Bensheim, [2]Markus Hospital, Department of Medicine, [3]Hospital Sachsenhausen, Crohn Colitis Center, Frankfurt a.M., Germany*

INTRODUCTION: The formation of antibodies to infliximab (ATIs) is closely associated with the loss of response to infliximab in patients with inflammatory bowel disease (IBD). Within the strategy of therapeutic drug monitoring, serum ATI levels have been mainly assessed by immunoassays based on the double-antigen format, in which ATIs were captured by immobilized infliximab or protein A on a carrier. However, in these assays, the presence of infliximab can interfere with the binding of labeled infliximab to the captured ATI leading to

false-negative results. In the present study, we developed a novel immunoassay for ATIs which enables measurement in the presence of infliximab.
AIMS&METHODS: The new assay based on the dissoziation of immune complexes between infliximab and ATI at low pH-values and the use of biotinylated and peroxidase labeled infliximab preventing the re-formation of immune complexes. The presence of ATIs in the samples positive by the new method but negative by the conventional method was confirmed by Western blot analysis. ATI levels were measured using the novel immunoassay and the conventional method in 29 patients with Crohn's disease (CD) under infliximab maintenance therapy. The serum infliximab trough levels were determined by enzyme-linked immunosorbent assay.
RESULTS: ATIs were detected in 7 out of 29 patients (24.1%) by the new method, but the conventional method detected only 1 patients (3.4%) who had the two highest ATI titers assayed by the new method. In the new method, the addition of infliximab to the samples dose-dependently blocked the detection of ATIs. Patients positive for ATIs had significantly lower serum trough levels of infliximab ($P < 0.01$) and significantly higher clinical activity scores ($p < 0.001$) as compared with patients negative for ATI.
CONCLUSION: The new method makes it possible to measure serum ATI levels in the presence of infliximab and anti-adalimumab antibodies (data not shown). This method is useful for deciding the optimal management strategies for IBD patients with loss of response to TNFalpha-antibodies.

P1418 DETAILED INFORMATION ABOUT ULCERATIVE COLITIS FROM MAGNIFIED ENDOSCOPIC FINDINGS AND MIRNAS EXPRESSION ANALYSIS

K. Matsushima[1,*], H. Isomoto[1], S. Urabe[1], Y. Akazawa[1], F. Takeshima[1], H. Hamada[2], K. Nakao[1]. *[1]Gastroenterology and Hepatology, [2]Medical Education Development Center, NAGASAKI UNIVERSITY, Nagasaki, Japan*

INTRODUCTION: Although the number of patients with ulcerative colitis (UC) is steadily increasing, the pathogenesis of UC is still unclear. We focused on their details about magnified endoscopic findings and miRNA expression patterns.
AIMS&METHODS: 1) Forty-eight UC patients underwent magnifying colonoscopy. Magnified endoscopic observation was compared with clinicopathological characteristics including clinical course within 2 years. We classified CV (crystal violet)-magnified chromoendoscopic findings into 3 grades as follows: CV-Grade 1(G1) is normal or slight irregular arrangement of round to oval pits; CV-G2, opening of intervening round to oval pits; CV-G3, irregular dilatation or disappearance of pits.2) We included 6 patients with UC and 3 healthy controls in the study. In UC patients, we obtained endoscopic biopsy samples from the inflamed mucosa at the anal side and normal-appearing mucosa at the oral side in each UC case. In healthy controls, biopsies were obtained from the rectal mucosa. Using RNA extracted from the biopsied samples, we examined mucosal miRNA expression profile of UC by miRNA microarray.
RESULTS: 1) In pathological findings, the frequency of severe inflammatory cells infiltration was 84% in CV-G3 patients *vs* 24% in CV-G1/2 ($p < 0.001$). In the similar way, crypt abscess was shown in 74% *vs* 27% ($p=0.005$) and Goblet cell depletion was in 95% *vs* 38% ($p < 0.001$). 75% of CV-G3 patients experienced relapse within 2 years, whereas only 20% of CV-1/2 patients experienced relapse ($p < 0.05$). 2) Expressions of 19 miRNAs in the active lesions were significantly down-regulated by more than 2-fold compared to the less inflamed oral-side mucosa. And 24 miRNAs were decreased compared to healthy controls. miR-371-5p expression of the active lesion was significantly suppressed compared to the unaffected mucosa and healthy controls. Five miRNAs of the endoscopically inflamed UC lesions were significantly up-regulated compared to unaffected UC mucosa. And 8 miRNAs were increased compared to healthy controls. Among these miRNAs, miRNA-155 and -223 were upregulated in active lesions *vs* oral side ($P < 0.01$). Their expression levels were well matched with magnified endoscopic or pathological severities.
CONCLUSION: Observation with magnified endoscopy could be rather predictive with respect to the disease activity and relapse in UC. The current study shows the potential involvement of miRNAs in the pathogenesis of ulcerlative colitis, some of which demonstrating a possible association with inflammation. Confirmation of the relations between endocopic findings and specific miRNAs requires further studies.

INTRODUCTION: Cancer in Inflammatory Bowel Disease (IBD) is a relevant clinical issue
AIMS&METHODS: To characterize, in a case-control, multicentre study, incident cases of cancer in IBD. The role of severity of IBD *vs* thiopurines (IMM) and anti-TNFs was evaluated. From Jan 2012-Apr 2013, characteristics of incident cases of cancer in IBD patients (pts) from 15 IBD centers were recorded. Each IBD pt with cancer (IBD-K) was matched with 2 IBD pts with no cancer (IBD-C) for IBD type (CD/UC), gender, age (±5yrs). Statistical analysis: Data (median, range), Chi-squared, T test, univariate analysis.
RESULTS: Incident cases of cancer were reported in 63 IBD pts (32 M;age 59,16-82), more frequently in CD (CD-K)(n=37;59%) than in UC (UC-K)(n=26;41%;p=0.01). IBD duration was comparable between IBD-K (12yrs,1-50 *vs* 11-35) and their matched 126 IBD-C (64M, age59,15-81). In IBD-K (n=63) cancer involved: 23 GI tract (8CD,15UC), 14 genitourinary (8CD;6UC), 6 skin (2melanoma in CD,1IMM, noanti-TNF;3NMSC in 3CD, 3IMM,2IMM+anti-TNF;1Kaposi,1UC noIMM); 6 lung (3CD,3UC),5 breast (4CD,1UC), 3 lymphoma (3 CD,3M,2IMM+anti-TNF), 6 others (5CD;1UC). Colon cancer diagnosed in 18 IBD (5IMM,4 anti-TNFs,3both): 5CD (IMM+antiTNFs 1),13UC (IMM4, antiTNF 3, both 2). GI cancers were more frequent in UC (58%) *vs* CD (22%;$p < 0.001$), while lymphoma and skin cancers in CD vs UC (8% *vs* 0%, $p < 0.0001$;14% *vs* 4%$p=0.03$). Cancer was more frequent in total (n=14;54%) vs distal (n=10;38%;p=0.03) and subtotal UC (n=2;8% $p < 0.001$), and in stricturing (46%) vs fistulizing (22%;$p < 0.001$) CD (inflammatory 32%;p=0.05). IMM and anti-TNFs use was observed in a comparable proportion of IBD pts developing or not cancer (IMM:IBD-K *vs* IBD-C:33% *vs* 40%;Anti-TNFs:IBD-K vs IBD-C 30% *vs* 39%; p=n.s).
CONCLUSION: Findings from a case-control study suggest a higher frequency of cancer in CD than in UC and that IBD severity, including extensive UC, may influence the overall cancer risk. IMM and anti-TNFs may influence specific cancer histotypes.

P1420 DEEP REMISSION IN FISTULIZING PERIANAL CROHN'S DISEASE: A CONTRAST-ENHANCED MAGNETIC RESONANCE IMAGING (MRI) STUDY IN 49 CONSECUTIVE PATIENTS ON LONG TERM ANTI-TNF-ALPHA MAINTENANCE THERAPY.

L. Thomassin[1,*], C. Savoye Collet[2], L. Armengol Debeir[1], V. Bridoux[3], C. Charpentier[1], C. Melchior[1], E. Koning[2], E. Lerebours[1], G. Savoye[1]. *[1]Gastroenterology, [2]Radiology, [3]Surgery, Rouen University Hospital, Rouen, France*

INTRODUCTION: Fistulizing perianal Crohn's disease is a challenging clinical condition difficult to treat. Response to treatment like anti-TNF-alpha is based on a simple clinical evaluation of fistula drainage. MRI evaluation makes possible to evaluated fistula tract activity and to assess remission beyond symptoms.
AIMS&METHODS: The aim of our study were to describe clinical and imaging course of patients with perianal fistulas on long-term maintenance anti-TNF-alpha, to determine the rate deep remission and to search for clinical or imaging features associated with perianal fistula healing. All patients with fistulizing perianal Crohn's disease treated from 2000 to 2012 by anti-TNF and evaluated by MRI at diagnosis and at the end of the study were included. The data analysis was retrospective. The clinical response evaluation was based on Present's criteria and MRI evaluation on Van Assche's score and presence or not of contrast enhancement of fistula tracts. Deep remission was defined as the absence of symptoms associated with the absence of MR sign of inflammatory activity (hyper T2 signal and contrast enhancing of tracts). Characteristics of patients in deep remission were compared to others in univariate and in multivariate analysis.
RESULTS: Forty nine patients, median age 33±2 years were included. All received anti-TNF-alpha (infliximab n=43) associated with azathioprine in 63% of cases. MRI and clinical evaluation were done after a median anti-TNF exposure of 40±3 months. Clinical remission, response and non response were observed in respectively 53%, 20% and 27% of patients. Improvement, stabilization and worsening of MRI score were observed in respectively 61%, 16% and 23% of patients. Among the 26 patients in clinical remission 10 had persisting inflammation on MR. Deep perianal remission was observed in 32.7% of patients. In univariate analysis deep remission was associated with the absence of rectal involvement, the absence of anti-TNF switch or surgery requirement and the loss of contrast enhancement of fistula tract on intermediate MRI evaluation. In multivariate analysis, only the absence of endoscopic rectal involvement (OR=4.6;CI 95%:1-20) was predictive of deep remission.
CONCLUSION: Deep perianal remission is achieved in one third of patients on anti-TNF. Only the absence of rectal involvement was predictive of deep remission. The place of MRI lesions monitoring beyond symptoms needs further investigation but seems a promising approach.

P1421 MUCOSAL HEALING DOES NOT CORRESPOND TO HISTOLOGICAL HEALING IN ULCERATIVE COLITIS

L. Laterza[1,*], I. Scoleri[1], E. Gaetani[1], G. Cammarota[1], V. Arena[2], A. Amato[3], A. Gasbarrini[1], F. Scaldaferri[1]. [1]*Internal Medicine and Gastroenterology,* [2]*Institute of Pathology,* [3]*Institute of Anesthesiology, Università Cattolica del Sacro Cuore, Rome, Italy*

INTRODUCTION: Ulcerative colitis (UC) is a chronic inflammatory disease limited to the large bowel mucosa, thus mucosal healing (MH) assessed by endoscopy could be a potential curative target in the therapy of these patients. In fact, MH demonstrated to modify the natural history of the disease, reducing the need for surgery and the risk of colorectal cancer. MH lower the risk of disease reactivation, but some patients relapse in spite of the presence of MH. It is reasonable to think that the microscopic disease activity beyond MH could explain these cases.
AIMS&METHODS: Our aim is to assess how many patients with MH have a microscopic disease activity and what kind of lesions are the most frequent in these cases.
We used Mayo endoscopic score to assess endoscopic activity. 25 patients with MH defined as Mayo score=0 were enrolled. For each patient microscopic disease activity has been evaluated by an expert pathologist based on the presence of acute or chronic inflammatory cell infiltrate, superficial infiltrate, transmucosal infiltrate, basal plasmacytosis, basal lymphoid aggregates, stromal changes, lamina propria eosinophils, crypt branching, crypt distortion, crypt atrophy/depletion, cryptitis, crypt abscesses, surface irregularity, mucin depletion, erosions and Paneth cell metaplasia.
RESULTS: No patients showed absence of histological lesions, whereas in all patients a chronic inflammatory infiltrate persisted, as superficial infiltrate in 90% of cases. In 70% of cases an acute inflammatory infiltrate could be demonstrated. 60% of patients showed mucin depletion, 50% of patients showed basal plamacytosis, basal lymphoid aggregates and lamina propria eosinophils. 30% of patients showed crypt distortion, cryptitis and Paneth cell metaplasia. 20% of patients showed crypt atrophy or depletion and erosions. Only 10% of patients had crypt abscesses and transmucosal infiltrate. No patients showed surface irregularity and stromal changes.
CONCLUSION: A microscopic disease activity persist in all patients with MH, thus the endoscopic remission does not correlate with histological healing. Further studies are required to assess if persistent histological lesions could predict clinical relapse.

P1422 RISK MARKERS FOR EARLY ATHEROSCLEROSIS IN YOUNG PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. Cappello[1,*], A. Licata[2], I. Bravatà[1], D. Dabbene[1], A. Aiello[1], V. Calvaruso[1], D. Torres[3], A. Tuttolomondo[3], C. Cammà[1]. [1]*Di.Bi.Mis - University of Palermo - Italy, UOC GASTROENTEROLOGIA ED EPATOLOGIA,* [2]*Di.Bi.Mis - University of Palermo - Italy, UOC GASTROENTEROLOGIA ED EPATOLOGIA,* [3]*Di.Bi.Mis - University of Palermo - Italy, UOC Medicina Interna e Cardioangiologia, Palermo, Italy*

INTRODUCTION: An increased cardiovascular risk in patients with Inflammatory Bowel Disease (IBD) has been reported. Research data on surrogate markers of early atherosclerosis and endothelial dysfunction in this setting are conflicting.
AIMS&METHODS: Aim of the study was to assess the prevalence of increased intima media thickness (IMT) and of raised indexes of arterial stiffness in young adults with IBD. Consecutive IBD patients (age 15 – 45 years) and healthy controls (HC) comparable for age and sex were enrolled. Data on clinical and demographic features, cardiovascular risk factors, personal and familial history of cardiovascular events, concomitant therapies were registered on a database. Left and right carotid IMT was evaluated using high resolution B-mode ultrasonography. Arterial stiffness was assessed by measurement of carotid-femoral PulseWave Velocity (PWV) and Augmentation Index (AI).
RESULTS: Fifty patients with IBD, median age 34 (IQR 14), 25 males, were recruited, together with 20 HCs. 36 patients had Crohn's disease (CD), 14 ulcerative colitis. Median duration of disease was 4 years (IQR 6). IBD was active in 12 patients (10 CD, 2 UC). 13 were on steroids, 23 on immunomodulators, 12 on anti-TNF therapy (9 adalimumab, 3 infliximab). 14 patients presented extra-intestinal manifestations. Most of them were non-smokers (64%); 44% of the IBD patients had a familial history of cardiovascular events; one had hypertension, one diabetes. There were no significant differences between patients and controls when comparing smoking habits, BMI, lipid profile, blood pressure values. Right and left carotid IMT were significantly higher in patients compared to controls (0.5 versus 0.4 for both; p = 0.03 and0.015 respectively), 7 patients and no HC had evidence of atherosclerotic plaques. Carotid-femoral PWV median values were significantly higher in IBD patients than in controls (8,45 versus 8,3, p=0.007), as well as AI (122% in IBD, 112,5 in healthy controls; p= 0.005). There was no association between type of IBD, disease activity and duration and both IMT and PWV, which instead were related to increasing age (p < 0.005).
CONCLUSION: In a homogeneous Mediterranean cohort of young adults with IBD, early onset of atherosclerosis and alteration of arterial elastic properties were common, regardless of disease activity and of treatment. Evaluation of young IBD patients should include initial assessment and possibly monitoring of IMT and arterial stiffness to keep cardiovascular risk under control.

P1423 BOWEL CONTRAST-ENHANCED ULTRASOUND PERFUSION IMAGING IN THE EVALUATION OF CROHN'S DISEASE PATIENTS UNDERGOING BIOLOGICAL THERAPY

M. Garcovich[1,*], D. Roccarina[1], A. Lupascu[1], M. E. Ainora[1], G. Caracciolo[1], L. Laterza[1], G. Bruno[1], F. Scaldaferri[1], A. Gasbarrini[1], M. A. Zocco[1]. [1]*Internal Medicine and Gastroenterology, Catholic University of Sacred Heart, Rome, Italy*

INTRODUCTION: Evaluation of inflammatory activity in patients with Crohn's disease (CD) represents a crucial aspect of treatment planning and monitoring. High-resolution bowel ultrasound has emerged as one of the most important imaging techniques in the diagnosis and follow up of these patients since it is a non-invasive method that easily allows repeated examination and provides both morphological and functional analyses. In particular, microvasculature activation and angiogenesis induced by inflammation are the basis for the enhanced visualization of inflamed bowel walls evidenced by contrast enhanced ultrasound (CEUS).
AIMS&METHODS: Our aim was to prospectively evaluate the modification in bowel wall microvasculature of CD patients treated with biological therapy.
Ten patients (6 males and 4 females; mean age±SD, 34±12 years) with a clinically active Crohn's disease (CDAI score >150) involving the terminal loop of small bowel (wall thickness > 5 mm), were enrolled in this study. Clinical assessment, laboratory tests and CEUS were performed at baseline and after 7, 15, 30 and 60 days of treatment with adalimumab or infliximab. Bowel wall microvasculature and contrast uptake were assessed by perfusion analysis in regions of interest (ROI) with a quantification software (Q-Lab, Philips). Variations between baseline and different time-points were calculated for three CEUS functional parameters (peak intensity, PI; area under the curve, AUC; slope of wash in, P_w) and were correlated with CDAI.
RESULTS: Before the beginning of the specific treatment all patients revealed diffuse transparietal enhancement after contrast agent injection. In 8 patients both P_w and AUC were significantly lower after 15 and 30 days from the beginning of treatment ($p<0.05$) and were correlated with a reduction of CDAI score ($p<0.05$). In the remaining 2 patients no significant vascularity changes were found during the follow up in spite of a mild reduction of CDAI score. After two months, 2 patients showed a new increase in P_w and AUC, even though the clinical findings continued to be negative. Both these patients developed clinical recurrence within 3 months.
CONCLUSION: According to the preliminary results of our study, the quantification of the terminal bowel loop vascularity after contrast agent injection might become a useful modality not only for assessing the efficacy of biological therapy but also a reliable predictor of relapse during the follow up. In particular, changes in perfusion parameters might suggest a closer clinical control and treatment revaluation also for patients in clinical remission.

P1424 ENDOSCOPIC AND HISTOLOGICAL ACTIVITY AS PREDICTORS OF RELAPSE IN PATIENTS UNDERGOING SURVEILLANCE COLONOSCOPY FOR ULCERATIVE COLITIS

N. Mohammed[1,*], O. Rotimi[2], C. F. Donnellan[3], S. M. Everett[3], A. C. Ford[1,3], P. J. Hamlin[1,3], J. S. Jennings[3], B. J. Rembacken[3], A. Sainsbury[3], V. Subramanian[1,3]. [1]*Gastroenterology, Leeds Institute of Molecular Medicine,* [2]*Histopathology,* [3]*Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

INTRODUCTION: Mucosal healing has shown to correlate with improved long term outcomes in patients with inflammatory bowel disease. Histological inflammation is often noted in endoscopically normal mucosa.
AIMS&METHODS: We aimed to investigate the predictive role of endoscopic and histological inflammation on disease relapse in UC patients in clinical remission.
We conducted a retrospective review of adult patients in clinical remission who underwent surveillance colonoscopies in our institution from January 2008 to December 2011. Electronic records were reviewed for endoscopy reports and subsequent clinical care. Data was recorded on age, gender, duration and extent of the disease, medications, steroid use in last 6 months, Mayo endoscopic score, Geboes grades and follow up data for any flares till date. Relapse was defined as patients symptoms requiring steroid treatment or escalation to current treatment in subsequent 12 months following colonoscopy.
Statistical analysis: Rate of clinical relapse and the predictive value of the variables of interest were assessed using SPSS version 17. All variable analysed in univariate fashion and included in multivariate analysis if p was less than ≤0.3. Multivariate analysis was based on an automated backward logistic selection process. P values <0.05 were considered significant.
RESULTS: 406 patients underwent surveillance colonoscopy during the study period of which 317 (Male: 172 Females: 145) met the inclusion criteria. 57 patients (Males 29, females 28) relapsed within 12 months (Table 1 provides the baseline characteristics). On univariate analysis age (OR 0.96 95%CI 0.94-0.98), Geboes grade ≥2 (4.53, 2.40-8.52) and Mayo score ≥1 (3.72, 2.05-6.73) were significantly associated with relapse. Duration of disease (p=0.09), use of immunomodulators (p=0.29) and recent steroid use (p=0.3) were included in the multivariate analysis. On multivariate analysis Geboes score of ≥2 (5.11, 2.73-9.59) and age (0.97, 0.97-0.99) were predictive of clinical relapse.

Variables	Flare up (n=57)	No flare (n=260)
Age (mean ± SD)	51.2 ± 14.6	57.9 ± 12.5
Endoscopic score ≤1	22	182
Endoscopic score ≥2	35	78
Geboes grade <2	33	224
Geboes grade >2	24	36

CONCLUSION: Histological activity and younger age are significant predictors of disease relapse in patients undergoing surveillance endoscopy. Endoscopic activity with standard white light endoscopy did not predict clinical relapse. Better non-invasive markers of disease relapse are required for patients with ulcerative colitis.

P1425 LUMINAL NITRIC OXIDE (NO) IS AN EARLY PREDICTOR OF COLECTOMY IN CORTICOSTEROID-TREATED ACUTE COLITIS

P. M. Hellström[1,*], M. Lönnkvist[2], M. Holst[3], T. Ljung[4]. [1]*Department of Medical Sciences, Uppsala University, Uppsala,* [2]*Department of Medicine,* [3]*Department of Woman and Child Health, Karolinska Institutet,* [4]*MSD, Merck Sharp Dohme, Stockholm, Sweden*

INTRODUCTION: NO is known to be up-regulated in inflammatory conditions and can be used as a marker of inflammatory activity. We analysed rectal NO before and after three days of glucocorticosteroid (GCS) therapy in hospitalized patients with severe acute colitis.
AIMS&METHODS: The aim of the study was to study the levels of rectal NO in relation to GCS response and colectomy. Fifty hospitalized patients with acute severe colitis, i.e. Mayo score >10 or Harvey Bradshaw index >10, together with bloody stools were studied. Their median age was 41 years (range 20-78). All patients were given treatment with GCS directly upon admission to the hospital and monitored for the subsequent 30 days. Rectal NO levels were measured with a balloon catheter and analysed as parts per billion (ppb) in rectal gas by chemiluminescence before therapy onset and at day 3 of treatment. Rectal NO levels were compared to clinical activity index and and C-reactive protein (CRP). Values are given as means ± SEM.
RESULTS: The GCS non-responders had significantly lower NO levels than the GCS responders at both baseline and day 3 ($p<0.05$). Furthermore, even lower NO levels were found in patients who were later subjected to colectomy ($p<0.01$) at both baseline and day 3. Using an upper cut-off level of 2239 ppb, the sensitivity and specificity was 86% and 81%, respectively. In ROC analysis, the area under the curve 0.88 and the likelihood ration 4.8. Kaplan-Meier analysis showed that patients with base3line NO levels lower than 2239 ppb were at significantly higher risk of colectomy within one month from onset of GCS treatment ($p<0.0001$). Twelve out of 18 (67%) patients with NO <2239 ppb were colectomized, whereas the corresponding number in patients with NO >2239 ppb was two out of 32 (6%) and odds ratio of 10. CRP levels did not differ between responders and non-responders to GCS therapy, neither did disease activity indices.
CONCLUSION: Rectal NO is a sensitive surrogate marker that is feasibly and conveniently measured. Rectal NO displays reliable predictive properties for colectomy over a 1-month period in patients with acute severe colitis treated with systemic GCS.

P1426 CORRELATION BETWEEN SEVERITY OF ENDOSCOPIC LESIONS AND CLINICAL ACTIVITY IN A COHORT OF CROHN'S DISEASE PATIENTS FOLLOWED UP FOR 5 YEARS AFTER ILEO-COLONIC RESECTION

S. Onali[1,*], E. Calabrese[1], C. Petruzziello[1], G. Condino[1], M. Ascolani[1], E. Lolli[1], F. Pallone[1], L. Biancone[1]. [1]*Department of Systems Medicine, Gastroenterology Unit, University of Rome Tor Vergata, Rome, Italy*

INTRODUCTION: Ileocolonoscopy (IC) represents the gold standard for assessing Crohn's Disease (CD) recurrence. Small Intestine Contrast Ultrasonography (SICUS), is a non invasive technique visualizing small bowel lesions in CD. The predictive role of severe endoscopic recurrence at 1 year for subsequent clinical recurrence at 3 years has been demonstrated, while the longer term predictive role of IC for predicting the clinical outcome of CD patients (pts) after surgery is undefined.
AIMS&METHODS: In order to assess this issue, in a prospective longitudinal study, we aimed to assess, in a cohort of CD pts undergoing ileo-colonic resection, possible correlations between the endoscopic score of recurrence at 1 year and clinical activity assessed yearly for up to 5 years. At this purpose, from July 2003 to Feb. 2012, 40 CD pts undergoing ileo-colonic resection were enrolled. IC and SICUS were performed at 1 yr and pts were prospectively followed up for 5 years, with clinical activity (CDAI) assessed yearly for 5 years. At 1 year, recurrence was assessed by IC (Rutgeerts≥2) and SICUS (wall thickness≥5 mm). Data were expressed as median (range). Correlations between the endoscopic score and CDAI were assessed by the Spearman correlation test.
RESULTS: CD group included 40 pts (23M, age 30 yrs, range 16-69), with stricturing (25/40; 63%) or penetrating CD (15/40; 37%). Among risk factors for recurrence, 16 (40%) pts were smokers, familial history of IBD was shown by 3 pts (8%). The Table summarizes the proportion of pts with endoscopic and SICUS findings compatible with recurrence at 1yr and with clinical recurrence in the 5 years follow up

Recurrence	1 yr Clinical (n=40)	IC (n=40)	SICUS (n=40)	2 yrs Clinical (n=40)	3 yrs Clinical (n=40)	4 yrs Clinical (n=40)	5 yrs Clinical (n=40)
Total N (%)	3 (7.5%)	31 (78%)	24 (60%)	10 (25%)	5 (13%)	3 (7.5%)	5/40 (12%)

When the severity of endoscopic recurrence at 1 year was correlated with the CDAI score, a significant correlation was observed with the CDAI score at 2 yrs ($p=0.007$; $r=0.41$), while no significant correlation was observed with the CDAI score at 1, 3, 4 and 5 years ($p=0.23$;$r=0.19$;$p=0.52$;$r=0.10$;$p=0.86$;$r=0.02$;$p=0.41$;$r=0.13$, respectively). In our study population, a low frequency of clinical recurrence was observed at 5 years (16/40; 40%).
CONCLUSION: In a cohort of CD patients followed up for 5 years after ileo-colonic resection, the severity of endoscopic recurrence at 1 year was predictive of clinical relapse at 2 years, but not at subsequent longer term follow up.

P1427 FREQUENCY AND OUTCOME OF TUBERCULOSIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE RECEIVING INFLIXIMAB IN OUR TERTIARY CENTER

T. Molnár[1], K. Farkas[1], F. Nagy[1], Z. Szepes[1,*], A. Bálint[1], R. Bor[1], T. Wittmann[1]. [1]*First Department of Medicine, UNIVERSITY OF SZEGED, Szeged, Hungary*

INTRODUCTION: The increasing use of biological therapy may be responsible for the increasing risk of tuberculosis (TB) infection in inflammatory bowel disease (IBD).
AIMS&METHODS: The **aim** of our retrospective study was to determine the frequency and outcome of TB infection in our IBD patients receiving infliximab. Using our database we assessed the data of IBD patients who has been receiving infliximab in the past 10 years in our tertiary centre to select those with TB infection. Before infliximab administration all patients were screened to exclude active TBC with chest x-ray, physician examination and with the history of TB infection.
RESULTS: Active pulmonary TB was diagnosed in 3 of 237 patients (2 with ulcerative colitis, one with Crohn's disease, mean age at the diagnosis of TB: 39 years) treated with infliximab (1.3% of patients, 0.84/100 patient-years). One of the patients developed relapse of previous TB. Every patient developed TB after the third infliximab infusion. Two received concomitant thiopurine, one concomitant prednisolone therapy at the time of infliximab therapy. Specific anti tuberculosis therapy (rifampicin+isoniazid+ pyrazinamide+ethambutol) was administered with good response. At the present every patient is in clinical remission, although one of them underwent an ileostomy operation due to severe perianal fistulosis.
CONCLUSION: The acceptable frequency of TB infections is less than 1/100 patients in IBD during anti-TNF therapy using adequate screening procedures. In our tertiary center the frequency of TB infections is within an acceptable range, although it might be further decreased by using special methods, etc. Quantiferon test in questionable cases. The response to anti tuberculosis therapy in anti-TNF induced TB infection was good.

P1428 RISK OF ISCHEMIC HEART DISEASE IN PATIENTS WITH ULCERATIVE COLITIS.

T. Ternushchak[1,*], I. Chopey[1], O. Ternushchak[2], K. Chopey[1], A. Bratasyuk[1]. [1]*Chair of Therapy and Family Medicine,* [2]*Surgical Diseases, Uzhhorod National University, Uzhhorod, Ukraine*

INTRODUCTION: Systemic inflammation is associated with development of atherosclerosis and ischemic heart disease (IHD) [1]. Patients with ulcerative colitis (UC) have a high risk of being diagnosed with IHD, especially within the first year after UC diagnosis, potentially reflecting ascertainment bias [2]. We found it's quite interesting since there are not many studies on this topic and they are mainly retrospective.
AIMS&METHODS: we conducted a longitudinal cohort study of patients with UC compared with non-UC population. A total of 186 UC patients and 214 matched controls were followed-up of about 5.8 years. The primary outcome was the development of cardiovascular events. Traditional and nontraditional IHD

risk factors were assessed. Using regression analysis, we estimated the incidence rate ratios (IRRs) for IHD with 95% confidence interval (CI) and impact of each risk factor on the outcomes.
RESULTS: patients with UC had an increased risk of IHD (IRR=1.84; 95% CI 1.79 to 1.89) compared with controls. The risk of IHD was particularly high in the first year after UC diagnosis (IRR=2.26 95% CI 1.34 to 3.18). During follow-up period after UC diagnosis, the risk of IHD was 1.43 (95% CI 1.31 to 1.55). UC patients had significantly lower rates of traditional IHD risk factors (hypertension, diabetes mellitus, smoking, dyslipidemia and body mass index (BMI) $\geq$ 30; $p<0.01$). Among nontraditional risk factors, an elevated C-reactive protein (CRP), serum tumor necrosis factor-alpha (TNF-α) and IL-6 levels were a risk factor for IHD development in UC group (IRR = 4.13; 95% CI 3.16 to 5.08). The risk of IHD was lower among UC patients using 5-aminosalicylic acids (IRR=1.27; 95% CI 1.06 to 1.48) than among non-users (IRR=1.61; 95% CI 1.26 to 1.94) ($p < 0.05$), especially among oral corticosteroid users. Also patients treated with thiopurines and TNF- α antagonist or surgically tended to have reduced IRRs for IHD.
CONCLUSION: an increased incidence of events was noted in UC patients despite having lower rates of traditional risk factors. Additionally, the increased long-term risk of IHD in UC may be related to chronic inflammation. It is required further investigation into how to reduce IHD risk in UC patients.

P1429 CYTOMEGALOVIRUS (CMV) AND EPSTEIN BARR VIRUS (EBV) SPECIFIC ELISPOT ASSAYS DETECT FREQUENT REACTIVATION OF CMV AND EBV IN ULCERATIVE COLITIS

D. Bettenworth[1], M. Ross[1], M. Brückner[1], J. B. Martin[1], H. Heinzow[1], A. Lügering[2], T. M. Nowacki[1,*]. [1]*Department of Medicine B, Gastroenterology, University Hospital of Münster,* [2]*Medical Care Center Portal 10, Münster, Germany*

INTRODUCTION: Patients suffering from Ulcerative Colitis (UC) are often immunosuppressed as a result of the disease, treatment or poor nutrition, rendering these patients susceptible to the reactivation of latent viral infections such as CMV or EBV. However, reliable non-invasive tools to assess the reactivation of pathogenic viruses are missing, especially since reactivation mainly occurs in the gut mucosa and not necessarily results in viremia.
AIMS&METHODS: We hypothesized that the detection of CMV- and EBV-specific CD8 effector T cells should permit the distinction between dormant and reactivated viral infection. Peripheral blood was obtained from 13 female and male UC patients; peripheral blood mononuclear cells (PBMC) were isolated and single cell resolution *ex vivo* ELISPOT measurements of CMV- and EBV-antigen triggered release of IFN-γ, Granzyme B (GzB) and Perforin (PFN) were employed to identify actively ongoing T cell responses towards these viruses. Detection of effector T cells, delineated by GzB and PFN production, determined antiviral activity and was correlated with disease activity indices (Colitis Activity Index).
RESULTS: CMV- and EBV-specific T cells were found to be in an activated state in a significant number of UC patients, in particular during flare-ups of the disease (EBV reactivity was detected in 6 of 13 patients, CMV reactivity in 5 of 13 patient. While CMV reactivity was associated with greater disease activity with significantly less CMV reactive patients being in clinical remission (0% vs. 63%, $P<0.05$), EBV reactivity was not associated with active disease (remission rates 33% vs. 43% for EBV reactive/nonreactive, respectively). Additionally, reactivity against CMV was associated with longer disease duration. Interestingly, PCR analysis on serum failed to detect CMV DNA during flares.
CONCLUSION: Our data show that during active UC there is a flare of T cell activity against CMV and EBV in a substantial proportion of patients, suggesting viral reactivation not detected by serum CMV DNA PCR. While it remains open whether viral reactivation is a cause or consequence of IBD, our data suggest that CMV reactivation is of clinical significance while EBV reactivation appears to be a bystander phenomenon. Monitoring of antiviral effector T cells with ELISPOT analysis can provide novel insights into the role of viral infection in UC as well as in other cases of immunosuppression in which patient care critically depends on sensitive and reliable detection of a reactivation of viral infection.

P1430 PREDICTIVE VALUE OF FAECAL CALPROTECTIN IN PATIENTS UNDERGOING COLONOSCOPY: A COST-EFFECTIVE ANALYSIS

U. I. Aujla[1,*], B. Hayee[1], R. Sherwood[2], G. Chung-Faye[1]. [1]*Gastroenterology,* [2]*Clinical Biochemistry, Kings College Hospital, London, United Kingdom*

INTRODUCTION: Faecal calprotectin (FC) is a sensitive surrogate marker of intestinal inflammation in patients presenting with gastrointestinal (GI) symptoms without an established diagnosis.
AIMS&METHODS: The aim of this study was to assess the role of FC to direct endoscopic inestigations in lower GI Symptoms and its cost-effectiveness, which has not been well studied. We retrospectively analysed FC tests and colonoscopies performed at a tertiary referral centre over a 3 year period. Electronic patient records were used to collect clinical information, laboratory, endoscopy and histology results
RESULTS: A total of 648 patients had both FC and a colonoscopy during this period. There were 258 male (40%): 390 female (60%). Median ages were 52.6 and 55.2 years, respectively. 120 patients were diagnosed with histology-confirmed inflammatory bowel disease (IBD), 88 with diverticular disease (DD), 46 with adenomas, 45 with irritable bowel syndrome (IBS), 17 with colorectal cancer (CRC). 246 were normal and 86 (13%) patients with a range of other diagnoses were excluded because of small numbers in each group.
The median FC concentration was significantly elevated in Ulcerative Colitis (UC) and Crohn's Disease (CD) patients compared to normals. There was no difference between the FC values of DD, Adenomas, and IBS patients compared to normals. Kruskal-Wallis' test showed a highly significant difference between the groups (X^2 =140, $P<0.0001$).
Table: 1

Working Diagnosis	Number (%)	FC (Median)	95% CI
UC	72 (11%)	215	120 – 420
CD	48 (7%)	218.5	138 – 475
IBS	45 (7%)	17	09 – 28
CRC	17 (3%)	57	48 – 133
Diverticular Disease	88 (14%)	29.5	16 – 45
Adenomas	46 (7%)	28.5	09 – 50
Normal	246 (38%)	27	21 – 35

As a screening marker of IBD, receiver operating characteristics (ROC) curve analyses with a pre-determined cut-off level of 60 µg/g stool for a normal test, showed a sensitivity of 78%, specificity of 68% and a negative predictive value of 85% for IBD. At the same FC level, the sensitivity of FC for CRC was only 47% and hence cannot be used as a screening marker of CRC.
In patients, aged less than 40 years with a normal calprotectin, colonoscopy could be avoided in the absence of alarm symptoms. Using this approach would result in a 12% reduction in total colonoscopies and its associated complications and a cost saving of 90% in this age group (assuming FC and colonoscopy costs of €45 and €450, respectively).
CONCLUSION: Our findings indicate that FC is significantly elevated in IBD but not in IBS patients, compared to normal controls. In young patients with no alarm symptoms and a normal FC, colonoscopy can be avoided and this strategy considerably reduces healthcare costs.

P1431 A SYSTEMATIC REVIEW OF DE NOVO IBD IN SOLID ORGAN TRANSPLANT RECIPIENT

X. Cao[1,*], sino iIBD group. [1]*gastroenterology, tianjin medical university general hospital, tianjin, China*

INTRODUCTION: De novo inflammatory bowel disease (IBD) arises following solid organ transplant (SOT) unbelievably although increased immunosuppression during post-transplantation, but not infrequently as there is increasing recognition of de novo IBD in this entity recently. It has an incidence that is an order of magnitude higher than that seen in the general population worldwide but the magnitude of this risk has yet to be determined.
AIMS&METHODS: MEDLINE, Cochrane Library, and EMBASE and international conference abstracts are searched and all case reports and cohort studies are included as randomized controlled trials would be difficult for this entity.
RESULTS: 2837 A review of the current literature to date yields a total of 78 reported cases of de novo IBD among 7555 transplants, 58 are in orthotopic liver transplantation (OLT) patients, 13 in kidney, 5 in heart, 1 in BMT and 1 in small bowel transplantation. These cases manifest as UC more commonly than CD as these cases are labeled as ulcerative colitis (UC) in 51, Crohn's disease (CD) in 19 and indeterminate colitis in 8 patients. Over 65% of cases following OLT occur when the indication for transplant is PSC or autoimmune hepatitis. The mean lag time between transplant and IBD diagnosis was 63.0 (10.1-240.0) months. The annual incidence is estimated around 0.2%. Among liver recipients, the annual incidence is much higher at 100 per 100,000 vs. 5.8 per 100,000 in the non-liver organ recipients, and cumulative rates are substantially higher among patients with PSC or AIH (30%) relative to others (10%) following OLT. These cases following OLT are more likely to occur in those patients who has experienced a CMV infection or who has a CMV mismatch, while CellCept and tacrolimus exposure seem be related with those after kidney transplantation.
CONCLUSION: De novo IBD is not limited to OLT recipients. These cases occur in OLT recipients at a rate much higher than the general population and other SOT recipients. It pose management difficulties post-operation since patients diagnosed with de novo IBD require additional medications beyond their transplant immunosuppression for treatment, recognition of this entity has important clinical implications. Interrogations of larger transplant databases would yield some information which could contribute to confirm previously identified risk factors.

P1432 EXTERNAL VALIDATION OF ILEOCOLONOSCOPY BASED SCORING SYSTEM FOR DIFFERENTIAL DIAGNOSIS BETWEEN INTESTINAL TUBERCULOSIS AND CROHN'S DISEASE

Y. M. Park[1,*], J. J. Park[1], S. J. Park[2], S. P. Hong[2], T. I. Kim[2], W. H. Kim[2], J. H. Cheon[2]. [1]*Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine,* [2]*Internal Medicine, Severance Hospital, Yonsei University, Seoul, Korea, Republic Of*

INTRODUCTION: To aid endoscopic differential diagnosis between intestinal tuberculosis(ITB) and Crohn's disease(CD), ileocolonoscopy based scoring system has been proposed.[1]
AIMS&METHODS: The aim of this study was to perform an external validation of this scoring system. A total of 202 consecutive patients with ulcers on ileocolonoscopy(106 ITB, 96 CD) were enrolled. Ileocolonoscopic features of these patients were retrospectively reviewed following predetermined criteria. A score of +1 was assigned to the four endoscopic parameters(anorectal lesions, longitudinal ulcers, aphthous ulcers, and cobblestoning) that are characteristic of CD, and a score of –1 was given to the other four parameters(involvement of <4 segments, patulous ileocecal valve, transverse ulcers, and scars or pseudopolyps) that are characteristic of ITB. Putative diagnosis for CD was made when the sum of the scores for the eight parameters was greater than zero, whereas the diagnosis for ITB was made when that sum was less than zero. Moreover, the diagnosis was regarded as indeterminate when the score was zero.
RESULTS: The mean value for the sum of the scores was 1.05 in patients with CD and –1.73 in patients with ITB($P<0.001$). Four parameters(anorectal lesions [68.8% vs 5.7%], longitudinal ulcers[40.6% vs 10.4%], aphthous ulcers[77.1% vs 22.6%], and cobblestoning [22.9% vs 2.8%]) were significantly more common in patients with CD than in ITB. Four other parameters(involvement of <4 segments[87.7% vs 46.9%], patulous ileocecal valve[25.5% vs 8.3%], transverse ulcers[53.8% vs 16.7%], and scars or pseudopolyps[47.2% vs 32.3%]) were more frequently observed in patients with ITB than in CD. Using ileocolonoscopy based scoring system, the diagnosis of either ITB or CD for this population could have been made correctly in 157 patients(77.7 %), incorrectly in seventeen patients(8.4%), and would not have been made twenty-eight patients(13.9%).
CONCLUSION: Ileocolonoscopy based scoring system is a simple and useful method for initial differentiation between ITB and CD.

P1433 POTENTIALLY HARMFUL RADIATION EXPOSURE RATE AMONG INFLAMMATORY BOWEL DISEASE PATIENTS IS NOT REDUCED IN THE ERA OF BIOLOGICALS

Z. Zelinkova[1,*], T. Hlavaty[1], T. Koller[1], J. Toth[1], A. Krajcovicova[1], M. Huorka[1]. [1]*5th Department of Internal Medicine, Division of Gastroenterology&Hepatology, University hospital, Bratislava, Slovakia, Bratislava, Slovakia*

INTRODUCTION: In the past years, the radiation exposure from diagnostic procedures performed to diagnose the complications of inflammatory bowel disease (IBD) has been documented in several studies. This exposure seems to achieve the level of potentially harmful radiation exposure rate, i.e. equal or more than 50mSv, in about 8% of IBD patients. It has been suggested that the use of anti-tumour necrosis factor (antiTNF) biologicals might reduce the radiation exposure in IBD patients. However, it is not clear whether the proportion of IBD patients with high radiation exposure is also reduced in the era of antiTNF treatment.
AIMS&METHODS: Aim of the study: To assess the rate of potentially harmful cumulative radiation exposure among IBD patients using antiTNF.
Methods: All patients with current antiTNF treatment for whom the information on radiation exposure was available were included and the information on radiation exposure was retrieved from medical reports. The cumulative radiation exposure was calculated based on the radiological standards for each diagnostic procedure. The potentially harmful radiation exposure was considered to be equal or more than 50 mSv.
RESULTS: In total, 120 IBD patients (58% males; mean age 40 years, range 19 to 74 years; 76 Crohn's disease and 44 ulcerative colitis; mean disease duration 10 years, range 1 to 46 years) were included.
The radiological procedures with radiation exposure of the abdomen were abdominal and pelvic CT (74 CT in 46 patients), CT colonography (one patient), CT enteroclysis (25 examinations in 23 patients), abdominal X-ray (18 X-rays in 15 patients), irigography (3 examinations in 3 patients) and ERCP (one patient). The majority of patients (67 patients, 55.8%) had at least one diagnostic procedure involving radiation, with the mean cumulative radiation exposure of 33 mSv (range 5 to 140mSv). Ten patients (8.3%) reached the potentially harmful cumulative radiation exposure of 50mSV or more.
CONCLUSION: The potentially harmful cumulative radiation exposure rate resulting from diagnostic radiological procedures for IBD remains high in the era of antiTNF biological therapy.

P1434 LONG TERM ADALIMUMAB EFFICACY IN STEROID-DEPENDENT CROHN'S DISEASE PATIENTS

A. Orlando[1,*], S. Renna[1], F. Mocciaro[2], M. Cappello[3], R. Di Mitri[2], I. Bravatà[3], M. Cottone[1]. [1]*DI.BI.MIS., Division of Internal Medicine ", "Villa Sofia-V. Cervello"Hospital, Palermo, Italy,* [2]*Gastroenterology unit, Civico-A.R.N.A.S. Hospital,* [3]*DI.BI.MIS., Department of Gastroenterology and Hepatology, University of Palermo, Palermo, Italy*

INTRODUCTION: Adalimumab (ADA) is effective in the induction of steroid-free remission in patients (pts) with steroid-dependent Crohn's disease (CD). We have already reported data on efficacy and prognostic factors of response to ADA in 110 steroid-dependent pts. At week 6, 91% of pts have had a clinical benefit. At the end of the follow-up (mean 14.6 months), 80.9% of responders have maintained the clinical benefit. Only higher induction regimen was related to remission at week 6. At the end of the follow-up, none of the variables were associated with remission.
AIMS&METHODS: All the 110 pts treated in the previous study were followed up for a further 24 months and the following variables were evaluated: maintenance of clinical benefit, ADA discontinuation, mucosal healing, dosage exalation, surgical treatment.
RESULTS: At the end of the follow up (mean 38.6 $\pm$ 8.6 months) 54 pts (49%) were still in maintaining treatment with ADA with significant clinical benefit, 56 pts stopped treatment because of ineffectiveness (35), side effects (15) or mucosal healing (6). Among no responders 16 pts were then treated with infliximab and 11 of them had a clinical response. During the follow up 26 pts received a new induction dosage with 160/80 mg of ADA because of lack of efficacy and 13 of them (50%) had a clinical response. Twenty-eight pts received a 40 mg weekly mainteining treatment and 14 of them (50%) had a clinical response. Mucosal healing were reported in 15 of 60 pts who underwent colonoscopy (25%). At the end of the follow up 19 pts were operated on. At univariable analysis a lower induction regimen (80/40 mg) were associated with a best response to infliximab ($P < 0.001$, OR 6, 95% CI, 1.01–35.91) while 160/80 mg induction regimen with a lower risk of surgery respect to 80/40 mg (p=0.04, OR 0.311 95% CI 0.969 - 0.998). At the end of follow-up 15 pts (13.6%) developed side effects that determined discontinuation of the treatment.
CONCLUSION: Half of the steroid dependent CD pts treated with ADA maintained a clinical benefit after a mean follow up of about 3 years and 25% of them obtained a mucosal healing, without high risk of side effects. The higher induction regimen (160/80 mg) was confirmed to be the best strategy to maintain a long term efficacy of ADA avoiding surgery. In case of lack of efficacy a new induction dosage or a weekly maintaining treatment are to consider a therapeutic option before discontinuing ADA.

P1435 SERIAL INTRALESIONAL INJECTIONS OF INFLIXIMAB CAN MODIFY COLONIC STRICTURING PROCESS

A. Echarri[1,*], V. Ollero[1], J. Gallego[2], J. A. Rodriguez[1], J. Castro[1]. [1]*Gastroenterology,* [2]*Radiology, HOSPITAL ARQUITECTO MARCIDE, Ferrol, Spain*

INTRODUCTION: Mucosal healing with antiTNF-treatments develops as a surrogate marker of disease modification. However, complete healing process is only achieved in 40-50% of the IBD patients on anti-TNF maintenance therapy, with partial mucosal healing seen in nearly 25-30% of the cases.
The persistance of colonic mucosal lesions can lead to complications as intestinal strictures, especially in the rectosigmoid location, that often leads to obstruction and surgery. Higher antiTNF concentrations given through local injection could favor healing and prevent complications.
AIMS&METHODS: The aims of our study were: to analyze the presence of inflammatory strictures in the recto-sigmoid area in CD patients on antiTNF treatment and to assess the effect of local treatment with Infliximab in the disease outcome.
Ninety eight CD patients who have been treated with antiTNF for severe or refractory disease were followed up during 4 years, analyzing the cases with persistence of inflammation and stenosis of the rectosigmoid region while the other colonic areas were healed. Nine patients with persistent recto-sigmoid stricturing disease refractory to sistemic antiTNF were injected with Infliximab circumferentially (concentration: 5mg/mi; 100mg per session), using a standard sclerotherapy needle trhough the channel of a gastroscope or pediatric colonoscope. The injection process was performed every 4 months until the healing was achieved.
RESULTS: We have found 16 patients that have showed a good clinical response to antiTNF treatment, with mucosal healing of the colonic mucosa but with persistance of inflammatory stricture in the rectosigmoid area. (16%)
Nine patients were treated during the follow-up period with serial intralesional injections of infliximab with the following results: 4 patients (44%), showed complete mucosal healing (in one case combination with balloon dilation was needed); 4 patients (44%), presented reduction in their inflammatory component, with an increase in caliber of the stenosis; and 1 case (12%), was operated two months after the single injection, because of intestinal obstruction.
Of the seven patients not treated, 5 (72%), were operated during the follow-up period.

CONCLUSION:
1-Rectosigmoid location, where strictures are frequent, could be an area of difficult healing with antiTNF systemic treatment.
2-Intralesional injection of infliximab is able to stop or slow down the stricture process formation.

P1436 EFFECTS OF ANTI-TNF-A AND STEROID TREATMENT ON MACROPHAGE ACTIVATION ESTIMATED BY SOLUBLE CD163 LEVELS IN INFLAMMATORY BOWEL DISEASE

A. Dige[1,*], S. Stoy[1], K. L. Thomsen[1], C. L. Hvas[1], J. Agnholt[1], H. J. Moeller[2], H. Groenbaek[1]. [1]*Medical Department V (Hepatology and Gastroenterology), [2]Department of Clinical Biochemistry, Aarhus University Hospital, 8000 Aarhus C, Denmark*

INTRODUCTION: Activated macrophages shed the hemoglobin-haptoglobin scavenger receptor CD163 from their surface into the circulation. We used soluble sCD163 as a marker of macrophage activation to investigate the *in vivo* macrophage activation in patients with inflammatory bowel disease (IBD) and the modulation of these macrophages by anti-inflammatory treatment.
AIMS&METHODS: We included 58 Crohn's disease (CD) patients and 40 ulcerative colitis (UC) patients; 90 healthy individuals served as controls (HC). All patients had active disease at inclusion and were followed for 7 weeks during treatment with either anti-tumor necrosis factor a (anti-TNF-α) or prednisolone. We measured plasma sCD163 levels at baseline, day 1 (anti-TNF-α treated) and 1 and 7 weeks after treatment initiation. Furthermore, using flow cytometry, the CD163 expression was measured on circulating CD14+ monocytes in 21 CD patients receiving anti-TNF-α treatment.
RESULTS: The baseline levels of sCD163 were similarly elevated in both CD (1.99 [1.80-2.18] mg/l) and UC patients (2.07 [1.82-2.32] mg/l) compared with HC (1.51 [1.38-1.63] mg/l), p=0.001, respectively. Anti-TNF-α treatment induced a rapid decrease in sCD163 levels in CD and UC patients at day 1 after initiation of treatment. Such rapid decrease was not observed in patients treated with prednisolone. In UC patients, anti-TNF-α treatment normalised sCD163 comparable to HC levels, whereas CD patients had constitutively increased sCD163 levels. We observed no changes in CD163 expression on circulating CD14+ monocytes during anti-TNF-α treatment.
CONCLUSION: This study demonstrates increased macrophage activation with elevated sCD163 levels in IBD patients. Anti-TNF-α reduced sCD163 levels acutely suggesting an effect on macrophage activation in IBD per se.

P1437 THERAPEUTIC DRUG MONITORING OF INFLIXIMAB IN INFLAMMATORY DISEASE PATIENTS IN A TEACHING HOSPITAL SETTING: PRELIMINARY RESULTS OF A PROSPECTIVE COHORT STUDY

A. Warman[1,*], J. W. A. Straathof[2], L. J. Derijks[1]. [1]*Clinical Pharmacy, [2]Gastroenterology & Hepatology, Máxima Medical Center, Veldhoven, Netherlands*

INTRODUCTION: Infliximab (IFX) trough levels correlate with clinical remission and endoscopic improvement of inflammatory bowel disease (IBD) and antibodies to infliximab (ATI's) are responsible for suboptimal IFX trough levels to a large extent. Although therapeutic drug monitoring (TDM) of IFX is advocated, this is not routinely implemented in clinical practice. We therefore conducted a prospective cohort study in our total IBD-population treated with IFX.
AIMS&METHODS: Patient demographics, medication- and clinical history were collected from the electronic hospital information system and blood was drawn for determination of IFX trough levels and ATI's. Subsequently, disease activity indices (Crohns disease activity index (CDAI) and Truelove Witts disease activity index (TWDAI) for Crohn's disease (CD) and ulcerative colitis (UC) respectively) and quality of life scores were obtained.
RESULTS: 110 patients were included in this study: 50 male / 60 female, 65 CD (59%) / 45 UC (41%), median age 40 years (range: 18-86). Individual IFX levels varied from <1.0 microg/ml to 38.8 microg/ml. In 19 (17%) patients IFX trough levels were not detectable. In this subgroup 11 patients (58%) had developed ATI's.
CONCLUSION: TDM of IFX in IBD-outpatients in a teaching hospital setting revealed large inter-individual differences in IFX trough levels. Above all, IFX trough levels were not detectable in a significant part of IBD-patients. TDM is indicated to reveal this group of patients. Individualizing IFX treatment of these patients may lead tot improvement of therapeutic dosage and less ATI formation. Further investigation is necessary to determine financial impact.

P1438 INCREASED RISK OF ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES IN PATIENTS WHITH PAST EXPOSURE TO THIOPURINES FOR INFLAMMATORY BOWEL DISEASE

A. Lopez[1,*], M. Mounier[2], A.-M. Bouvier[2], J.-B. Chevaux[1], L. Beaugerie[3], M. Maynadie[2], L. Peyrin-Biroulet[1]. [1]*Hepato Gastro-enterology, University Hospital of Nancy, Vandoeuvre-lès-Nancy, [2]Hepato Gastro-enterology, University Hospital of Dijon, Dijon, [3]Hepato Gastro-enterology, Saint-Antoine hospital, Paris, France*

INTRODUCTION: Immunosuppressive thiopurines like azathioprine are associated with an increased risk of leukemogenesis. We assessed the risk of myeloid disorders (MD), such as acute myeloid leukemia (AML) and myelodysplastic syndromes (MS) in French patients with inflammatory bowel disease (IBD).
AIMS&METHODS: We performed a prospective observational cohort study of 19,486 patients with IBD, enrolled from May 2004 to June 2005, who were followed up until December 31, 2007. The incidence of MD in the general population, used for reference, was determined from the French Network of Cancer Registries.
RESULTS: During the 49,736 patient-years follow-up, 5 patients were diagnosed with incident MD, consisting of 2 AML and 3 MS. Four (one patient with ongoing treatment and 3 patients with past exposure) out of 5 patients were exposed to thiopurines. The risk of MD was not increased among the overall IBD population, compared with the general population, with a standardized incidence ratio (SIR) of 1.80 (95% confidence interval [CI] 0.58-4.20). The risk of MD was not increased among IBD patients with ongoing thiopurine treatment (SIR = 1.54, 95 % CI = 0.05-8.54), while those with past thiopurine exposure had an increased risk of MD (SIR = 6.98, 95% CI 1.44-20.36).
CONCLUSION: Past exposure to thiopurines increases the risk of MD by 7-fold among IBD patients. This finding should be part of risk assessment when initiating azathioprine either alone or in combination with anti-TNF therapy in IBD patients.

P1439 DIETARY HABITS AND INFLAMMATORY BOWEL DISEASE OUTCOMES: A TUNISIAN MONOCENTRIC STUDY.

B. M. Nadia[1,*], L. Asma[1], S. Meriem[1], F. Monia[1], B. Jalel[1], F. Azza[1]. [1]*Gastroenterology A, La Rabta Hospital, tunis, Tunisia*

INTRODUCTION: Preliminary studies suggest that lifestyle changes, dietary adjustments and specific supplements could be useful additions to treatment in patients with Crohn's disease and ulcerative colitis.
AIMS&METHODS: AIM: to examine the influence of dietary habits in a cohort of Tunisian patients with inflammatory bowel diseases on their disease course.
Patients and Methods : Patients with Crohn's disease or ulcerative colitis diagnosed at least 2 years ago were evaluated. They were enrolled from either inpatient or outpatient clinics. Prospective registration of alimentary habits was conducted through a recall questionnaire to provide informations on the daily intake of nutrients during a 1-week period. Retrospective analysis of clinical data on the disease outcome was carried out. We investigated correlations between dietary habits and the need for surgery, immunosuppressors or immunomodulators and the occurance of an acute severe flare, defining a severe course disease. Statistical analysis was performed with SPSS software version 21.0.
RESULTS: Seventy consecutive patients were colliged: 36 patients having Crohn's disease (51,4%), and 34 patients having ulcerative colitis (48,6%). Male to female ratio was 0,71. Severe Crohn's disease was noted in 68% of patients: there were 13 patients who had severe acute colitis, 24 patients had underwent surgery and 48 patients have been put on immunosuppressors or immunomodulators. Patients who had severe acute colitis had slightly a higher intake per week of tea (237ml vs 148ml, p=0,05) and significantly less intake of coffee (30ml vs 191ml, p=0,028). Patients who underwent intestinal resection consumed per week significantly more pulses (72,6g vs 36,88g, p=0,015), more cereals (487,5g vs 322,9g, p=0,025) and more tea (250g vs 145,9g, p=0,022). They had also significantly a higher intake per week of carbohydrate (71,2% vs 53,74%, p=0,039) and considerably less consumption of coffee (0,1ml vs 186,9ml, p=0,034) and less intake of protein (9,75g vs 14,32g, p=0,032). Overall, cheese consumption was significantly less common in patients with a severe engineering (5,1% vs 22,6%, p= 0,03).
CONCLUSION: A high consumption of coffee and cheese and a great intake of protein may be associated with favorable outcomes in patients with inflammatory bowel diseases. Our findings should be confirmed on prospective studies evaluating the influence of diet on the disease course of inflammatory bowel disease.

P1440 SAFETY AND EFFICACY OF BOLUS ADMINISTERED FERRIC CARBOXYMALTOSE (500 MG) IN THE TREATMENT OF IRON DEFICIENCY ANAEMIA IN IBD PATIENTS

D. Jacobsen[1,2,*], M. Wiesenthal[3], F. Hartmann[1], A. Dignass[4], G. Virgin[5], J. Stein[2,6]. [1]*Marien hospital, [2]Crohn-Colitis-Centrum Rhein-Main, [3]University of*

Frankfurt, [4]Apaglesion Markus Hospital, Frankfurt a.M., [5]Vifor Pharma, Munich, [6]Hospital of Sachsenhausen, Frankfurt a.M., Germany

INTRODUCTION: Iron deficiency anaemia (IDA) is a common haematological complication in IBD with potentially serious clinical consequences and often requires intravenous (IV) iron therapy. Ferric carboxymaltose (FCM) is a stable, non-dextran iron formulation which can be administered intravenously in large single doses to treat IDA.
AIMS&METHODS: To evaluate safety and effictiveness of multiple or single bolus IV injections of 500 mg FCM administered within 2 minutes compared to standard infusions (15 min) of 500 mg FCM in IBD patients with IDA. Secondary endpoints were improvements in haemoglobin and iron indices. Adult IBD patients with haemoglobin values less than 12 g/dL and ferritin less than 30 µg/L or transferrin saturation less than 16% received 500 mg FCM either as a single bolus injection in 2 minutes (n = 40) or intravenous infusion over 15 min (n = 41).
RESULTS: The increase in haemoglobin and iron indices was similar in both FCM groups. Both groups also reported similar incidences and types of adverse events, all known for FCM, and no serious adverse events were reported. Furthermore, transient, unsymptomatic hypophosphatemia not associated with adverse events or clinical sequelae occurred in similar rates in both groups.
CONCLUSION: FCM administered in single doses of up to 500 mg within 2 minutes is safe, well tolerated and associated with improvements in haemoglobin and iron indices comparable to administration of FCM via infusion.

P1441 CLINICAL PREDICTORS OF IMMUNOMODULATION AND PHENOTYPE PROGRESSION IN CROHN'S DISEASE

E. Rodrigues-Pinto[1,*], F. Magro[1], R. Coelho[1], P. Andrade[1], J. Santos-Antunes[1], S. Lopes[1], C. Camila-Dias[2], G. Macedo[1]. *[1]Gastroenterology, Centro Hospitalar São João, Porto, [2]Health Information and Decision Sciences, Centro Hospitalar São João, Faculty of Medicine University of Porto, Portugal*

INTRODUCTION: Crohn's disease (CD) has a progressive course with decreasing frequency of inflammatory pattern [B1] and increasing frequency of stenotic [B2] and/or penetrating [B3] phenotype.
AIMS&METHODS: Evaluate clinical criteria for earlier initiation of immunomodulators or anti-tumor necrosis factor alpha (antiTNFα), as well, as earlier change of the phenotype (B1 to B2 or B3). Cross-sectional study of 736 patients with CD followed in the inflammatory bowel disease outpatient clinic.
RESULTS: Azathioprine was started earlier in male patients (63 months [47.4, 78.6] *vs* 71 months [52.8, 89.2], p=0.005) and in patients with involvement of the upper gastrointestinal tract [L4], regarding patients with ileocolic [L3], colonic [L2] or ileal [L1] involvement (51 months [31.3, 70.6] *vs* 60 months [43.6, 76.4] *vs* 71 months [32.4, 109.6] *vs* 84 months [66.1, 101.8], p=0.026). AntiTNFα therapy was started earlier in patients diagnosed before 40 years old (p=0.004) and in patients with perianal disease (197 months [145.0, 249.0] *vs* 341 months [276.0.; 406.0] p < 0.001). The change in phenotype was earlier in patients with L4 location in respect to L1, L2 or L3 (95 months [58.6, 131.4] *vs* 138 months [99.3, 176.7] *vs* 174 months [128.2, 219.8] *vs* 253 months [200.0, 306.0], p < 0.001), as well as, in male patients (128 months [99.0, 157.0] *vs* 195 months [154.7, 235.3], p=0.004).
CONCLUSION: Diagnosis before 40 years old, the involvement of the upper gastrointestinal tract, perianal disease and male gender are associated with an increased need for immunomodulation and earlier progression of phenotype.

P1442 IMMUNOMODULATION CHANGES PHENOTYPE AND NEED FOR SURGERY IN CROHN'S DISEASE

E. Rodrigues-Pinto[1,*], F. Magro[1], R. Coelho[1], P. Andrade[1], J. Santos-Antunes[1], S. Lopes[1], C. Camila-Dias[2], G. Macedo[1]. *[1]Gastroenterology, Centro Hospitalar São João, [2]Department of Health Information and Decision Sciences, Faculty of Medicine University of Porto, Porto, Portugal*

INTRODUCTION: In Crohn's disease (CD) there is cumulative structural damage. Early in the disease, it is characterized by a nonstenotic, nonpenetrating behaviour (B1), with progression, over time, to fibro-stenosing (B2) and/or penetrating (B3) phenotype, with frequent need for surgery.
AIMS&METHODS: To evaluate whether treatment with immunomodulators or anti-tumor necrosis factor-alpha (antiTNFα) changes the progression of disease and/or need for surgery in CD. Cross-sectional study in patients with CD followed in the inflammatory bowel disease outpatient clinic.
RESULTS: 736 patients with CD (368 female) were followed during 12.3 years (± 8.4). Of these patients, 87% had B1 phenotype at diagnosis and 24% of them progressed to phenotype B2, 20% progressed to B3 and 49% required surgery. Patients who maintained B1 phenotype initiated earlier either azathioprine either antiTNFα than those who progressed to B2 or B3 (respectively, 25 months [0 – 371] *vs* 56 months [0 – 420], p < 0.001 and 67 months [0 – 364] *vs* 102 months [0 – 395], p < 0.001). The median time till change of phenotype (B1 to B2 or B3) was higher in patients under azathioprine (361 months [306.3, 415.7] *vs* 72 months [47.8, 96.2], p < 0.001), as well as, in those under antiTNFα (141 months [130.4, 167.8] *vs* 61 months [86.2, 100.9], p < 0.001). This was also observed after exclusion of patients with less than 3 years (p < 0.001 for azathioprine and for antiTNFα) and 5 years of follow-up (p < 0.001 for azathioprine and for antiTNFα). Patients who were never submitted to surgery due to CD started either azathioprine either antiTNFα earlier than the ones who were operated (respectively, 19 months [0 – 420] *vs* 70 months [0 – 394], p < 0.001 and 50.5 months [0 – 364] *vs* 103.5 months [0 – 395], p < 0.001). The median time to first surgery was higher in patients under azathioprine (361 months [306.3, 415.7] *vs* 71 months [47.6, 94.4], p < 0.001), as well as, in those under antiTNFα (271 months [84.7, 104.9] *vs* 108 months [74.6; 141.4], p < 0.001).
CONCLUSION: Treatment with immunomodulators and/or antiTNFα changes the phenotype of the disease and the need for surgery in CD.

P1443 MACROCYTIC ANAEMIA SECONDARY TO SULPHASALAZINE IN PATIENTS AFFECTED BY ULCERATIVE COLITIS AND CROHN'S COLITIS: IS A REAL ISSUE?

E. Lolli[1,*], E. Calabrese[1], P. Scarozza[1], G. Condino[1], M. Ascolani[1], S. Onali[1], C. Petruzziello[1], F. Zorzi[1], L. Biancone[1], F. Pallone[1]. *[1]Gastroenterology Unit, University of Rome Tor Vergata, Rome, Italy*

INTRODUCTION: Anaemia is a multifactorial complication of inflammatory bowel disease (IBD) with a wide prevalence of 9–74%. Sulphasalazine (SASP) inhibits methylene-tetrahydrofolate reductase, impairing folate absorption and subsequently affecting erythropoiesis. Megaloblastic anaemia during SASP therapy has been reported, but not quantified.
AIMS&METHODS: Our retrospective study evaluated the presence of macrocytic anaemia related to folate deficiency in patients (pts) treated with SASP, affected by ulcerative colitis (UC) or Crohn's disease (CD) colitis. A total of 1226 UC and CD pts were analyzed retrospectively. Eighty seven per cent of pts were excluded from the final analysis. One hundred sixty out of 1226 pts (13%) were analysed. One hundred thirty-nine UC pts (85 M; median age 50; median disease duration 132 mos; 61% extensive colitis, 16% left UC, 23% distal UC) and 21 CD pts (11 M; median age 36; median disease duration 28 mos; 38% penetrating behaviour, 62% non penetrating non structuring) were considered.
RESULTS: In UC group 4/139 pts had concomitant diseases possibly interfering with folate absorption (celiac disease in 1 and microcythemia in 3). Ninety-three per cent of pts were in remission with a median follow-up of 42 mos. SASP duration therapy was 48 mos; concomitant treatments possibly interfering with folate absorption were proton pump inhibitors in 10% of pts, immunomodulators in 17 % of pts, hypoglycemic agents in 5% of pts, anticonvulsivants in 0,7 % and NSAIDs in 6% of pts. Fourty-three out of 139 pts (32%) had anaemia (28/43 with normal MCV, 12/43 with reduced MCV, 3/43 with increased MCV). Nine out of 139 pts (6 %) had macrocytosis without anaemia. Only 9/43 pts (21%) were taking folate supplementation and 7/43 (16 %) iron supplementation. In colonic CD group 1/21 pts was affected by microcythemia. Eighteen out of 21 pts were in remission with a median follow-up of 34 mos. SASP duration therapy was 24 mos; concomitant treatments possibly interfering with folate absorption were proton pump inhibitors in 5% of pts, immunomodulators in 24% of pts. Five out of 21 pts (24%) had anaemia (3/5 with normal MCV, 1/5 with reduced MCV, 1/5 undefined). Only 1/5 pts (20%) was taking folate supplementation and 1/5 (20%) iron supplementation. Only 1/5 (20%) pts had macrocytosis without anaemia. Folate levels were normal in both groups but only 3/48 pts with anaemia (6 %) had only folate deficiency.
CONCLUSION: In our retrospective study considering UC and colonic CD pts treated with SASP, a low rate of macrocytic anaemia was found and few patients underwent folate supplementation.

P1444 THE FFA2 ANTAGONIST GLPG0974: OPPORTUNITY TO TREAT NEUTROPHIL-DRIVEN INFLAMMATION

F. P. Vanhoutte[1,*], F. Namour[2], S. Dupont[2], D. Polancec[3], W. Haazen[4], M. Petkova[4], A. Van der Aa[1], G. van 't Klooster[1], J. Beetens[1]. *[1]Galapagos NV, Mechelen, Belgium, [2]Galapagos SASU, Romainville, France, [3]Fidelta d.o.o., Zagreb, Croatia, [4]CPU, SGS Life Science Services, Antwerp, Belgium*

INTRODUCTION: Free fatty acids (FFA) have been shown to act as direct signalling molecules through activation of several GPCRs. FFA2 is activated by short chain fatty acids (SCFA) such as acetate, propionate or butyrate. FFA2 is mainly expressed on immune cells (neutrophils, monocytes, B lymphocytes), enterocytes, entero-endocrine cells and adipocytes. FFA2 has been shown to play a major role in SCFA-induced neutrophil activation and migration. Studies in FFA2 knock-out mice suggest an important contribution of FFA2 to the development and control of inflammation. In IBD patients, FFA2 expression in colon biopsies was shown to be upregulated and was reduced after successful treatment with Remicade.
We identified GLPG0974 as a potent and selective antagonist of human FFA2. *In vitro*, it potently inhibits acetate-induced calcium flux in HEK293 cells and acetate-induced human neutrophil migration. In a human whole blood assay, GLPG0974 inhibits acetate-stimulated neutrophil activation, as evidenced by CD11b activated epitope [AE] expression. It is highly selective for FFA2 over the close homologues FFA1 and FFA3, as well as other non-related GPCRs.
AIMS&METHODS: The safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of GLPG0974 were evaluated in healthy volunteers after single (SD) and multiple administrations for 14 days (MAD). The PD was assessed by flow cytometric measurement of neutrophil activation (CD11b[AE] expression) in whole blood upon *ex vivo* stimulation by acetate.

RESULTS: Single doses up to 250 mg and multiple doses up to 400 mg daily were safe and well-tolerated.
GLPG0974 administered under fed conditions as capsules or oral solution, was slowly absorbed with a median t_{max} of about 3 h and eliminated with a mean $t_{1/2}$ of about 5.5 h. The GLPG0974 PK was dose proportional over the 50 to 400 mg daily dose range.
After single administration, GLPG0974 substantially inhibited acetate-stimulated neutrophil activation in whole blood compared to baseline. In general, the inhibitory effect peaked at 2 h post dose. The PK/PD data showed a clear relationship between drug exposure and PD effect. In the MAD study neutrophil activation was inhibited to the same extent as observed in the SD study. The inhibitory activity was sustained for at least 12 h after dosing.
CONCLUSION: Inhibition of neutrophil migration into the gastro-intestinal tract may prevent neutrophil-induced tissue damage as observed in ulcerative colitis. A Proof-of-Concept study is initiated to evaluate the safety and efficacy of GLPG0974 in patients with this condition.

P1445 ADALIMUMAB ACHIEVES COMPLETE REMISSION AT 52 WEEKS IN JAPANESE PATIENTS WITH INTESTINAL BEHÇET'S DISEASE

F. Hirai[1,*], S. Tanida[2], N. Inoue[3], K. Kobayashi[4], M. Naganuma[3], A. Camez[5], R. B. Thakkar[6], B. Huang[6], V. Arora[6], M. Ozawa[7], T. Hibi[8]. [1]*Fukuoka University Chikushi Hospital, Fukuoka,* [2]*Nagoya City University Hospital, Aichi,* [3]*Keio University School of Medicine, Tokyo,* [4]*Kitasato University East Hospital, Kanagawa, Japan,* [5]*AbbVie, Ludwigshafen, Germany,* [6]*AbbVie, North Chicago, United States,* [7]*AbbVie GK,* [8]*Kitasato Institute Hospital, Tokyo, Japan*

INTRODUCTION: Behçet's disease (BD) is a chronic, relapsing, multisystem inflammatory disease with oral, dermatologic, genital and intestinal involvement. Elevated serum levels of tumor necrosis factor (TNF) are observed in pts with active disease.[1] The aim of this study was to evaluate the efficacy and safety of adalimumab (ADA), a fully human anti-TNF monoclonal antibody, through 52 weeks (wks) in intestinal BD.
AIMS&METHODS: In this open-label, uncontrolled study, 20 Japanese pts with intestinal BD with typical ileocecal ulcers (≥1cm), refractory to corticosteroids and/or immunomodulators and with severe gastrointestinal (GI) symptoms received ADA 160/80mg at wk 0/2, followed by 40mg every other week (eow) for 52 wks. Dose escalation to 80mg eow was permitted for flare or inadequate response. GI symptom severity was graded from 0 (no symptoms) to 4 (most severe). Ulcer healing was compared to baseline: graded from 0 (healing) to 3 (no change or worsening). The primary endpoint was proportion of pts with marked improvement (MI; defined as reduction of both scores to ≤1) at wk 24; proportion of pts with complete remission (CR; defined as reduction of both scores to 0) was a key secondary endpoint. Non-responder imputation was used for missing data.
RESULTS: 17 pts completed the study; 2 pts and 1 pt discontinued due to adverse events (AEs) and personal reasons, respectively. Mean pt age was 42 yrs. No pts had ocular symptoms at baseline. ADA was increased to 80 mg eow in 6 pts. At wks 24 and 52, 9/20 (45%) and 12/20 (60%) pts achieved MI, respectively. CR was noted in 4/20 (20%) pts at wk 24; the same 4 pts achieved CR at wk 52. Other major symptoms of BD (oral aphthous ulcers, erythema nodosum, and genital ulcers) resolved rapidly (at wk 4), which was sustained up to wk 52. The most frequently observed AE was nasopharyngitis (9 pts); other AEs were consistent with previous ADA trials in inflammatory bowel disease, and no new safety signals were observed.
CONCLUSION: In this study, among pts who responded early, ADA induced and maintained complete remission, comprising endoscopic and GI symptom improvement, through 52 wks in Japanese pts with intestinal BD.

P1446 GUT DIRECTED HYPNOSIS FOR PATIENTS WITH INFLAMMATORY BOWEL DISEASES (IBD)

M. Greifenegg[1], M. Michalski[1], C. Dejaco[1], G. Moser[1,*], Working Group for Psychosomatics in Gastroenterology, Medical University of Vienna.
[1]*Gastroenterologie, MEDIZINISCHE UNIVERSIÄT WIEN, Vienna, Austria*

INTRODUCTION: About 30% of patients with IBD suffers from psychological distress and has a high demand on psychological support. Gut-directed hypnotherapy is suggested to be one of novel treatments for IBD.
AIMS&METHODS: Aim of the study was to evaluate the feasibility and acceptability of this hypnosis for psychological distressed IBD patients in a group setting, and to show possible effects on physical and general wellbeing as well as depression and anxiety. Method: Nineteen patients with IBD received 5-10 sessions of gut-directed-hypnotherapy in group setting (GHT, 6 patients per group) with a mean follow up (FU) of one year. To assess the physical, psychological and general wellbeing, Visual Analog-scales and the Hospital-Anxiety-Depression-Scale were provided at the first and last GHT session, and at FU. Standardized questions were asked to evaluate feasibility and acceptability of GHT.
RESULTS: 17 Patients filled out all questionnaires. At FU there was a significant improvement in physical ($p=.032$), psychological ($p<.0001$) and general ($p=.004$) wellbeing, and a significant reduction of depression ($p<.012$) and anxiety ($p<.0001$). Patients described GHT as a feasible and helpful method and more than 90% would recommend GHT to other IBD patients.
CONCLUSION: GHT is helpful for IBD patients' quality of life and can be offered for psychological distressed IBD patients integrated into a standard treatment plan at tertiary centres. Controlled trials are needed to show possible effects of GHT on the course of the disease.

P1447 EFFECT OF REMISSION STATUS ON THE ABILITY TO MAINTAIN OR ACHIEVE CLINICAL AND ENDOSCOPIC REMISSION AFTER 12-MONTH MAINTENANCE TREATMENT WITH MMX MESALAZINE IN ADULTS WITH ULCERATIVE COLITIS

G. R. Dhaens[1,*], S. Inglis[2], E. Magee[3], P. Streck[3], D. Solomon[3], D. T. Rubin[4], The Ulcerative Colitis Remission Study Group. [1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Shire Pharmaceutical Development Ltd, Basingstoke, United Kingdom,* [3]*Shire Development LLC, Wayne, PA,* [4]*University of Chicago Medicine, Chicago, IL, United States*

INTRODUCTION: MMX® mesalazine, a once-daily (QD) oral 5-aminosalicylic acid formulation, is effective in induction and maintenance of ulcerative colitis (UC) remission. Little is known about the correlation between achieving remission and long-term outcomes with maintenance therapy following induction.
AIMS&METHODS: This open-label prospective study (NCT01124149) compared long-term outcomes between patients (pts) in complete remission (CR; clinical and endoscopic) and partial remission (PR) after acute therapy with MMX mesalazine. During the induction phase, pts with active mild-to-moderate UC (acute flare or newly diagnosed with modified UC Disease Activity Index [UC-DAI] total score 4-10, endoscopy score ≥1, and Physician's Global Assessment ≤2) received MMX mesalazine 4.8 g/d QD for 8 wks. Pts achieving CR (modified UC-DAI ≤1; rectal bleeding and stool frequency scores of 0; ≥1-point reduction in endoscopy score) or PR (modified UC-DAI ≤3; combined stool frequency and rectal bleeding score ≤1; not in CR) during induction were eligible for enrolment in the maintenance phase: MMX mesalazine 2.4 g/d QD for 12 mos. The primary efficacy endpoint was the proportion of pts in CR after 12 mos of maintenance.
RESULTS: Of 722 pts enrolled, 717 were treated and 639 completed the 8 wk induction; 472 achieved CR or PR. Of 469 pts enrolled in maintenance, 461 were treated and 459 had ≥1 post-dose efficacy assessment. 373 pts completed the 12 mo maintenance; key reasons for early withdrawal were lack of efficacy (n=40) and adverse events (AEs; n=24). Of pts in CR and PR, respectively, at Mo 0 of maintenance, 47.8% (87/182) and 26.0% (72/277) were in CR at Mo 12 ($P<0.001$). Pts with endoscopy scores ≤1 and symptom scores of 0 at Mo 12 are shown in the table. Common treatment-emergent AEs during maintenance were (pts in CR at Mo 0; pts in PR at Mo 0): UC (7.7%; 10.4%); headache (3.3%; 3.6%); influenza (1.6%; 2.9%); and nasopharyngitis (2.7%; 2.2%).

Mo 12 score	Pts in CR at Mo 0 n=182	Pts in PR at Mo 0 n=277
Endoscopy ≤1	139 (76.4%)	176 (63.5%)
Rectal bleeding = 0	119 (65.4%)	158 (57.0%)
Stool frequency = 0	114 (62.6%)	118 (42.6%)

CONCLUSION: The primary endpoint was met: at Mo 12 of maintenance, significantly more pts (22%) were in CR who began maintenance in CR compared with those who began maintenance in PR. No new safety signals were identified.

P1448 FREQUENCY AND CLINICOPATHOLOGICAL FEATURES OF LOSS OF RESPONSE TO INFLIXIMAB IN CROHN'S DISEASE

H. ARAKI[1,*], J. TAKADA[2], T. IBUKA[1], T. KATO[1], H. MORIWAKI[1].
[1]*Department of gastroenterology,* [2]*GIFU UNIVERSITY HOSPITAL, Gifu, Japan*

INTRODUCTION: Although Infliximab (IFX) has proven to be an effective medication for patients with Crohn's Disease (CD), loss of response (LOR) to the 5 mg / kg dose is a common occurrence. LOR to IFX decrease quality of life of a patient undergoing treatment.
AIMS&METHODS: This study investigated clinicopathological features associated with the LOR to IFX. Fifty-nine CD patients achieved remission after the induction therapy and received regular maintenance therapy consecutively in our institute. None of the patients had received previous biological therapy. Our study protocol was designed to include patients who maintained response to IFX (G-I), and patients who had lost response to IFX (G-II). We evaluated clinical outcome and long term outcome of LOR to IFX in comparison with patients maintained response to IFX.
RESULTS: Loss of response occurred in 25 of the 59patients (42%). We enrolled 34 patients in G-I,25 patients of LOR in G-II. Median disease duration until first IFX was 4.9 years in G-I, 9.4 years in G-II ($p<0.05$), average age was 33.8 years in G-I, 32.2 years in G-II, the ratio of males to females was 27:6 in G-I, 16:9 in G-II (ns). In disease location, colonic type: ileo-colonic type: ileal type was 11:9:11 in G-I, 2:7:16 in G-II ($p<0.05$). In concomitant therapy, enteral nutrition therapy (half elemental diet) was administered in 24.2% in G-I, 36% in G-II (ns), azathioprine was administered in 27.3% in G-I, 64% in G-II (ns). In previous therapy, surgery had been performed in 30.3% in G-I, 48% in G-II, balloon dilation had been performed in 3% in G-I, 20% in G-II. Cumulative admission rate (1year, 3years, 5years) by the Kaplan-Meier method was 21%, 33%, 33% in G-I, 44%, 62%, 80% in G-II($p<0.01$). Cumulative operation rate (1year, 3years, 5years) was 9%, 9%, 9% in G-I, 12%, 16%, and 34% in G-II (ns). Median duration until LOR is 487days in G-II. After drug response is lost, we escalated the dose of Infliximab to 10 mg/ kg in 14 patients, reduced the interval of administration in 7 patients, switched to adalimumab in 4 patients. After we escalated the dose or reduced interaval, mean level of C reactive protein decreased 2.0mg/dl to 1.5mg/dl in G-II. Recent level of C reactive protein was 0.22mg/dl in G-I, 0.54mg/dl in G-II.
CONCLUSION: During the observation period, LOR increase risk of surgery and admission. In Japan, we are not able to measure serum trough levels of IFX and ATIs in common. Our results showed that remission after induction, short disease duration until the introduction of IFX and colonic type CD was protective against loss of response.

P1449 ONSET OF ULCERATIVE COLITIS INDUCED BY THE ANTI-IL-17A MONOCLONAL ANTIBODY THERAPY

I. Ozola Zalite[1,*], A. Pukitis[1], E. Ostrovskis[1], J. Baranova[1], J. Pokrotnieks[1].
[1]*Gastroenterology Center, Pauls Stradins Clinical University Hospital, Riga, Latvia*

INTRODUCTION: Interleukin (IL)-17A is an important cytokine in the pathogenesis of psoriasis. Th17 cells are involved in the regulation of innate and adaptive immunity mechanisms, activation of T cells and monocytes/macrophages is regarded as an important factor in the pathogenesis of ulcerative colitis (UC). Association between psoriasis and UC is rarely described.
AIMS&METHODS: We reported clinical case with patient, who received fully human anti-IL-17A IgG1κ monoclonal antibody therapy due to plaque type psoriasis and onset of UC.
RESULTS: A 29-year-old man with no previuos history of UC had plaque type psoriasis since the age of 16 years. For 5 months he has been receiving subcutaneous injections of secukinumab (150mg) in the framework of multicenter study. Patient was admitted to our hospital with diffuse cramp type abdominal pain, bloody diarrhea, and temperature 37.4°C. The blood count was normal, C-reactive protein (CRP) was 265.32 mg/l. Ultrasonography revealed mild splenomegaly (13.2 x 5.7 cm). Intestinal infections were excluded. Colonoscopy showed total severe UC (Mayo index 2), confirmed by clinical symptoms (Rachmilewitz index 9) and morphology. CT showed thickened colon ascendens and caecum walls (no transmural lesions) reactive mild lymphadenopathy in ileocaecal region. Patient received mesalazin, methylprednisolon (i/v) and antibacterial therapy. Level of CRP dropped to 34.2 mg/l. The patient recovered and was discharged on 24th day using per oral mesalazin (2400mg/daily), methylprednisolon (32mg/daily, p/o) with recomendation to tee off azathioprine.
CONCLUSION: Biologic therapy still carry the risk to exacerbate other autoimmune process despite of the treatment of specific one. Our clinical case showed particularly rare finding; anti-IL-17A induced ulcerative colitis.

P1450 HIGH DOSE INFLIXIMAB IN CROHN'S DISEASE: CLINICAL EXPERIENCE, SAFETY, AND EFFICACY

S. Hendler[1], B. L. Cohen[2], J. F. Colombel[2,*], B. E. Sands[2], L. F. Mayer[1,2], S. Agarwal[1]. [1]*Division of Allergy and Clinical Immunology,* [2]*Division of Gastroenterology, Icahn School of Medicine at Mount Sinai, New York, United States*

INTRODUCTION: Standard treatment dose of infliximab (IFX) is ineffective in some Crohn's disease (CD) patients requiring dose intensification by increasing the dosage or shortening interval of treatment.
AIMS&METHODS: To evaluate safety and efficacy of high dose (HD) IFX (> 10 mg/kg every (q) 8 weeks or equivalent) in CD and characterize predictors of response to dose intensification.
Electronic medical records (EMRs) were queried for CD patients who received HD IFX (10 mg/kg q7weeks – 20 mg/kg q4weeks) during 2010-2012. EMRs fulfilling criteria were reviewed for history, medications, and laboratory data. Safety and efficacy of dose intensification was analyzed.
RESULTS: 319 patients with CD were identified; 87 received HD IFX. Of the HD IFX patients, median age at diagnosis and initiation of HD IFX were 16.5 and 28.5 years, respectively. 93% met criteria for moderate-severe or severe-fulminant disease activity; 55% had history of penetrating disease; 58% had ileocolonic involvement. 29% failed at least 1 other biologic therapy including standard dose of IFX. 69% received HD IFX doses between 10 mg/kg q7weeks and 10 mg/kg q4weeks; 31% received between 15 mg/kg q8weeks and 20 mg/kg q4weeks. 46% of patients initiated HD IFX therapy with an immunomodulator. At 4, 24, and 52 weeks of therapy, 20%, 28%, and 18% of patients experienced a full response, and 46%, 30%, and 23% experienced a partial response, respectively. In 58 patients on HD IFX, CRP was reduced from a median of 21.9 mg/L prior to HD IFX to 4.7 mg/L at a median of 16.5 weeks ($p<0.001$). Patients who responded fully or partially at 4 weeks had a higher median baseline CRP than those who did not respond (24.9 vs 3.5 mg/L, p=0.04). 44% remained on HD IFX at the end of followup (median 103.5 weeks). The median length of treatment before discontinuation was 30.5 weeks. 11 cases of infection required hospitalization; none were mycobacterial; 3 of these were in patients receiving combination immunosuppressant therapy. 2 patients developed melanoma and 1 SCC of the skin. Reasons for discontinuation of HD IFX: infection (n=1), infusion reaction (n=2), autoimmune disease (n=2), other (n=16), inadequate response (n=22), and successful de-escalation to standard treatment dose of IFX after a full response to HD (n=6).
CONCLUSION: HD IFX therapy may offer a therapeutic benefit to CD patients who have failed to achieve a response with standard treatment doses or in patients who have failed other therapies. Safety of HD IFX therapy appears to be consistent with the known side effect profile of anti-TNF therapy. Baseline CRP value may be a predictor for clinical response to IFX dose intensification.

P1451 SAFETY AND EFFICACY OF FUMARIC ACID ESTERS (FAES) IN STEROID DEPENDENT CROHŃS DISEASE

J. Stein[1,2,*], A. Dienethal[3], C. Maresch[4], H. Radeke[5].
[1]*INTERDISZIPLINÄRES CROHN-COLITIS-CENTRUM RHEIN-MAIN,* [2]*Hospital of Sachsenhausen,* [3]*Interdisziplinäres Facharztzentrum Sachsenhausen, Frankfurt a.M.,* [4]*University of Giessen, Giessen,* [5]*University of Frankfurt, Frankfurt a.M., Germany*

INTRODUCTION: Fumaric acid esters (FAEs) have been used successfully in the treatment of moderate to severe psoriasis vulgaris and several noninfectious granulomatous skin diseases (i.e. disseminated granuloma annulare, cheilitis granulomatosa, sarcoidosis)
AIMS&METHODS: Here, we report the safety and efficacy of Fumaric acid esters (FAEs) in steroid dependent Crohńs Disease (CD).
RESULTS: Five patients (two male, three female) presented with Crohńs Disease that have proved to be refractory to various therapies, including corticosteroids and TNFalpha-antibodies were treated with FAEs in tablet form (Fumaderm) according to the therapeutic schedule for psoriasis patients (240 mg td). After treatment with FAE (3-4 months), steroid free remission (CDAI $<$ 150, fecal calprotectin $<$ 200 µg/ml, CRP $<$ 5 mg/L) was achieved in three patients. The side effects observed in this trial correspond to the well-known spectrum of adverse effects of FAE (minor gastrointestinal complaints: 1 pt, temporary lymphopenia: 2 pts, temporary flush: 3 pt).
CONCLUSION: On the basis of our findings FAE therapy seems to be a safe and effective regimen for patients with refractory and/or steroid dependent CD. However controlled trials are necessary to fully explore the efficacy, optimal dosage, and safety of FAE in the management of CD.

P1452 THE PROCESSED BLOOD VOLUME PER BODY WEIGHT FOR GRANULOCYTE AND MONOCYTES ADSORPTION SESSION IN PATIENTS WITH CROHN'S DISEASE PATIENTS

K. Kamikozuru[1,*], N. norio[1], S. toshiyuki[1], M. kawai[1], K. tozawa[1], Y. yokoyama[1], K. fukunaga[1], N. hida[1], S. nakamura[1], H. miwa[2]. [1]*DIVISION OF LOWER GASTROENTEROLOGY,* [2]*DIVISION OF upper GASTROENTEROLOGY, HYOGO COLLEGE OF MEDICINE, Hyogo, Japan*

INTRODUCTION: Granulocyte/ monocytes adsorption (GMA) has been introduced as non-pharmacological therapy for active Inflammatory Bowel Disease (IBD) patients refractory to conventional medications. We have already reported that the processed blood volume per body weight (PV/BW) in GMA session is an essential factor for its efficacy in Ulcerative Colitis patients.
AIMS&METHODS: To investigate the essentiality of PV/BW in GMA for Crohn's Disease (CD) patients, we conducted retrospective cohort study in CD patients. This study involved 29 active CD patients who enrolled remission induction therapy with standard GMA sessions (PV:1800ml). Eligible patients were divided into two groups: High BW (HBW: $>$50kg, n=14) and Low BW group (LBW: $<$50kg, n=15). The primary endpoint of this study is the difference in response rate between these two groups. The responder was defined as the patients who decrease CD activity index (CDAI) score more than 70 points after GMA sessions compared pre GMA sessions.
RESULTS: The 29 CD patient's average CD activity index (CDAI) was 273.7±97.55, the average of CD duration was 8.27±6.32 years the average of simple endoscopic score for Crohn's disease (SES-CD) was 17.1±5.73, the average age was 31.3±5.15 old, the average body weight(BW) was 51.5±7.62 kg. The 11 patients had lost response to anti-TNF-α therapy. There were no differences between HBW and LBW groups in these backgrounds. The response rate in LBW group was significantly high compere to HBW group (80 vs 50 %, $p<0.05$). And The responder's BW was lighter than that of non-responder's BW after performing 5th or 10th weekly GMA significantly (P=0.009). We performed GMA dealing with 1800ml blood volume, so the responder's amount of dealing volume per BW was higher than that of non-responder's significantly (P=.0..009). The average of the responder's amount of dealing volume per BW was 37.5±4.73ml/kg, and that of non-responder's was 32.0±3.97ml/kg.
CONCLUSION: These results indicate the PV/BW is essential in CD patient's GMA, as well as in UC patient's GMA. Additional prospective controlled with larger cohorts of patients should strengthen our findings.

P1453 THERAPEUTIC EFFECT OF INFLIXIMAB FOR INDUCTION AND MAINTENANCE OF REMISSION IN INTESTINAL BEHÇET'S DISEASE

K. Takemoto[1,*], K. HAMADA[1], D. Kawai[1], R. Takenaka[1], H. Tsugeno[1], S. Fujiki[1]. [1]*Digestive Endoscopy Center, Tsuyama Central Hospital, Tsuyama, Japan*

INTRODUCTION: Behçet's disease is a multisystem disorder originally characterized by recurrent oral and genital ulcerations, ocular inflammation, and skin lesions. Intestinal Behçet's disease with gastrointestinal ulcers accounts for approximately 3 - 26% of Behçet's disease. The treatment strategies for intestinal Behçet's disease has not been well established because of the number are limited. Recently, Naganuma reported the efficacy of infliximab for inducing and maintening in intestinal Behçet's disease. The aim of this study was to assess the efficacy of infliximab for induction and maintenance of remission in intestinal Behçet's disease in our institution.
AIMS&METHODS: A total of 8 cases with intestinal Behçet's disease were treated in our institution between April 2000 and April 2013. Treatment strategies were as follows: First, corticosteroid was administered for induction of remission. After the remission was obtained, corticosteroid was tapered. Infliximab was administered in cases with recurrence during tapered corticosteroid. In all cases, the clinical courses were followed for $>$2 yr (2.5-13ys).
RESULTS: Patients were composed of 6 men and 2 women, with a mean age of 51 years (range; 21 - 84 years). Six patients complained of right lower abdominal pain, one patient complained of left lower abdominal pain, and one had bloody stool. Total colonoscopy was performed and deep punched-out ulcers in the terminal ileum or the colon were found in all patients. After the administration of corticosteroid, all patients achieved remission at an early time. While corticosteroid tapering, four patients had recurrences and following administration with infliximab was required. Three patients maintained remission with scheduled treatment of infliximab alone, but in one patient withdrawn the infliximab because of miliary tuberculosis was occured during treatment. After withdrawn the infliximab, corticosteroid introduced again and maintainted remission. One patient was also maintained remission with combination therapy of infliximab and methotrexate. Among the remaining 4 patients, maintained remission was obtained.
CONCLUSION: Corticosteroid is effective for induction of remission in intestinal Behçet's disease. Infliximab can be an effective theraphy to induce and maintain remission, especially in steroid-dependent patients. Our findings should be contributed to establish the treatment of intestinal Behçet's disease.

P1454 ADALIMUMAB VERSUS INFLIXIMAB FOR THE TREATMENT OF MODERATE TO SEVERE ULCERATIVE COLITIS IN ADULT PATIENTS WITH NO PRIOR ANTI-TNF EXPERIENCE: AN INDIRECT COMPARISON META-ANALYSIS

K. Thorlund[1,*], E. Druyts[2], E. Mills[3], J. Marshall[4], R. Fedorak[5]. [1]*Clinical Epidemiology and Biostatistics, McMaster University, Hamilton,* [2]*Faculty of Medicine,* [3]*University of Ottawa, Ottawa,* [4]*Gastroenterology, McMaster University, Hamilton,* [5]*Gastroenterology, University of Alberta, Alberta, Canada*

INTRODUCTION: Adalimumab and infliximab have been approved for the treatment of ulcerative colitis by several regulatory bodies across the globe. Both are viable treatment options when patients become refractory or intolerant to conventional therapy. Since placebo controlled randomized clinical trials for adalimumab were only published recently, the comparative effectiveness of adalimumab versus infliximab has not yet been established via accepted meta-analytic indirect comparison methods.
AIMS&METHODS: An exhaustive search strategy covered major medical databases and recent conventional meta-analyses to identify eligible randomized clinical trials (RCTs). A Bayesian random-effects indirect comparison meta-analysis was performed for five selected and patient-important clinical outcomes at 8 weeks and 52 weeks. Odds ratio (OR) estimates and associated 95% credible intervals (CrI) were produced.
RESULTS: Five eligible RCTs were identified from which data on clinical remission, clinical response, mucosal healing, response on the inflammatory bowel disease questionnaire (IBDQ), colectomy, serious adverse events and discontinuation due to adverse events were extracted at 8 weeks and 52 weeks. For all efficacy outcomes at both time points, the indirect comparison meta-analysis of adalimumab versus infliximab favoured infliximab. At 8 weeks, clinical remission (OR=0.44, 95% CrI 0.23-0.98), clinical response (OR=0.45, 95% CrI 0.23-0.89) and mucosal healing (OR=0.46, 95% CrI 0.25-0.86) were all statistically significant, whereas IBDQ was not. At 52 weeks, OR estimates for all efficacy outcomes favoured infliximab, but none were statistically significant. Adalimumab and infliximab were both similar and with lower adverse event rates when compared with placebo, and the indirect comparison of the two yielded odds ratios close to 1.00 with wide CrIs.
CONCLUSION: Our findings suggest that infliximab is significantly more effective than adalimumab for the treatment of moderately to severe ulcerative colitis at 8 weeks and is numerically more effective at 52 weeks. The two treatments also appear equally safe.

P1455 CHRONIC TREATEMENT WITH ALPHA2DELTA LIGAND REDUCE COLONIC INFLAMMATION AND INFLAMMATORY-ASSOCIATED HYPERSENSITIVITY IN MICE

L. Boudieu[1,*], M. Meleine[1], A. Gelot[1], A. Accarie[1], A. Eschalier[1], F. A. Carvalho[1], D. Ardid[1]. [1]*Pharmacologie Fondamentale et Clinique de la Douleur, UMR1107 NEURO-DOL Inserm/UdA, Clermont-Ferrand, France*

INTRODUCTION: Abdominal pain is a common feature of patients suffering from Inflammatory Bowel Disease (IBD) or Irritable Bowel Syndrome (IBS) for which current analgesic therapies are still unsatisfactory. Recent studies highlighted the antinociceptive effect of $\alpha2\delta$ ligands, initially commercialized as anticonvulsant, in patients suffering from IBS. However, their impact on inflammation-associated visceral pain has been poorly investigated.
AIMS&METHODS: We proposed to investigate $\alpha2\delta$ ligand beneficial effects on inflammatory-associated colonic hypersensitivity (CHS) and on inflammatory condition in mice. To induce chronic colonic inflammation, we administered 1% DSS in drinking water for 14 days. From day 7 to day 14, pregabalin or its vehicle was administered subcutaneously at 30mg/kg each day. At day 14, mouse colonic hypersensitivity was evaluated by colorectal distension (CRD). Briefly, at day 10, 2 electrodes were implanted into the abdominal oblique muscle, and at day 14, distension probe were inserted at 1cm from the anal margin. Then, electrodes were connected to a Bio-Amp recording system linked to an acquisition interface device. CRD was performed by inflating distension probe from 20µL to 100µL by 20µL increment step. Visceromotor responses (VMR) were quantified as the area under the EMG activity curve during the 10s stimulation period minus the area measured during the 10s baseline. This VMR were correlated with CHS. After CRD, the animals were euthanized and several tissues were collected to investigate $\alpha2\delta$ ligands effects on inflammation level.
RESULTS: Chronic pregabalin treatment alleviated the CHS induced by DSS treatment, as revealed by a decreased VMR to CRD test in pregabalin DSS-treated mice in comparison to control DSS-treated mice. In addition to this antinociceptive, pregabalin treatment reduced neutrophil recruitment and pro-inflammatory cytokine production, showing a new original anti-inflammatory effect of $\alpha2\delta$ ligands treatment
CONCLUSION: In summary, $\alpha2\delta$ ligands showed beneficial effects in the management of visceral hypersensitivity. Moreover, our findings highlight their novel efficacy in inflammatory CHS which could be, in part, due to an anti-inflammatory effect. Finally, this work underlines the interest in studying the clinical relevance of $\alpha2\delta$ ligands in IBD patients in remission to alleviate IBS-like symptoms, particularly abdominal pain, but also to increase length of remission periods by preventing initiation or triggering of acute severe inflammation phases.

P1456 ASSESSMENT OF LOSS OF RESPONSE TO INFLIXIMAB THERAPY IN INFLAMMATORY BOWEL DISEASES USING ANTIBODIES TO INFLIXIMAB AND TROUGH LEVELS.

L. Guidi[1,*], M. Marzo[1], C. Felice[1], D. Pugliese[1], G. Andrisani[1], G. Mocci[1], O. Nardone[1], B. Tolusso[2], E. Gremese[2], G. Rapaccini[1], A. Papa[1], A. Armuzzi[1]. [1]*IBD Unit,* [2]*Division of Rheumatology, Complesso Integrato Columbus, Catholic University, Rome, Italy*

INTRODUCTION: Currently the management of inflammatory bowel disease (IBD) patients on infliximab therapy who lose response is mostly empirical: an increase of dose up to double or a decrease of treatment intervals represent the common clinical practice, with a consequent increase of drug use and high costs. Measuring trough levels (TL) and antibodies to infliximab (ATI) may be of great benefit in optimizing therapy.
AIMS&METHODS: We aimed to evaluate the relationship between TL and ATI assay with loss of response and infusion reactions in an Italian IBD unit. Sera were obtained from 82 IBD patients on infliximab maintenance therapy from at least 6 months. Patients were classified as being or not in clinical response. The occurrence of acute reactions to infliximab infusions was recorded. ATI and TL were measured by a commercial ELISA (Immundiagnostik AG, Bernsheim, Germany).
RESULTS: ATI were detected in 18 patients (22%), 50% of which were in clinical response as compared to 80% of patients without detectable serum ATI levels (p=0.0271 by χ^2 test). 5/18 (28%) of ATI positive patients had infusion reactions as compared to 2/64 (3%) ATI negative (p=0.0047 by χ^2 test). 60/82 patients had infliximab TL >0,1 µg/ml and 80% of them were in clinical response, as compared with 54% of patients with TL lower than 0,1 ug/ml (p=0.0043 by χ^2 test). Median TL were not significantly different among clinical responders and non-responders.
CONCLUSION: The combination of ATI and infliximab TL assay could help in managing loss of clinical response in IBD.

P1457 CCX507, AN ORALLY BIOAVAILABLE SECOND GENERATION ANTAGONIST OF THE CHEMOKINE RECEPTOR CCR9

M. Walters[1,*], K. Ebsworth[1], P. Zhang[1], J. P. Powers[1], D. Dairaghi[1], L. Ertl[1], B. Zhao[1], Y. Wang[1], S. Miao[1], L. Lohr[1], J. Jaen[1], P. Bekker[1], T. Schall[1]. [1]*ChemoCentryx, Mountain View, United States*

INTRODUCTION: The chemokine receptor CCR9 directs the trafficking of inflammatory cells into GI tissue. The therapeutic benefit of CCR9 inhibition was demonstrated by results from the PROTECT-1 clinical trial, in which the orally bioavailable CCR9 antagonist CCX282-B / vercirnon showed efficacy in the treatment (induction and maintenance) of moderate-to-severe Crohn's disease patients, including those with colonic involvement (1).
AIMS&METHODS: CCX507 is a next generation CCR9 antagonist being developed for the treatment of IBD. This molecule potently inhibits the CCL25-mediated chemotaxis of human Molt-4 cells in the presence of 100% human serum with A_2 and A_{10} values of 5.5 and 50.2 nM, respectively (A_2 and A_{10} are analogous to IC_{50} and IC_{90} values, respectively). CCX507 inhibits the CCL25-mediated chemotaxis of retinoic acid stimulated primary human CCR9+ T cells, in the presence of 100% human serum, with A_2 and A_{10} values of 9.7 and 87 nM, respectively. CCX507 also potently inhibits the CCL25-mediated chemotaxis of murine thymocytes, in the presence of 100% mouse plasma, with A_2 and A_{10} values of 12 and 108 nM, respectively. CCX507 does not bind to any other chemokine receptor.
The ability of CCX507 to inhibit the trafficking of T cells into the intestine was determined using an adoptive transfer model in mice. Administration of CCX507 resulted in a significant decrease of CD45.2+ T cells within the IEL population. Analysis of the plasma levels of CCX507 revealed that drug levels in mice that had a significant reduction in CD45.2+ T cell trafficking were consistently maintained above the mouse A_{10} value. Dosing of CCX507 in both the mdr1a-/- and CD4+ CD25- T cell transfer models of colitis significantly reduced disease severity.
RESULTS: CCX507 has successfully completed the single ascending dose arm of a Phase I study in healthy volunteers at doses up to 30 mg. All doses of CCX507 were well tolerated. Modeling of the steady state PK profile indicates that a 30-mg single daily dose of CCX507 will provide good coverage of the CCR9 receptor at the A_{10} level required for maximal pharmacological effects.
CONCLUSION: In summary, CCX507 is a novel, potent, selective and orally bioavailable CCR9 antagonist currently in development for the treatment of IBD.

P1458 SECONDARY NON RESPONSE TO ANTI-TNF IS RELATED TO ANEMIA, INCREASED WHITE BLOOD CELL, HIGH C-REACTIVE PROTEIN AND LOW SERUM ALBUMIN

M. Bafutto[1,*], E. C. Oliveira[1], A. A. F. Bafutto[2], R. D. Marciano[2], J. Rezende Filho[1]. [1]*Departamento de Medicina da Universidade Federal de Goiás,* [2]*Departamento de Medicina da Pontifícia Universidade Católica de Goiás, Instituto Goiano de Gastroenterologia, Goiânia, Brazil*

INTRODUCTION: Secondary non-response is defined as recurrence of disease activity during maintenance therapy after achieving an appropriate induction response. It can occur in 20-40% of patients during the first year of treatment and is related to the disease and drug metabolism(1,2). Serum levels of Hemoglobin, Hematocrit, White Blood Cell(WBC),Platelets, C-Reactive Protein(CRP), Total Protein and Albumin could provide information about degree of inflammation and indirect signs of disease activity. Albumin an Ant-TNF co-transporter may also be related to the Drug clearance.
AIMS&METHODS: AIMS: Evaluate the serum level of Hemoglobin, Hematocrit, White Blood Cell(WBC),Platelets, C-Reactive Protein(CRP), Total Protein and Albumin in anti-TNF secondary non-response patients. Methods: Between July 2010 and October 2012, 50 Conh s Disease (CD) patients that was in manteinace after responded to induction of Anti-TNF therapy were followed with clinical visits at each 3 months. At visit the patients after a clinical evaluation based on Harvey-Bradswal index, blood samples were collected for laboratory tests: Hemoglobin, Hematocrit, WBC, Platelets, CRP, Total Protein and Albumin. In cases that recurrence was suspected the patients were submitted to entero CT or MRS for confirmation and divided in two Groups – 1. Responder group (RG) – 38 patients with no signs of loss respond.2. Loss response group (LRG) – 12 patients with confirmed loss respond. Non paried t test was used for statistical analyses.
RESULTS: Results: Statistically significant results between RG and LRG (M[SD]xM[SD]) were seen in hemoglobin levels 14,3[1,20]x11, 9[2,64]p=0,03, hematocrit 43, 9[4,19]x32, 9[11,7]p=0,02, WBC 6.287[1,61]x 11.150[4,02] p=0,005, CRP 1,89[0,78]x44,1[45,1]p=0.01,Total Protrein 7,37[0,25]x5, 25[1,01] p=0.0002 and Albumin 4,53[0.25]x3, 12[0,73]p=0.0001. Non significant trends were seen in Platelet count (p=0.09).
CONCLUSION: Conclusion: Secondary non-response to Anti-TNF in CD is related to anemia, increased WBC, high CRP and low serum Albumin. These preliminary results warrant further larger studies.

P1459 EXPERIMENTAL STUDY ON EVALUATION OF THE USE OF MESALAZINE IN RATS SUBJECT TO BOWEL INJURY BY NON-STEROIDAL ANTI-INFLAMMATORY DRUG

M. Bafutto[1,*], A. A. O. Bafutto[2], R. D. Marciano[2], E. C. Oliveira[3], M. B. G. Costa[2]. [1]*Departamento de Medicina da Universidade Federal de Goiás, Instituto Goiano de Gastroenterologia,* [2]*Departamento de Medicina, Pontifícia Universidade Católica de Goiás,* [3]*Departamento de Cirurgia da Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

INTRODUCTION: Background: Non-steroidal anti-inflammatory drugs (NSAIDs) often cause damage to the small and large intestine. There is no established treatment so far besides the immediate suspension of the drug. Mesalazine (5-aminosalicylic acid, 5-ASA) is a drug with supposedly anti-inflammatory properties. 5-ASA is the primary therapy used in the induction and maintenance of remission of mild-to-moderate inflammatory bowel diseases, particularly ulcerative colitis1,2,3.
AIMS&METHODS: Aims: To observe and to quantify the inflammatory reaction induced by anti-inflammatory drugs in small and large intestine of mice with and without concurrent use of mesalazine. Methods: Twelve (12) male Wistar rats weighing between 220-250g were used. Each rat was injected intraperitoneally with diclofenac sodium 15mg/kg in the first and third days of the experiment. In the control group (CG): 6 rats were under observation for five days. In Group Mesalazine (MG): 6 mice had mesalazine (oral gavage) po 50mg/kg for 5 days. After 5 days, the mice in both groups were killed. The small and large intestines of the 12 rats were then sent for histological evaluation. Samples were taken from the jejunum (2), ileum (2) and large intestine (4). (Ascending: 1; Transverse: 1; Descendant: 1; and sigmoid
RESULTS: In the control group (CG), the mice showed mild (2) and moderate (4) inflammation in the small intestine, whereas the mesalazine group (MG) mice presented with absent (2) and light (4) inflammation. In the large intestine, MG had three rats with absent inflammation and 3 rats with mild inflammation whereas the CG had 4 rats with mild inflammation and 2 with moderate inflammation. On the analyses of the small intestine, the score was 10 (CG) and 4 (MG) $p = 0.04$ and large intestine 8 (GC) and 3 (GM) $p = 0.09$.
CONCLUSION: The use of mesalazine reduces intestinal inflammation caused by non-hormonal anti-inflammatory drugs.

P1460 THE TYPE OF IRON DEFICIENCY ANAEMIA, BUT NOT THE UNDERLYING DISEASE, PREDICTS INTESTINAL IRON ABSORPTION IN IBD PATIENTS

M. Wiesenthal[1,*], D. Jacobsen[1,2], F. Hartmann[1], A. Dignass[3], J. Stein[2,4]. [1]*Marien Hospital,* [2]*interdisciplinary Crohn-Colitis-Center Rhein-Main,* [3]*Apaglesion Markus Hospital,* [4]*Sachsenhausen Hospital, Frankfurt a.M., Germany*

INTRODUCTION: Anemia (A) in patients with inflammatory bowel disease (IBD) is multifactorial, however the two most common causes of anemia in IBD are iron deficiency and anemia of inflammation (ACI). Although the exact pathogenesis of ACI is unknown, one hypothesis suggests that-caused by the effects of inflammatory cytokines-ACI arises in part as a result of an impaired intestinal Iron absorption.
AIMS&METHODS: Recently it has been shown, that the acute phase protein hepcidin impairs intestinal iron uptake. We therefore hypothesized that iron absorption is impaired in patients with active IBD at least in part as an increased hepcidin release by the liver. 71 adult subjects with IBD (31 UC, 40 CD) and 26 healthy controls were recruited until February 2013. After an overnight fast, serum hemoglobin levels, Serum ferritin (SF) and serum markers of inflammation [high-sensitive C-reactive protein (hsCRP) and IL-6] were measured. Serum samples for hepcidin assay were obtained at 8 a.m. and measured by LC-MS. Ferrous sulfate (100 mg) was administered orally, followed by determination of serum iron concentrations hourly for 4 hours. An area under the curve (AUC) for iron absorption was calculated for each patient data set. Patients with anemia were classified as having iron deficiency anaemia (IDA), anaemia of chronic disease (ACD) or according to[1].
RESULTS: There was a significant inverse correlation between the AUC and hsCRP ($p < 0.001$) and the AUC and hepcidin levels ($P = 0.017$). Both in UC and CD patients the difference between baseline and 2-hour serum iron level (D[Fe]2hr) independently of disease location was significantly decreased in ACD (fig. 1).
CONCLUSION: Compared to healthy controls and subjects with inactive disease IBD patients ACD have impaired oral iron absorption, which correlates with disease activity and markers of Inflammation but is independent of disease location and type of IBD

P1461 THE USE OF SIROLIMUS FOR REFRACTORY INFLAMMATORY BOWEL DISEASE: A SINGLE CENTRE EXPERIENCE

M. Mutalib[1,*], S. Blackstock[1], F. Kiparissi[1], K. Lindley[1]. [1]*GREAT ORMOND STREET HOSPITAL NHS FOUNDATION TRUST, LONDON, United Kingdom*

INTRODUCTION: Refractory inflammatory bowel disease (IBD) in children is challenging. The primary outcome of this study was to assess the therapeutic efficacy of Sirolimus in children with refractory IBD. Secondary outcomes included Sirolimus tolerance and duration of therapy.
AIMS&METHODS: We retrospectively reviewed medical and nursing records of all patients with IBD on Sirolimus (23 patients) between 2006 and 2012. Clinical response was assessed by PUCAI or PCDAI. All patients had an activity index at baseline and 3 months after induction of Sirolimus. Endoscopic and histological findings before starting Sirolimus were compared to the next available endoscopy at least 3 months later. A total of eight cases were excluded, 6 due to incomplete data and 2 due to short treatment time (less than one month).
RESULTS: 15 cases had severe refractory IBD, 4 were Crohns disease (CD), 11 were Ulcerative colitis (UC), 9 were males. The mean age of onset of disease was 8.7 years. The mean number of years after diagnosis until induction with Sirolimus was 3.1 years. The oral daily dose range was between 0.5mg and 5mg with a targeted serum trough level of 5-10ng/ml. The mean trough level was 7.5ng/ml. 16 patients had failed standard medical therapy and all stayed on conventional treatment while on Sirolimus. 15 patients had received steroids, thiopurines, 5-ASAs, 13 infliximab, 8 adalimumab, 5 methotrexate, 2 tacrolimus and two basiliximab prior to starting Sirolimus. 8/11 patients with UC had a response shown by improvement in their PUCAI score at 3 months, 3/11 had no response. Of the patients who responded 2 achieved remission with concomitant administration of Basiliximab, one was started on Mycophenalate while the fourth child required complete gut rest and parenteral nutrition for 6 weeks. 3/8 responders and 2/3 non responders went on to have Colectomys. 3 CD patients had clinical response to their PCDAI scores. 1 CD patient was successfully weaned off prednisolone, 1 off methotrexate. 5/11 patients with UC achieved histological mucosal healing while 4 patients still had some disease activity. Of the CD patients one achieved mucosal healing while 3 demonstrated ongoing inflammation, No side-effects were reported to Sirolimus in the included patients.
CONCLUSION: Our study was limited by its retrospective design; however we demonstrated clinical and histological response to Sirolimus in children with refractory IBD who failed conventional medical therapy. With careful patient selection, Sirolimus (as an adjunct immunosuppressant) appears to be safe and effective medical therapy to be considered in children with severe refractory IBD.

P1462 DRUG INDUCED LUPUS IN PATIENTS WITH CROHN'S DISEASE TREATED WITH ANTI-TNF AGENTS

N. Kiel[1,*], S. Buckton[1], H. Seltenreich[1]. [1]*Gastroenterology and Hepatology, Nambour General Hospital, Nambour, Australia*

INTRODUCTION: Anti tumour necrosis factor alpha medications have become integral in the treatment of moderate to severe Crohn's disease. Drug-induced lupus erythematosus (DILE) and ANA positivity have been associated with these medications. There is, however, little data available that identifies which patients are likely to develop DILE when placed on these medications, whether the severity of DILE correlates with antibody titre and if the concomitant use of immunotherapies such as thiopurines and methotrexate reduces DILE development.
AIMS&METHODS: Clarify the prevalence of drug induced lupus erythematosus in patients with Crohn's disease being treated with adalimumab or infliximab, and also to further clarify the relationship between antibody titre and severity of lupus symptoms.
Retrospective chart review of 68 patients with Crohn's disease, treated with either infliximab or adalimumab at the Nambour Hospital, between 2002 and 2012 was conducted. Information was obtained from medical records and hospital pathology records. All patients with DILE diagnosed by an immunologist or rheumatologist were included in the study. Patients with DILE were matched with healthy controls, who had no symptoms of DILE and currently receiving anti-TNF medication for crohn's disease.
RESULTS:

	Patients with DILE (n=8)	Controls (n=8)
Mean age (years)	51.5	36.6
Males	3	2
Females	5	6
Concurrent immunosuppression (thiopurines or methotrexate)	0	3
IFX	7	4
Adalimumab	1	4

Table 1: Demographic data
Of the 68 patients treated with infliximab or adalimumab between 2002 and 2012, 9 developed an ANA > 2560 of whom 8 had a positive dsDNA between 9 and 40. All of the 8 patients with a positive ds DNA developed symptoms consistent with a diagnosis of DILE.
The control group had a lower mean age than the treatment group (table 1). The male:female ratio was similar between the two groups (table 1). None of the patients who developed DILE were on concomitant immunsuppressive medication. All the patients who developed symptoms of Drug induced lupus developed a high ANA >2560 and positive dsDNA. Of the eight patients who developed DILE, 5 developed a discoid or malar rash, seven developed arthritis, one developed serositis (pulmonary) and none developed neurological symptoms. Of the eight controls, only one developed a low titre dsDNA, but no symptoms consistent with DILE.
CONCLUSION: Although our study suggests a correlation between ANA and dsDNA positivity and development of DILE, further studies are required to investigate if ANA titre is directly correlated with symptom severity in drug induced lupus, whether concurrent use of immunosuppressant medication with anti-TNF medications is protective against the development of drug induced lupus.

P1463 LONG-TERM OUTCOME OF PERIANAL AND ENTEROCUTANEUS FISTULIZING CROHN'S DISEASE TREATED WITH TUMOR NECROSIS FACTOR ALPHA (TNF-A) ANTAGONISTS

R. Bor[1,*], K. Farkas[1], Z. Szepes[1], A. Bálint[1], F. Nagy[1], M. Szűcs[2], S. Ábrahám[3], G. Baradnay[3], G. Lázár[3], T. Wittmann[1], T. Molnár[1]. [1]*First Department of Internal Medicine,* [2]*Department of Medical Physics and Informatics,* [3]*Department of Surgery, University of Szeged, Szeged, Hungary, Szeged, Hungary*

INTRODUCTION: There are only limited clinical observational data about the short and long-term efficacy of anti-TNF-α therapy in patients with perianal and enterocutaneus fistulizing Crohn's disease (CD).
AIMS&METHODS: Our aim was to retrospectively evaluate the outcomes, the complications and the therapeutic success rates of anti TNF α therapy in fistulizing CD.
The records of 69 perianal and 7 enterocutaneous fistulising CD patients were assessed retrospectively. Responses to biological therapy were determined by clinical activity indices. We assessed whether rectal involvement, disease location, disease behaviour and smoking are in association with the response to biological therapy and further surgery.

RESULTS: 14.7% of patients had simple perianal and 8 patients had enterocutaneus fistula at the beginning of anti-TNF-α therapy. Seton drainage was performed in 39 patients. Complete fistula closure was achieved in 38.3% of the patients. In 10.3% were refractory to biologicals. Repeated seton-drainage was needed in 20.6%. After the discontinuation of anti TNF-α, fistulas recurred in 53.9% of the patients. None of the examined parameters showed association with the response to biological therapy and the need for surgery.
CONCLUSION: More than every third patient revealed complete fistula closure. Seton drainage had to be performed in the majority of cases. Frequency of fistula recurrence is high after stopping the therapy.

P1464 TO EVALUATE THE EFFICACY AND SAFETY OF 6-THIOGUANINE THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE – A LONDON DGH EXPERIENCE

R. Saleem[1,*], A. Gera[1], T. H. Tranah[1], A. Paolino[1], A. Loganayagam[1].
[1]*Gastroenterology, Queen Elizabeth Hospital, South London Healthcare NHS, London, United Kingdom*

INTRODUCTION: Conventional thiopurines (Azathioprine/6-Mercaptopurine) are considered to be safe and effective in the treatment of inflammatory bowel disease (IBD). Unfortunately more than 50% of patients discontinue thiopurine therapy, mainly due to the development of adverse events or therapy resistance[1]. In recent years, 6-thioguanine (TG) has been used as an alternative thiopurine in IBD patients failing to tolerate or to respond to conventional thiopurine therapy. The aim of this study was to evaluate the tolerability, safety and efficacy of 6-thioguanine in the treatment of IBD patients in a London District General Hospital (DGH).
AIMS&METHODS: A retrospective database analysis was performed on all IBD patients who had previously failed to respond or to tolerate conventional thiopurine therapy and were subsequently treated with TG at 20 mg once daily. Rates and reasons for treatment failure were assessed. Clinical features, laboratory values, abdominal imaging and endoscopic remission rates were evaluated.
RESULTS: Total of twelve patients received TG and median treatment duration was 8 months (range 1-12). There were 7(58%) female and 5(42%) male. Mean age was 37 years (range 19-62). 6/12(50%) patients had Ulcerative Colitis (UC) and 6/12(50%) had Crohn's Disease (CD). Indications for initiation of 6-thioguanine therapy were conventional thiopurine intolerance 10(83%) and non-response to treatment 2(17%). Two patients stopped taking treatment within first month due to fear of side effects; one of them wanted to become pregnant. Of 10 patients two failed TG therapy: one due to adverse event (hair loss) and other due to therapy failure. 4/10(40%) patients had partial response, having occasional mild flare ups while further 6/10(60%) patients remained in sustained clinical remission at 6 months on treatment, although one of the patient did not turn up to follow up appointment following 6 months of therapy. Tolerability and efficacy rates were similar in both UC and CD. All patients were closely monitored and no abnormality in liver function tests detected.
CONCLUSION: Our study showed that TG was well tolerated in this selected group of difficult to treat patients. In addition, the use of small dose 20mg daily of TG appears to be relatively safe in IBD patients who failed conventional thiopurine therapy. Well designed prospective trials are required to further evaluate the safety and efficacy of 6-thioguanine.

P1465 GRANULOCYTAPHERESIS IN STEROID-DEPENDENT AND STEROID-RESISTANT PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE OBSERVATIONAL STUDY

R. Sacco[1,*], A. Romano[1], M. Bertini[1], S. Metrangolo[1], C. Giampietro[2], C. Nencini[2], E. Tumino[1], A. Mazzoni[2], F. Scatena[2], G. Bresci[1].
[1]*Gastroenterology,* [2]*Transfusional Center, Pisa University Hospital, Pisa, Italy*

INTRODUCTION: Granulocytapheresis (GCA) has a mounting importance in the treatment of inflammatory bowel diseases (IBDs); however, the differential effectiveness of this treatment in steroid-resistant and steroid-refractory patients needs further investigation.
AIMS&METHODS: We report the results of a prospective observational experience on the use of GCA in patients with either ulcerative colitis (UC) or Crohn's disease (CD) who were steroid-dependant (SD) or steroid-refractory (SR). In total, 118 patients were evaluated: 83 were affected from UC (55 SD and 28 SR), and 35 from CD (22 SD and 13 SR). All patients were treated with GCA, using the AdacolumnTM system, an adsorption column which selectively binds granulocytes and monocytes, for one session/week for 5 consecutive weeks. Concomitant steroid treatment was not permitted. Disease activity was evaluated by clinical disease index (CAI) in patient with UC and by Crohn's Disease Activity Index (CDAI) in those with CD: a clinical remission was defined as CAI $\leq$6 or CDAI $<$150. All patients were followed for 12 months after the end of GCA.
RESULTS: All patients completed the study; no complications were reported. The remission rates at the end of GCA, 6 and 12 months are reported in Table 1, while the values of CAI and CDAI during the follow-up period are shown in Table 2.

Tab.1

End of GCA 6 months 12 months UC	CD
Overall (n=83) 74% 69% 48%	Overall (n=35) 65% 57% 43%
SD (n=55) 71% 67% 45%	SD (n=22) 63% 54% 41%
SR (n=28) 67% 64% 39%	SR (n=13) 61% 53% 38%

Tab.2

Baseline 6 months 12 months UC (CAI)	CD (CDAI)
Overall 9.5±2.4 3.3±3.9 4.3±3.4	Overall 247±37 100±89 95±85
SD 9.5±2.5 3.3±3.9 4.3±3.5	SD 245±37 110±124 80±80
SR 9.5±2.6 3.4±3.9 4.0±3.	SR 251±42 87±19 116±106

CONCLUSION: On the basis of this large observational experience, GCA appears effective and well tolerated for the treatment of UC and CD in patients who are either SD or SR. GCA might be therefore considered as a useful alternative therapeutic approach in these patients. However, these findings need further validation in randomized multicenter trials, with the aim to shed new lights on the use of GCA for the treatment of IBDs.

P1466 STEROID SPARING WITH ADALIMUMAB IN CROHN'S DISEASE PATIENTS: A REAL-LIFE EXPERIENCE IN A TERTIARY REFERRAL CENTER

S. Onali[1,*], C. Petruzziello[1], E. Lolli[1], F. Zorzi[1], G. Condino[1], L. Biancone[1], F. Pallone[1], E. Calabrese[1]. [1]*Gastroenterology Unit, University of Rome Tor Vergata, Rome, Italy*

INTRODUCTION: There is a need for long-term treatment alternatives that maintain clinical remission and reduce exposure to corticosteroids in Crohn's disease (CD) patients. Data regarding the long-term steroid-sparing effect of maintenance medications, including anti-TNF therapies, are limited. Adalimumab (ADA) is a fully human monoclonal antibody that is widely approved for the treatment of CD.
AIMS&METHODS: Aim of the study was to evaluate steroid-sparing efficacy of ADA in a cohort of CD patients in clinical practice. This retrospective study included 73 patients treated with ADA for CD between 2007 and 2013 (male: 41%; median age: 40.5 yrs; median disease duration: 12 yrs; previously exposure to anti-TNFs: 57.5%; combination therapy with azathioprine or methotrexate: 13%; steroid-dependence: 68.5%; median CDAI at ADA initiation: 235). Indication to anti-TNFa treatment included active luminal disease, perianal disease and presence of extra-intestinal manifestations. Steroid-free clinical remission was defined as absence of symptoms of active disease without steroids during maintenance and 1 year after ADA discontinuation.
RESULTS: Overall 62/73 (85%) of the patients achieved clinical remission and steroid sparing during maintenance and one year after ADA discontinuation. For perianal disease, remission was achieved in 9 out of 11 patients. In these patients ADA were used in combination to a surgical approach. Median time of ADA treatment was 17 months (1-59). Eleven patients (15%) did not achieve steroid clinical free remission and needed of budesonide in 10 patients and systemic steroid course in only 1 patient.
CONCLUSION: Our findings suggest that ADA therapy in clinical practice may be effective in terms of long-term efficacy and steroid sparing in our population of CD patients.

INTRODUCTION: Influenza vaccination is recommended for immuncompromised patients with inflammatory bowel disease (IBD).
AIMS&METHODS: We evaluated the serologic and clinical immune response to influenza vaccine in immuncompromised IBD patients.158 immuncompromised IBD patients were vaccinated. 62 patients refused vaccination. Split and whole virion vaccines were used. Serum samples for pre and postimmunization

antibody titers for influenza vaccine were collected. Cell-mediated responses to influenza A and B vaccines were evaluated using an INF-γ, IL-2, and TNF-α ELISA. Leukocyte and lymphocyte levels were also assessed.
RESULTS: 25 patients had local, 32 systemic reactions after vaccinations. 7 patients developed influenza-like symptoms. INF-γ, TNF-α, IL-2, leukocyte and lymphocyte levels did not change after vaccination. Significant differences were shown between pre- and post-vaccination influenza A and B antibody titers only in case of split virion vaccines.
CONCLUSION: Influenza vaccines were safe and well tolerated. Influenza vaccination did not influence cell-mediated immune response, but increased influenza A and B postimmunisation antibody titers. Split virion vaccines are more effective than whole virion vaccines.

INTRODUCTION: -
AIMS&METHODS: To assess impact of early and sustained clinical remission on HRQOL in pts with active UC after SC GLM. Pts with moderate to severe UC defined by Mayo score of 6-12 including endoscopy subscore $\geq$2 with inadequate response or intolerance to conventional UC therapies but naïve to anti-TNF were randomized in the Ph3 portion of PURSUIT Induction to PBO or GLM 200mg,100mg or 400mg,200mg at wks 0 and 2. At wk6,GLM-treated pts who achieved clinical response were randomized to PBO or 50 or 100mg GLM q4w in PURSUIT Maintenance. Disease specific HRQOL was measured using the IBDQ and generic HRQOL was measured using SF-36 and EQ-5D.SF-36 was summarized by PCS and MCS. Normalized QoL was defined as SF-36 PCS or MCS $\geq$50, and IBDQ remission with total score$\geq$170. Clinical remission was defined as a Mayo score $\leq$2 points with no individual subscore$>$1.
RESULTS: Compared to PBO, a significantly greater proportion of GLM-treated pts achieved remission at wk6. GLM-treated pts who achieved clinical remission at wk6 had greater mean improvement in PCS,MCS,EQ-5D and IBDQ than those who did not achieve remission (PCS: 8.0 vs. 2.9, $p<0.001$; MCS: 10.7 vs. 2.6, $p<0.001$; EQ-5D: 21.4 vs. 7.2, $p<0.001$; and IBDQ: 54.7 vs. 17.7, $p<0.001$). Pts in clinical remission were more likely to achieve normalized PCS, normalized MCS, and IBDQ remission than those who didn't achieve clinical remission (PCS: 53.6% vs. 25.3%, $p<0.001$;MCS: 63.6% vs. 31.6%, $p<0.001$;IBDQ: 85.5% vs. 32.2%, $p<0.001$). GLM-treated pts who achieved clinical remission during induction AND maintained clinical remission at wk54 in maintenance were more likely to achieve normalized PCS, and MCS, and IBDQ remission than those who did not (PCS:73.5% vs. 22.7%, $p<0.001$; MCS: 63.3% vs. 28.4%, $p<0.001$; IBDQ remission: 89.8% vs. 22.7%, $p<0.001$). Those who achieved clinical response or mucosal healing demonstrated better improvement in HRQOL than those who didn't achieved these outcomes, but improvements in HRQOL were numerically lower than for pts in clinical remission.
CONCLUSION: Early and sustained clinical remission was associated with normalized HRQOL outcomes and should be considered as treatment goal for pts with moderate to severe UC.

P1469 EFFICACY OF ORAL TACROLIMUS AND INFLIXIMAB INFUSION IN THE TREATMENT OF ACTIVE ULCERATIVE COLITIS IN JAPAN.

Y. Nuki[1,*], K. Asano[1], Y. Maehata[1], J. Umeno[1], T. Moriyama[1], S. Nakamura[2], M. Esaki[1], T. Matsumoto[1]. [1]*Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University,* [2]*Center for Advanced Medical Innovation, Kyushu University, Fukuoka, Japan*

INTRODUCTION: Oral tacrolimus and infliximab infusion have been proven to be effective treatments for active ulcerative colitis (UC). In clinical practice, however, it is still unclear which is the better therapeutic choice.
AIMS&METHODS: We aimed to investigate the efficacy of oral tacrolimus and infliximab infusion in the treatment of moderate-to-severe UC. This was a retrospective survey in which 34 consecutive patients with moderate-to-severe UC were enrolled from September 2009 to March 2013. Nineteen patients were treated with infliximab and fifteen were tacrolimus. The disease activity was evaluated using Ulcerative Colitis Activity Index (UCAI) reported by Seo M, et al. Clinical remission was defined as UCAI score of $<$120 and clinical response was defined as UCAI score of $<$150. Relapse was defined by the persistent UCAI score of $>$150 or lack of efficacy requiring a change in the treatment within 10 weeks after the initial administration. We investigated induction rates for remission and response in the two treatment grroups at week 10. Patients who achieved clinical response were followed-up until March 2013. We investigated relapse rates in the treatment groups using the Kaplan-Meier method. Cox regression analysis was performed to identify predictors for time to relapse.
RESULTS: There was no difference in the induction rates for remission and response between the two groups. In the infliximab group, remission rate and response rate at week 10 were 78.9% and 89.5%, respectively. In the tacrolimus group, remission rate and induction rate were 80.0% and 93.3, respectively. Among 31 patients who had achieved clinical response, 10 (32.3%) relapsed during the mean follow-up period of 77.6 weeks (infliximab group, 29.4%; tacrolimus, 35.7%). Time to relapse was not significantly different between the two treatment groups. Cox proportional-hazards regression analysis revealed that left-sided colitis was an independent predictor for relapse in the infliximab group, while no clinical characteristics predicted relapse in the tacrolimus group.
CONCLUSION: Both tacrolimus and infliximab were efficacious in the treatment of moderate-to-severe UC. In the infliximab group, left-sided colitis was associated with higher relapse rate.

P1470 EFFECTIVENESS OF THE SCREENING FOR LATENT TUBERCULOSIS IN INFLAMMATORY BOWEL DISEASE PATIENTS WITH PREVIOUS BCG VACCINATION

Z. Zelinkova[1,*], T. Hlavaty[1], I. Pav[2], T. Koller[1], J. Toth[1], M. Huorka[1]. [1]*5th Department of Internal Medicine, Division of Gastroenterology&Hepatology, University hospital, Bratislava, Slovakia,* [2]*Department of Gastroenterology, University Hospital Petrzalka, Bratislava, Slovakia*

INTRODUCTION: Screening for latent tuberculosis (LTB) prior anti-tumor necrosis factor (antiTNF) treatment is recommended. The diagnostic yield of different screening methods for LTB may be affected by previous BCG vaccination and the use of immune suppressive medication (IS). Furthermore, there are limited data on the effectiveness of this screening in reduction of TB reactivation during antiTNF treatment.
AIMS&METHODS: We aimed to determine whether the use of IS influences the outcomes of screening for LTB based on tuberculine skin test (TST) and interferon gamma releasing assay (IGRA) methods in a population of inflammatory bowel disease (IBD) patients vaccinated with BCG. We evaluated the incidence of TB reactivation during antiTNF treatment in this population. All consecutive patients with previous BCG vaccination were included. The outcomes of the LTB screening were retrieved from medical records and TB reactivation during antiTNF therapy was noted. The differences between the proportions of IS using patients tested positive for LTB vs. those tested negative were analysed by chi-square test.
RESULTS: In total, 182 IBD patients (99 males/83 females; mean age 38 years, range 18-75 years) were screened for LTB prior the initiation of antiTNF therapy. An induration at TST was found in 24 cases, the average induration was 11 mm, ranging from 4 to 25 mm. Nineteen out of these 24 tests were performed at the moment of the use of IS (79% vs. 92% in the group with negative TST, p=n.s.). Quantiferon Gold test was positive in 12 cases (6.6%), nine of these tests were performed at the moment of the use of IS (75% vs. 93% in the group with negative Quantiferon Gold test, p=0.009.). This test was inconclusive in 4 cases (2%), three of these patients were on IS medication. T-spot was inconclusive in two cases, in six cases the results were negative (5 tests at the moment of the IS use).
LTB was diagnosed in 13 cases (7%) based on positive Quantiferon test (11 cases) and in two patients based on an 18 mm large TST induration. These patients received a six months prophylactic treatment with isoniazid. During the further follow-up of a minimum of antiTNF treatment of 6 months, no clinically overt cases of TB reactivation were observed.
CONCLUSION: The use of immune suppressive medication does not seem to influence the diagnostic yield of tuberculine skin test but it does interfere with interferon gamma releasing assays. Nevertheless, the combination of these two methods results in an effective prophylaxis of TB reactivation during antiTNF treatment also in IBD patients using immune suppressive medication.

P1471 CUTANEOUS MANIFESTATION DURING ANTI-TNF A THERAPY IN PEDIATRIC INFLAMMATORY BOWEL DISEASE

A. Dilillo[1,*], G. Mazza[1], F. Civitelli[1], C. Banzato[1], S. D'Epiro[2], F. Nuti[1], M. Aloi[1], E. Del Giudice[1], M. Clemente[1], A. G. Richetta[2], F. Viola[1], S. Cucchiara[1]. [1]*Department of Pediatrics, Gastroenterology and Liver Unit,* [2]*Department of Dermatology, Sapienza University, Rome, Italy, Rome, Italy*

INTRODUCTION: Anti-TNF antibodies play an important role in the management of IBD, rheumatologic diseases, psoriasis. They have a good safety profile

but many studies have reported some adverse reactions. Skin manifestations are the most common adverse events and occur in 20–25% of patients (pts). There are only few data on cutaneous manifestations during anti-TNFα therapy in IBD children.

AIMS&METHODS: We conducted a retrospective study among pts with IBD receiving Infliximab, (IFX) and Adalimumab, (ADA). Duration of therapy, type and location of skin lesions, time of onset, disease activity, concomitant immunosuppressors(IM) and corticosteroids(CS) at the time of skin manifestation were reported. We evaluated differences between IFX and ADA in terms of frequency of cutaneous manifestations.

RESULTS: 74 pts (40 males, 63 with CD,9 with UC and 2 with undefined-IBD) were enrolled. The mean age at first skin manifestation was 16.3±3.2 years. Forty (54%) pts developed at least one cutaneous manifestation during anti-TNFα therapy: folliculitis (14 pts), psoriasis (14), eczematous and seborrheic dermatitis (5), skin infections (7), acne (12), xerosis cutis (7). In terms of distribution and location of skin lesions, folliculitis mainly affected arms and legs (35%pts), whereas in pts with psoriasis the scalp and pubic region were the mostly involved areas, 48% and 24% of pts respectively. There was no difference between males and females in the development of skin lesions (p=0.6). There was no significant difference in terms of disease activity (p=0.5). The mean duration of anti-TNFα therapy at the onset of skin events was 11.75 months (mts). 17 (43%) pts were on concomitant IM therapy, whereas no pts had been on CS during the previous 3 mts. There wasn't a clear association between a specific anti-TNF-agent and the occurrence of skin lesions, but IFX treated pts developed skin manifestations more frequently than pts receiving ADA (72% vs 42%, respectively). We also observed a longer time of onset of cutaneous lesions in pts receiving ADA (p=0.005).

CONCLUSION: In our pts folliculitis and psoriasiform lesions are the most common cutaneous manifestations during anti-TNF therapy. Skin events are frequent during biological therapy thus remarking the importance of a team management of pediatric IBD also including a dermatologist. In our experience the majority of lesions are easy to treat and are not a reason to stop anti-TNF therapy. Only rarely it's necessary to interrupt therapy for some time.

P1472 IMPROVEMENT IN MARKERS OF BONE METABOLISM WITH ADALIMUMAB IN CHILDREN WITH MODERATELY TO SEVERELY ACTIVE CROHN'S DISEASE: RESULTS FROM IMAGINE 1

A. Griffiths[1,*], R. Baldassano[2], T. Walters[1], J. Bronsky[3], J. Hyams[4], A. Lazar[5], Y. Wang[6], S. Eichner[6], R. Thakkar[6]. [1]*The Hospital for Sick Children, Toronto, Canada,* [2]*Children's Hospital of Philadelphia, Philadelphia, United States,* [3]*University Hospital Motol, Prague, Czech Republic,* [4]*Connecticut Children's Medical Center, Hartford, United States,* [5]*AbbVie, Ludwigshafen, Germany,* [6]*AbbVie, N. Chicago, United States*

INTRODUCTION: Objective: To measure changes in bone metabolism in paediatric patients (pts) with moderately to severely active Crohn's disease (CD) treated with adalimumab (ADA) enrolled in the clinical trial IMAGINE 1.

AIMS&METHODS: In IMAGINE 1[1], pts aged 6-17 years with Baseline (BL) PCDAI >30 and CD resistant or intolerant to conventional therapy, including prior infliximab, received open-label induction of ADA at wks 0/2 according to body weight (≥40kg, 160/80mg; <40kg, 80/40mg). At wk 4, pts were randomized to double-blind higher-dose (HD) ADA (≥40kg, 40mg every other week [eow]; <40kg, 20mg eow) or lower-dose (LD) ADA (≥40kg, 20mg eow; <40kg, 10mg eow). Pts experiencing disease flare or non-response could move to blinded weekly dosing after wk 12. Changes in serological markers of bone formation (osteocalcin [OC], bone specific alkaline phosphatase [BSAP]) and resorption (serum type I collagen N-telopeptide [NTx]) from BL were calculated at wk 26 and 52 for LD and HD ADA. Subgroup analyses by prior IFX use, disease severity at BL, and response at wk 4 (defined as PCDAI decrease ≥15 points from BL) were also performed. Last observation carried forward (LOCF) was used to impute missing data. Signed rank test was applied to evaluate changes within each treatment group.

RESULTS: Overall, pts achieved improvement in OC and BSAP with LD and HD ADA at wks 26 and 52 (Table). Increases in OC and BSAP were achieved with both doses at wks 26 and 52 in pts naïve to prior IFX and with severe disease (PCDAI≥40). BSAP improvement was more pronounced in wk 4 responders. Significant change in NTx was observed at wk 26 with HD ADA (Table).

Table. Median BL values of serological markers of bone metabolism and median change from BL at Wks 26 and 52 (LOCF)

	Osteocalcin (μg/L)		BSAP (μg/L)		NTx (nm BCE)	
	LD ADA 20/10mg N=63	HD ADA 40/20mg N=64	LD ADA 20/10mg N=62	HD ADA 40/20mg N=65	LD ADA 20/10mg N=62	HD ADA 40/20mg N=65
Baseline	15.10	13.20	42.80	45.10	25.15	26.60
Week 26	2.5†	2.5†	11.9§	9.0§	1.6	4.3*
Week 52	0.5	2.6†	4.6*	3.1*	-1.3	-0.8

*p<0.05; †p<0.01; §p<0.001 using signed rank test for no change from BL within each treatment group

CONCLUSION: Both HD and LD ADA treatment improved bone metabolism in children with moderately to severely active CD. Pts naïve to IFX derived the greatest treatment benefit.

P1473 OROFACIAL GRANULOMATOSIS AND ENTERAL NUTRITION IN PEDIATRIC CROHŃS DISEASE

C. Olbjørn[1,*], G. Perminow[2]. [1]*Department of Pediatrics, AKERSHUS UNIVERSITY HOSPITAL, Lørenskog,* [2]*Department of Pediatrics, Oslo University Hospital, Ullevål, Oslo, Norway*

INTRODUCTION: Crohńs disease in children and adolescents can be treated with exclusive enteral nutrition (EEN) as induction therapy. Some patients have oral complaints, suspicious of orofacial granulomatosis (OFG). Symptoms are lip swelling, aphtous lesions, cheilitis and granulomatous inflammation in the mouth. OFG might be a part of Crohn's disease and is believed to be, at least partly, an allergic reaction to benzoates and cinnamon. Diet restrictions and elemental diet (amino- acid formula) are used to treat the condition.

AIMS&METHODS: Retrospectively, we wanted to investigate the efficacy and tolerability of exclusive enteral nutrition in children and adolescents with Crohn's disease and OFG at our institution.

During the period May 2005 to January 2012 we diagnosed altogether 70 patients, 64 with Crohn's disease according to the Porto criteria, 12 with concomitant OFG. 6 patients presented with isolated OFG.

RESULTS: Out of the 64 patients with Crohńs disease, 17 were given 5- ASA, azathioprine and or budesonide. All patients who received 5-ASA, azathioprine and or a course of budesonide remained in remission. 45 patients (70%) received EEN and azathioprine. The disease distribution was more extensive in these patients with significantly higher PCDAI, fecal calprotectin ((median 1041 mg/kg (normal range <50mg/kg), CRP (mean 30 mg/l) and ESR (mean 24 mm/h)) before treatment compared to 632 mg/l, 16 mg/l and 18 mm/t respectively. The 6 patients with isolated OFG had a normal fecal calprotectin as well as normal CRP and ESR at time of diagnosis. In 28 (62%) of the EEN treated patients we observed a complete normalization of the ESR, CRP and fecal calprotectin. Fifteen (54%) of the patients who went into remission with EEN and azathioprine are still doing well with azathioprine as maintenance. All OFG patients, with or without concomitant Crohn's disease, responded well to treatment with exclusive elemental diet with a reduction of lip swelling and resolution of aphtous ulcers and cheilitis. The improvement was evident within a few days. Their symptoms were later controlled with a diet free of benzoates and cinnamon.

CONCLUSION: Exclusive enteral nutrition is efficacious and well tolerated in children with Crohn's disease and OFG. In OFG the liquid diet should be an elemental formula. Benzoate free and cinnamon-free diet is of benefit in OFG patients in order to control the symptoms.

P1474 INFLUENCE OF GENOTYPE ON BIOCHEMICAL MARKERS OF INFLAMMATION IN CHILDHOOD INFLAMMATORY BOWEL DISEASE.

C. Rungo[1,*], V. Wewer[2], C. Jakobsen[2]. [1]*Department of Epidemiology Research, Statens Serum Institut, Copenhagen,* [2]*Paediatric Department, Hvidovre University Hospital, Hvidovre, Denmark*

INTRODUCTION: There is paucity of data on the influence of genotype on biochemical inflammation markers in paediatric inflammatory bowel disease (IBD).

AIMS&METHODS: We aimed to investigate associations between IBD related predefined single nucleotide polymorphisms (SNPs) and the level of biomarkers within the first year after diagnosis in a population based cohort of paediatric IBD patients. A historical population-based cohort including all incident paediatric patients with IBD, diagnosed in Eastern Denmark (January 1. 1998 – December 31. 2006) was created. Multiple regression analysis was used to analyze associations between 52 SNPs and the level of biochemical markers of inflammation (albumin, hemoglobin, c-reactive protein, erythrocyte sedimentation rate, leucocytes) measured at diagnosis, 30 days, 6 months and one year after diagnosis. The analysis was adjusted for age, gender and disease localization.

RESULTS: The cohort consisted of 235 patients. In 190 patients (83 Crohn's disease [CD], 95 ulcerative colitis [UC] and 12 IBD-unclassified [IBD-U]) genotyping and retrieving information on blood sample results within the first year after diagnosis was succesful. Mean age at diagnosis was 12.4 years (range 0.4-15 years). In multivariate analysis three different SNPs (rs6785049, rs10500264,

rs4986791) located on three different genes; Pregnane-X-receptor, SLC7A10 and TLR-4, respectively, were associated with a significant increase of the level of hemoglobin ($p<.0001$) and albumin ($p<.0001$) in patients with CD or UC within the first year after diagnosis. The mean changes in the level of hemoglobin was small (mean change 0.2 mmol/l [range -0.2-0.6] in SNP rs10500264) and (mean change 0.4 mmol/l [range 0.1-0.9] in SNP rs6785049) whereas the changes in the albumin level was more marked. In patients with UC homozygous for the C allele (CC genotype) in SNP rs4986791 the mean increase in albumin (g/l) from diagnosis to one year after diagnosis was 2.5 (from 40.0-42.5) compared to UC patients with the genotype CT 0.5 (from 39.6-40.1).

CONCLUSION: In this pilot study on 190 pediatric patients with IBD, we identified an association between three different SNPs and the level in hemoglobin and albumin within the first year after diagnosis, which suggests a genetic contribution to the inflammatory response in paediatric IBD.

Janowitz Division of Gastroenterology, New-York, United States,* [8]*Gastroenterology, UNIVERSITY AND HOSPITAL LILLE, Lille, France*

INTRODUCTION: We described in children the incidence of and factors associated with post-operative complications (POC) in inflammatory bowel disease (IBD).

AIMS&METHODS: Using a population-based Registry, among 692 IBD incident cases (532 Crohn's disease (CD) and 160 ulcerative colitis (UC),153 (128 CD) patients (22%) underwent one abdominal surgery. Median age at surgery was 16 yrs [14-17]. Medical charts were reviewed for early (<30 days) and late (≥30 days) POC according to Dindo's criteria(1). Factors associated with POC were assessed using Cox models and expressed as HR with 95%CI.

RESULTS: After 8 yrs [3-12] of follow-up,78 (51%) experienced one POC with a total of 115 POC(median1[1-2]) including 51 patients with one POC and 27 with more than one. POC were significantly more frequent in UC than in CD (72%*vs*45%;p=0.01). Children with UC presented more frequently at least 2 POC than those with CD (45% *vs* 29%;p=0.01). A total of 64 early POC was observed in 47 patients (31%), with 33 infectious. Early POC were more frequent in UC than in CD (83% *vs* 55%;p=0.03). Regarding all POC, their graded distribution was 38% (n=42) for grade 1,35% (n=39) for grade 2, 28% (n=31) for grade 3 and 1.8% for grade 5 (n=2). The frequency of severe POC (grade>2) was similar in CD and UC (28% *vs* 27%). 51 late POC were observed in 39 patients (24%), with 45 non-infectious. The cumulative risk of any POC was 31% (95% CI, 24-39) at 1 mo and 44% (36-52) at 6 mos. Multivariate analysis found that type of IBD was the only factor associated with any POC (HR relative to UC *vs*. CD, 2.2;[1.3-3.8]). Gender, systemic steroid, immunosuppressants (IS) before abdominal surgery were not predictors for POC. In UC, shorter was the time from the diagnosis to the colectomy higher was the risk for POC (HR=1.50[1.01-2.20]). In CD, age at diagnosis <14 yrs was associated with an increased risk for POC (HR=1.8 [1.01-3.10]). Time from IBD diagnosis to abdominal surgery <18 mos (HR=2.7[1.1-6.6]) and parenteral nutrition (HR=2.7 [1.2-6.1]) were associated with an increased risk for infectious POC.

CONCLUSION: 50% of children with IBD experienced at least one POC that occurred either early (31%) or late (24%). Only UC was significantly associated with an increased risk of POC. A short time from diagnosis to surgery was poor prognosis in UC and associated in all IBD with an increased risk for infectious POC. Systemic steroid and IS were not associated with an increased risk of infectious POC.

P1476 ANTI-TNF ALPHA THERAPY AND MUCOSAL HEALING: THE KEY TO CHANGE THE STORY OF PEDIATRIC CROHN'S DISEASE?

F. Nuti[1,*], F. Civitelli[1], A. Dilillo[1], G. Di Nardo[1], M. Aloi[1], S. Oliva[1], F. Viola[1], S. Cucchiara[1]. [1]*Department of Pediatrics, Sapienza University Rome, PEDIATRIC GASTROENTEROLOGY AND HEPATOLOGY UNIT, Rome, Italy*

INTRODUCTION: Efforts have been made to optimize the use of available therapies to improve Crohn's disease (CD) patients' outcome, but up to now no therapy changed the natural history of the disease. Mucosal healing (MH) appears as a therapeutic goal able to predict sustained clinical remission. Therapy with anti-TNFα antibodies, Infliximab (IFX) and Adalimumab (ADA), have been proven effective in achieving MH with a more potent and rapid effect compared to immumomodulants (IMM). Few studies evaluating MH as a therapeutic goal in pediatric CD are available.

AIMS&METHODS: Aim of our study is to assess the efficacy of IFX and ADA in obtaining MH in a pediatric CD cohort. Secondary aim is to evaluate differences in response in children with early (<1 year) or late (>1 year) disease.

Pediatric CD patients (pts), between 6 and 18 years of age, starting IFX or ADA from January 2009 were enrolled. All pts were naïve to biological therapies but could have been previously treated with corticosteroids, IMM and aminosalycilates.

Pts' characteristics collected at baseline are: age at diagnosis, indication for therapy, age at enrollment, disease duration and location, and concomitant medications. An endoscopic procedure was performed before starting biologics and after 9 to12 months to evaluate MH. Clinical and endoscopic disease activity were assessed by Pediatric Crohn's Disease Activity Index (PCDAI) and Simple Endoscopic Score (SES CD) respectively at time 0 (T_0) and at the time of endoscopic follow-up (FU). Pts underwent anti-TNFα therapy with appropriate induction and maintenance therapeutic schemes.

RESULTS: Thirty-one pts (21 IFX and 10 ADA) were enrolled, 18 males. At enrollment mean age was 12.7± 2.9 years and mean disease duration was 13 ± 15.3 months. Fifteen pts (6 IFX) were in the early disease group, 16 (15 IFX) in the late disease group. At T_0 16 pts (52%) were on IMM, 10 of them were still on IMM at FU. Mean ± SD values of PCDAI and SES CD at T_0 and FU are 30±17.6 and 11.3 ± 11.5, and 15.5± 8.6 and 6.5 ± 7.5 respectively; both values were significantly reduced at FU ($p < 0.05$). Dividing patients on the basis of disease duration prior to therapy introduction SES CD values decreased significantly at FU both in early and in late disease pts, however more significantly in the first group ($p<0.0001$ vs 0.02).

CONCLUSION: In our cohort biological therapy appears effective in achieving mucosal healing in pediatric patients affected by CD, probably more efficaciously if introduced early in the course of the disease. Larger studies with longer FU will highlight the effect of MH on disease evolution.

P1477 ANTI-TNF DEPENDENCY IN PAEDIATRIC IBD- THE SCOTTISH EXPERIENCE

F. L. Cameron[1,*], M. L. Wilson[2], D. Goudie[3], W. M. Bisset[4], R. K. Russell[5], D. C. Wilson[2]. [1]*Child Life and Health, University of Edinburgh,* [2]*Child Life and Health, Univerity of Edinburgh, Edinburgh,* [3]*Paediatric Department, Raigmore Hospital, Inverness,* [4]*Paediatric Gastroenterology, Hepatology and Nutrition, Royal Aberdeen Children's Hospital, Aberdeen,* [5]*Paediatric Gastroenterology, Hepatology and Nutrition, Yorkhill Hospital, Glasgow, United Kingdom*

INTRODUCTION: Management of paediatric IBD (PIBD) has changed significantly in the last 10 years with the advent of biological agents which are beneficial in the induction and maintenance of remission.

AIMS&METHODS: Recent evidence is emerging on biological dependency and the aim of our study is to identify patients in our national cohort who become dependent on Infliximab (IFX) and/or Adalimumab (ADA) after response to induction therapy. A retrospective case note review was carried out in all PIBD treatment centres in Scotland within our national network. Children <18 year were included who were given Infliximab (IFX) and/or Adalimumab (ADA) in a paediatric centre and dependency was defined as relapse of symptoms requiring repeated infusions to regain complete or partial response. Data was collected from 1.1.00 until 01.03.12 with follow up until 30.9.12 on duration of treatment, clinical response and adverse events.

RESULTS: 65 patients had IFX and/or ADA for at least 12 months - 42 males, 64 with CD and 1 UC. 38 of 65 (58%) had anti-TNF dependency. 49 patients were on IFX for a median of 1.67 years receiving 4- 25 doses with a median of 11. 14 patients failed IFX and proceeded to maintenance ADA. Commonest disease location was colonic (37%) and behaviour was inflammatory (B1 and B1p 81%). 61% were on steroids at baseline and all were on immunomodulators. 98% had response/remission after induction. The most common indications were luminal CD, immunomodulatory failure and steroid dependency. 40% required escalation of therapy, either increased dose or frequency. 55% stopped treatment after 12 months (44% loss of response, 33% successful planned IFX withdrawal and 7% allergic reaction); 45% continued to study end.

16 patients (14 prior IFX) were on ADA for a median of 2.18 years, all had CD and 12 were male; 13 were on ADA at study end, 2 stopped for loss of response and 1 had successful planned ADA withdrawal. IFX failure was most commonly primary non-response, in 7 (44%). 9 (56%) required escalation of therapy to weekly dosing. 81% had a response or remission after induction. No serious adverse events were noted during or after biological therapy.

CONCLUSION: 58% on IFX/ADA at 12 months then become dependent on anti-TNFs, with only a minority having successful planned drug withdrawal. Both drugs appear safe and well tolerated; only 7% stopping IFX or ADA due to allergy or side effects after 12 months. The need for dose escalation and identification of those who can successfully cease biologicals remain major issues.

P1478 COLONIC ULTRASONOGRAPHY IN PEDIATRIC ULCERATIVE COLITIS: COMPARATIVE STUDY WITH COLONOSCOPY

F. Civitelli[1,*], G. Di Nardo[1], S. Oliva[1], F. Ferrari[1], A. Dilillo[1], F. Nuti[1], M. Aloi[2], F. Viola[1], S. Cucchiara[1]. [1]*Pediatrics, Gastroenterology and Liver Unit, Sapienza University, Rome, Italy,* [2]*Pediatrics, Gastroenterology and Liver Unit, Sapienza University, Rome, -*

INTRODUCTION: Bowel ultrasonography (US) is a non-invasive tool in the evaluation of inflammatory bowel diseases, especially Crohn's disease. There are only few data on its role in Ulcerative Colitis (UC), particularly in children.
AIMS&METHODS: To evaluate the usefulness of bowel US in the assessment of pediatric patients (pts) with UC and compare US findings with clinical and endoscopic data. Thirty pediatric pts (median age 15 years; range 2-21; 14 males) were prospectively enrolled. Eight pts had a clinical suspicion of UC, 22 had an already established diagnosis and showed a disease flare-up. All pts underwent clinical evaluation, bowel US with Color-Doppler examination (Toshiba equipment, 3.5 MHz convex and 7.5 MHz linear transducers) and ileo-colonoscopy. US and endoscopy were carried out by different operators, blind to the results of the other technique. For each patient Pediatric Ulcerative Colitis Activity Index (PUCAI) and Mayo endoscopic subscore were calculated. The US assessed parameters were Bowel Wall Thickness (normal value < 3 mm), BW stratification, vascularity and presence of austrae:each parameter was assigned a value of 0 or 1 depending on the presence or absence of alteration.
RESULTS: 27/30 pts were finally diagnosed as UC. Extension of disease according to Paris Classification was: E2 (left-side colitis) in 12/27 (45%), E4 (pancolitis) in 15/27 (55%) pts. This extension was independently confirmed in 24/27 pts by US, that yielded a 90% concordance (K) with endoscopy for disease extension (CI 0.82-0.96; SE 0.03). Disease activity was mild (PUCAI 10-34) in 7 pts (25%), moderate (PUCAI 35-64) in 12 (45%) and severe (PUCAI >65) in 8 (30%). The mean values of PUCAI, Mayo score and US score respectively were: 40.5 ± 24.4, 2 ± 1 and 3 ± 1. The US score strongly correlated with PUCAI ($r=0.90$, $p<0.0001$) and Mayo index ($r=0.94$, $p<0.0001$). A positive correlation was also found between PUCAI and Mayo score ($r=0.88$, $p<0.0001$). Multiple regression analysis showed that variables making a significant contribution to the final value of Mayo score were BWT ($p=0.0008$), vascularization ($p=0.02$) and stratification ($p=0.02$). The mean BWT in affected colonic segments was 5 ± 2 mm. BWT allowed to discriminate between moderate-severe and mild disese activity ($p=0.001$).
CONCLUSION: Our data show a strong relationship between US and clinical and endoscopic findings, thus suggesting that colonic US might represent a useful first line tool in the evaluation of pediatric UC pts. It allows to assess the extension and activity of disease and to estimate the severity of a flare-up, prior to further invasive tests.

INTRODUCTION: To evaluate adalimumab (ADA) efficacy at week (wk) 4 in paediatric patients (pts) with moderately to severely active Crohn's disease (CD) enrolled in the randomised clinical trial IMAgINE 1.
AIMS&METHODS: In IMAgINE 1[1], pts aged 6-17 yrs with baseline (BL) PCDAI >30 and CD resistant or intolerant to conventional therapy, including prior infliximab (IFX), received open-label induction of ADA at wks 0/2 according to body weight ($\geq$40kg, 160/80mg; $<$40kg, 80/40mg). Proportion of pts in clinical remission (PCDAI$\leq$10) and response (PCDAI decrease $\geq$15 points from BL) were measured at wk 4. Non-responder imputation (NRI) was used for missing data. Median change in C-reactive protein (CRP) levels (mg/dL) from baseline was measured at wk 4. The safety profile for ADA in IMAgINE 1 has been reported previously[1].
RESULTS: At wk 4, 155 (81%) pts responded to induction and 52 (27%) were in clinical remission. Remission and response rates were comparable between the induction dose groups (Table). A numerically higher proportion of IFX-naïve pts were in remission at wk 4 compared to pts who had prior IFX (Table), however the differences were not statistically significant. A decrease in median CRP was observed for both dose groups (-0.6 mg/dL ADA 160/80mg; -1.1 mg/dL ADA 80/40mg) at wk 4, but was not statistically significant between the groups (P=.097).
Table. Efficacy at wk 4 in ADA-treated pts in IMAgINE 1 (NRI)

	ADA 160mg/80mg N=123	ADA 80mg/40mg, N=69	P-value*
Baseline PCDAI score, mean	40.0	42.6	NA
Remission, n/N (%)	36/123 (29)	16/69 (23)	0.36
IFX-naïve	22/65 (34)	12/42 (29)	0.57
IFX-experienced	14/58 (24)	4/27 (15)	0.33
Response, n/N (%)	97/123 (79)	58/69 (84)	0.38
IFX-naïve	56/65 (86)**	35/42 (83)	0.69
IFX-experienced	41/58 (71)	23/27 (85)	0.15

NA: Not applicable. *Chi-square test comparison between dose groups; **$P<0.05$ for IFX-naïve vs IFX-experienced comparison; $P>0.05$ for all other IFX-naïve vs IFX-experienced comparisons.
CONCLUSION: ADA induced clinical remission and response in children with moderately to severely active CD as early as wk 4. The early clinical benefits were comparable for both induction doses, with a trend towards greater benefits observed in anti-TNF naïve patients.

P1480 SERUM ADIPOKINE LEVELS DURING INFLIXIMAB THERAPY IN PEDIATRIC CROHN'S DISEASE

K. Frivolt[1,2,*], T. Schwerd[1], S. Schatz[1], F. Freudenberg[1], C. Prell[1], P. Bufler[1], S. Koletzko[1]. [1]*Dr. v. Hauner Children's Hospital, University Munich Medical Center, Munich, Germany,* [2]*2nd Department of Pediatrics, Comenius University Medical School, Bratislava, Slovakia*

INTRODUCTION: Crohn's disease (CD) is an inflammatory disorder of the intestine and the visceral adipose tissue, characterized by adipocyte hyperplasia and increased fat tissue concentrations of TNFα, leptin and adiponectin. In vitro TNFα suppresses the expression of leptin and the anti-inflammatory mediator adiponectin.
AIMS&METHODS: We aimed to investigate the early effect of anti-TNFα therapy with infliximab (IFX) on visceral adipose tissue and assessed serum adipokine levels in pediatric CD. Serum concentrations of adipokines (leptin, adiponectin and resistin) were retrospectively measured with commercially available ELISAs before the 1st, 2nd and 4th IFX infusion (week 0, 2 and 14). Results of 18 CD patients were compared with 15 gender and weight/BMI matched healthy controls (HC). We recorded the mathematically weighted Pediatric Crohn's Disease Activity Index (wPCDAI), laboratory parameters, anthropometric data and treatment response. Wilcoxon signed-rank test was applied to analyze differences between patients and HC and changes during IFX therapy at the 3 time points.
RESULTS: The IFX treated patients included 10 males and 8 females (median age 14.9 years, range 12.2-17.5). The wPCDAI decreased from 26.3 (7.5-72.5) to 15 (0.0-35.0) and 8.8 (0.0-45.0) after 2 and 14 weeks, respectively ($p<0.01$). Baseline resistin levels were higher in patients than in HC: median 14.7 ng/ml (range 5.1-50.5) vs 7.3 ng/ml (0.5-14.5), respectively ($p<0.001$), and decreased with IFX at both time points ($p<0.01$ compared to baseline, n.s. to HC). At baseline leptin levels did not differ from HC, but leptin levels were significantly higher in girls compared to boys ($p<0.0001$). In girls, leptin levels increased after 2 weeks from 9.5 ng/ml (7.6-30.1) to 16.0 ng/ml (7.9-35.2) ($p<0.05$). In boys, leptin increase showed only a trend from 2.0 ng/ml (0.6-12.9) to 2.8 ng/ml (1.7-8.6) (n.s.). Adiponectin baseline levels in patients were not different from HC: 7765 ng/ml (4591-11897) vs 8660 ng/ml (5029-10795) (n.s.). Adiponectin notably peaked 2 weeks after 1st IFX infusion to 9200 ng/ml (4075- 20706), ($p<0.01$) but thereafter fell to 6470 ng/ml (2956-12681), which was lower compared to values in HC ($p<0.05$), at baseline ($p<0.05$) or at 2 weeks ($p<0.001$).
CONCLUSION: TNFα blockade by IFX effectively reduced disease activity and inflammatory markers including resistin in CD and led to an early increase of leptin and adiponectin. Leptin parallels weight gain. We speculate that successful induction therapy with IFX is partially mediated by the anti-inflammatory properties of released adiponectin.

P1481 NOD2, IRGM, AND ORMDL3 POLYMORPHISMS INCREASE RISK OF PEDIATRIC INFLAMMATORY BOWEL DISEASE IN LITHUANIAN POPULATION

G. Pranculiene[1], R. Steponaitiene[2], R. Kucinskiene[1], K. Adamonis[2], L. Labanauskas[1], J. Skieceviciene[2], L. Kupcinskas[2,*]. [1]*Department of Children Disease,* [2]*Institute for Digestive Research, Lithuanian University of Health Sciense, Kaunas, Lithuania*

INTRODUCTION: Recent GWAS and meta-analyses have revealed about 163 susceptibility genes/loci for inflammatory bowel diseases (1). However, only a small number of studies were performed in children population.
AIMS&METHODS: The aim of the study was to assess the frequency of *NOD2*, *IL23R*, *ATG16L1*, *IRGM*, *IL10*, *NKX2-3* and *ORMDL3* polymorphisms in a case-control panel of Lithuanian children. Seventy six unrelated IBD children [30 with Crohn's disease (CD) and 46 with ulcerative colitis (UC)] at the age of ≤17 years and 158 healthy controls were genotyped for the following known genetic susceptibility variants: *NOD2* Arg702Trp (rs2066844), Gly908Arg (rs2066845) and Leu1007insC (rs2066847), *IL23R* rs11209026, *ATG16L1* rs2241880, *IRGM* rs4958847, *IL10* rs3024505), *NKX2-3* rs11190140 and *ORMDL3* rs2872507.
RESULTS: Our study revealed that Leu1007insC was strongly associated with CD (21.4% CD vs 4.7% controls, p = 3.687 x 10(-8), OR = 5.54, 95% CI: 2.85-10.75). (16% CD *vs* 2% in controls, p =1,21x10^{-5}, OR=6,56; 95% CI:2,54-16,91). *IRGM* variant also significantly increased risk for CD (16% CD *vs* 7% in controls p=0,033, OR=2,32; 95% CI:1,05-5,14). Whereas, presence of variant *ORMDL3* allele strongly predisposed to UC (50% UC *vs* 33% controls, p= 4,15x10^{-3}, OR=1,99; 95% CI:1,23-3,20).
CONCLUSION: The results of our study revealed that polymorphism Leu1007insC in *NOD2* and *IRGM* variant are associated with increased risk of CD, whereas the *ORMDL3* variant associated with susceptibility to UC in the Lithuanian pediatric population.

P1482 LOW DOSE AZATHIOPRINE TREATMENT MONITORED BY THIOPURINE METABOLITES IS SAFE AND EFFECTIVE IN KOREAN PEDIATRIC PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. J. Kim[1,*], S. Y. Lee[2], Y. M. Lee[3], Y. Lee[3], Y. H. Choe[3]. [1]*Pediatrics, Ilsan Paik Hospital, Inje University College of Medicine, Goyang-si,* [2]*Laboratory Medicine and Genetics,* [3]*Pediatrics, Samsung Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Azathioprine (AZA) is used to maintain clinical remission in inflammatory bowel disease (IBD). This study evaluated the role of 6-thioguanine nucleotide (6-TGN) and thiopurine S-methyltransferase (TPMT) as predictors of adverse effects and clinical response to AZA, and determined the optimal dose of AZA in Korean pediatric IBD patients.
AIMS&METHODS: One hundred and nine IBD patients (age range, 3 to 21 years) who required AZA to maintain remission were monitored for thiopurine metabolites since September 2010. Of these, 83 cohorts who had received a consistent dose of AZA for at least 3 months prior to September 2010 were selected and followed until October 2011 to assess adverse drug reactions (ADR), disease activity and optimal AZA dose at pre- and post-thiopurine metabolite monitoring period.
RESULTS: The distribution of the TPMT genotype was as follows: 102 patients had *1/*1 (wild type), one had *3C/*3C (homozygote), four had *1/*3C, one had *1/*6, and one had *1/*16 (heterozygote). ADR occurred in 31 patients before thiopurine metabolite monitoring and in only nine patients after monitoring. AZA dose was 1.4 ± 0.31 mg/kg/day at pre-monitoring and 1.1 ± 0.46 mg/kg/day at post-monitoring ($P < 0.001$). However, there were no statistical differences in disease activity between pre- and post-thiopurine metabolite monitoring period ($P = 0.34$).
CONCLUSION: Since monitoring, ADR markedly decreased and the AZA dose was reduced to 1.1 ± 0.46 mg/kg/day with maintaining remission. This dose of AZA was lower than those reported in Western countries.

P1483 THE DIAGNOSTIC ACCURACY OF COMBINING FAECAL CALPROTECTIN WITH COMMON BLOOD TESTS IN THE INVESTIGATION OF SUSPECTED PAEDIATRIC INFLAMMATORY BOWEL DISEASE

P. Henderson[1,2,*], S. J. Lawrence[1], A. Casey[1], D. C. Wilson[1,2]. [1]*Gastroenterology and Nutrition, Royal Hospital for Sick Children,* [2]*Child Life and Health, University of Edinburgh, Edinburgh, United Kingdom*

INTRODUCTION: We have previously shown that FC has better diagnostic accuracy than individual blood parameters in suspected paediatric inflammatory bowel disease (PIBD). However, the diagnostic accuracy of combining FC and blood tests has yet to be established.
AIMS&METHODS: We aimed to determine the diagnostic accuracy of a panel of PIBD biomarkers using a case-control design. Cases of PIBD cared for in Edinburgh have been recorded prospectively since 1997, with FC becoming available as a routine clinical biochemistry test on 01.01.05. All children >1yr and <18yr of age undergoing their primary investigation for suspected bowel inflammation were eligible. A retrospective search of the PIBD database and endoscopy records between 01.01.05-31.12.11 identified all PIBD and non-PIBD (control) cases with FC and blood samples (Hb, WCC, Plt, Alb, ESR, CRP) taken in the 6 months prior to full upper and lower endoscopy. Children with a known gastrointestinal disease or who had undergone previous endoscopy were excluded. Population-based normal blood parameters were used. Statistical analyses were performed using R and GraphPad Prism.
RESULTS: 221 children met the inclusion criteria including 108 cases of PIBD (69 Crohn's disease, 28 ulcerative colitis, 11 IBD-unclassified). The PIBD group were older at endoscopy (12.7yr *vs* 9.9yr) with terminal ileum intubation rates comparable in both groups (p=0.142). Common indications for endoscopy in the control group were abdominal pain, rectal bleeding and diarrhoea; all children had a minimum follow up of 16 months. Median FC level in the PIBD group was 1235ug/g (IQR 684-1667) compared to 60ug/g (20-155) in controls ($p < 0.0001$). Sensitivity and specificity for FC alone (>50ug/g) were 0.97 (95% CI 0.92-0.99) and 0.48 (95% CI 0.38-0.57) compared to the best blood parameter (ESR) at 0.71 (95% CI 0.61-0.79) and 0.86 (95% CI 0.78-0.92). Using *any* abnormal blood test, sensitivity and specificity were 0.85 (95% CI 0.76-0.91) and 0.63 (95% CI 0.52-0.73). Combining an abnormal ESR *or* abnormal FC provided a sensitivity of 0.99 (95% CI 0.93-1.00) with specificities of 0.38 (95% CI 0.28-0.47) and 0.69 (95% CI 0.59-0.77) using >50ug/g and >200ug/g FC cut-off values.
CONCLUSION: FC provides excellent sensitivity and moderate specificity for PIBD but diagnostic accuracy is improved when combining an abnormal ESR (>20mm/hr) and a FC cut-off of >200ug/g; the addition of certain symptoms such as rectal bleeding would likely improve this diagnostic utility. A raised FC and an abnormal ESR should lead to prompt endoscopic assessment of children with suspected bowel inflammation.

P1484 LONG-TERM SAFETY OF ADALIMUMAB IN PAEDIATRIC PATIENTS WITH CROHN'S DISEASE

R. Baldassano[1,*], F. Ruemmele[2], J. Rosh[3], W. Faubion[4], J. Kierkus[5], J. Hyams[6], A. Lazar[7], Y. Wang[8], S. Eichner[8], R. Thakkar[8]. [1]*Children's Hospital of Philadelphia, Philadelphia, United States,* [2]*Universite Sorbonne Paris-Cite, Hospital Necker-Enfants Malades, Paris, France,* [3]*Goryeb Children's Hospital/ Atlantic Health, Morristown,* [4]*Mayo Clinic, Rochester, United States,* [5]*Children's Memorial Health Institute, Warsaw, Poland,* [6]*Connecticut Children's Medical Center, Hartford, United States,* [7]*AbbVie, Ludwigshafen, Germany,* [8]*AbbVie, N. Chicago, United States*

INTRODUCTION: The safety profile of adalimumab (ADA) in children with moderately to severely active Crohn's disease (CD) enrolled in the clinical trial IMAGINE 1 up to week 52 has been reported previously[1]. Cumulative safety data including the on-going open-label extension (OLE) is presented in this report.
AIMS&METHODS: Patients (pts) who completed IMAGINE 1[1] had the option to continue in the on-going OLE. Treatment-emergent adverse events (AEs) were monitored regularly and by spontaneous reporting. Rates of AEs were assessed per 100 patient-years (PY) of exposure for any pt enrolled in the double-blind clinical trial IMAGINE 1 and followed through the 31 July 2011 cut-off or up to 70 days after the last dose of ADA. Subgroup analysis by prior infliximab (IFX) use was also performed.
RESULTS: 192 paediatric pts had received ADA for CD, totaling 304.1 PY of exposure. As of 31 Jul 2011, 29/192 (15%) pts had up to 3 years of exposure. The most common AE for all pts was injection site reaction; all were non-serious. The most common serious AE (SAE) was flare or worsening of CD. Rates of SAEs, infections and AEs leading to discontinuation were consistent with IMAGINE 1[1]. Serious AEs were experienced by significantly more pts exposed to prior IFX than IFX-naïve pts (Table). No malignancies,TB, demyelinating disease, or deaths were reported.
Table. Overview of Treatment-emergent Adverse Events (AE) as of 31 July 2011

	Any ADA N=192, 304.1 PYs	IFX naïve N=107, 199.7 PYs		Prior IFX N=85, 104.4 PYs	
	Events (E/100PY)	n (%)	Events (E/100PY)	n (%)	Events (E/100PY)
Any AE	2414 (793.8)	107 (100)	1536 (769.2)	82 (96.5)	878 (841.0)
Serious AE	123 (40.4)	38 (35.5)	64 (32.0)	43* (50.6)	59 (56.5)
AE leading to discontinuation	64 (21.0)	22 (20.6)	29 (14.5)	27 (31.8)	35 (33.5)
Opportunistic infection (excluding TB)	2 [a] (0.7)	1 (0.9)	1 (0.5)	1 (1.2)	1 (1.0)
Serious infection	24 (7.9)	12 (11.2)	15 (7.5)	8 (9.4)	9 (8.6)
Injection site reaction	100 (32.9)	23 (21.5)	61 (30.5)	16 (18.8)	39 (37.4)
Hematologic AE	33 (10.9)	12 (11.2)	17 (8.5)	13 (15.3)	16 (15.3)
Hepatic AE	14 (4.6)	10 (9.3)	11 (5.5)	2 (2.4)	3 (2.9)

[a] *Aeromonas* infection and histoplasmosis disseminated; *p<0.05 IFX naïve vs prior IFX (Fisher's exact test)

CONCLUSION: Prolonged ADA treatment, up to 3 years, in children with moderately to severely active CD has a safety profile that is consistent with known ADA data[1] and no new safety signals have been identified.

OTHER LOWER GI DISORDERS III – Poster Area

P1485 HEMOSPRAYTM TREATMENT IS EFFECTIVE FOR LOWER GASTROINTESTINAL BLEEDING

I. L. Holster[1,*], E. Brullet[2], E. J. Kuipers[1], R. Campo[2], A. Fernández-Atutxa[2], E. T. Tjwa[1]. [1]*Gastroenterology and hepatology, Erasmus MC University Medical Centre, Rotterdam, Netherlands,* [2]*Centro de Investigación biomédica en red de enfermedades hepáticas y digestivas (CIBERehd), Hospital of Sabadell, Corporació Sanitaria Universitaria Parc Taulí, Sabadell, Spain*

INTRODUCTION: Acute lower gastrointestinal bleeding (LGIB) is diverse in origin and can be substantial, requiring urgent hemostasis. As this is sometimes not achieved by current modalities such as injection, hemoclip placement and/or thermal therapy, an alternative is much required. Hemospray™ is a promising novel hemostatic agent for upper gastrointestinal hemorrhage. Evidence on the efficacy of Hemospray™ therapy in lower GI bleeding is very limited, based on extrapolations of what happens in upper GI bleeding and in small series of patients.

AIMS&METHODS: We aimed to expand our knowledge on the application of Hemospray™ for the treatment of LGIB in a wide range of conditions to further define the optimal patient population for this new therapeutic modality. From October 2011 to April 2013, all patients endoscopically treated with Hemospray™ for an active LGIB in Sabadell Hospital Spain and Erasmus Medical Centre University Hospital Rotterdam were collected. Data on sex, age, comorbidity, clinical presentation, medication use, procedural details and outcome were prospectively collected, anonymized and analyzed. Hemospray™ was deployed onto the active bleeding site until hemostasis was confirmed.

RESULTS: Nine patients (median age 63 yrs, range 22-79 yrs, 56% male) with LGIB were treated with Hemospray™ (5-30 g) during the referred period. Four patients were on antithrombotic therapy at time of bleeding. LGIB occurred spontaneous in 5 patients (colorectal anastomosis, rectal ulcer, colonic diverticulum, cecal adenocarcinoma, and thrombo-leucocytopenic proctitis) and post-polypectomy in four others. In all cases, successful initial hemostasis was obtained with use of Hemospray™; as monotherapy in 6 cases and as salvage therapy (after failed hemostasis with clips and/or epinephrine) in 3 cases. Rebleeding within 7 days occurred in 2/9 patients (22%), one rectal diverticular bleed and one post-polypectomy bleed in the transverse colon. Both patients were on acetyl salicylic acid. No rebleeding after 30 days occurred. No perforation, symptomatic systemic embolism or bowel obstruction were observed during 30-day follow-up.

CONCLUSION: Hemospray™ is a welcome alternative in the management of colorectal bleeding; as primary or secondary modality but also in a large diffuse bleeding area when only thermal therapy is available. We advise cautious use of Hemospray™ onto spurting bleeds.

P1486 THE ANALYSIS OF RISK FACTORS FOR ISCHEMIC COLITIS IN SAGA UNIVERSITY HOSPITAL IN JAPAN.

K. Nio[1,*], S. Yamaguchi[1], D. Yamaguchi[1], Y. Sakata[1], R. Shimoda[1], H. Sakata[1], R. Iwakiri[1], K. Fujimoto[1]. [1]*internal medicine and gastrointestinal endoscopy, Saga medical school, Saga-shi, Japan*

INTRODUCTION: Ischemic colitis is often occurred in the left-side colon because of insufficient blood supply. Several factors causing inadequate intestinal blood flow, use of non-steroidal anti-inflammatory drugs (NSAIDs) and arteriosclerosis, could be risk factors. We evaluated the risk factors for ischemic colitis.

AIMS&METHODS: Between January 1998 and December 2012, 76 patients diagnosed ischemic colitis in Saga University hospital in Japan. Gender and age matched control cases were selected from patients of other diseases hospitalized during the same period. We evaluated the influences of comorbidities such as cerebrovascular disease, ischemic heart disease, hypertension, hyperlipidemia, diabetes mellitus, chronic kidney disease, hyperuricemia and osteoporosis, medications including NSAIDs, antithrombotic agents and bisphosphonate, and habits of smoking, alcohol, and chronic constipation.

RESULTS: Sex ratio of men *versus* women for ischemic colitis was 23:53. Chronic kidney disease and chronic constipation were significant risk factors for ischemic colitis (chronic kidney disease: odds ratio [OR] = 8.474, 95% CI: 2.923-22.844, chronic constipation: OR = 2.041, 95% CI: 1.079-3.862), but the others were not(cerebrovascular disease: OR = 0.609, 95% CI: 0.238-1.559, ischemic heart disease: OR = 1.249, 95% CI: 0.609-2.561, hypertension: OR = 1.098, 95% CI: 0.611-1.971, hyperlipidemia: OR = 1.263, 95% CI: 0.648-2.461, diabetes mellitus: OR = 0.576, 95% CI: 0.238-1.393, hyperuricemia: OR = 2.260, 95% CI: 0.369-13.860, osteoporosis: OR = 0.636, 95% CI: 0.189-2.144, use of NSAIDs: OR = 1.522, 95% CI: 0.511-4.530, antithrombotic agents: OR = 0.828, 95% CI: 0.397-1.726, bisphosphonate: OR = 1.480, 95% CI: 0.091-24.030, habits of smoking: OR = 1.126, 95% CI: 0.555-2.283, alcohol: OR = 0.996, 95% CI: 0.528-1.876).

CONCLUSION: This case-control study revealed that chronic kidney disease and chronic constipation were significant risk factors for ischemic colitis. Other arteriosclerosis risk factors, including hypertension, hyperlipidemia, diabetes mellitus, hyperuricemia and habits of smoking, would not serve as risks of ischemic colitis.

P1487 LIVER CIRRHOSIS IS A RISK FACTOR OF REPEAT ACUTE HEMORRHAGIC RECTAL ULCER OF INTENSIVE UNIT PATIENT

K. C. Hsiao[1,*], P.-K. Chang[1]. [1]*Colorectal Surgery, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan, Province of China*

INTRODUCTION: Acute hemorrhagic rectal ulcer (AHRU) can be found in patients with severe comorbid illness who are long-term bedridden, and per anal suturing is a quick and feasible treatment. However, recurrent bleeding occurs frequently after suture ligation of a bleeder and could be life threatening. But, the risk factor for recurrent bleeding is not well known. Our study tried to clarify the risk factor of repeat AHRU of intensive care unit patient.

AIMS&METHODS: From January 2004 to December 2009, the medical records of 32 patients who were admitted to the intensive care unit (ICU) of the Tri-Service General Hospital, a tertiary referral center in Taiwan, and who underwent per anal suturing of acute hemorrhagic rectal ulcer were retrospectively reviewed.

RESULTS: Of 96 patients who received emergency treatment for acute massive hematochezia, 32 patients were diagnosed as AHRU. 8 (25%) patients had recurrent bleeding following suture ligation of AHRU and underwent reoperation; no patient had recurrent bleeding after the second operation. The duration from the first hematochezia attack to surgery ($P = 0.04$), liver cirrhosis ($P = 0.002$), and coagulopathy ($P = 0.01$) were risk factors for recurrent bleeding after suture ligation of a bleeder. Multivariate logistic regression analysis indicated that liver cirrhosis (OR = 37.77, $P = 0.014$) was an independent risk factor for recurrent bleeding.

CONCLUSION: AHRU could be a major cause of acute massive hematochezia in patients with severe illness. Our data showed that per anal suturing can quickly and effectively control bleeding. We found that liver cirrhosis was an independent risk factor for recurrent bleeding. Therefore, treat the liver cirrhosis patient with AHUR should more aggressively such as early detection and proper suture ligation.

P1488 DO SEASONAL TRENDS IN POSITIVITY EXIST WITH THE GUAIAC-BASED FAECAL OCCULT BLOOD TEST?

M. R. R. Carroll[1,*], H. Seaman[2], P. Butler[1], J. Snowball[1], S. Hlloran[1]. [1]*Bowel Cancer Screening Programme, NHS BOWEL CANCER SCREENING PROGRAMME SOUTHERN HUB,* [2]*Biochemistry and Physiology, University of Surrey, Guildford, United Kingdom*

INTRODUCTION: Several bowel cancer screening programmes, including the NHS Bowel Cancer Screening Programme (BCSP) in England, use a guaiac-based faecal occult blood test (gFOBt). Seasonal variations in quantitative faecal immunochemical tests for haemoglobin (FIT) positivity have been reported, with lower positivity in spring and summer compared with autumn and winter, thought to be caused by haemoglobin degradation in higher temperatures. This study aims to establish whether this is also observed in gFOBT in southern England.
AIMS&METHODS: Men and women aged 60-69 years are eligible for biennial routine bowel cancer screening. The gFOBt card comprises six windows (or 'spots') onto which the participant is asked to apply two samples from three separate stools. Test cards are returned to a BCSP Hub where each spot is tested to determine 'spot positivity'. Samples usually arrive dry at the laboratory, which is likely to reduce haemoglobin degradation. The number of positive spots determines test positivity. Data for the BCSP Southern Hub (January 2008 to September 2012) were analysed; analysis was limited to the first screening episode.
RESULTS: In total, 8,521,790 spots were analysed. Spot positivity for men (2.50%) was consistently higher than for women (1.65%) and increased with age. Variations in seasonal positivity were similar for men and women. The pattern of spot positivity by month was inconsistent year-on-year and there was no clear evidence that it was different in the spring/summer compared with autumn/winter.
CONCLUSION: Seasonal variation did not appear to account for any fluctuations in spot positivity observed in the gFOBT samples, a strength of gFOBT at a time when more countries and screening programmes are switching to FIT. This suggests gFOBT could be used in hotter, drier climates where FIT are likely to deteriorate faster than gFOBT, reducing the possibility of false-positive test results. More work is required to explore these data further.

P1489 DIAGNOSTIC YIELD OF COLONOSCOPY IN THE DIAGNOSIS OF "MELENA" AFTER A NORMAL UPPER ENDOSCOPY

M. L. Ruiz Rebollo[1,*], L. del Olmo- Martínez[1], A. Macho Conesa[1], M. F. Muñoz[2], G. GONZÁLEZ-REDONDO[1], E. BERROA DE LA ROSA[1], J. M. GONZÁLEZ HERNÁNDEZ[1]. [1]*SERVICIO DE APARATO DIGESTIVO,* [2]*INVESTIGATION UNIT, HOSPITAL CLINICO UNIVERSITARIO, VALLADOLID, Spain*

INTRODUCTION:
"Melena" is common in clinical practice, the source found in upper endoscopy. However, sometimes no lesion is found and a colonoscopy is performed to rule out a lower gastrointestinal source
AIMS&METHODS: Diagnostic yield of colonoscopy in patients with melena after a normal upper endoscopy, and the rate of therapeutic intervention. Patients attended at our Institution (March 2004/ July 2012) with a colonoscopy performed for "melena" with a previous normal upper endoscopy. Colon was divided into right colon (from cecum till the splenic flexure) and left colon (from splenic flexure till rectum). Data recorded: age, sex, comorbidities, Hb level, procedure setting, drug intake, days between upper and lower endoscopy, cecal and ileum intubation, bowel preparation, endoscopy findings, therapeutic intervention and change in patient management. Statistical analyses performed with SPSS (Chicago, IL USA; v13.0)
RESULTS: 220 patients elegible: 134 male (61%)/ 86 female (39%), median age 72,52±12.18. Almost half (44%) were on antiagregant or anticoagulant drugs. Mean Hb level 8.85±2.4. Comorbidities in 82% of pts. 175 (80%) inpatients and 20% outpatients. Bowel preparation was good in 85.5%. Cecum reached in 92% and ileum intubated in 9% of the procedures. Days between upper and lower procedures were 5.51± 5.2. Colonoscopy found a suspected bleeding source in 79 pts (39%). Endoscopic therapy performed in 3 pts (rate 1.4%). A change in patient management after the procedure was done in 44 cases (56.4%)

BLEEDING LESION (79 patients)	RIGHT COLON (50 patients)	LEFT COLON (36 patients)
Tumour	12	13
Arteriovenous malformation	23	5
Advanced polyps	2	4
Bleeding diverticulosis	2	-
Ischemic colitis	2	7
Inflammatory bowel disease	1	3
Radiation colitis	-	2
Other conditions	1	2

CONCLUSION: Our overall diagnostic yield of colonoscopy to investigate melena after a non-diagnostic upper endoscopy was 36%. However, the rate of therapeutic intervention (1.4%) was very low, suggesting that the majority of these procedures are diagnostic only and could be performed on an outpatient setting. A change in patient management was performed in more than a half (56.4%) of the patients with positive findings.

P1490 EFFECTIVENESS OF THE THERAPEUTIC BARIUM ENEMA FOR RECURRENT COLONIC DIVERTICULAR BLEEDING IN SHORT PERIODS

M. Inuyama[1,*], A. Fujimoto[1], N. Hirano[1], S. Nakano[1], Y. Igarashi[1], Y. Sumino[1]. [1]*Division of Gastroenterology, Department of Gastroenterology and Hepatology, Internal Medicine, Toho University Omori Medical Center, Tokyo, Japan*

INTRODUCTION: Many patients with colonic diverticular bleeding experience recurrent bleeds within short periods, even when the source of the bleeding is detected and clipped. In this study we found the therapeutic barium enema to be effective for colonic diverticular rebleeding within 7 days after administration for lower gastrointestinal endoscopy at admission.
AIMS&METHODS: We retrospectively analyzed 218 consecutive cases of colonic diverticular bleeding treated between 2003 and 2010. Lower gastrointestinal endoscopy was performed immediately after admission in all of the cases. Some of these patients received a therapeutic barium enema in addition to conventional methods. Barium sulphate solution was administered using a double balloon enema tip. Next, an additional 600 ml of 60 w/v percentage barium was administered. After confirming that the ascending colon and caecum were filled with barium, the enema tube was clamped and the patient's position was changed every five minutes (prone, left lateral, supine, and right lateral positions) for 2 hours. The enema tube was then withdrawn.
RESULTS: The source of bleeding was identified in 140 (64%) of the 218 patients, and all of these patients underwent endoscopic hemostasis with clipping. After the clipping, 110 patients were observed conservatively (Group A) and 30 patients received additional high-dose barium impaction therapy within 5 days from admission (Group B). In the other 78 patients in whom no bleeding source was detected, 55 were observed conservatively (Group C) and 23 received therapeutic barium enemas within 5 days from admission (Group D). The rebleeding rates within 7 days were as follows: Group A, 37/110 (33.6%); Group B, 3/30 (10.0%); Group C, 13/55 (23.6%); Group D, 1/23 (4.3%). Significant differences were found between Group A and Group B (p=0.0117), and between Group C and Group D (p=0.0450), in log-rank tests by the Kaplan-Meier method to determine the free rates of rebleeding.
CONCLUSION: The therapeutic barium enema effectively prevents recurrent colonic diverticular bleeding in short periods.

P1491 CLINICAL EVALUATION OF THE HOOD METHOD FOR DETECTING RESPONSIBLE DIVERTICULA AND ENDOSCOPIC BAND LIGATION FOR HEMOSTASIS IN PATIENTS WITH COLONIC DIVERTICULAR HEMORRHAGE

S. Soichiro[1,2,*], T. Shigeno[2], K. Fujimori[2], K. Kanai[1], K. Yoshizawa[2]. [1]*Gastroenterology, Shinshu University School of Medicine, Matsumoto,* [2]*Gastroenterology, Shinshu Ueda Medical Center, Ueda, Japan*

INTRODUCTION: Although colonic diverticular hemorrhage is a common cause of lower gastrointestinal bleeding, the low detection rate of the responsible diverticulum and insufficient evaluation of endoscopic hemostasis remain unsatisfactory.
AIMS&METHODS: First group comprised 85 patients who underwent conventional colonoscopy for observation and clipping for hemostasis. Second group comprised 53 patients who underwent hood method for observation and endoscopic band ligation (EBL) for hemostasis. We retrospectively evaluated the detection rate of the responsible diverticulum by conventional colonoscopy and hood method, and the results of hemostasis by clipping and EBL.
RESULTS: Regarding diagnosis of colonic diverticular hemorrhage, the hood method was significantly better than conventional colonoscopy for detecting the responsible diverticulum ($p = 0.04$). Although active bleeding was noted in only approximately 30% of cases in both groups, non-bleeding visible vessels were more common in cases receiving the hood method ($P < 0.001$). Regarding endoscopic hemostasis, EBL was significantly better than clipping in the results of hemostasis ($p = 0.01$). In most cases treated with EBL, the responsible diverticulum resolved with scar formation at the original site.
CONCLUSION: Although the hood method is useful for detection of potential non-bleeding visible vessels and consequently improves the detection of responsible diverticula, the detection rate (52%) remains not to be satisfied yet. EBL therapy demonstrated excellent results for endoscopic hemostasis and few complications, and acts as an "endoscopic diverticulectomy", which is available for preventing future rebleeding from the original diverticulum.

P1492 EFFECTIVENESS OF A NURSE LED ANAEMIA CLINIC IN IDENTIFYING IRON DEFICIENCY AND PLANNING FURTHER INVESTIGATION

S. N. Bonnington[1,*], B. K. Chaudhury[1], C. Berthou[1], R. Perowne[2], V. Mitra[3], S. Maitra[4]. [1]*Gastroenterology, University Hospital of Hartlepool, Hartlepool,* [2]*Gastroenterology, Queen Elizabeth Hospital, Gateshead,* [3]*Gastroenterology, Freeman Hospital, Newcastle upon Tyne, United Kingdom,* [4]*Gastroenterology, Columbia Asia Hospital, Calcutta, India*

INTRODUCTION: Iron deficiency anaemia (IDA) occurs in 2-5% of adult men and postmenopausal women in the developed world and is a common cause of referral to gastroenterologists. The British Society of Gastroenterology (BSG) guidelines (updated 2011) state that all patients with IDA should be tested for coeliac disease (grade B recommendation) and that all men and postmenopausal women should be considered for upper and lower gastrointestinal tract (GI) investigation (grade A recommendation).
In this clinic, a specialist nurse assesses patients and checks haemoglobin (Hb), MCV, ferritin, and endomysial antibodies (EMA). Appropriate further investigations are then arranged.
AIMS&METHODS: The data from three sequential audits in 2004, 2005, and 2012 was collated and reviewed to assess compliance with BSG guidelines. All three audits used a standardised data collection proforma. The 2004 and 2005 audits used retrospective case note review, while the 2012 audit used an audit proforma prospectively.
RESULTS: A total of 183 patients were referred during the three audit periods (2004, 2005, and 2012). In all audit periods, female patients outnumbered males by a ratio of more than 1.8:1. The mean time from referral to be seen in clinic was 25 days, 28 days, and 13 days respectively. Hb and MCV were checked in all patients and ferritin in 98% – 100%. Among patients referred, IDA was confirmed in 86%, 79%, and 90% respectively. EMA was checked in 89%, 100%, and 97% respectively. Of patients found to have IDA, the proportion sent for both upper and lower GI investigation was 72%, 95%, and 99% (90% attended and completed the investigations). In the 2004 audit, a further 17% underwent gastroscopy only (9% in 2005) and 12% had colonoscopy only (0% in 2005).

Investigation findings:	2004	2005	2012
GORD / benign ulcer disease	36%	13%	30%
Diverticulosis / haemorrhoids	45%	13%	15%
Colorectal cancer	9%	2%	3%
Coeliac disease	3%	6%	5%

CONCLUSION: The nurse led clinic for anaemia has proved to be an effective way to manage the large number of referrals for investigation of IDA. Significant pathology is identified early as a result of the requested investigations (up to 9% colorectal cancers and up to 6% coeliac disease). Notable improvements in the service since 2004 are reduced waiting times and increased compliance with investigation recommendations. The proportion of patients referred who are confirmed to have IDA has also increased.

P1493 A RANDOMIZED PROSPECTIVE STUDY OF ENDOSCOPIC BIPOLAR HEATER PROBE TREATMENT OF CHRONIC RECTAL BLEEDING FROM RADIATION COLITIS

V. Sharma[1,*], R. sharma[1], D. Mangal[2]. [1]*Gastroenterology, REGIONAL INSTITUTE OF HEALTH, MEDICINE & RESEARCH,* [2]*Oncology and Radiotherapy, Sea rock Cancer centre, sk soni hospital, Jaipur, India*

INTRODUCTION: Radiation colitis, an insidious, progressive disease of increasing frequency, develops 6 mo to 5 years after regional radiotherapy for malignancy, owing to the deleterious effects of the latter on the colon and the small intestine. Management of chronic radiation colitis remains a major challenge owing to the progressive evolution of the disease, including development of fibrosis, endarteritis, edema, fragility, perforation, partial obstruction, and cancer. Patients are commonly managed conservatively.
AIMS&METHODS: Our purposes were to (1) evaluate efficacy and safety of bipolar heater probe endoscopic coagulation compared to prior medical therapy for bleeding radiation telangiectasia, and (2) consider the impact of treatments on patients' impression of their overall health and activity
Six months of medical management had failed in 2 men and 9 women with chronic, recurrent hematochezia and anemia after radiation treatment of pelvic malignancies. Patients had multiple rectal telangiectasias coagulated with bipolar heater probes CD 120 U with Olympus HPU 20 unit in a randomized, prospective study. Patients followed for 6 months.
RESULTS: Rectal bleeding stopped within four treatment sessions. During 6 months of endoscopic versus medical therapy, severe bleeding episodes diminished significantly for bipolar heater probe versus 6 months of prior medical therapy (79% vs 37%) ; mean hematocrits rose significantly for patients undergoing bipolar heater probe (40.2 vs 30.1) treatment, and their impression of overall health improved. During long-term follow-up, new telangiectasias or rectal bleeding were easily controlled. No major complications resulted.
CONCLUSION: Bipolar heater probe is safe and effective relative to medical therapy for palliation of patients with lower gastrointestinal bleeding from radiation colitis, all patients improved in ability to travel and day to day working and in their overall impression of their health.

INTRODUCTION: Radiofrequency ablation (RFA) is a new option for treatment of chronic radiation proctitis (RP), noticeably in patients who failed argon plasma coagulation (APC).
AIMS&METHODS: Our aim was to evaluate the feasibility, efficacy and safety of RFA for treatment of RP. Data from patients with RP treated by RFA were retrospectively collected from 5 European centers. Main outcomes measurements were the following: a three-item symptom scale (0 to 10 points, see reference) including diarrhoea (0 to 3), bleeding (0 to 4), and tenesmus/rectal pain (0 to 3), red blood cell (RBC) transfusions (number of RBC packs, number of patients off transfusions), lowest hemoglobin rates, and complications. Wilcoxon matched-pairs signed-ranks test was used to estimate the difference in response in the 6 months before and after RFA treatment.
RESULTS: 13 patients had RFA for treatment of RP (5 female and 8 male patients, aged 63 to 87 (mean age 76 ± 8). Past history included prostate (7), bladder (1), cervix (4), and anus (1) cancers. 3 patients were treated with aspirin, 2 with anticoagulants. 5 patients had received previous APC treatment (1 to 5 sessions), 1 had bipolar coagulation (1 session) and 2 had laser therapy (1 to 5 sessions). RFA was performed with the Halo^{90} ablation catheter and the HaloFlex system (Covidien), with a power of 12 to 15 J/cm^2. Patients received a mean number of 2.0 RFA sessions (range 1-4). Treatment was deemed feasible, quick and easy in all patients. No early complications were recorded. Two patients were referred for additionnal APC treatment. Symptom scores decreased in all patients, from mean score of 4.8 ± 0.7 (range 4 to 6) to 1.4 ± 0.9 (range 0 to 3) ($p<0.001$). Among 10 patients who were transfusion-dependent (mean number of 8.6 ± 8.3 RBC packs, range 2 to 27, over the 6-month before RFA), 8 patients (80%) were off transfusions within the 6 months following RFA. In the 6 months after RFA treatment has been completed, an increase in hemoglobin rate was recorded in all patients (from 7.3 ± 0.9 g/dL to 10.2 ± 1.2 g/dL, mean increase 2.9 ± 1.1 g/dL, $p<0.001$). One patient developed a fibrotic narrowing of the rectum, with no sign of obstruction.
CONCLUSION: RFA allowed a complete treatment of RP in a safely and clinically efficient manner. RFA significantly decreased clinical symptoms and the need for RBC transfusions, and lead to a significant increase of the hemoglobin rate. A prospective evaluation is strongly considered.

P1495 MEK5/ERK5 EXPRESSION IS INCREASED IN COLON CANCER ADENOMAS AND ADENOCARCINOMAS, AND MEK5/ERK5 SIGNALLING ACCELERATES CELL CYCLE PROGRESSION AND MIGRATION IN SW620 COLON CANCER CELLS

A. E. S. Simões[1], D. M. Pereira[1], S. E. Gomes[1,*], R. E. Castro[1,2], C. J. Steer[3], S. N. Thibodeau[4], P. M. Borralho[1,2], C. M. P. Rodrigues[1,2]. Biochemistry and Human Biology, Faculty of Pharmacy, University of Lisbon, Lisbon, Portugal,* [3]*University of Minnesota,* [4]*Mayo Clinic, Minneapolis, United States*

INTRODUCTION: ERK5 and its direct activator, MEK5, are overexpressed in prostate and breast cancer correlating with an overall poorer disease prognosis, and leading to increased proliferation, metastasis and chemoresistance. In addition, we have previously demonstrated that ERK5 silencing increases colon cancer (CC) cell apoptosis and 5-FU-induced apoptosis, highlighting the relevance of ERK5 signalling in CC.
AIMS&METHODS: In the present study, we evaluated the expression of ERK5 and MEK5 by immunoblotting in 284 human samples of CC, including normal colonic mucosa, tubulovillous adenomas, and adenocarcinomas with proficient or deficient DNA mismatch repair system (pMMR and dMMR, respectively). In addition, we produced a stable cell line model with differential ERK5 activation via lentiviral transduction and cell sorting of SW620 colon carcinomas cells to overexpress constitutively active MEK5 (MEK5AA), dominant-negative MEK5DD, and empty vector control. Next, we evaluated the impact of

MEK5/ERK5 signalling in cell cycle progression and migration by flow cytometry with PI staining, and wound healing assay, respectively.
RESULTS: Our results show that ERK5 and MEK5 are overexpressed in adenomas ($p<0.01$) and pMMR and dMMR adenocarcinomas ($p<0.05$). According to TNM stage classification, tumors classified with (T_4), (N_{1-2}) and (M_1), representing more aggressive tumors, displayed higher ERK5 overexpression ($p<0.05$), suggesting that ERK5 might be relevant in CC progression and to the acquisition of more invasive and metastatic potential. In vitro, we demonstrated that ERK5 overactivation (MEK5-DD) significantly accelerates cell cycle progression ($p<0.01$) and increases cell migration by ~ 2-3 fold from 24 to 56 h ($p<0.001$), in comparison with inactive ERK5 (MEK5-AA) and empty vector control cell lines.
CONCLUSION: Our results suggest that MEK5/ERK5 signalling pathway is important for tumor onset and progression, possibly representing a novel relevant therapeutic target in CC treatment.

P1496 SMAD7-INDUCED PLASTICITY OF TUMOR-INFILTRATING TH17 CELLS ARMS TNF-ALPHA TO KILL COLORECTAL CANCER CELLS

A. Rizzo[1,*], C. Rocchi[1], C. Stolfi[1], M. F. Neurath[2], T. Macdonald[3], F. Pallone[1], G. Monteleone[1], M. C. Fantini[1]. [1]*System Medicine, University of Rome "Tor Vergata", Rome, Italy,* [2]*First Medical Clinic, University of Erlangen, Erlangen, Germany,* [3]*Barts and The London School of Medicine and Dentistry, London, United Kingdom*

INTRODUCTION: Transforming Growth Factor (TGF-)-Beta is deeply involved in colorectal cancer development and the disruption of the TGF-beta signaling in dysplastic cells is required for tumor to grow. Nevertheless, TGF-beta is highly expressed by tumor cells to escape the immune-surveillance mediated by T cells. Accordingly, T cell-specific overexpression of Smad7, an intracellular inhibitor of the TGF-beta signaling, resulted protective in colitis-associated colorectal cancer. However whether Smad7 expression in T cells might influence colorectal cancer growth independently of chronic inflammation and which T cell subset is involved in this process, is currently unknown.
AIMS&METHODS: To address this issue, the immune response against cancer was investigated in T cell-specific Smad7 transgenic mice and wild type littermates subcutaneously transplanted with syngenic MC38 colon carcinoma cells.
RESULTS: Smad7Tg mice resulted resistant to tumor development as compared to Wt and protection was dependent on CD4+ but not CD8+ T cell. Smad7 overexpression in CD4+ T cells induced Tbet and IFN-gamma while inhibited IL17A in Th17 cells. Moreover, the immune environment generated by Smad7 overexpression in CD4+ cells sensitized tumor cells to the TNF-alpha-mediated apoptosis in an IL17A-dependent but IFN-gamma-independent manner.
CONCLUSION: These data underscore the intimate connection between the immune response and cancer development and directly provide a mechanism involving Th17 plasticity induced by Smad7 expression.

P1497 CONTRIBUTION OF LARGE INTESTINAL MICROBIOTA AND BACTERIOCINS TO THE DEVELOPMENT OF COLORECTAL NEOPLASIA

D. Kohoutova[1,2,*], D. Smajs[3], J. Bures[2]. [1]*Research Department of Cancer Biology, University College London, London, United Kingdom,* [2]*2nd Department of Internal Medicine - Gastroenterology, Charles University in Praha, Faculty of Medicine at Hradec Kralove & University Teaching Hospital, Hradec Kralove,* [3]*Department of Biology, Masaryk University, Faculty of Medicine, Brno, Czech Republic*

INTRODUCTION: Sporadic colorectal cancer (CRC) represents an immense problem worldwide. The exact role of all the potential contributors on its aetiology and pathogenesis has not been clarified yet, however, large bowel microbiota play an extremely important role. Bacteriocins are peptides or small proteins, which are produced by bacteria of the *Enterobacteriaceae* family, especially by *Escherichia coli*. Bacteriocins are divided into more groups, colicins and microcins are the most important ones. Bacteriocins have antibacterial, antineoplastic, proapoptotic and probiotic effects.
AIMS&METHODS: We have established completely new methods of bacteriocin typing. Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonoscopy in patients with colorectal adenoma (17 men, 13 women, mean age 63±9), with colorectal carcinoma (23 men, 7 women, mean age 67±11) and in the controls (average risk population with normal endoscopy findings and with negative history of colorectal adenoma, carcinoma or idiopatic bowel disease; 9 men, 11 women, mean age 55±15). After appropriate microbiological culture bacteriocinogeny of each strain and the genotypes of *Escherichia coli* were investigated by PCR methods.
RESULTS: There were 666 strains isolated and futher investigated. Statistically significant difference in bacteriocinogeny was found out between patients with non-advanced (N-A) and patients with advanced (A) colorectal neoplasia (N-A: 39% vs A: 72%; p=0.010). There was a trend towards statistically significant difference in the frequency of *Escherichia coli* genotype B2: genotype B2 (which is associated with more virulent strains) was found in patients with N-A colorectal neoplasia in 24% vs in patients with A colorectal neoplasia in 52%; p=0.054). Increasing bacteriocinogeny, microcinogeny and colicinogeny & microcinogeny was associated with increasing stage of CRC (assessed according to the TNM classification) – results see in the Table 1.
Table 1:

	I	II	III	IV
Staging	I 6/12	II 10/12	III 26/38	IV 6/6
Bacteriocinogenic strains	(50%)	(83%)	(68%)	(100%)
Colicinogenic strains	3/12 (25%)	4/12 (33%)	20/38 (53%)	4/6 (67%)
Microcinogenic strains	5/12 (42%)	8/12 (67%)	24/38 (63%)	6/6 (100%)
Strains producing colicin and microcin	2/12 (17%)	2/12 (17%)	18/38 (47%)	4/6 (67%)

CONCLUSION: We have confirmed, that large bowel mucosa in patients with advanced colorectal neoplasia is colonised by *Escherichia coli*, which belongs to more virulent strains. Large intestinal microbiota with their products including bacteriocins contribute to the pathogenesis of colorectal neoplasia and CRC.

P1498 LOW MOLECULAR WEIGHT PROTEIN TYROSINE PHOSPHATASE (LMWPTP) IS UPREGULATED IN PRIMARY COLORECTAL CANCER AND AFFECTS CANCER SIGNALING PATHWAYS.

E. Hoekstra[1,*], L. Kodach[2], J. Hardwick[2], E. Kuipers[1], M. Bruno[1], M. Peppelenbosch[1], G. Fuhler[1]. [1]*Gastroenterology and Hepatology, Erasmus MC, Rotterdam,* [2]*Gastroenterology and Hepatology, LUMC, Leiden, Netherlands*

INTRODUCTION: Cancer cell functions are tightly regulated by protein phosphorylation and dephosphorylation. Enhanced kinase activation and phosphorylation is often observed in colorectal cancer (CRC). Whereas kinases are seen as potential oncogenes, dephosphorylation of proteins by phosphatases is commonly assumed to be tumor suppressive. However, some phosphatases may also stimulate tumor growth and invasion. One of these is low molecular weight protein tyrosine phosphatase (LMWPTP), overexpression of which in cell lines is sufficient for cellular transformation.
AIMS&METHODS: The aim was to investigate the expression levels of LMWPTP in primary CRC specimens, and elucidate its role and signaling targets in CRC cells. LMWPTP expression was analysed on sections from biopsies of low grade dysplasia (LGD; n=9), high grade dysplasia (HGD; n=7), and adenocarcinoma (AC; n=12) by immunohistochemistry. Normal colon tissue (n=2), active ulcerative colitis (n=6) served as controls. This staining was subsequently performed on a tissue microarray (TMA) of 72 patients with colorectal adenoma (N=47) and/or carcinoma (N=164) and their corresponding normal tissue (N=63). To investigate downstream targets of LMWPTP, we manipulated the LMWPTP expression *in vitro* by lentiviral transduction of HCT116 and Caco-2 cells with siRNA against LMWPTP.
RESULTS: In our initial screen LMWPTP expression in intestinal epithelial cells (IEC) was limited to 9% of IEC in non-cancerous tissues. In contrast, expression of LMWPTP significantly increased with subsequent levels of dysplasia (42%, 80% and 100% positive IEC in LGD, HGD and AC respectively). Staining of the TMA confirmed these results: the mean % positive IEC was 27±3% in normal tissues, 64±4% in adenoma and 90±3% in carcinoma ($p<0.001$). There was a significant difference between different cancer-stages within patients (N=15, paired testing; $p<0.001$), however, Dukes stage or patient survival did not correlate with LMWPTP expression. Knocking down LMWPTP in CRC cells reduced phosphorylation of the EGF-receptor and PKB *in vitro* by approximately 50%.
CONCLUSION: LMWPTP expression is drastically upregulated in epithelial dysplasia and CRC. During transformation of IECs, LMWPTP expression increases, suggesting a role for LMWPTP in the pathogenesis of CRC. As LMWPTP knockdown decreases EGFR and PKB phosphorylation, overexpression of LMWPTP in CRC samples may contribute to the enhanced EGF and PKB signaling, known to play a role in CRC development. In conclusion, LMWPTP is overexpressed in CRC, may function as an oncogene, and represent a compelling target for future therapy.

P1499 MYOFIBROBLAST-DERIVED SECRETED FRIZZLED-RELATED PROTEIN 1 (SFRP1) CAN INHIBIT COLORECTAL CARCINOMA FIELD CANCERISATION

G. Valcz[1], A. V. Patai[2,*], I. Fűri[2], A. Kalmár[2], B. Péterfia[2], T. Krenács[3], S. Spisák[4], F. Sipos[2], G. Műzes[2], B. Wichmann[5], B. Molnár[2,5], Z. Tulassay[2,5]. *[1]Molecular Medicine Research Unit, Hungarian Academy of Sciences, Budapest, [2]2nd Department of Internal Medicine, [3]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary, [4]Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [5]Molecular Medicine Research Unit, Hungarian Academy of Sciences, Budapest, Hungary*

INTRODUCTION: Besides frequent mutations of canonical Wnt pathway in colorectal cancer (CRC), intercellular Wnt regulator SFRP1 plays a crucial role in the inhibition of autocrine Wnt loop of epithelial cells. We hypothesized that this effect may appear in genetically/epigenetically altered, but histologically normal adjacent tumour (NAT) areas, and inhibit field cancerisation.
AIMS&METHODS: Our aim was to compare mRNA expression of *SFRP1* in stromal sections of NAT (n=49) and CRC (n=49) areas by Affymetrix microarray chip. To identify the origin of SFRP1, dual fluorescent SFRP1 – α-SMA immunohistochemistry was applied on NAT (n=5) and CRC (n=5) samples. To examine *SFRP1* methylation status of α-SMA+ stromal cells, we examined *SFRP1* methylation status of laser capture microdissected α-SMA+ cells from NAT (n=3) and CRC (n=3) samples with methylation-specific PCR.
RESULTS: *SFRP1* mRNA expression in CRC stroma significantly decreased compared to NAT region ($p<0.001$). This change also appeared at protein level, mainly in stromal α-SMA+ myofibroblasts (CRC: 27,65±18,27 vs. NAT: 85,73±12,61%; $p<0.05$). In line with this, in CRC areas we found significantly increased ($p<0.05$) *SFRP1* DNA hypermethylation in laser capture microdissected α-SMA+ myofibroblasts.
CONCLUSION: Myofibroblast-derived SFRP1 may act as a tumour suppressor and inhibit field cancerisation in NAT areas. Paralell with tumour growth, increased hypermethylation and consequentional underexpression of *SFRP1* in stromal myofibroblast may exert a synergistic effect with the enhanced autocrine epithelial Wnt loop.

P1500 SYSTEMIC DENDRITIC CELLS IN COLORECTAL CANCER ARE MORE ACTIVATED AND LYMPH NODE HOMING: POTENTIAL ROLE IN DISEASE PROGRESSION AND FUTURE OF CANCER IMMUNOTHERAPY

G. H. Lee[1,2,*], G. Malietzis[1,2], N. Yassin[1,2], E. Mann[1], D. Bernardo[1], S. Clark[2], R. Phillips[2], S. Knight[1], H. O. Al-Hassi[1]. *[1]Department of Medicine, Antigen Presentation Research Group, Imperial College London, [2]Academic Institute, St Mark's Hospital, Harrow, United Kingdom*

INTRODUCTION: Dendritic cells (DC) are antigen presenting cells that migrate to lymphoid tissues to initiate cytotoxic or tolerogenic immune response to cancer antigens. CD40 is a co-stimulatory molecule and a marker for DC activation. Increased CD40 expression on DCs can be associated with maturation and enhanced cytokine production against cancer cells [1]. Activation of DC is accompanied by up regulation of the lymph node migration marker C-chemokine receptor7 (CCR7) [2]. However, DC in cancer are unable to elicit effective immune responses against tumour cells. Previous studies on DC in colorectal cancer (CRC) were on cell lines and animal models. We aimed to determine the phenotype and activation status of systemic DC in CRC patients.
AIMS&METHODS: Peripheral blood mononuclear cells were obtained from CRC patients before any surgical intervention (n=21) together with age and sex-matched healthy controls (n=21). DC were identified as HLA-DR positive and lineage (anti-CD3, CD14, CD16, CD19, CD34 and CD56) negative cells. DC were further classified as CD11c+ myeloid DC (mDC) or CD11c- putative DC (pDC). CD40, CD80, CD86 and CCR7 expression was determined on DC by flow-cytometry.
RESULTS: In CRC, expression of CD40 was significantly higher on all DC (27.59%±2.521 vs 17.30±2.989, p=0.012) compared to control. This increase was driven by the mDC subset, which was significantly increased in CRC (32.36%±4.278 vs 19.50%±2.223, p=0.011). There was also statistically significant increase in CCR7 expression in mDC in CRC patients compared to control (35.42%±3.862 vs 16.00%±2.150, $p<0.0001$). There were no differences in CD80 and CD86 expression between groups.
CONCLUSION: DC in CRC patients are activated and their potential capacity to migrate to lymph nodes is increased. Increased CD40 expression may indicate increase in partially activated DC subpopulation. Our results using fresh DC show contrasting results to previous studies done using monocyte-derived DC, which showed reduced CD40 expression in CRC. Hence, results should be interpreted with caution when using cytokine stimulated DC as they may not resemble DC normally present in blood. Furthermore, increased expression of CCR7 in mDC in CRC could suggest its possible role in cancer metastasis. DC may stimulate either immunogenic or suppressive responses upon migration to lymph nodes. Therefore, further studies are warranted to investigate which immune response DC in CRC are inducing, which is an important step towards creating more suitable anti-tumour vaccines.

P1501 ASSOCIATION BETWEEN MICROBIAL DYSBIOSIS AND COLORECTAL CANCER DEVELOPMENT USING APC MIN MICE MODEL.

J. Gagnière[1,2,*], J. Raisch[1], V. Bonnin[1], M. Medina-Martinez[3], N. Barnich[1], D. Pezet[1,2], A. Darfeuille-Michaud[1,2], M. Bonnet[1]. *[1]UMR 1071 Inserm/UdA, M2iSH, Clermont Université, [2]CHU, Clermont Ferrand, France, [3]University of Girona, Girona, Spain*

INTRODUCTION: Tumor microenvironment of colorectal carcinoma (CRC) is a complex association between non neoplastic and tumoral cells and a large amount of microorganisms. These microorganisms could be linked to cancer by several mechanisms, including chronic inflammation and/or production of carcinogenic metabolites.
AIMS&METHODS: The aim of this study was to analyze the microbiota composition associated to normal and tumoral gut mucosa in multiple intestinal neoplasia (Min) mice, in accordance to tumoral development and compared to that associated to mucosa of wild type (WT) mice. The dominant and subdominant bacterial populations (*Escherichia coli, Bacteroides/Prevotella, Faecalibacterium prausnitzii, and Bifidobacterium*) were quantified in all samples by quantitative PCR using Taqman® probes.
RESULTS: Total mucosa-associated eubacteria were increased in Min compared to WT mice. Interestingly, the level of mucosa-associated eubacteria in Min mice was significantly correlated with the number of colonic tumors. Mucosa and tumors-associated *E. coli* were only detected in the older Min mice (>15 weeks) with a higher level associated to tumoral tissues. Concerning *Bacteroides*, similar levels of mucosa and tumors-associated bacteria were measured in Min mice, and a lower level of *Bacteroides* was detected in mucosa of WT mice. In our experimental conditions, *Faecalibacterium prausnitzii* associated to intestinal mucosa was undetectable. Finally, a decrease of mucosa-associated *Bifidobacterium* was observed on both older WT and Min mice. Moreover, mucosa-associated *Bifidobacterium* was significantly decreased in both normal and tumoral tissues of Min mice presenting more than 2 colonic tumors.
CONCLUSION: Intestinal mucosa-associated microbiota was significantly altered in Min mice compared to WT mice. During tumoral development, dysbiosis was observed in both tumor and adjacent normal tissues of Min mice. This study allows better understanding how gut microbiota dysbiosis is associated with CRC in Min mice model, and may suggest a possible involvement of *E. coli* in colorectal carcinogenesis.

P1502 INNATE IMMUNITY IN HEREDITARY NON POLYPOSIS COLORECTAL CANCER

M. Scarpa[1,*], C. Ruffolo[2], F. Canal[2], M. Scarpa[1], S. Basato[3], F. Erroi[3], A. Fiorot[3], L. Dall'Agnese[3], A. Pozza[3], A. Porzionato[3], I. Castagliuolo[3], A. Dei Tos[2], N. Bassi[2], C. Castoro[1]. *[1]Veneto Institute of Oncology (IOV-IRCCS), Padova, [2]"Ca Foncello" Hospital, Treviso, [3]University of Padova, Padova, Italy*

INTRODUCTION: Pattern Recognition Receptors (PRRs), such as TLRs and NLRs, are well known for their pivotal function in innate immunity but their role in cancer immunosurveillance is elusive. Indeed, TLR5, TLR7 and TLR8 agonist have shown a potent antitumor activity and TLR4 signalling was associated to adaptive immunosurveillance in ulcerative colitis. However, TLR4-MyD88 signalling has been linked to tumour growth and progression in mice and it was associated with colorectal cancer poor prognosis.
Hereditary non polyposis colon cancer (HNPCC) is characterized by defects in DNA mismatch repair genes (most frequently MSH2, MLH1, PSM2 or MSH6).
AIMS&METHODS: The aim of the study was to examine TLRs and NODs expression in the healthy mucosa of patients with familiar history of colorectal cancer and to assess TLR4 and MyD88 expression in HNPCC to understand if alteration of mismatch repair genes expression may affect TLR4-MyD88 signalling.
Firstly, a prospective cohort of 63 patients who had colonoscopy for cancer screening or colonic resection for colorectal cancer was enrolled. Colonic biopsies of healthy mucosa were taken to quantify TLRs1-10, NODs and MyD88 mRNA expression by real time RT-PCR. Familial and medical history were retrieved. Secondly, immunohistochemistry for TLR4, MyD88, MSH2, MLH1, MSH6 and PSM2 expression on epithelial cells was quantified in 98 patients operated for colorectal cancer. Non parametric statistics was used.
RESULTS: The mRNA levels of TLR2, TLR4, TLR5, TLR10, NOD1 and NOD2 resulted significantly upregulated in the healthy colonic mucosa of subjects who had a familial history of cancer in comparison to subjects with a negative familial history. In particular, those subjects who had a familial history of colorectal cancer showed an overexpression of TLR4 and TLR8 transcripts (p=0.05 and p=0.02, respectively). By contrast, in the diseased mucosa,TLR4 expression on epithelial colorectal cancer cells was significantly decreased in patients with a single mismatch repair gene defect compared to patients with no defect (p=0.03).
CONCLUSION: TLRs and NODs upregulation in healthy colon of patients with familiar history of cancer and, specifically, that of TLR4 and TLR8 in case of family history of colorectal cancer, might be interpreted as an enhancement of innate immunity cancer surveillance in a high risk setting. Moreover, a

decreased expression of TLR4 in colorectal cancer with a single mismatch repair gene defect suggest a possible impairment of immunosurveillance mechanisms in case of defect of DNA damage repair.

P1503 THE PROGNOSTIC VALUE OF CDKN2A HYPERMETHYLATION IN COLORECTAL CANCER: A META-ANALYSIS

X. Xing[1,*], M. Chen[1]. [1]*the First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

INTRODUCTION: The prognostic value of CDKN2A promoter hypermethylation in colorectal cancer remains controversial. We systematically reviewed the evidence for assessment of CDKN2A methylation in colorectal cancer to elucidate this issue.
AIMS&METHODS: Pubmed, Embase and ISI web of knowledge were searched to identify eligible studies to evaluate the association of CDKN2A hypermethylation and overall survival and clinicopathological features of colorectal cancer patients. Combined hazard ratios (HRs) or odds ratios (ORs) with 95% confidence interval (95% CI) were pooled using a random-effects model.
RESULTS: Overall, CDKN2A hypermethylation in the primary tumor had significant association with an enhanced mortality risk of colorectal cancer patients in the random effects model (combined HR 1. 65, 95% CI 1.29–2.11), despite the exhibition of heterogeneity among studies (I^2 69%, p=0.0004). For the exploration of the source of heterogeneity, meta-regression and subgroup analysis were conducted by study location, publication year, number of patients and methylation rate, REMARK score and ELCWP score. Study location was found to be significantly correlated with the inter-study heterogeneity (p= 0.008) while other covariates was not. Furthermore, subgroup analysis revealed that the significant correlation between CDKN2A hypermethylation and OS was present in Europe (HR 1.49; 95% CI 1.28-1.74) and Asia (HR 3.30; 95% CI 1.68-6.46). We also observed the significant association of CDKN2A hypermethylation and OS of patients in studies with REMARK score greater than 12 (HR 1.75, 1.22-2.51), further confirming the prognostic role of CDKN2A hypermethylation in CRC. Of note, the pooled HR estimate by multivariate analysis was 1.38 (95% CI: 1.02–1.87), suggesting that CDKN2A hypermethylation might be an independent prognostic factor for patients with colorectal cancer.
Additionally, we assessed the association between CDKN2A hypermethylation and clinicopathological features of colorectal cancer patients. As indicated in Table 3, CDKN2A hypermetylation had a significant association with lymphovascular invasion (positive vs. negative: OR 1.68, 95% CI 1.15–2.47), lymph node metastasis (positive vs. negative: OR 1.68, 95% CI 1.09–2.59), and tumor location (proximal vs. distal: OR 2.09, 95% CI 1.34–3.26).
CONCLUSION: This meta-analysis indicated that CDKN2A hypermethylation might be a predictive factor for unfavorable prognosis of colorectal cancer patients.

P1504 INDIAN HEDGEHOG IS REQUIRED FOR INTESTINAL ADENOMA FORMATION

N. V. Buller[1,*], S. L. Rosekrans[1], J. Heijmans[1], G. J. Offerhaus[2], B. K. Lanske[3], V. Muncan[1], M. E. Wildenberg[1], G. R. van den Brink[1,4]. [1]*Tytgat Institute for Liver and Intestinal Research, Academic Medical Center, Amsterdam,* [2]*Department of Pathology, University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Department of Oral Medicine, Infection and Immunity, Harvard School of Dental Medicine, Boston, United States,* [4]*Department of Gastroenterology and Hepatology, Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Activating mutations in the Hedgehog (Hh) pathway are found in basal cell carcinomas and medulloblastomas. The role of Hh signaling in intestinal tumorigenesis has not yet been clarified. Hh is expressed by enterocytes and signals in a paracrine manner from the epithelium to the mesenchyme. Hh controls mesenchymal factors such as Bone Morphogenetic Proteins and Activins which negatively regulate the proliferation of precursor cells. Since Indian Hedgehog (Ihh) is the major Hh expressed in the intestinal epithelium we decided to study the potential role of Ihh signaling in intestinal adenoma formation.
AIMS&METHODS: In order to study the effect of loss of *Ihh* signaling in sporadic tumorigenesis we conditionally deleted *Ihh* in mice in the intestinal epithelium using the *Cyp1a1Cre* promoter. These mice were crossed with conditional mutant Apc^{15lox} mice to generate $Cyp1a1Cre\text{-}Ihh^{fl/fl}\text{-}Apc^{fl/+}$ mice. At 4-7 weeks of age mice were intraperitoneally injected with 80 mg/kg β-naphthoflavone for 5 days. $Cyp1a1Cre\text{-}Ihh^{+/+}\text{-}Apc^{fl/+}$ littermates served as controls. Four months after recombination, we sacrificed and analyzed the mice (n=15).
RESULTS: *Ihh* expression was upregulated in polyps of $Cyp1a1Cre\text{-}Ihh^{+/+}\text{-}Apc^{fl/+}$ mice as assessed by in situ hybridization. Deletion of *Ihh* resulted in a marked reduction of 90.3% in the number of polyps (17.2 ± 13.65 polyps per mouse vs. 1.7 ± 1.5, $P < 0.01$). The polyp size did not differ between groups. Neither did the number of proliferating or apoptotic cells in the polyps, as assessed by immunostaining for BrdU and cleaved caspase 3. Analysis of Hh responsive cells in the mesenchyme of the polyp showed a decrease of the number of α-sma en desmin double positive cells (smooth muscle cells). COX2 is expressed early in adenoma to carcinoma transition and believed to play an important role in adenoma formation. Stromal cells are known to be a source of COX2. In accordance with this, examination of *Cox2* expression by Q-PCR and immunostaining showed up regulation in polyps of $Cyp1a1Cre\text{-}Ihh^{+/+}\text{-}Apc^{fl/+}$ mice in compared to normal intestinal epithelium ($P < 0.01$, resp. $P < 0.05$). In contrast, *Cox2* expression in the polyps of $Cyp1a1Cre\text{-}Ihh^{fl/fl}\text{-}Apc^{fl/+}$ mice was not significantly up regulated.
CONCLUSION: Surprisingly, in contrast to its role as an anti-proliferative signal in the normal epithelium, *Ihh* acts as a tumor promoter. The expression of *Ihh* is increased in polyps and mice that lack *Ihh* develop fewer polyps. This finding is accompanied by loss of smooth muscle cells in the mesenchyme of the polyp and decreased *Cox2* expression.

P1505 THE BONE MORPHOGENETIC PROTEIN PATHWAY EITHER ENHANCES OR INHIBITS THE WNT PATHWAY DEPENDING ON SMAD4 AND P53 STATUS IN COLORECTAL CANCER.

P. Voorneveld[1,*], L. Kodach[1], R. Jacobs[1], W. Mesker[2], G. van den Brink[3,4], J. Offerhaus[5], M. Peppelenbosch[6], P. ten Dijke[7], J. Hardwick[1]. [1]*Gastro-enterology & hepatology,* [2]*Surgery, LEIDEN UNIVERSITY MEDICAL CENTER, Leiden,* [3]*Gastro-enterology & hepatology,* [4]*Tytgat Institute for Liver & Intestinal Research, Academic Medical Center, Amsterdam,* [5]*Pathology, Utrecht Medical Center, Utrecht,* [6]*Gastro-enterology & hepatology, Erasmus MC, Rotterdam,* [7]*Molecular Cell Biology, LEIDEN UNIVERSITY MEDICAL CENTER, Leiden, Netherlands*

INTRODUCTION: In intestinal crypt-villus homeostasis, morphogenic signalling pathways such as BMP and Wnt interact to control cell fate. In the normal intestine BMP signalling is responsible for differentiation and apoptosis and inhibits Wnt signalling, which is responsible for proliferation and inducing stemness. In tumourogenesis, cells acquire mutations which result in the disruption of these morphogenic pathways and in changes in pathway crosstalk. We set out to investigate how several of the common mutations found in colorectal cancer might change the BMP-Wnt interaction. With cancer therapy increasingly focussed on the targeted pharmacological modulation of the specific molecular pathways underlying carcinogenesis, understanding of how the major pathways interact and how mutations influence this is of critical importance.
AIMS&METHODS: BMP signalling was activated in a series of 8 CRC cell lines and Wnt activity was measured using a β-catenin reporter assay. HCT116 SMAD4-/- cells, HCT116 R248 cells (p53 mutant) and shSMAD4 in LS174T cells were used to investigate BMP-Wnt interaction dependent on SMAD4 and p53. Expression of Wnt-target genes was evaluated by q-PCR array. MTT assays were performed to study cytotoxic effects of 5-FU in CRC cells. The expression patterns of SMAD4, p53 and β-catenin at the invasive front of 94 stage I/II CRCs were analyzed using immunohistochemistry.
RESULTS: Activation of BMP signalling results in downregulation of Wnt signalling only in SMAD4 positive and p53 WT cell lines. Loss of SMAD4 shifts BMP signalling from inhibiting to enhancing Wnt signalling. In p53 mutant cells Wnt signalling inhibition by BMP is abolished. While BMP signalling significantly increases the sensitivity of SMAD4 positive cancer cells to 5-FU, it reduces 5-FU sensitivity in SMAD4 negative cancers. Pre-treatment of SMAD4 negative cancer cells with a BMPReceptor 1a inhibitor significantly increases chemo sensitivity. Loss of SMAD4 and/or aberrant p53 expression at the invasive front of CRC is correlated with a high expression of β-catenin.
CONCLUSION: Our data suggest that BMP signalling either inhibits or enhances the Wnt pathway based on the SMAD4 and p53 status and can therefore be either tumour-suppressive or tumour-promoting. Inhibition of BMP signalling increases chemosensitivity in SMAD4 negative colorectal cancer, a chemoresistant molecular subtype with a poor prognosis.

P1506 SUSCEPTIBILITY FOR COLITIS-ASSOCIATED CANCER DEVELOPMENT IN SAMP1/YIT MICE

S. Ishihara[1,*], N. Fukuba[1], Y. Tada[1], H. Sonoyama[1], A. Oka[1], R. Kusunoki[1], N. Oshima[1], I. Moriyama[1], T. Yuki[2], K. Kawashima[1], Y. Kinoshita[1]. [1]*Internal Medicine II, Shimane University Faculty of Medicine,* [2]*Gastrointestinal Endoscopy, Shimane University Hospital, Izumo, Japan*

INTRODUCTION: SAMP1/Yit mice, which spontaneously develop transmural, patchy intestinal inflammation in the ileum, are widely recognized as a murine model of Crohn's disease. However, inflammatory colonic lesions are not found in this strain. Although recent studies have revealed dysfunctions of regulatory T cells and interleukin (IL)-10-producing regulatory B cells in these mice, little is known regarding the role of such an immune background in development of colitis-associated cancer.
AIMS&METHODS: We evaluated colitis-associated cancer development in SAMP1/Yit mice and compared our findings to age-matched control AKR/N mice. Experimental colitis was induced in 7-week-old male SAMP1/Yit and AKR/ N mice by administration of dextran sodium sulfate (DSS) for 10 days. The colitis activity parameters body weight, colon length, histological score, and colonic expressions of tumor necrosis factor (TNF)-alpha and macrophage inflammatory protein (MIP)-2 were assessed in inflamed colon tissues obtained from those mice. In addition, a mouse colitis associated cancer (CAC) model was induced by intraperitoneal injection of azoxymethane (AOM) in both strains, then a 3-cycle administration of DSS was given and examinations performed on day 60. The incidence of colitis-associated tumor development, and numbers and size of colonic tumors were determined, and compared between the mouse groups.

RESULTS: There were no differences regarding macroscopic and histological findings of the colon between SAMP1/Yit and AKR/N mice before DSS administration. In the colitis model, body weight loss, colon shortening, histological colonic inflammation severity, and TNF-alpha and MIP-2 expressions were significantly greater in SAMP1/Yit mice than AKR/N mice. As for the CAC model, the incidence of colitis-associated tumors was significantly higher in SAMP1/Yit mice (100%) than AKR/N mice (12.5%).
CONCLUSION: DSS-induced colonic inflammation was greater in SAMP1/Yit mice as compared to AKR/N mice, which may indicate its influence on susceptibility for colitis-associated cancer development.

P1507 SERRATED LESIONS SHARE COMMON RISK FACTORS WITH COLONIC ADVANCED NEOPLASMS IN 6,218 CHINESE COHORT

S. C. Ng[1,*], H. W. Hirai[1], J. Y. Lau[2], J. Y. Ching[1], R. Tang[1], A. J. Hui[3], P. Y. Lam[3], T. Lam[1], J. C. Wu[1], F. K. Chan[1], J. J. Sung[1]. *[1]Medicine and Therapeutics, [2]Surgery, Chinese University Of Hong Kong, [3]Alice Ho Miu Long Nethersole Hospital, Hong Kong, Hong Kong*

INTRODUCTION: Few studies have evaluated risk factors and the magnitude of risk for serrated lesions.
AIMS&METHODS: To assess risk factors associated serrated lesions and advanced neoplasms (AN) in a cohort of Chinese population, we analyzed findings from 6,218 consecutive adults aged≥50 years who underwent colonoscopy to the cecum. We quantified the risk of advanced neoplasm (adenoma≥1 cm, a polyp with tubulovillous/villous histology or high-grade dysplasia, or adenocarcinoma) and serrated lesions (hyperplastic polyps or serrated adenomas). Variables examined included family history of colorectal cancer (CRC), smoking, alcohol use, hypertension and body mass index (BMI). Age-adjusted univariate and multivariate logistic regression analyses were performed for each variable to calculate odds ratios (ORs) and 95% confidence intervals (CIs) associated with having serrated lesions and AN compared with having no polyps.
RESULTS: 3,647 subjects (58.8%) had no polyps, 344 (5.5%) had AN, 1486 (23.9%) had adenomas, 532 (8.56%) had serrated lesions. Mean age was 56.65 ±6.15 and 46.8% were male. 21% and 34% of serrated lesions and AN, respectively, were found in the proximal colon. Age ≥50 was associated with risk of serrated lesions and AN. In multivariate analyses after age adjustment, male gender (OR, 1.23; 95% CI, 1.02 – 1.50), current/previous smoking (OR, 1.98; 95% CI, 1.49 – 2.65) and BMI of ≥25 (OR, 1.34; 95% CI, (1.10 - 1.64) were associated with an increased risk of serrated lesions. Male gender (OR, 2.02; 95% CI; 1.57 – 2.59), a family history of colorectal cancer (OR, 1.62; 95% CI, (1.21 – 2.16), current/previous smoking (OR, 1.46; 95% CI, (1.02 – 2.09), hypertension (OR, 1.55; 95% CI, (1.20 – 2.01), and BMI≥25 (OR 1.40, 95% CI (1.10 - 1.79) were positively associated with an increased risk of AN.
CONCLUSION: Age, male sex, smoking and obesity are common clinical risk factors for serrated lesion and advanced neoplasms. Environmental and genetic factors play a role in the pathogenesis of these lesions.

P1508 FTY 720 INHIBIT THE TUMOR FORMATION IN A DEXTRAN SODIUM SULPHATE ENHANCED APCMIN/+ MOUSE MODEL

S. Y. Kim[1,*], B. J. Lee[1], Y. A. Jung[1], S. H. Kim[1], J. W. Choe[1], M. K. Joo[1], J.-J. Park[1], J. S. Kim[1], Y.-T. Bak[1]. *[1]Gastroenterology, internal medicine, Korea university kuro hospital, Seoul, Korea, Republic Of*

INTRODUCTION: Sphingolipids activate multiple signal transduction pathways associated with cancer development. Sphingosine kinase 1 (SphK1) generates sphingosine-1-phosphate (S1P), which is a ligand for S1P receptors and a key molecules in sphingolipid-mediated functions including cell growth, differentiation and survival. Upregulation of SphK1 has been shown to be associated with colitis and colitis-associated cancer. The *Apc* $^{min/+}$ mouse is one of the well-known models of intestinal tumorigenesis. Colitis induced by DSS can enhance formation of colonic tumorigenesis in this model, which is more relevant to human colitis-associated cancer (CAC). In this study, we evaluate the FTY 720, functional S1PR antagonist on colonic tumorigenesis in DSS- *Apc* $^{min/+}$ mouse model.
AIMS&METHODS: The aim of this study is to define the role of regulation of sphk1/sphK2 in murine colitis and CAC.
C57BL/6 and *Apc* $^{min/+}$ mice were used for all experiments. Acute colitis was induced with 3% DSS for 5 days. Mice were treated with PBS or FTY (1mg/kg.i.p) and sacrificed at 8 days.
Histologic assessment of colitis was evaluated after H & E stain. Four-week old *Apc* $^{min/+}$ mice were given 2% DSS and then FTY 720 (1mg/kg.i.p) or PBS was administrated for 5 weeks and sacrificed 24hrs after final dose injection. To determine whether the effects of FTY 720 are due to suppression of inflammation during early CAC induction, same dose of FTY 720 was administrated to mice for 7 days of DSS cycle. Mice were sacrificed 5 weeks after DSS treatment. Tumor formation and size were assessed in the colon. Genetic expression of SphK1/2 was determined using real-time PCR in mice rectum. Immunohistochemistry and Western blots for Sphk1, pAkt, cyclin D1 were performed in mice colon and colonic epithelial cells.
RESULTS: FTY 720(1mg/kg) significantly ameliorated the acute DSS-colitis. Both earlier and delayed treatment of FTY 720 significantly reduced the number (16.1±3.4, 10.8±3.8, 9.8±4.5, $p<0.05$) and size of macroscopic tumors compared to PBS-treated mice (3.32±0.68 mm, 2.78 ±1.3, 2.26±1.17mm, $p<0.05$). Immunoactivies of Sphk1, pAkt and cyclin D1 were significantly suppressed in colonic tumors by FTY 720 treatment. Also Sphk1/Sphk2 gene expression ratio was significantly reduced by FTY 720 treatment (50 folds, $p<0.01$).
CONCLUSION: FTY 720, functional S1PR antagonist suppresses colitis and colitis associated cancer in B6J and *Apc*$^{min/+}$ mice by the modulation of Sphk1 expression and other proliferative signaling pathways. The regulation of Sphk1/Sphk2 expression might be one of the important signaling pathways in the pathogenesis of CAC.

P1509 ASSOCIATION BETWEEN BODY MASS INDEX (BMI) AND PREVALENCE OF COLONIC ADVANCED NEOPLASM

T. Y. T. Lam[1,*], S. S. M. Ng[2], M. C. S. Wong[3], J. Y. L. Ching[1], V. C. W. Chan[1], J. J. Y. Sung[1]. *[1]Medicine and Therapeutics, [2]Surgery, [3]School of Public Health, Chinese University of Hong Kong, Shatin, Hong Kong*

INTRODUCTION: There is increasing evidence to show the impact of obesity on the incidence of colorectal cancer (CRC). It is important to understand the association of obesity with pre-neoplastic conditions to identify high risk subjects and implement appropriate preventive measures.
AIMS&METHODS: This study assesses the association between colonic advanced neoplasms (CAN) and BMI (and other co-morbidities) among a Chinese population.
CAN is defined as CRC, or any colorectal adenoma which has a size of equal to or larger than 10 mm in diameter, high grade dysplasia, villous or tubulovillous histologic characteristics, or any combination thereof. In addition, BMI(kg/m^2) ≥18.5 to <23 is defined as normal weight; <18.5 as underweight; ≥23 to <25 as overweight; ≥25 as obesity.
Asymptomatic Chinese subjects were recruited into a community colorectal cancer screening program in Hong Kong from June 2008 till December 2012. They were offered either fecal immunochemical test or colonoscopy. The colonoscopic results were recorded and odds ratio of detection of CAN in relationship to BMI and other comorbidities were determined by multivariate regression analysis.
RESULTS: Among 10758 subjects, 4961(46.1%) underwent complete colonoscopy and provided detailed demography and medical history. The mean age was 57.1 (4.9) and male proportion was 47.5% (2357/4961). The CAN detection rate was 5.5% (272/4961). Table 1 shows the results of multivariate regression analysis. When compared to normal weight subjects, the adjusted OR of prevalence of CAN in overweight subjects was 1.47 (95%CI: 1.07-2.02), obese subjects was 1.55 (95%CI: 1.14-2.11). Furthermore, men with overweight [aOR: 1.97 (95%CI: 1.43-2.71)] and obesity [aOR: 2.18 (95%CI: 1.62-2.95)] were associated with a higher risk of CAN. Overweight [aOR: 1.7 (95%CI: 1.01-3.00)] and obese [aOR: 1.93 (95%CI: 1.21-3.08)] subjects with family history of CRC also had a higher risk of CAN.
Table 1
Odds ratios (95% CI) of colorectal advanced neoplasm

	OR (95% CI)	aOR (95% CI)
Underweight	0.87 (0.40-1.91)	1.01 (0.46-2.22)
Overweight	1.63 (1.19-2.23)	1.47 (1.07-2.02)
Obesity	1.81 (1.34-2.44)	1.55 (1.14-2.11)
Age	1.09 (1.06-1.11)	1.07 (1.05-1.10)
Male	1.93 (1.50-2.48)	1.64 (1.28-2.15)
HTN	1.73 (1.34-2.25)	1.32 (1.14-2.11)
DM	1.41 (0.93-2.13)	-
Family history of CRC	1.50 (1.11-2.04)	1.55 (1.13-2.12)
Smokers	1.85 (1.30-2.64)	1.44 (0.98-2.09)

CONCLUSION: To conclude, individual with a high BMI (≥23 kg/m^2), male gender and family history of CRC were associated with a higher risk of CAN. Appropriate screening strategies are needed to determine for these high risk groups of individuals.

P1510 INTRAUTERINE GROWTH RETARDATION ALTERS THE COLONIC EPITHELIAL BARRIER AND INCREASES THE RISK OF COLONIC DISEASES IN ADULT RATS

V. Haure-Mirande[1,*], P. de Coppet[1], C. Bonnet[1], A. Bourreille[2], G. Le Dréan[1], J.-P. Segain[1]. *[1]IMAD-INRA / Nantes University, [2]IMAD-CHU, Nantes, France*

INTRODUCTION: Infants born with intrauterine growth retardation (IUGR) are at increased risk for developing metabolic diseases in adulthood such as type 2 diabetes (1). It has been proposed that an adverse intrauterine environment could induce stable epigenetic modulation of gene expression, which in turn, alters the function of metabolic organs later in life (2). Epigenetic and metabolic modifications are also involved in the pathogenesis of inflammatory bowel disease and colorectal cancer but their origins are not completely understood (3).

AIMS&METHODS: The objective of this study was to determine the impact of IUGR upon colonic epithelial barrier and colonic diseases.The rat model of IUGR was obtained by restricting protein intake in pregnant rats. Birth weights of IUGR pups are 15-20% lower than controls. By the age of 5-8 months, colons were collected and colonocytes isolated. Permeability was assessed by mounting colonic tissues in Ussing chambers. Expression of key genes and epigenetic modifications were analysed by immunohistology, western-blot, qPCR and ChIP assays. Susceptibility to colitis was assessed by dextran sodium sulfate (DSS) treatment and colitis induced-carcinogenesis by azoxymethane (AOM) injection. Histological scores and neoplastic lesions were measured.
RESULTS: Proliferation of epithelial cells was decreased in colonic crypts from IUGR rats without modification of apoptosis, suggesting a lower self-renewal of colonic epithelium. IUGR increased intestinal permeability and this effect was associated with disorganisation of tight-junction proteins. Expressions of the transporter (MCT1) and ß-oxidation enzyme (scACAD) of butyrate were down-regulated in IUGR colonocytes suggesting impairment of butyrate utilisation, the main energy source for colonocytes (5). Among the posttraductional modifications of H3 and H4 histones, IUGR induced a drastic loss of H4K16 acetylation, an epigenetic mark of colorectal cancer (5). The severity of DSS-induced colitis was higher in IUGR rats than in controls. Moreover, the number of AOM-induced preneoplastic lesions (MDF) was higher in IUGR rats.
CONCLUSION: Our study suggests that IUGR induces epigenetic and metabolic modifications in colonic epithelium, which could affect the intestinal barrier and predispose to gastrointestinal diseases.

P1511 ERBB3 PHOSPHORYLATED BY HEREGULIN PROMOTES ANGIOGENESIS IN COLORECTAL CANCER

Y. Hanada[1,*], A. Tatsuguchi[1], K. Mitsui[1], M. Yonezawa[1], S. Tanaka[1], S. Fujimori[1], C. Sakamoto[1]. [1]*Division of Gastroenterology, Nippon Medical School, Tokyo, Japan*

INTRODUCTION: The erbB family, including epidermal growth factor receptor (EGFR), erbB2, erbB3, and erbB4, plays various and distinctive roles both physiologically and pathologically, including cell proliferation, differentiation, migration, and apoptosis. There are multiple mechanisms underlying erbB-mediated tumor progression. We have shown that heregulin stimulates vascular endothelial growth factor (VEGF) secretion via phosphorylation of erbB3 (p-erbB3) using colorectal cancer cell lines in vitro. The clinical significance of phosphorylated erbB3 expression has yet to be explored in colorectal cancer.
AIMS&METHODS: To investigate heregulin, p-erbB3, and VEGF protein expression in human colorectal cancer and determine the relationship between their expression and angiogenesis and patient prognosis.
We examined 155 surgical resections from colorectomy patients. Cellular localization of heregulin, p-erbB3, and VEGF protein in colorectal cancer surgical resections was analyzed by immunohistochemistry. Microvessel density (MVD) was determined by immunostaining for CD34. Immunohistochemical results were compared with clinicopathological factors and patient prognosis.
RESULTS: MVD was higher in heregulin- and VEGF-positive cases than in heregulin- and VEGF-negative cases. In addition, MVD was higher in p-erbB3-positive cases than in p-erbB3-negative cases. Statistically, heregulin expression correlated with p-erbB3 or VEGF expression. In univariate analysis, heregulin and p-erbB3 correlated with worse prognosis in colorectal cancer patients. In multivariate analysis, heregulin and p-erbB3 retained independent prognosis significance.
CONCLUSION: These data suggest that heregulin contributes to colorectal cancer development by promoting angiogenesis via phosphorylation of erbB3.

P1512 METAGENOME ANALYSIS OF PLASMA DERIVED CFDNA IN HEALTHY PATIENTS AND COLON DISEASES

B. K. Barták[1,*], S. Spisák[2], N. Solymosi[3], P. Ittzés[3], A. Bodor[3], D. Kondor[3], G. Vattay[3], Z. B. Nagy[1], A. Kalmár[1], A. Schöller[1], Á. V. Patai[1], Z. Tulassay[2], I. Csabai[3], B. Molnár[2]. [1]*2nd Department of Internal Medicine, Semmelweis University,* [2]*Molecular Medicine Research Group, Hungarian Academy of Sciences,* [3]*Department of Physics of Complex Systems, Eötvös Loránd University, Budapest, Hungary*

INTRODUCTION: There are many theory of the cell free DNA (cfDNA) origin such as apoptosis, necrosis and active secretion; however the exact nucleotide composition is unknown. We are constantly exposed to foreign DNA from various sources like benign or malicious microbes in and on our body, pollens in the inhaled air and as the largest amount with the daily food supply. Here we report a new possible mechanism, which can be contribute the quantity and quality of the cfDNA.
AIMS&METHODS: Our aims were to determine the DNA content of cfDNA by NGS sequencing technology and identify differences among four clinical groups and analyze the unmapped read from NGS sequencing data.
CfDNA was extracted from plasma samples which were collected (TUKEB 2009/037) from 50-50 normal, IBD, colorectal adenoma and -cancer patients. Fractions were separated via electrophoresis and DNA fragments were recovered from the gel slices. Intact DNA above 10kb (1st), the fraction is between 200bp to 10kb (2nd) and nucleosomal DNA (3rd) fractions were separated. Indexed DNA fragment library resequencing was performed on SOLiD IV system. The sequencing yielded 50 nt long reads a total of 86.6 Gbases. Sequence alignments were performed by SHRiMP and Bowtie aligners. We have verified our data using SRA data sets.
RESULTS: We analyzed cfDNA NGS data from own and previously published cohort of over 1000 patients. On average above 70% of the reads were mapped to the human reference genome. The non-aligning reads were aligned to genomes of various other organisms. Significant portion of the sequence tags (0.5-50 ppm) can be mapped back with high confidence to the genome of Enterobacteriaceae (Escherichia coli, Shigella sonnei) and commonly consumed food substances such as potato or rice. The number of tags can be fitted with a log-normal distribution which consistent with our fractionation result, furthermore the time dependent DNA degradation processes and the different absorption efficiency. IBD is a potential promotion factor of the absorption.
CONCLUSION: Though the sporadic occurrence of food related miRNA and DNA in blood has already been reported in previous studies, the presence of fragments which can carry complete genes seems to be novel. Our findings can be change fundamentally our general ideas from the digestion processes and macro molecular transport, furthermore may be contributing to understanding cancer development or making blood based diagnostic markers.

P1513 PROGNOSTIC SIGNIFICANCE OF DR-70 LEVELS IN DYSPLASTIC COLON POLYPS

A. Yesil[1], C. Gonen[1,*], F. Gunduz[1], S. Özkara[2]. [1]*Gastroenterology,* [2]*Pathology, Haydarpasa Numune Training and Research Hospital, Istanbul, Turkey*

INTRODUCTION: Background: The AMDL-ELISA DR-70 (fibrinogen degradation products [FDP]) test isthe first in vitro diagnostic cancer test approved by the USFDA to monitor colorectalcancer since 1982 when carcinoembryonic antigen (CEA) was approved. Objective:This study investigated the relationship between DR-70 serum levels anddysplastic colon polyps.
AIMS&METHODS: This is a single center prospective analysis of selected patientswith colon polyps. 50 healthy blood donors and 130 patients with adenomatous polypsdetected by colonoscopy were included in the study. Patients were divided into twogroups (i.e., "low grade" - Group 1a and "high grade" - Group 1b) according to theextent of the dysplasia in the polyp. Blood samples from each participant wereanalyzed for serum CEA and DR-70 levels. Main Outcomes Measures: Prognostic significance of DR-70 levels in dysplasticcolorectal polyps described.
RESULTS: The median DR-70 level was 0.5 ug/ml in the healthy control group and 1.1
ug/ml in Group 1b (i.e., the high grade polyp) ($p<0.001$). DR-70 was higher in Group 1b
as compared Group 1a ($p<0.001$). However, the mean DR70 values for the low grade
polyp group (i.e., Group 1a) and the control group were similar ($p=0.067$).
The median DR-70 level was 0.5 ug/ml in the healthy control group and 1.1ug/ml in Group 1b (i.e., the high grade polyp) ($p<0.001$). DR-70 was higher in Group 1bas compared Group 1a ($p<0.001$). However, the mean DR70 values for the low gradepolyp group (i.e., Group 1a) and the control group were similar ($p=0.067$). Limitations: We did not include CRC patients in the sample population. Moreover, wecould not include serrated adenomas because only five of our patients presented withthis condition. Lastly, the patient sample size, i.e., 130 cases, may not be sufficientlylarge to determine the cut-off level between dysplastic lesions and healthy controls
CONCLUSION: DR-70, a marker used to measure FDP, which is generated by all majorcancers, is a potential marker to identify patients with advanced adenomatous polyps, i.e., precursors of colorectal cancer.

P1514 THE SENSITIVITY AND SPECIFITY OF DR-70 IMMUNOASSAY AS A TUMOR MARKER FOR GASTROINTESTINAL CANCERS

C. Gonen[1,*], A. Yesil[1], N. Paker[2], S. Özkara[3], F. Gunduz[1]. [1]*Gastroenterology, Haydarpasa Numune Training and Research Hospital,* [2]*Biochemistry, Duzen,* [3]*Pathology, Haydarpasa Numune Training and Research Hospital, Istanbul, Turkey*

INTRODUCTION: The sensitivity and specificity of DR-70 as a tumor marker for the detection of gastrointestinal cancers was evaluated and compared to that of conventional tumor markers (i.e., CEA and CA 19-9), The relationship between the clinical parameters of the gastrointestinal cancers and the serum DR-70 values versus that of CEA and CA 19-9 was examined.

AIMS&METHODS: Blood sera from 101 patients with gastrointestinal malignancies and 105 healthy blood donors were collected prospectively. The tumor extension and spread was classified using organ-specific TNM classification and histologic grade. All patients and controls were also tested for DR-70, CEA, and CA 19-9 levels.

RESULTS: The median levels of DR-70 were 1.6 μg/mL and 0.5 μg/mL in cancer patients and the healthy control group, respectively ($P < 0.001$). The sensitivity, specificity, and the best cut-off value for DR-70 in patients with malignancy were 97.0%, 95.2%, and < 0.75 μg/mL, respectively. The positive predictive value was 95.1%, and the negative predictive value and the efficacy were 97.1% and 96.1%, respectively. Although the sensitivities of CEA and CA 19-9 were 52.5% and 38.6%, respectively, the sensitivity increased to 66.3% with the combined use of both. The specificities were 94.2% and 99.0% for CEA and CA 19-9, respectively. The serum DR-70, CEA, and CA19-9 levels were higher in cancer patients as compared to the control group ($P < 0.001$).

CONCLUSION: Due to its high sensitivity, specificity, and positive and negative predictive values, DR-70 can be used more frequently as a tumor marker for the diagnosis of gastrointestinal cancers and in the detection of tumor progression and treatment follow-up due to the positive correlation between DR-70 levels and tumor stage.

P1515 INTERVAL CANCERS IN LYNCH SYNDROME FAMILIES UNDER COLORECTAL SURVEILLANCE

L. Sanchez Mete[1,*], M. Anti[1], V. Stigliano[1]. [1]*Regina Elena National Cancer Institute, Rome, Italy*

INTRODUCTION: Mutation carriers in Lynch syndrome (LS) have a lifetime risk for CRC of 52-82% at the age of 70 years(yrs). Several studies reported colorectal cancer (CRC) within an interval of 2 years after a negative colonoscopy, therefore International Guidelines for LS suggest colonoscopic surveillance interval of 1-2 year. Nowadays the effectiveness of a less (2 years) or more intensive (1 year) interval surveillance protocol is still not defined.

AIMS&METHODS: Aim of the present study was to evaluate the most optimal surveillance interval for mutation carriers in LS families.

Among subjects who referred to the Family Cancer Clinic of our Institution LS families with a known deleterious mutation of Mismatch Repair (MMR) genes were selected. All the carriers with at least 2 surveillance examinations were included in the study. All colonoscopies were performed by experienced gastroenterologist and after 2006 Narrow Band Imaging and Magnification were used at each examination. The recommended interval of surveillance was 1-2 years according with International Guidelines.

RESULTS: 71 patients (33 males/38 females) from 30 LS families were included in the study. Mean age at baseline surveillance colonoscopy was 39,8 years (range 18-68 years). 40 patients carried a deleterious mutation of MSH2 gene and 31 of MLH1 gene. After a mean follow up of 61,6 months (range 12-371) and a total of 268 colonoscopies, 4 out of 71 patients (5,6%) developed CRC under surveillance. One out of these 4 patients had a sub-optimal bowel preparation. Mean interval from previous colonoscopy was 24 months (range 16-30 months). Mean age at diagnosis was 40 years (range 32-50 years). Two patients carried a large deletion of MSH2 gene and the other 2 a deleterious mutation of MLH1 gene. None of the patients had a prior history of CRC.

CONCLUSION: In our series interval CRCs were detected in 5,6% of LS under endoscopic surveillance with a mean interval of 24 months, according with previous studies. In three patient CRC was diagnosed at an early stage (T1-T2N0), whereas in one at a more advanced stage (T2N1). In the last case the bowel preparation was suboptimal and the surveillance colonoscopy was performed with a 16 months interval. All patients were asymptomatic and all underwent a high quality colonoscopy with advanced imaging techniques (NBI and magnification). No specific genotype was associated with a more rapid malignant transformation.

In conclusion, in our experience the risk of developing CRC in LS mutation carriers could be reduced by a one year colonoscopic surveillance program rather than every 2 years.

P1516 UPTAKE OF COLORECTAL CANCER SCREENING IN SOUTH EAST LONDON; A PROSPECTIVE QUESTIONNAIRE SURVEY OF DEMOGRAPHIC AND PSYCHOLOGICAL FACTORS

N. Dharni[1,*], D. Armstrong[1], A. J. Wright[1], G. Chung-Faye[2]. [1]*Primary Care and Public Health Sciences, King's College London,* [2]*Gastroenterology, King's College Hospital NHS Trust, London, United Kingdom*

INTRODUCTION: Colorectal cancer screening is offered in the UK to individuals aged 60-75 years through the self-completed faecal occult blood test (FOBt). Nationally uptake of screening is 60% but only 40% in South East (SE) London. Reasons for this low uptake are unclear.

AIMS&METHODS: This study examined whether demographic and/or psychological factors account for variation in FOBt uptake in SE London. A prospective phone survey was conducted with participants (n=507) two months before being invited for screening. The questionnaire was based on an integrated psychological framework (Michie et al 2005), including constructs such as intentions, emotions and environmental context. Socioeconomic status (SES) was measured combining education, housing tenure and car ownership. Participants reported their ethnic group. Uptake was assessed from screening records. Data were analysed using logistic regression and mediation analysis.

RESULTS: White British (WB), Black African (BA), Black Caribbean (BC) and White Other (WO) ethnic groups were included. Participants' SES varied, though there were more participants from less deprived backgrounds than those from more deprived backgrounds.

Table 1 displays the odds ratios (OR) for FOBt uptake by ethnicity. BA and WO participants were less likely to complete the FOBt than WB participants. However, BC participants did not differ in their likelihood of completing the FOBt compared to WB participants. In terms of SES, those of low SES were generally less likely to complete the FOBt, although this result was marginally non-significant (OR=-0.754, p=0.073).

Table 1: Ethnicity as a predictor of FOBt uptake

Ethnicity	OR	P value
BA	0.318	0.004
BC	1.681	0.259
WO	0.445	0.008

Ethnic differences were mediated by psychological factors, with lower FOBt uptake by BA participants being partly due to their having lower intentions (BA participants vs. WB participants=-0.505, 95% confidence intervals (CI) 0.911-0.215) and greater difficulty planning FOBt completion (BA participants vs. WB participants=-0.168, 95% CI 0.412-0.041). For WO participants, lower FOBt uptake was mediated by greater planning difficulties only (WO participants vs. WB participants=-0.128, 95% CI 0.327-0.011).

CONCLUSION: There were significant differences between ethnic groups in FOBt uptake, which persisted when controlling for SES. These differences appear to result from BA and WO participants having lower intentions and more difficulties planning how and when to complete the FOBt compared to WB participants. Screening uptake interventions may benefit from targeting these factors.

P1517 HIGHER SENSITIVITY FOR THE DETECTION OF ADENOMAS BY A HB/HP BED SITE TEST USING A NOVEL SAMPLING DEVICE

T. Knittel[1,*], K. Lüthgens[2], G. Frost[3]. [1]*University of Goettingen, Goettingen,* [2]*Labor Enders, Stuttgart,* [3]*Frost Diagnostika GmbH, Otterstadt, Germany*

INTRODUCTION: Point of care diagnostic tests are widely used for the detection of occult blood in the stool to enable an early detection of bowel cancer or adenomas. Due to their higher specificity and sensitivity compared to formerly used biochemical tests, immunochromatographic tests on haemoglobin (Hb) and the haemoglobin/haptoglobin complex (Hb/Hp) in stool samples are regarded as superior. The aim of the study was to compare the sensitivity and specificity of an i-FOB test using a novel or a standard sampling device.

AIMS&METHODS: The new i-FOB test, named ''FD Hb/Hp complex professional'', uses a novel stool sampling system, which enables the testing of a precisely defined quantity of stool independent of its consistency. 245 stool samples from healthy controls and patients with different types of lower GI disease were tested with an i-FOB test using the novel (new test) or a standard (old test) sampling device. All 245 subjects underwent lower GI tract endoscopies including biopsies, healthy controls were defined by the absence of endoscopic or histological abnormalities. Statistical analysis was performed using a chi-squared test.

RESULTS: For the detection of adenomas applying Hb as a marker the sensitivity of the test using the novel sampling device was a lot higher (93%) compared to the old test (57%). The new system detected 9 out of 11 adenomas while the old system detected only 5 cases. Using Hb/Hp as a read out the novel sampling system detected 6 cases with colorectal adenoma compared to 3 cases using the standard sampling device with a sensitivity of 39% vs 28%, respectively. In this series each case of a positive Hb result was paralleled by a positive Hb/Hp finding and specificity was above 99% in every setting..

In all other disease conditions the new and the old test system only showed minor differences.

Furthermore, Hb and the Hb/Hp complex had different detection rates in that in general the sensitivity of Hb as marker was higher compared to the Hb/Hp complex.

Disease	n	New Test Hb	Old Test Hb	New Test Hb/Hp	Old Test Hb/Hp
Colon adenoma	11	9	5	6	3
Colon carcinoma	4	4	4	1	1
Colon polyps	4	4	3	1	1
Colon diverticulosis	9	1	0	0	0
Crohn's disease	6	2	1	2	1
Ulcerative colitis	4	2	1	1	1
Healthy controls	207	2	1	1	1

CONCLUSION: This new test system analysing Hb or Hb/Hp in a precisely defined amount of stool obtained by a novel sampling device, allows a better detection of faecal occult blood derived from colon adenomas and might be also beneficial in other settings characterised by occult bleeding.

P1518 THE COMPARISON OF K-RAS MUTATION IN COLORECTAL MUSCULARIS PROPRIA CARCINOMA ACCORDING TO MORPHOLOGICAL DEVELOPMENTS

T. Hisayuki[1,*], S.-E. Kudo[1], H. Miyachi[1], K. Ichimasa[1], S. Matsudaira[1], H. Oikawa[1], Y. Mori[1], M. Misawa[1], T. Kudo[1], T. Hayashi[1], K. Wakamura[1], E. Hidaka[1], S. Ohkoshi[1], F. Ishida[1], S. Hamatani[1]. [1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama, Japan*

INTRODUCTION: To investigate differential expression of K-ras mutation in depressed-type lesion in comparison with polypoid- or flat types.

AIMS&METHODS: A total of 22800 neoplasms were resected endoscopically or surgically at our unit from April 2001 to June 2012. Of these 347 muscularis propria carcinoma were included. Thirty specimens of MP carcinoma were obtained by surgical resection or endoscopic submucosal dissection. According to their morphological developments, we classified them into three types : polypoid(n=30), flat(n=20), and depressed types(n=34). K-ras mutation was examined using reverse sequence-specific oligonucleotide with polymerase chain reaction method(PCR-rSSO).

RESULTS: Single-base transition from GGT to GAT in codon 12 was detected in ten samples, and twelve samples presented with GGC to GAC transition in codon 13. Our study showed a high frequency of G to A transition of codon 13 mutation of the K-ras gene. K-ras mutation was found in polypoid type by 50.0%(15/30), flat type by 55.0%(11/20), and depressed type by 20.6%(7/34). To explain flat type in detail, eigteen LST-G and two LSTs-NG (pseudo-depressed type) were included in flat-type lesions. Eleven(61.1%) of 18 LST-G had K-ras mutation, while two LSTs-NG had no K-ras mutation(0/2). In summary, the frequency of K-ras mutation was significantly lower in depressed-type lesions and LSTs-NG (pseudo-depressed type) [7/36(19.4%)] as compared to the other types [26/48(54.2%)] of MP carcinomas.

CONCLUSION: Depressed-type lesions and LST-NG (pseudo depressed type) were suggested to come through a distinct genetic pathway.

P1519 HOW RELIABLE ARE IMMUNOHISTOCHEMICAL STAINING FOR DNA MISMATCH REPAIR PROTEINS PERFORMED AFTER NEOADJUVANT CHEMO-RADIATION IN PATIENTS WITH RECTAL CANCER ?

A. Vilkin[1], M. Halpern[2], S. Morgenstern[2], D. Boltin[3], R. Gingold-Belfer[1], Y. Niv[3], Z. Levi[1,4,*]. [1]*Gastroenterology,* [2]*Pathology, Rabin Medical Center,* [3]*Gastroenterology, RMC, PETACH TIKVA,* [4]*Tel Aviv University, Tel Aviv, Israel*

INTRODUCTION: The use of immunohistochemistry (IHC) for mismatch repair proteins (MMR) is being increasingly used. We aimed to compare the efficacy of IHC staining performed on biopsy specimens obtained at endoscopy with the surgical specimens following neoadjuvant therapy

AIMS&METHODS: 32 rectal cancer subjects had paired pre & post neoadjuvant tissue available for IHC staining for $hMLH_1$, $hMSH_2$, $hMSH_6$, and PMS_2. *Absent* staining was defined as total loss of protein in the tumor. *Focal & weak* staining was defined as no more than moderate intensity staining present in $<10\%$ of the tumor cells. 13 rectal cancer patients that did not receive neoadjuvant treatment served as controls.

RESULTS: The IHC of the *pre* neo-adjuvant biopsies showed that 2 subjects had absent stain for at least one of the MMR proteins and 30 subjects had strong stain for all MMR proteins. Overall, out of 30 subjects with strong pre neoadjuvant staining of all MMR proteins, in only 18 subjects (60.0%) there was also strong staining of all MMR proteins in the post neoadjuvant material. In the post neoadjuvant material, a pattern of *focal & weak* staining emerged in a significant proportion of all MMR proteins [PMS_2 (33.3%); $hMSH_6$ (13.3%); *hMLH1* (10.0%); $hMSH_2$ (6.7%)].

CONCLUSION: Our study suggests that neoadjuvant therapy is associated with the emergence of a false focal staining pattern in all MMR proteins. Therefore, IHC from the pre neoadjuvant endoscopic biopsies should be preferred. We also highlight the importance of obtaining multiple biopsies before chemoradiation is commenced.

P1520 COMPREHENSIVE MIRNA EXPRESSION PROFILE ANALYSIS IN ADENOMA-CARCINOMA SEQUENCE

Z. B. Nagy[1,*], B. Wichmann[2], S. Spisák[2], B. K. Barták[1], A. Kalmár[1], A. Schöller[1], A. V. Patai[1], I. Füri[1], B. Molnár[2], Z. Tulassay[2]. [1]*2nd Department of Internal Medicine, Semmelweis University,* [2]*Molecular Medicine Research Unit, Hungarian Academy of Sciences, Budapest, Hungary*

INTRODUCTION: Recent studies described the changes of the miRNA expression in precancerous lesions and in colorectal cancer. miRNA remain stable in formalin-fixed, paraffin-embedded (FFPE) tissue samples. Several miRNA extraction kits are available, but it is still controversial that total RNA or enriched miRNA isolation kits are better for extraction and investigation of miRNA.

AIMS&METHODS: Our primary aim was to find any viable miRNA by using different extraction protocols.

Our further aims were to identify the miRNA expression alterations between normal colonic tissue (N), tubulovillous adenoma (AD) and colorectal cancer (CRC) FFPET samples after selecting the top isolation method and to find characteristic miRNA patterns between the three clinical groups. Other purpose was to predict gene targets of the most interesting miRNA *in silico*.
miRNA were isolated using High Pure miRNA Isolation Kit (Roche), miRCURY^{TM} RNA Isolation Kit (Exiqon), High Pure RNA Paraffin Kit (Roche), MagNA Pure 96 Cellular RNA LV Kit (Roche) to determine any differences in the 4 extraction methods after deparaffinization of FFPET sections from human N (n=3), AD (n=3) and CRC (n=3) FFPET samples. To analyze the miRNA expression patterns qPCR Human Panel I+II (Exiqon) method detecting 742 human miRNA was performed. Gene target prediction was done using four algorithms.
RESULTS: The High Pure miRNA Isolation Kit showed most of the expressed miRNA on both Panels, moreover the number of expressed miRNA. Different miRNA expressions could be detected in N, AD and CRC samples. Out of the 752 analyzed miRNA, 256 miRNA showed significant ($p<0,05$) differences in the comparison of N vs. AD, furthermore most of them (n=251) were found to be downregulated in AD samples. miR-124 shown significantly decreased 6 times level ($p<0,05$) in AD samples. miRNA showed expression alteration between N vs. CRC cases, most of them were upregulated. miR-31 produced increased expression through N vs. CRC. We found 244 miRNA expression alterations in AD in comparison to CRC samples, moreover 242 miRNA were overexpressed in CRC. miR-99a was found to be most upregulated in CRC group. Predicted mRNA targets were selected from the most significantly up- and down-regulated miRNA and validation was confirmed with all genome expression data.
CONCLUSION: According to our preliminary results, miRNA expression patterns could be determined among the three analysed stages and after further validation with increased sample number, groups of selected miRNA can be suitable for diagnostic classification of pre-cancerous and cancerous lesions.

P1521 AFATINIB, A TYROSINE KINASE INHIBITOR, ENCAPSULATED WITH POLYMERIC MICELLES TO IMPROVE THE THERAPEUTIC EFFECT FOR HER2-OVEREXPRESSED TUMORS

A.-S. Ho[1,*], C.-C. Cheng[2], C.-C. Chang[3], H.-C. Lin[1], T.-Y. Luo[2], J. Chang[4]. *[1]Division of Gastroenterology, Cheng Hsin General Hospital, Taipei, [2]Isotope Section, Institute of Nuclear Energy Research, Taoyuan, [3]Division of Gastroenterology, Taipei Medical University Hospital, [4]Graduate Institute of Medical Sciences, Taipei Medical University, Taipei, Taiwan, Province of China*

INTRODUCTION: HER2, a receptor protein with tyrosine kinase domain, overexpressed in tumors, including breast tumor, gastric tumor, colorectal tumor, and participated in the cell proliferation of tumor cells. Studies have indicated that tyrosine kinase inhibitor such as afatinib can block HER2 activation, and hence reduce tumor growth. On the other hand, nanoparticles such as polymeric micelles, which possess the enhanced permeability and retention (EPR) effect, were used as a drug carrier to improve the accumulation of drugs in tumor tissues. Therefore, we aimed to encapsulate afatinib with the polymeric micelles for improving the therapeutic effect of HER2-overexpressed tumors in this study.
AIMS&METHODS: The expressions of HER2 in the variety of tumor cells were detected using Western Blotting. A dose-dependent method of afatinib was performed in high-expressed HCT-15 cells and low-expressed MKN45 cells to validate the therapeutic effect of this tyrosine kinase inhibitor response to HER2 expression. Moreover, apoptosis and *in vivo* inhibitory effect were measured after afatinib-encapsulated micelles administration.
RESULTS: We observed that HER2 overexpressed in breast (MCF-7), prostate (PC-3), gastric (AGS), colorectal (HCT-15), and hepatocellular (HepG2) tumor cells as compared to lung cancer cells (A549). We selected high-expressed HCT-15 and AGS cells, and low-expressed MKN45 cells for testing the specific therapeutic effect of afatinib. We found that afatinib had higher inhibitory effect to HCT-15 and AGS cells as compared to MKN45 cells, indicating afatinib specifically inhibited HER2-overexpressed tumors. Furthermore, afatinib-encapsulated micelles led to higher inhibitory effect and apoptosis, demonstrating that micelles help afatinib enter to the HER2-overexpressed tumor cells. In vivo inhibitory assay of HCT-15-induced tumor xenografts demonstrated that afatinib-encapsulated micelles significantly reduced tumor growth as compared to afatinib performance alone.
CONCLUSION: In this study, we demonstrated the specific expression of HER2 in the variety of tumor cells, and created a novel micelles-carried afatinib for the therapeutic application of HER2-overexpressed tumors. The improved therapeutic effect of this micelles-carried afatinib may be applied in clinical practice for prolonging the survival of HER2-overexpressed tumor patients.

P1522 MANAGEMENT OF POLYP CANCERS WITHIN A NATIONAL BOWEL CANCER SCREENING PROGRAMME

G. Longcroft-Wheaton[1,*], P. Bhandari[1]. *[1]gastroenterology, PORTSMOUTH HOSPITALS NHS TRUST, Portsmouth, United Kingdom*

INTRODUCTION: Endoscopic management of early colonic neoplasia or polyp cancer remains unclear. There are no national guidelines or good quality data to guide clinicians with these difficult lesions.
AIMS&METHODS: The aim of this study is to identify the incidence of early cancer and variation in practice of managing these lesions. Data was prospectively collected in all patients undergoing screening within the Solent Bowel Cancer Screening Programme (BCSP) in the United Kingdom. The database was interrogated to identify all neoplasia. The endoscopists suspicion of cancer was noted from the reports. MDT outcome was recorded, along with final management of the cancer
RESULTS: In total 3976 patients underwent screening colonoscopy between 2007 -2012. N=5768 neoplastic polyps found giving a mean polyp detection rate of 1.5/patient. Cancer was found in 235/3976 (6%) patients. Mean age was 67yrs. 142/235 (60%) were male. 145/235 (62%) had advanced cancer, confirmed at surgery. 90/235 (38%) patients had polyp cancer. 83% of them in rectosigmoid.
1) 13/90 were pedunculated polyps (mean size 23 mm, range 12-35mm)
2) 77/90 were flat polyp cancers (mean size 24mm, range 8-80mm)
See table 1 below
13/13 pedunculated polyp cancers were endoscopically resected. In 6/13 cases cancer was suspected prior to resection. Histology was reported accurately on 12/13 (92%) polyp cancers using Haggitt classification. 1/13 required surgery due to invasive features on histology.
30/77 (39%) of flat or sessile polyp cancers were endoscopically resected. Endoscopist suspected cancer in only 13/30 (43%) cases prior to resection. Histology was reported confidently by Kukuchi levels in 19/30 (63%) of lesions. 9/19 required surgery due to invasive features on histology. In 11/30 (37%) cases the histology report was inconclusive due to a poor quality EMR specimen. This led to surgery in all 11 patients but no residual disease or LN involvement was found.

Size(mm)	Pedunculated	Flat	Total
0-10	0/13 **0%**	17/77 **22%**	17/90 **19%**
11-20	6/13 **46%**	27/77 **35%**	33/90 **37%**
>20	7/13 **54%**	33/77 **43%**	40/90 **44%**

Table 1: Breakdown of polyp cancer size and morphology

CONCLUSION: 1) The in-vivo endoscopic diagnosis of cancer prior to resection is suboptimal and can be improved
2) Post EMR histology reporting is inconclusive in a large proportion of flat polyps leading to unnecessary surgery
3) Clinical care could be improved by optimising in-vivo diagnostic skills and resecting large flat lesions in single piece by ESD.

P1523 FROM SURGERY TO THE DELIVERY OF ADJUVANT THERAPIES IN STAGE III COLORECTAL CANCER PATIENTS: THE ROLE PRE-OPERATIVE NEUTROPHIL TO LYMPHOCYTE RATIO.

G. Malietzis[1,2,*], M. Giacometti[1], R. H. Kennedy[1], R. Glynne-Jones[3], N. Anyamene[3], O. Aziz[1], J. T. Jenkins[1]. *[1]Department of Colorectal Surgery, St Mark's Hospital, [2]Department of Medicine, Imperial College, London, [3]Mount Vernon Cancer Centre, Mount Vernon Hospital, Northwood, United Kingdom*

INTRODUCTION: The role of adjuvant chemotherapy [AC] is established in stage III colorectal cancer but a significant proportion do not proceed with therapy after colorectal resection. Preoperative neutrophil to lymphocyte ratio (NLR) has been found to be an independent negative prognostic outcome marker in patients with colorectal cancer (CRC) [1,2]. In an era of increasingly personalised cancer treatment, we assessed whether NLR might determine the likelihood of proceeding with adjuvant therapy.
AIMS&METHODS: All patients diagnosed with stage III CRC undergoing curative elective resection from 2006 to 2011 were assessed from a prospective database. Demographics, operative factors and postoperative outcomes were recorded. Data fields were complete for all patients in the study. Univariate analysis determined predictors of failure to initiate AC that were then submitted to multivariate analysis to determine independent predictors. Factors including sex, age, operation type (laparoscopic versus open), 30-day major morbidity [Clavien-Dindo (CD)≥3], Enhanced Recovery protocol, TNM stage, ratio of positive lymph nodes, vascular invasion, tumour site, Charlson morbidity score, preoperative albumin and preoperative NLR were assessed. Emergency presentations and operations were excluded.
RESULTS: 271 patients were analysed. Median age of 68.5 years [IQR, 57.25-77.00]. 177 patients (57%) were male. Multivariate regression analysis identified NLR>3 (OR 0.42, (95% CI 0.23-0.78) P=0.006) and age ≥65 years (OR 0.13, (95% CI 0.06-0.26); P<0.001) as independent prognostic factors for failure to proceed with AC. NLR> 3.0 was significantly associated with age, higher T and N stage and a low pre-operative albumin level.
CONCLUSION: In this prospective cohort study, preoperative NLR> 3.0 and age were independent predictors of failure to proceed to adjuvant chemotherapy: NLR>3.0 was related to > 50% reduction in the likelihood of starting therapy. Preoperative NLR may assist clinicians where individual risks need to be considered before initiating adjuvant therapy, particularly in older patients.

P1524 POST POLYPECTOMY ENDOSCOPIC SURVEILLANCE: DO DIFFERENT SPECIALISTS MEET THE INTERNATIONAL GUIDELINES ON COLORECTAL CANCER PREVENTION?

J. E. Pizzala[1,*], M. González[1], I. Oría[1], M. Sobrero[1], P. Carrillo[1], P. Daffra[1], M. Giménez Villamil[1], J. De paula[1], C. Macías Gómez[1]. [1]*HOSPITAL ITALIANO DE BUENOS AIRES, Buenos aires, Argentina*

INTRODUCTION: The "US Multi-Society Task Force on Colorectal Cancer and American Cancer Society" suggests specific guidelines for the colonic post polypectomy follow-up. However, some relevant publications concluded there is a low adherence by physicians to such international guidelines.
AIMS&METHODS: To assess if in our Hospital different specialists (gastroenterologists, surgeons and clinicians) meet the surveillance intervals suggested by the guidelines.
We carried out a restropective clinical record analysis of patients who underwent a surveillance colonoscopy after polypectomy from July 2011 to April 2012 at a University Hospital. All patients included were treated and followed in our institution. We reevaluated the previous therapeutic colonoscopy that caused the follow-up and then we compared the surveillance period suggested by the guidelines based on these reports with the period observed in our data base. Patients with incomplete colonoscopy, submucosal invasion histology, serratum adenomas, and/or inadequate colonic cleansing were excluded. Whether patients influence physician decisions on the timing of the surveillance colonoscopy is unknown.
RESULTS: We analyzed 331 post polipectomy surveillance colonoscopy. Only 24% of the studies were carried out according to the guidelines. The percentage of surveillance colonoscopies performed before the period suggested by the guidelines, discriminated on physician specialty was: Gastroenterologists (GE) in 59%, Surgeons (SO) in 83% and Clinicians (CN) in 75%. The percentage of colonoscopies performed according to the guidelines was: GE in 34%, SO in 17% and CN in 22%. And the percentage performed after the period was: GE in 7%, SO in 0% and CN in 3%. We also compared the surveillance intervals based on the polyp findings observed in the previous colonoscopy (table).

	On time intervals	Anticipated intervals	Average months (Anticipated)	Delayed intervals	Average months (delayed)
Rectal hyperplastic polyps	3%	97%	51	0%	0
1 or 2 small tubular adenomas with low grade dysplasia	15%	85%	33	0%	0
3 to 10 adenomas or one >1 cm or any with villous features or high-grade dysplasia	36%	59%	22	5%	16
>10 adenomas on a single examination	67%	33%	12	0%	0
large sessile adenomas that are removed in piecemeal	47%	0%	0	53%	12

CONCLUSION: Although patients evaluated by gastroenterologists showed the best rates of adherence to the guidelines, all specialists showed a strong trend to shorten the follow-up intervals. This situation led to an overuse of resources and an unnecessary increase in health care costs

P1525 THE CLINICOPATHOLOGICAL CHARACTERISTICS OF TUMORS WITH A NEGATIVE COLONOSCOPY WITHIN THE PREVIOUS TEN YEARS.

K. Kodama[1,2,*], S.-E. Kudo[1], K. Wakamura[1], H. Miyachi[1], T. Hayashi[1]. [1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama city,* [2]*Department of digestive disease, Kakunodate municipal hospital, Semboku city, Japan*

INTRODUCTION: Total colonoscopy(TCS) is considered to have the highest sensitivity for colorectal cancer(CRC). A 10-year interval is recommended according to adenoma-carcinoma sequence, however, considering the presence of de-novo cancer and missing rate, the appropriate interval of screening TCS has been unknown.
AIMS&METHODS: The aim of this study is to evaluate the characteristics of CRCs of following a previous negative TCS. Records of patients who underwent an endoscopic resection or operation of invasive carcinoma at our hospital, from 2002 to 2010, were reviewed retrospectively. The patients were divided into two groups. GroupA included patients with a negative colonoscopy within the previous one to 10 years. GroupB included patients without a previous colonoscopy or with a previous colonoscopy more than 10 years prior. Tumor stage (classified by TNM classification), tumor location (left or right-sided), size were analyzed.
RESULTS: A total of 2208 resected invasive carcinomas were available to analyze. GroupA contained 2151 lesions, GroupB contained 57 lesions. In each groups, tumor staging were as follows ; GroupA T1 703(32.7%), T2 305(14.2%), T3 922(42.8%), T4 221(10.3%). GroupB T1 24(42.1%), T2 8(14%), T3 20(35.1%), T4 5(8.8%). In each groups, average of tumor size were 39.4±24.3mm and 25.6±19.7 in diameter. In GroupA, 1537(71.5%) tumors were located at left-side colon, meanwhile 33(57.9%) in GroupB. Tumors in Group B were smaller and tend to be located in right-side colon compared to GroupA.
CONCLUSION: The clinicopathological characteristics between GroupA and B were similar. It would be necessary to analyze prognosis of each group in order to evaluate the appropriate interval of colonoscopy.

P1526 INTERVAL CANCERS DIAGNOSED AFTER THE FIRST COLORECTAL CANCER SCREENING PROGRAMME IN THE FINISTERE DISTRICT (FRANCE) : CHARACTERISTICS AND ANALYSIS OF SURVIVAL

M. Cariou[1,*], C. Agnello[2], Y. Foll[3], O. Pennec[2], J. Jezequel[2], J.-B. Nousbaum[2], M. Robaszkiewicz[2]. [1]*Digestive Tumor Registry of Finistere,* [2]*Gastroenterology,* [3]*ADEC 29, University Hospital, Brest, France*

INTRODUCTION: Several trials have shown that screening for colorectal cancer (CRC) by fecal occult blood tests (FOBTs) can reduce CRC mortality. However, interval cancers are the major limitation of the FOBT. The objective of this study was to analyze the characteristics and the survival of the interval cancers diagnosed in the two years after a negative FOBT at the end of the first CRC screening programme organized in the Finistere area between September1st 2004 and September 1st 2006.
AIMS&METHODS: All CRC diagnosed in individuals aged 50-74 years and registered in the database of the Finistere registry of digestive cancers were cross-referenced with the database of the Cancer Prevention Coordination Centrer (ADEC 29) to analyze their screening status. CRC diagnosed in the screening population were classified into four groups according to their screening status : screen-detected by FOBT (203 CRC), screen-excluded for medical reasons (53 CRC), individuals who had declined the screening, called non-responder (478 CRC) and the interval cancers (114 CRC). In each group 3 years-overall and specific survival were estimated using the Kaplan-Meier method. The log-rank test was used for univariable comparisons of time-to-event end points. End of follow-up date due to death or censoring was 1st September 2011.
RESULTS: The participation rate of the first screening programme was 48 %. Among 102 978 persons who had performed the FOBT, 96 316 had a negative test. Among these persons, 114 interval cancers were diagnosed within 2 years. The stage distribution of interval cancers and cancers diagnosed in the non responder group were similar with 48 % of stages III and IV. The 3 years-overall cumulative survival rates in the four groups were :

		Overall cumulative survival rates (%)		
	Number	1 year	2 years	3 years
Screen detected group	203	95.6%	92.1%	89.1%
Screen-excluded group	53	94,3%	88,7%	88,7%
Non responder group	478	85.9%	75.8%	70.1%
Interval cancers	114	89.3%	79.3%	72.0%

The survival of patients with interval cancers was not statistically different from the survival in the non responder group. The overall survival at 3 years was 72 %, whereas it was 89.1 % for patients with CRC detected by FOBT ($p < 0.0001$).
CONCLUSION: FOBT improve CRC prognosis in the screen detected group. Prognosis of interval cancers is similar to prognosis of cancers detected in subjects who did not answer the screening program. The high number of interval cancers constitutes a limit which justifies the replacement of the FOBT by a more sensitive screening test as the immunological test.

P1527 THE RISK FACTORS FOR DEVELOPING METACHRONOUS NEOPLASMS DURING SURVEILLANCE AFTER INITIAL RESECTIONS OF COLORECTAL ADENOMAS AND INTRAMUCOSAL CARCINOMAS

S. Kimura[1,*], M. Tanaka[2]. [1]*Internal Medicine, Sannohe Municipal Hospital, Hachinohe,* [2]*Pathology and Laboratory Medicine, Hirosaki Municipal Hospital, Hirosaki, Japan*

INTRODUCTION: The object of the study was to investigate the risk factors for developping metachronous colorectal adenomas and carcinomas during colonoscopic follow-up after initial resections.
AIMS&METHODS: The study included 403 patients (mean age 66.2+-9.9yr, M:F= 1.55:1) with initial endoscopic resections of colorectal adenomas and/or intramucosal carcinomas with repeated follow-up colonoscopys after at least one year interval (a median follow-up period 73.9 months). They were classified into 225 patients with no recurrent lesions during surveillance (group A) and 178 with subsequent resections of recurrent lesions (group B). The patients in group B were subclassified into 109 with recurrent non-advanced lesions (group B-1) and 69 with recurrent advanced lesions (larger than 10mm in size, adenoma with high grade dysplasia or carcinoma) (group B-2). The number, maximum size, location, configulation, histology of colorectal tumors in initial resections were statistically compared with each other groups.
RESULTS: The mean number of lesions at initial resection in group A,B,B-1, and B-2 were 1.38, 1.94, 1.95, and 1.93, respectively. Many more lesions were resected in group B than group A ($p<0.001$), although no difference between group B-1 and B-2. The size of lesions in group A,B,B-1, and B-2 were 8.46mm, 9.41mm, 9.18mm, and 9.61mm, respectively. Larger lesions were resected in group B than group A ($p<0.05$), although no difference between group B-1 and B-2. The location of lesions in group A and B were 58.2%, 48.9% in left-sided, 28.9%, 23.6% in right-sided, and 12.9%, 27.5% in bilateral, respectively. Right-side shift in group B comapred to group A was observed ($p<0.005$), although no difference between group B-1 and B-2. The configulation of lesions in group A and B were 65.5%, 58.1% (sessile), 19.8%, 30.3% (pedunculated), 8.5%, 7.1% (LST), and 6.2%, 4.5% (flat), respectively. Pedunculated lesions were more frequent in group B than group A ($p<0.05$), although no difference between group B-1 and B-2. High-grade adenomas or carcinomas in the resected lesions were found 27.6%, 36.0%, 29.4%, and 43.5% in group A, B, B-1, and B-2, respectively. The statistical difference was observed between group B-1 and B-2 ($p<0.05$).
CONCLUSION: Increasing number, increasing size, right-sided location, and pedunculated shape of lesions at initial colonoscopies were the risk factors associated with recurrent lesions during surveillance. In contrast advanced pathology at initial colonoscopies were the risk factors for recurrent advanced lesions.

P1528 CZECH COLORECTAL CANCER SCREENING PROGRAM AT THE POINT OF SWITCH TO THE POPULATION BASED PROGRAM – FEASIBILITY STUDY

S. Suchanek[1,*], B. Seifert[2], O. Majek[3], L. Dusek[3], M. Zavoral[1]. [1]*Department of Gastroenterology, 1st Faculty of Medicine of Charles University and Military University Hospital,* [2]*Institute of General Medicine, 1st Faculty of Medicine of Charles University, Prague,* [3]*Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic*

INTRODUCTION: The opportunistic National Colorectal Cancer (CRC) Screening Program in the Czech Republic (3.8 million inhabitants aged over 50) was introduced in 2000. To asymptomatic individuals aged 50 – 54, the annual fecal occult blood test (FOBT) is offered, followed by FOBT+ colonoscopy, if positive. At age of 55, there is a choice of either FOBT biannually or screening colonoscopy in 10 years interval. Since the beginning of 2013 only immunochemical FOBT (FIT) is recommended. The participation of target population has reached the 25.0% level in year 2011. But according to results of preventive colonoscopies performed in years 2011 – 2012 it seems that this kind of program settings has reached its maximum.
AIMS&METHODS: Feasibility study of switch to population based program has been performed, concerning the colonoscopy capacity
RESULTS: In 2011, there have been 528,476 FOBTs performed. Because of 6.1% FOBT positivity, 32,237 patients have been indicated for colonoscopy. The nationwide network of 160 specialized endoscopic units (Centers for Screening Colonoscopy) has been set. In case of target population participation increase by 10%, 20% and 30%, in each Center 20, 40 and 60 patients will be examined annually in addition. If FIT with lower cut-off level (and therefore higher positivity) will be used, the capacity of each Center needs to be increased significantly, as described in the table. In case of combination of highest participation increase (30%) and highest FOBT positivity (13%) expected, the need of 89,313 preventive colonoscopies per year will rise. Concerning the solution of this prediction, the important fact is that only 12% of all colonoscopies were performed within the CRC screening program, 20% were therapeutical and 68% diagnostic or follow-up examinations.

FOBT positivity	Number of FOBT+ colonoscopies	Increase	Colonoscopies per one Center per year in addition
6,1%	**32 237**	**0**	
7,0%	36 993	4 756	30
8,0%	42 278	10 041	63
9,0%	47 563	15 326	96
10,0%	52 848	20 611	129
11,0%	58 132	25 895	162
12,0%	63 417	31 180	195
13,0%	68 702	36 465	228

CONCLUSION: The switch to population based CRC screening program in the Czech Republic is feasible only if adequate FIT with reasonable cut-off level will be used and all colonoscopies will be indicated rationally

P1529 CERTIFIED COLON CANCER TREATMENT CENTERS IN BRANDENBURG/GERMANY: DO THEY PROVIDE BETTER QUALITY ?

W. Pommerien[1,*], D. Nürnberg[2], C. Schneider[2]. [1]*Städtisches Klinikum Brandenburg, Brandenburg an der Havel,* [2]*Ruppiner Kliniken, Neuruppin, Germany*

INTRODUCTION: A network of certified colon cancer treatment centers (CCCTC) have arisen in Germany (to date approx. 270 centers). The establishment of such a center is associated with a considerable effort for the hospital implementing it. For the first time an analysis is underway in Brandenburg, to determine if a change in the treatment quality can be detected.
AIMS&METHODS: Between 2009 and 2011 eight colon cancer treatment centers have been certified in Brandenburg. In 2011, 39% of 1427 patients with colon cancer operations were cured in these centers.
According to the index numbers of Onkozert, relevant treatment criteria are compared for four groups of clinics (CCCTC; hospitals with >50 operated colorectal carcinomas (CRC) and 20-49, respectively; other). The groups are reviewed with respect to the homogenicity of age and UICC-stage. In the cancer registry of Brandenburg about 95% of all CRC cases are registered.
RESULTS: In all 4 hospital groups one criteria was achieved without difference: 90% R0-resection of CRC in all primary cases. The demanded neoadjuvant chemotherapy treatment in rectal carcinomas UICC II/III has been administered to 80% of patients, but occurred more often in CCCTC and with a considerable difference between the individual departments. In smaller departments the share of adjuvant therapy is larger, so that multi-modal therapies are altogether administered similarly often. The quality of the TME-rectal preparation after Mercury do not differ in the department groups, but the documentation is suboptimal.
The quota of 80% of chemotherapy in patients with colon carcinoma UICC III was not reached in all the groups (CCCTC 56%, no chemotherapy because of justified reasons 33%). The index number of patients (95%) with 12 lymph nodes examined post-operative, is only reached by the CCCTC. The departments with 20-49 operations reached 80%. The 5-year survival rate for colorectal carcinoma UICC III lies with 69,2% slightly lower than the 70% demanded by the S3-guideline.
CONCLUSION: The portion of treated patients in CCCTC in Brandenburg is above the national average. A difference in treatment quality in 2011 for CCCTC can only be detected in the number of lymph nodes examined post-operative. The quality of CRC treatment has risen state wide.

P1530 FACTORS THAT PREDICT CLINICAL OUTCOMES TO PRUCALOPRIDE IN THE MANAGEMENT OF CHRONIC CONSTIPATION

A. D. Farmer[1,*], P. Harvey[2], Q. Aziz[1]. [1]*Barts and the London School of Medicine, WINGATE INSTITUTE OF NEUROGASTROENTEROLOGY, London,* [2]*Gastroenterology, Shrewsbury & Telford NHS Trust, Shrewsbury, United Kingdom*

INTRODUCTION: Chronic constipation (CC) is a prevalent disorder with traditional management focussing on lifestyle measures and laxatives. Prucalopride (Resolor), a selective 5-HT_4 receptor agonist, has efficacy in treatment of CC (1,2). However, factors that predict clinical response are incompletely understood.
AIMS&METHODS: Our aims were to identify baseline factors, either physiological or psychological, that may predict positive clinical outcomes in patients taking prucalopride for CC. A single centre, prospective open label trial was undertaken in consecutive patients with CC, defined as less than 2 spontaneous complete bowel movements (SCBM) per week, who were commenced on prucalopride from November 2011-October 2012. Validated questionnaires were used to assess the severity of symptoms (patient assessment of constipation symptoms (PAC-SYM)), somatic symptoms (patient health questionnaire-12), anxiety/depression and the personality trait of neuroticism (big five inventory-neuroticism scale (BFI-N)). Patients were excluded if they did not wish to complete the questionnaires. Other investigations, such as colonic transit studies (CTS), were undertaken as clinically appropriate. At follow up, clinical response was defined as the proportion of patients achieving 3 or more SCBM per week.

RESULTS: 84 patients (82 female, mean age 50 years, range 18-83) had a mean SCBM per week of 1.6 (range 0.5-2). No patients were excluded. At a mean follow up of 4.8 weeks (range 4-8) 41/84 (48.8%) patients achieved clinical response. 7/84 (8.3%) did not tolerate treatment due to side effects. In an intention to treat analysis, mean SCBM per week increased from 1.6 to 3.2 (p=0.01) with mean PAC-SYM scores reducing from 27.7 to 20 (p=0.001). Logistic regression analysis demonstrated that BFI-N (odds ratio 8.7, 95% confidence interval (CI), 1.99-64, $p<0.01$) and slow transit constipation (STC) (odds ratio 1.4, 95% CI, 1.20-2.1, $p<0.01$) were independently associated with positive treatment outcomes.
CONCLUSION: Prucalopride is a useful, generally well tolerated, treatment for the management of CC in secondary care. These data suggest that efficacy could be enhanced by targeting patients with STC and in those who have higher neuroticism scores. Further work is now warranted to confirm these findings in a larger cohort of patients.

P1531 INCREASED SMALL BOWEL AND COLONIC VOLUMES WITH IMPAIRED MOTILITY IN CHRONIC CONSTIPATION (CC): SIGNIFICANT DIFFERENCES BETWEEN SLOW TRANSIT CONSTIPATION (STC) AND IBS WITH CONSTIPATION (IBS-C) SHOWN BY NOVEL MRI TECHNIQUE

C. Lam[1,*], G. Chaddock[2], K. Garsed[3], C. Hoad[2], C. Costigan[4], E. Cox[2], S. Pritchard[2], L. Marciani[1], P. Gowland[2], R. Spiller[1]. [1]*NIHR Nottingham Digestive Diseases Biomedical Research Unit,* [2]*SPMMRC, University of Nottingham, Nottingham,* [3]*Gastroenterology, Derby Hospitals Foundation Trust, Derby,* [4]*Nottingham University Hospitals Trust, Nottingham, United Kingdom*

INTRODUCTION: Many CC patients are dissatisfied with treatment reflecting our current inability to accurately target underlying mechanisms. Our aim was to exploit our new MRI techniques to noninvasively assess colonic function.
AIMS&METHODS: 29 patients (ages 18-68, F:M =27:2) with CC unresponsive to simple laxatives including 19 STC and 10 IBS-C were compared with 11 previously reported healthy volunteers (HV). Whole gut transit (WGT) was assessed from an MRI scan showing the distribution of 5 marker pills ingested 24 h before. A validated Transit Score (TS) was converted to WGT time in hours[1]. Patients then ingested 1 litre of macrogol (MCG) followed by hourly MRI scans for 4 h and scored bowel symptoms from 0-10 (none-severe). Colonic movements were assessed using a motility index based on colonic wall movement. Hypersensitivity index were scored using bloating symptom/ascending colon (AC) volume.
RESULTS: Mean (SD) See Table 1. Both STC and IBS-C had significantly greater WGT time than HV. STC but not IBS-C had greater fasting small bowel water content (SBWC) and AC volumes and reduced motility index 2 h after MCG ingestion than HV. Furthermore STC showed impaired response to MCG with longer time to first bowel movement, reduced stool frequency on study day, greater distension of the colon and reduced motility index compared with IBS-C and HV groups. The hypersensitivity score at 2 h following MCG ingestion were higher in IBS-C compared to STC and HV.
Table1:

Mean (SD)	HV	IBS-C	STC	P value(1-way ANOVA), *=p<0.05 compared to HV, **=p<0.05 compared to IBS-C
WGT (hr)	30±25	64±38*	106±42*,**	<0.0001
SBWC (ml)	83±64	131±118	196±144*	0.0213
Fasting AC (ml)	193±84	215±75	330±94*,**	0.0002
AC volume at 2 hours following MCG ingestion (ml)	357±153	364±190	618±180*,**	0.0002
Motility index at 2 hours following MCG ingestion	80±48	72±46	29±37*,**	0.0054
Time to first bowel movement(min)	117±62	114±92	674±1130*,**	0.0027
Bowel frequency on study day	9±3	6±3	3±1*,**	0.0002
Hypersensitivity index (l^{-1})	6±5	22±16*	12±7*,**	0.0018

CONCLUSION: Despite similar symptoms STC differ from IBS-C showing impaired motility reflected in increased fasting SBWC and AC volumes and after MCG challenge, greater AC distension, more discomfort, lower motility and delayed bowel response. IBS-C colonic motility is similar to HV but IBS-C report more discomfort despite similar distension suggesting hypersensitivity.

P1532 HISTOPATHOLOGIC FEATURES OF SURGICAL SPECIMENS IN PATIENTS WITH CHRONIC INTESTINAL PSEUDO-OBSTRUCTION IN JAPANESE POPULATION

H. Ohkubo[1,*], E. Yamada[1], E. Sakai[1], T. Higurashi[1], H. Endo[1], H. Takahashi[1], A. Nakajima[1]. [1]*Gastroenterology Division, Yokohama City University, Yokohama, Japan*

INTRODUCTION: Chronic intestinal pseudo-obstruction (CIPO) is an intractable disease in which clinical symptoms of intestinal obstruction appear without any mechanical cause. According to the diagnostic criteria, diagnosis is based on typical clinical manifestations, radiological evidence of distended bowel loops with air-fluid levels, and exclusion of any organic obstruction of the gut lumen. Although not mandatory, highlighting the pathologic abnormalities (i.e. myopathy, neuropathy, mesenchymopathy) is also an essential clue for diagnosis and understanding the mechanism of this intractable disease. However, no histopathological diagnostic algorithm has been established. The aim of our study is to clarify the proportion of each disease type using immunohistochemistry and propose the algorithm most effective for the classification of each subtype.
AIMS&METHODS: Thirty-two patients with a prior diagnosis of CIPO, 9 males and 23 females, mean age of 46.2 (15 to 75) years at diagnosis and 50.2 (19 to 75) years at surgery, with available full-thickness biopsy (FTB) samples were enrolled in this study. All specimens were stained with hematoxylin and eosin (HE), and a systematic immunohistochemical study, using smooth muscle α-actin (SMAA), HuC/D antibody, and CD117 (c-kit) antibody, was performed with reference to previous studies. Absence of expression on the muscularis propria was considered to be an abnormal finding in SMAA staining. Neuropathy was defined as a pathologic defect in both ganglia and ganglion cells. ICC abnormality (mesenchymopathy) was defined as a severe defect or a total absence of ICC network. The proportion of each subtype and overlap ratio are calculated.
RESULTS: Of all the 32 patients, myopathy was observed in 10 patients (31.3%), neuropathy in 17 patients (53.1%), and mesenchymopathy in 10 patients (31.3%). In 17 neuropathy patients, 4 patients also showed myopathy and 3 patients showed mesenchymopathy. No overlap was observed between myopathy and mesenchymopathy.
CONCLUSION: This is the first study to clarify the proportion of each disease subtype using systemic immunohistochemistry. Hu C/D and CD117 immunostaining unveiled undetected abnormalities on standard histology in 83% of cases. To obtain efficient differential diagnosis, Hu C/D staining should be performed at first to diagnose neuropathy. After the exclusion of neuropathy, CD117 staining should be conducted to diagnose mesenchymopathy. Because of no overlap between myopathy and mesenchymopathy, the rest are to be diagnosed as myopathy.

P1533 PERIPHERAL TRANSCUTANEOUS NEUROMODULATION IN THE TREATMENT OF IDIOPATHIC FUNCTIONAL CONSTIPATION: PRELIMINARY RESULTS OF A PILOT STUDY

I. Stundiene[1,*], P. Zeromskas[1], J. Valantinas[1]. [1]*Clinics of Gastroenterology, Nephrourology and Surgery, Vilnius University, Medical Faculty, Vilnius, Lithuania*

INTRODUCTION: Transcutaneous tibial nerve stimulation is a possible alternative to sacral nerve stimulation. It is non-invasive, cheap and well tolerated.
AIMS&METHODS: The aim of the study was to assess the efficiency of posterior tibial nerve (PTN) transcutaneous electrical nerve stimulation (TENS) in the treatment of idiopathic functional constipation.
This prospective study assessed 30 patients (26 women; mean age 57±17 years) with functional idiopathic constipation, resistant to maximal therapy, treated with TENS. TENS was done on PTN route, with self-adhesive electrodes 2 times a week for 6 weeks. One session lasted for 30 minutes. Number of the bowel movements per 2 weeks was the primary outcome. KESS (Knowles – Eccersley-Scott Symptom scoring system) constipation score, laxatives, suppositories and enemas used as well as Gastrointestinal Quality of Life Index (GIQLI) was evaluated pre- and post-treatment. Anorectal physiologic studies and colonic transit time were also performed in each patient.
RESULTS: After 6 weeks 14 patients (46.6 %) had a $\geq$ 50% increase in stool frequency and reported a significant symptomatic improvement. Overall two week stool frequency increased from 4.37 ± 2.44 pre-treatment to 7.63 ± 3.76 post-treatment ($p<0.001$) and the use of laxatives decreased ($p<0.05$). KESS constipation score improved significantly ($p<0.001$) after the treatment.
The effect was seen in 3 (33%) of 9 patients with slow transit constipation. Colonic transit had normalized in 1 patient after the treatment. Four patients (36%) of 11 with functional obstructive defecation benefited from treatment. The best results were observed in normal transit constipation group – the effect was seen in 7 out of 9 patients (77 %). Slow colonic transit together with dyssinergic defecation was seen in 1 patient and there was no effect after the treatment.
There was a statistically significant improvement in all four GIQLI subscales. The score of symptom subscale increased from 51.7 ± 6.3 pre-treatment to 56.87 ± 7.46 post-treatment ($p<0.001$), emotion subscale - from 9.13 ± 4.49 to 11.57 ± 3.87 ($p=0.001$), physical functioning – from 15.8 ± 4.77 to 17.57 ± 4.49

(p=0.006) and social functioning subscale – from 13.1 ± 2.48 to 13.4 ± 2.42 (p= 0.039).

CONCLUSION: The first results of this study are encouraging. Posterior tibial nerve transcutaneous electrical stimulation may be a new and easy-to-use therapeutic option to treat functional idiopathic constipation.

P1534 ENTEROPATHY IN PATIENTS WITH DIABETES MELLITUS TYPE 2: THE ROLE OF ENDOTHELIAL DYSFUNCTION AND LIPID PEROXYDATION

I. Skrypnyk[1,*], Y. Mandryka[1], G. Maslova[1]. [1]*Internal Medicine #1, UKRAINIAN MEDICAL STOMATOLOGICAL ACADEMY, Poltava, Ukraine*

INTRODUCTION: The problem of treatment patients with diabetes mellitus (DM) type 2 is caused by the high frequency of comorbid diseases that potentiate the polysystemic risk of complications, including the gastro-intestinal tract (GIT). The formation and progression of enteropathy on the background of the insulin-independent DM are associated with the combination of injuring factors, first of all, intestinal dysbiosis and diabetic autonomic neuropathy with the development of gastrointestinal motor-evacuation function dyscoordination. However, some pathogenetic mechanisms of DM type 2 and enteropathy combinations are studied insufficiently.

AIMS&METHODS: The aim was to determine the endothelial dysfunction role in the enteropathy development in DM type 2 patients.

Materials and methods. The study involved 74 enteropathy patients with DM type 2, including 41 (55.4%) women, 33 (44.6%) men, the mean age 56.4 ± 9.8 years and the duration of DM type 2 was 7-10 years. The DM type 2 was in subcompensation phase: the level of HbA1c ≤7.5% without ketoacidosis. To correct carbohydrate metabolism patients received combined glucose-lowering therapy. The level of nitrite, the total nitric oxide synthase (NO-synthase) activity, the malon dialdehyde (MDA) and the catalase were determined in the blood serum.

The enteropathy with the obstipation syndrome was diagnosed in 49 (66.2%) patients with DM (group I); with the diarrhea syndrome – in 25 (33.8%) (group II).

RESULTS: The imbalance of the free radicals generation and their inactivation was noticed in patients with DM type 2 in combination with enteropathy: increased concentration of the MDA in groups I and II in 1.2 and 1.4 times respectively, while reducing the catalase activity in 1.3 times ($p<0.05$). The reduction of the nitrite concentration in 1.48 times in blood serum of group II patients was detected on the background of increased in 1.6 times ($p<0.05$) total NO-synthase activity, with a tendency to change these parameters in patients of group I. The increase in the total production of NO-synthase, primarily inducible, promotes the high-power NO release, with its metabolism in an aggressive free radical – peroxynitrite, which has a direct damaging effect on the organism.

CONCLUSION: DM type 2 associated with the reduction of endothelial NO-synthase, leading to a decrease production of NO in the vascular endothelium, including the intestinal mucosa, which can be considered as a risk factor for enteropathy. The maximum lipid peroxydation processes activity and endothelial dysfunction in DM type 2 is noticed on the background of enteropathy proceeding with the diarrhea syndrome.

P1535 NALOXEGOL SYMPTOM RESPONDER RATES IN PATIENTS WITH OPIOID-INDUCED CONSTIPATION: RESULTS FROM 2 PROSPECTIVE, RANDOMIZED, CONTROLLED TRIALS

J. Tack[1,*], W. D. Chey[2], L. Webster[3], J. Lappalainen[4], P. N. Barker[4], M. Sostek[4]. [1]*University of Leuven, Leuven, Belgium,* [2]*Univ. Michigan Health System, Ann Arbor, MI,* [3]*CRI Lifetree Research, Salt Lake City, UT,* [4]*AstraZeneca, Wilmington, DE, United States*

INTRODUCTION: Opioid-induced constipation (OIC), a side effect associated with chronic use of opioid analgesics for pain management, is characterized by straining, hard stools, and incomplete evacuation of stool. The objective of this analysis was to examine the efficacy of the peripherally acting, μ-opioid receptor antagonist naloxegol (NGL) in OIC patients using multiple OIC response criteria.

AIMS&METHODS: Two phase 3 randomized, double-blind, 12-week studies (KODIAC-04 [K04, NCT01309841] and KODIAC-05 [K05, NCT01323790]) were conducted. Oral NGL (12.5 mg, 25 mg) or placebo was given once daily to outpatients with noncancer pain and OIC. OIC symptom data were further analyzed in patients who had an NGL treatment response (primary endpoint), defined as ≥3 spontaneous bowel movements [SBMs]/wk with ≥1 SBM/wk increase over baseline for ≥9 of 12 wks and ≥3 of the last 4 wks of treatment. A pre-specified analysis of NGL symptom responders was defined as those who met the above criteria plus additional symptom improvement criteria (improvement and no worsening from baseline) in ≥1 of the following: straining score by ≥0.5 point; Bristol Stool Scale score by ≥1 point; number of days with complete SBM by ≥1 day). Differences between treatment groups in each study were analyzed by the Cochran Mantel-Haenszel test stratified by response to laxatives at baseline.

RESULTS: The NGL 25-mg group showed an improvement in the primary endpoint compared to placebo in both studies (K04, $P=0.001$; K05, $P=0.021$) with improvements maintained when symptoms were incorporated into response (K04, $P=0.003$; K05, $P=0.006$, respectively). For NGL 12.5 mg compared to placebo, significance for the primary endpoint was seen in K04 ($P=0.015$) but not K05 ($P=0.202$), and response incorporating symptoms was $P>0.05$ in both studies.

Table. Naloxegol Response Rates for Weeks 1–12 in Patients With Response as per SBMs vs SBMs + Symptoms

	Number (%) of Patients Responding			
	K04		K05	
Treatment Group	Response: SBMs	Response: SBMs + Symptoms	Response: SBMs*	Response: SBMs + Symptoms*
Placebo	63 (29.4)†	54 (25.2)†	68 (29.3)	53 (22.8)
12.5 mg	87 (40.8)‡§	71 (33.3)‡	81 (34.9)	65 (28.0)
25 mg	95 (44.4)†§	83 (38.8)†§	92 (39.7)§	80 (34.5)§

*n=232; †n=214; ‡n=213; §$P<0.025$ vs placebo.

CONCLUSION: When using a stringent definition of treatment response that incorporates SBM frequency and symptom improvement criteria, NGL 25-mg response rates were higher versus placebo ($P<0.01$) in both studies.

P1536 POLYETHYLENE GLYCOL SHOULD BE USED IN PREFERENCE TO LACTULOSE IN THE TREATMENT OF CHRONIC CONSTIPATION

K. Thomas[1], J. Morgan[1], R. Nelson[1], N. Martin[2,*]. [1]*Colorectal Surgery, Northern General Hospital, Sheffield,* [2]*Scunthorpe General Hospital, Scunthorpe, United Kingdom*

INTRODUCTION: Constipation is a common clinical problem. Lactulose and Polyethylene Glycol (PEG) are both commonly used osmotic laxatives that have been shown to be effective and safe treatments for chronic constipation. However, there is no definitive data as to which provides the best treatment.

AIMS&METHODS: To identify and review all relevant data in order to determine whether Lactulose or Polyethylene Glycol is more effective at treating chronic constipation and faecal impaction.

We searched the MEDLINE, EMBASE and CINAHL databases, and the Cochrane Central Register of Controlled Trials for all randomised controlled trials (RCTs) comparing the use of lactulose and polyethylene glycol in the management of faecal impaction and chronic constipation.

Studies were included if they were randomised controlled trials which compared lactulose with polyethylene glycol in the management of chronic constipation.

Data on study methods, participants, interventions used and outcomes measured was extracted from each study. Data was entered into the Cochrane Review Manager software (RevMan 5.1) and analysed using Cochrane MetaView.

RESULTS: In the present meta-analysis, we considered for the first time all twelve randomised controlled trials so far performed.

The twelve trials enrolled a total of 1046 participants and were conducted between 1997 and 2012. The trials were conducted in seven different countries. Participant age ranged from 3 months to 70 years. Adults only were recruited for 4 studies. Six trials reported stool frequency per week.

Singularly taken, all showed that PEG resulted in a higher stool frequency per week when compared with Lactulose. Three trials reported form of stool on the Bristol Stool Scale, all reported a higher Bristol Stool Score when using PEG compared with lactulose (softer stool). Four trials reported relief of abdominal pain. Two favoured PEG in this outcome; one found Lactulose and PEG to be comparable in this outcome. Three trials reported on use of additional products, all favoured PEG as requiring less use of additional products.

CONCLUSION: The findings of our work indicate that Polyethylene glycol is better than lactulose in outcomes of stool frequency per week, form of stool, relief of abdominal pain and the need for additional products. On subgroup analysis, this is seen in both adults and children, except for relief of abdominal pain. Polyethylene Glycol should be used in preference to Lactulose in the treatment of Chronic Constipation.

P1537 HOW SAFE IS PRUCALOPRIDE FOR THE TREATMENT OF CHRONIC CONSTIPATION? A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Gatta[1,2,*], R. Kerstens[3], C. Scarpignato[2]. [1]*Gastroenterology and Digerstive Endoscopy Unit, Versilia Hospital, Lido di Camaiore,* [2]*Department of Clinical & Experimental Medicine, University of Parma, Parma, Italy,* [3]*Department of Biostatistics, Movetis-Shire NV, Turnhout, Belgium*

INTRODUCTION: Available therapies for chronic constipation (CC) have limited efficacy. Gastrointestinal prokinetics represent an attractive option, but both cisapride and tegaserod, the two agents with proved efficacy in CC, have been withdrawn because of cardiac adverse events. Prucalopride is the first selective, high-affinity 5-HT_4 agonist, without any significant activity towards other (5-HT and non 5-HT) receptors or channels (e.g. hERG) at the therapeutic doses.
AIMS&METHODS: To perform a systematic review and meta-analysis of the large clinical trials using prucalopride to treat patients affected by CC in order to assess its safety. MEDLINE, EMBASE, the Cochrane Central Register of Controlled Trials as well as abstracts from the major American, European and Asian meetings were searched up to November 2012. Large ($\geq$ 250 patients) randomized controlled trials (RCTs) in adult patients with CC, treated with prucalopride, were included. Risk of bias for RCTs was assessed as described in the Cochrane handbook. Relative risks (with 95% CI) were computed using a random effects model in order to provide a more conservative estimate. The outcomes assessed were adverse events, drop-outs due to adverse events as well as Increase of QTc > 450 ms from baseline at week 12. Results were analyzed only if, for each variable considered, data were available from at least 3 RCTs.
RESULTS: Five studies, comparing different doses of prucalopride to placebo, were identified. They included more than 2500 patients, most (up to 92.5 %) of whom were female. All studies were at low risks of bias. The results are shown in Table 1.

	Prucalopride 2 mg daily versus Placebo	Prucalopride 4 mg daily versus Placebo	Prucalopride 4 mg daily versus 2 mg daily
Adverse Events during the 12 weeks of treatment	RR: 1.21 (95% CI: 1.06 to 1.37)	RR: 1.12 (95% CI: 1.04 to 1.19)	RR: 0.98 (95% CI: 0.92 to 1.04)
Drop-Out due to Adverse Events during the 12 weeks of treatment	RR: 1.81 (95% CI: 0.82 to 4.02)	RR: 2.53 (95% CI: 1.61 to 3.96)	RR: 1.61 (95% CI: 0.84 to 3.09)
Increase of QTcF > 450 ms from baseline at week 12	RR: 0.77 (95% CI: 0.41 to 1.43)	RR: 0.59 (95% CI: 0.07 to 4.62)	RR: 0.77 (95% CI: 0.12 to 4.59)
Increase of QTcB > 450 ms from baseline at week 12	RR: 0.88 (95% CI: 0.61 to 1.27)	RR: 0.93 (95% CI: 0.40 to 2.16)	RR: 0.93 (95% CI: 0.43 to 1.99)

CONCLUSION: At the recommended therapeutic doses (2 mg daily), prucalopride is safe for treating CC. The most frequently reported adverse effects were headache and GI events, which occurred mainly on the first day(s) of treatment. Furthermore, there were no significant changes in QT_c interval even when the 4 mg dose was compared to placebo.

P1538 HOW EFFECTIVE IS PRUCALOPRIDE FOR THE TREATMENT OF CHRONIC CONSTIPATION? A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Gatta[1,2,*], R. Kerstens[3], C. Scarpignato[2]. [1]*Gastroenterology and Digerstive Endoscopy Unit, Versilia Hospital, Lido di Camaiore,* [2]*Department of Clinical and Experimental Medicine, University of Parma, Parma, Italy,* [3]*Department of Biostatistics, Movetis-Shire NV, Turnhout, Belgium*

INTRODUCTION: Chronic constipation (CC) is a challenging condition that impairs quality of life and, because of its high prevalence and chronicity, consumes significant healthcare resources. Prucalopride is the first selective, high-affinity 5-HT_4 agonist, with a predominantly enterokinetic effect, translating into a significant clinical efficacy.
AIMS&METHODS: To assess the efficacy of prucalopride to treat patients affected by CC performing a systematic review and meta-analysis. MEDLINE, EMBASE, the CCRCT as well as abstracts from the major American, European and Asian meetings were searched up to November 2012. Outcome assessed are shown in Table 1. Outcomes were measured as Relative Risk of improving with prucalopride or as Raw Mean Difference (RMD), both computed using a random effects model in order to provide a more conservative estimate. When I2 statistic was > 25%, heterogeneity between studies was considered significant.
RESULTS: Five studies, comparing different doses of prucalopride to placebo, were identified. They included more than 2500 patients, most of whom were female. The results are shown in Table below.
CONCLUSION: • Prucalopride is effective for treating CC and also improves significantly the quality of life.
• The two regimens tested (i.e. 2 mg and 4 mg daily) provide a similar clinical benefit, with no evidence of dose-response effect.

P1539 SOLITARY RECTAL ULCER SYNDROME: THE ROLE OF ANORECTAL PHYSIOLOGY TESTS IN REFRACTORY CASES

N. Özkütük[1,*], Rukiye Vardar, Nalan Gülşen Ünal, Suna Yapalı, Esin Turasan, Serhat Bor. [1]*Gastroenterology, Ege University Medical school, izmir, Turkey*

INTRODUCTION: Since physiology of the solitary rectal ulcer syndrome (SRUS) is not known properly, a complete success does not attained. However; it is argued that success may be obtained using biofeedback treatment the effectiveness of which has been proven in functional anorectal disorders. The aim of the study was to examine the correlation between clinical and demographic characteristics and anorectal physiology tests among the patients diagnosed as SRUS in a tertiary referral center.
AIMS&METHODS: 18 cases diagnosed as SRUS were included in the study through the results of colonoscopic and histopathological examinations. Demographic data regarding age, sex, medical and operational history, rectal bleeding, rectal pain and defecation frequency and type of stool (Bristol Stool Scale) were collected. Anorectal manometry, balloon expulsion and rectal sensitivity tests were performed.
RESULTS: 62% of the cases were women (11/18), mean age was 41±14 (18-70) years. 17 cases (94%) had rectal bleeding. All of the cases described one or more defecation complaints such as incomplete evacuation, excessive straining or assistance with finger as well as unsuccessful medical treatment. Seven cases had unsuccessful operation due to the SRUS diagnosis. Fourteen cases (77%) were diagnosed as functional constipation according to Rome III criteria. According to Bristol Stool Scale; it was found out that 9 of the cases (50%) had type 1 stool, 5 cases (27%) had type 3-4 stool and ineterestingly 4 cases had type 6-7 stool without any laxative medication. The anorectal manometry demonstrated that 11 cases (61%) had dyssynergia. Eleven cases (61%) presented prolonged balloon expulsion time. Rectal sensitivity decreased in 4 (22%), increased in 4 (22%) and was normal in 10 of the cases (56%). Anal canal resting pressure was low in 3 cases (16%) while the rest was normal. There was no difference among those cases in whom dyssynergic defecation compared to normal defecation patterns in terms of gender (p=0.08) whereas it was seen that cases with dyssynergic defecation were older (46±9 vs 32±15) (0.04).
CONCLUSION: It was proved that anorectal coordination disorder was accompanied by mostly SRUS diagnosed with clinical and anorectal physiology tests. It was suggested that anorectal physiology worsened as disease-age increased due to the fact that cases with dyssynergic defecation were older than those cases with normal defecation patterns. Performing anorectal physiology tests at the time of diagnosis for SRUS may help uncover underlying anorectal coordination disorder and may correct pathology of the disease using biofeedback method.

P1540 PATIENT PERSPECTIVE ON CONSTIPATION'S CHARACTERISTICS, IMPACT ON QUALITY OF LIFE AND FACTORS AFFECTING TREATMENT CHOICE. AN INTERNATIONAL INTERNET SURVEY

P. Jouet[1,*], M. Bellini[2], M. Halphen[3], J. M. Sabate[1]. [1]*Hepato-gastroenterology, CHU Louis Mourier, Colombes, France,* [2]*Gastroenterology, University of Pisa, Pisa, Italy,* [3]*Development, Norgine, Harefield, United Kingdom*

INTRODUCTION: Constipation is a common gastrointestinal disorder which is often chronic and associated with an impaired quality of life (QoL). Laxatives are a treatment of choice after failure of lifestyle and dietary changes. However different laxatives can be used and factors affecting the choice of laxative are poorly studied.
AIMS&METHODS: The objective of this survey was to assess the characteristics of the patients' constipation, impact on QoL and factors associated with laxative choice.
In December 2011, a market research survey was conducted by Norgine Ltd in 9 European countries, Australia and South Africa. Participants >18 years who had been using laxatives (medicinal or natural product) in the last year answered 30 questions, describing the characteristics of the constipation, impact on quality of life and factors affecting choice of laxatives.
RESULTS: 766 respondents were surveyed (women 73%, 52% in the 25–44 years age group). Constipation duration was >6 months (e.g. chronic) in 78% and >5 years in 41%. It was judged severe (with faecal impaction) in 18% and moderate but persistent in 34%. An impact on QoL was reported in 98% (large or very large in 36%), on physical wellbeing (80%), diet (55%), appetite (41%), sleep (35%), concentration at work (32%) and social life (31%). Respondents were most commonly ''irritated'' by their constipation (51%), followed by ''embarrassed'' (41%), ''stressed'' and ''concerned'' both in 38%. Overall, the most commonly used laxatives were herbal/natural product 44% followed by Macrogols 42% (PEG+electrolytes (PEG+E-Movicol®) 24%, others 18%), stimulant laxatives 37%, fibers 34%, lactulose 25% and others 11%.
One third of respondents had been taking their current laxative for more than one year. In respondents taking PEG+E, two thirds only took it when they had symptoms, and 60% took one sachet or less per day. Reasons for switching were most commonly because a perceived lack or loss of efficacy 47%, followed by doctors recommendation in 34% and side effects in 23%.
The most important qualities sought in a laxative were that it works well (39%) and quickly (27%), with limited side-effects (32%).
CONCLUSION: The results of this international survey show that the severity of constipation impacts patients' QoL. Herbal/natural products and Macrogols were the most used treatments. The determinants in laxative choice were efficacy, propensity for side effects and medical recommendation.

P1541 HOME ELECTRIC STIMULATION IS BETTER THAN STANDARDIZED BIOFEEDBACK TRAINING FOR WOMEN WITH FECAL INCONTINENCE

R. Gingold-Belfer[1], N. Cohen-Zubary[2], I. Lambort[1], N. Wasserberg[3], S. Aizic[1], S. Levy[4], Y. Niv[1], R. Dickman[1,*]. [1]*Gastroenterology,* [2]*Physiotherapy Service,* [3]*Surgery, Rabin Medical Center, Petach Tikva,* [4]*The Academic College of Tel-Aviv, Rabin Medical Center, Tel-Aviv, Israel*

INTRODUCTION: Home electric stimulation (HES) and standardized biofeedback training (SBT) are effective treatments for fecal incontinence (FI). Studies that randomized incontinent women to treatment by these 2 methods only are missing.
AIMS&METHODS: To compare effectiveness of HES and SBT in women suffering from FI.
Consecutive women suffering from FI were randomized to HES or SBT only for a period of 6 weeks. Patients were evaluated by a questionnaire regarding their demographics, medical and childbearing history. Subjective measures of outcome included the Fecal Incontinence Grading Scale (FIGS), quality of life questionnaire (SF-36) and a diary for the assessment of bowel movements before and after treatment. Objective measure of outcome included the pelvic floor muscle (PEM) contraction assessed by surface electromyography (EMG).
RESULTS: A total of 36 women with FI were randomized to HES or SBT (18 in each treatment group). Groups were matched by mean age: 65.5±13.5 years, mean BMI (kg/m^2): 26.2±3.9, mean disease duration: 1.42±0.8 yrs, mean number of births: 2.7±1.3 and reports of obstetric trauma (25%). Only patients that received HES reported a significant improvement of FIGS (p=0.0015) and a significant drop in the number of leaked solid and liquid stool (p=0.012, p= 0.07, respectively). SF-36 scores were not affected significantly by treatment in both groups. A significant improvement of PEM contraction was achieved in 89 % of patients from both groups.
CONCLUSION: Home electric stimulation only was found to be more efficient than standardized biofeedback training only if assessed by both subjective and objective measures.

P1542 EFFICACY AND SAFETY OF PRUCALOPRIDE IN THE TREATMENT OF CHRONIC CONSTIPATION: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

R. P. Alquiroz[1,*], I. H. Cua[2]. [1]*institute of digestive and liver diseases, st lukes medical center, quezon city,* [2]*Institute of Digestive and Liver Diseases, St. Luke's Medical Center, Quezon, Philippines*

INTRODUCTION: Chronic constipation is a very common functional gastrointestinal disorder which can be associated with significant impairments in quality of life for some people with the condition. Its management has, traditionally, been based on dietary and lifestyle changes and the use of a variety of laxative agents. Prucalopride, appears to be highly selective for the serotonin 5-HT4 receptor and is, therefore, a potent stimulator of gut motility.
AIMS&METHODS: The main objective of this meta-analysis is to test the clinical efficacy and safety of the selective and high affinity serotonin-4 (5-HT4) receptor agonist prucalopride in the management of chronic constipation. Articles were identified through MEDLINE, EMBASE, the Cochrane Central Register of Controlled Trials and internet electronic databases. We searched abstracts, lists of review articles and retrieved studies by manual and internet search strategies. Two reviewers independently assessed trial quality and extracted data. Analyses were performed using the Mantel-Haenszel test. Random effects models were used when heterogeneity was noted.
RESULTS: A total of six (6) studies with total sample size of 3616 patients were included. The outcome in the improvement of mean number of stools per week showed that there was no significant difference between the prucalopride and placebo group (OR 0.78; 95%CI 0.96 to 2.53, *p* 0.38). However the overall effect leans toward the study treatment (prucalopride). The test for heterogeneity was not significant. The numbers of adverse events were more common with prucalopride than with placebo (RR 1.22; 95% CI 1.14 to 1.32, p <0.00001).
CONCLUSION: Prucalopride has no significant effect compared to placebo for the treatment of chronic idiopathic constipation. The drug appeared safe, but adverse events were significantly common, particularly headache, nausea and diarrhea, and patients should be warned of these potential side effects of treatment.

P1543 PERINEAL RETRAINING FOR FECAL INCONTINENCE: INCREASING THE NUMBER OF SESSIONS RAISES THE CHANCE TO SUCCESS

S. Marjoux[1,*], H. Damon[1], L. Siproudhis[2], J.-L. Faucheron[3], T. Piche[4], L. Abramowitz[5], M. Eleouet[2], I. Etienney[6], P. Godeberge[7], G. Valancogne[8], A. Denis[9], F. Mion[1], A.-M. Schott[9], On behalf of the Oralia Trial Group, ..
[1]*Digestive diseases, Hopital Edouard Herriot, Lyon,* [2]*Digestive diseases, CHU Rennes, Rennes,* [3]*Digestive surgery, CHU Grenoble, Grenoble,* [4]*Digestive diseases, Hopital l'Archet 2, Nice,* [5]*Digestive diseases, Hopital Bichat,* [6]*Proctology, Groupe hospitalier Diaconesses Croix Saint-Simon,* [7]*Digestive diseases, Institut Mutualiste Montsouris, Paris,* [8]*Physiotherapy, Centre de rééducation Tête d'Or,* [9]*Epidemiology, CHU Lyon, Lyon, France*

INTRODUCTION: Fecal incontinence (FI) is a frequent complaint that deeply affects quality of life (QoL). Perineal retraining (PR) may improve conservative treatment for FI. The best modalities of PR have to be determined to raise the chance to success in FI.
AIMS&METHODS: Our aims were to determine the number of PR sessions useful to improve FI and to identify clinical factors which could predict chance to achievement. We interested to patients who benefited from PR in a randomized assessor blinded clinical trial (the ORALIA trial) in 8 centers. In this study, patients were randomly assigned to standard conservative treatment (SC group) or to PR including biofeedback in addition to medical treatment. Patients in failure in the SC group benefited from PR in 2nd line. PR was performed in an outpatients setting according to optimized and standardized procedures based on 20 sessions of 30 mn within a 4-month period with 2 to 3 sessions per week for the 1st month and 1 to 2 per week thereafter. The physiotherapist tested anal squeeze by muscular testing at each session. Statistical analyses were performed in Statistical Analysis System software 9.2 (SAS Institute, NC).
RESULTS: 104 patients benefited from PR, as 1st line for 67 and 2nd line for 37. Data about all the 20 sessions were available for 62 patients (59%). Anal squeeze quality, cough reflex squeeze and capacity to differ stool evacuation were improved after 10 sessions and between 10 and 20 sessions ($p<0.001$) (Table).

	1st session	10th session	20th session
Squeeze quality: (n,%)			
Nothing	5 (8%)	0 (0%)	0 (0%)
Incomplete squeeze	42 (68%)	17 (28%)	10 (17%)
Complete squeeze	15 (24%)	45 (72%)	52 (83%)
Cough reflex squeeze (n,%)	19 (31%)	39 (63%)	52 (84%)
Capacity to differ stool evacuation (mn)	5.7±11.6	8.3±13.1	13.8±17.3

The following clinical factors were analyzed: age, sex, 1st or 2nd line PR, history of anorectal surgery, anal squeeze time and strength, FI incidents, Wexner score, QoL. Multivariate analysis failed to determine a clinical factor that could predict the chance to achieve FI improvement with PR.
CONCLUSION: There is a significant improvement between 1st and 10th and between 10th and 20th session of PR in FI. PR should not be stopped after 10 sessions even if there is no initial improvement. This study did not allow identifying predictive factors of success of PR in FI. Consequently, PR should be tried in any case of FI.

P1544 CLINICAL AND PATIENT RELATED RISK FACTORS ASSOCIATED WITH A PERSISTENT DISEASE COURSE IN NEW CHRONIC CONSTIPATION PATIENTS

V. K. Dik[1,*], P. Siersema[1], H. Smeets[2], M. Van Oijen[1,3]. [1]*Gastroenterology & Hepatology,* [2]*Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, Netherlands,* [3]*Division of Digestive Diseases, David Geffen School of Medicine at UCLA, Los Angeles, United States*

INTRODUCTION: Up to 90% of patients with constipation report symptoms on a long-term basis. However, the natural history may differ between patients and can be divided in a non-persistent and persistent disease course. Information on factors associated with the natural history of chronic constipation (CC) are scarce.
AIMS&METHODS: We aim to identify demographic and clinical factors associated with a persistent disease course in new CC patients. New CC patients were retrospectively identified and followed up in a Dutch health insurance database (~1.2 million subjects) between January 2005 and December 2010. Subjects with laxative prescriptions for a cumulative ≥90 days within a period of one year and/or with a Diagnosis Related Group (DRG) of chronic constipation were identified. Only subjects who met these criteria, with absence of CC in the preceding year, were regarded as *new* CC patients. Patients with colorectal cancer, irritable bowel syndrome or with less than one year of follow-up after CC diagnosis were excluded. A persistent disease course was defined as constant laxative use (without pauses of >90 days) until the end of follow-up. Others were defined as having non-persistent disease. Data on demographics, reimbursed prescriptions and DRGs were used to identify potential risk factors. Adjusted hazard ratios (HR) and 95% > confidence intervals (95% > CI) were estimated for potential risk factors using Cox proportional hazard models.
RESULTS: A total of 18,416 new CC patients were identified (mean age 64.0 ± 17.9, 64% female) of which 15% had persistent disease. Independent factors associated with an increased risk for persistent disease were older age (HR 2.10, 95% > CI 1.87-2.35 for >70 vs. <50 years), male gender (HR 1.29, 95% > CI 1.20-1.40) and the use of opioids (HR 1.51, 95% > CI 1.40-1.64) and psycholeptics (HR 1.17, 95% > CI 1.08-1.26). The use of calcium antagonists was associated with a decreased risk of persistent disease (HR 0.91, 95% > CI 0.84-0.99). Urbanization level, a non-Dutch nationality, the use of beta-blocking agents and antidepressants, and a diagnosis of hypothyroidism, Parkinson disease or multiple sclerosis were not associated with disease course, although non-Dutch older patients tended to have an increased risk for persistent disease (HR 1.20, 95% > CI 0.99-1.47).
CONCLUSION: Only a minority of new CC patients develops a persistent disease course, but, if present, it is associated with older age, male gender, and use of opioids and psycholeptic medication. Results of this study may help identifying CC patients who are at an increased risk of developing persistent disease.

P1545 A COMPARATIVE STUDY OF THREE-DIMENSION HIGH-RESOLUTION SYSTEM AND WATER-PERFUSION SYSTEM IN ANORECTAL MANOMETRY

Z.-H. Yuan[1], Z.-J. Xu[1], K. Wang[1,*], Z.-W. Xia[1], Y. Ge[1], L.-P. Duan[1].
[1]*Department of Gastroenterology, Peking University Third Hospital, Beijing, China*

INTRODUCTION: The detailed differences of comprehensive motility parameters of anorectal function between the three-dimension high-resolution manometry (3D-HRM) and water-perfusion mamometry (WPM) were not clear.
AIMS&METHODS: To compare the characteristics between three-dimension high-resolution manometry (3D-HRM) and water-perfusion mamometry (WPM) in anorectal function evaluation.
63 subjects were enrolled in the study (46 chronic constipation patients and 17 healthy volunteers). All of them underwent anorectal manometry (ARM) by both 3D-HRM and WPM. WPM was performed using 8-channel water-perfusion catheter with side holes spaced at 1-cm interval and diameter of 4.7mm. 3D-HRM was performed using 256 (16*16)-channel solid-state catheter with diameter of 10mm, displaying in topographic and three-dimension form using analysis software. Measurements of anal sphincter pressure at rest, during voluntary contraction, during forced defecation, and rectal sensory thresholds were compared.
RESULTS: Anal sphincter and rectal pressures recorded by 3D-HRM tended to be higher (anal resting pressure: 94.8±26.3 vs 63.9±21.4mmHg, P=0.000; anal squeezing pressure: 218.3± 61.1 vs 174.5± 50.9mmHg, P=0.000; defecation anal pressure: 76.4±31.4 vs 44.5±20.1mmHg, P=0.000; defecation rectal pressure: 43.7±20.8 vs 35.1±20.4mmHg, P=0.033) and urge defecation thresholds tended to be lower (128.6±52.4 vs 157.7±73.5ml, P=0.017) than those recorded with WPM. The two methods showed to be significantly correlated in the aspects of anal resting pressure (r=0.575, P=0.000), anal squeezing pressure (r=0.610, P=0.000), defecation anal pressure (r=0.568, P=0.000), anal relax ratio (r=0.573, P=0.000), first defecation threshold (r=0.621, P=0.000), urge defecation threshold (r=0.595, P=0.000) and maximal tolerated threshold (r=0.663, P=0.000). Also, there were weak correlations in the length of high pressure zone (r=0.390, P=0.002) and defecation rectal pressure (r=0.419, P=0.002). However, there was no correlation in minimum relaxation volume (MRV) for rectal anal inhibitory reflex (RAIR) (r=0.156, P=0.255) between the two methods. 3D-HRM could find paradoxical puborectalis contraction during defecation, but WPM could not provide the message.
CONCLUSION: In addition to MRV, all pressure and sensory parameters were consistent between 3D-HRM and WPM, but 3D-HRM provided more detail information of anorectal anatomy.

P1546 SHORT- AND LONG-TERM EFFICACY OF TREATMENT WITH TEMPERATURE-CONTROLLED RADIOFREQUENCY ENERGY (SECCA) IN PATIENTS WITH FAECAL INCONTINENCE

A. Visscher[1,*], T. Lam[1], M. Meurs-Szojda[1], C. Mulder[1], R. Felt-Bersma[1].
[1]*Gastroenterology, VUmc, Amsterdam, Netherlands*

INTRODUCTION: Controlled delivery of radio frequent energy (Secca) has been suggested as treatment for faecal incontinence (FI). The supposed mechanism of action of Secca is shrinkage and remodelling of the mechanical properties of the anorectum.

AIMS&METHODS: To evaluate the short- and long-term efficacy of Secca treatment for faecal incontinence (FI). Between 2005 and 2010, 31 patients who failed conservative management for FI received Secca at our outpatient clinic. FI was scored using the Vaizey score (VS). Follow up was performed after 6 months, 1 yr, 3 yrs, 5 yrs and 7 yrs. Anal sonography and anal manometry was performed at 3 months and compared with baseline. Using decreases in VS compared to baseline, patients were assessed as having a good clinical response (≥ 50% reduction in VS), a moderate clinical response (≥ 20- < 50% reduction) or no clinical response (< 20%). Initial response to Secca was measured at 6 months as having good or mild clinical response. Regarding long-term results, 7 respectively 10 patients were not yet available for 5 and 7 yr follow up. Impact of FI on experienced QOL was measured using the FIQL.
RESULTS: All 31 patients, (mean age 61 yrs, 30 females) received Secca. Mean length of FI was 10 yrs. Twenty-one patients (68%) had an anal sphincter defect. From baseline to 7 years follow up, mean VS was 18 (SD 3) at baseline, 14 (SD 4) at 6 months, 14 (SD 4) at 1 year, 14 (SD 4) at 3 years, 13 (SD 6) at 5 years, (for all $P < 0.001$) and 14 (SD 6) at 7 years, ($P=0.02$). During follow-up, 17/31 (55%), 13/31 (42%), 10/31 (32%), 6/23 (26%) and 4/13 (31%) of patients still experienced a good or a moderate clinical response. An achieved good or moderate clinical response was maintained up to 5 years, ($P < 0.001$), but lost statistical significance at 7 years of follow up, ($P=0.06$). No increases in anorectal pressure were found in any patients. FIQL scores coping and embarrassment temporarily improved (up to 6 months) in those with an initial response to Secca. No predictive factors for achieving success could be demonstrated.
CONCLUSION: Secca is a safe, minimally invasive procedure for FI. A good and moderate clinical response was achieved in 55% of patients after 6 months which decreased to 30% after 3 years and remained stable up to 7 years. No increased anal pressures or anorectal function alteration became apparent.

P1547 ANAL INCONTINENCE, SEXUAL COMPLAINTS AND ANORECTAL FUNCTION IN PATIENTS WITH A THIRD DEGREE ANAL SPHINCTER RUPTURE: LONG TERM FOLLOW-UP

A. Visscher[1,*], T. Lam[1], N. Hart[1], C. Mulder[1], R. Felt-Bersma[1].
[1]*Gastroenterology, VUmc, Amsterdam, Netherlands*

INTRODUCTION: Anal incontinence (AI) affects activities of daily life and can have a devastating effect on the physical and emotional wellbeing. The primary cause of AI in women is vaginal delivery. With this study we aim to evaluate the long-term alteration of anorectal function in women after primary surgical repair of a third degree obstetrical anal sphincter injury (OASI) in relation to clinical outcome.
AIMS&METHODS: Women who suffered a third degree OASI between 1998 and 2008 in our hospital and underwent anorectal function evaluation (AFE) consisting of anal manometry and anal endosonography three months post-partum were included. These women were invited to participate in the present study by sending them standardized questionnaires regarding complaints of AI (Vaizey/Wexner), urine incontinence (UI) (ICIQ), sexual function (FSFI) and quality of life (QOL) (Rand-36) and were asked to undergo additional AFE.
RESULTS: Sixty-six women underwent AFE three months post-partum. With a mean OASI follow-up of 5.0 years (2.4-11.4), 40 women (61%) with a mean age of 38 years (SD 4.7), participated for follow up regarding complaints of AI and UI. Prevalence of AI was 63% (flatus), 50% (liquid stool) and 20% (solid stool). UI was present in 48% of women. Of these 40 women, 32 (80%) also returned questionnaires regarding QOL and sexual function. Overall sexual function was lower (total FSFI of 23) than the sexual dysfunction cut-off value of 26.55, ($P < 0.05$). Compared to control values, all FSFI subscales were lowest in women with larger OASI, ($P < 0.001$). Sixteen women (20%) underwent additional AFE. Women with combined internal anal sphincter (IAS) and external anal sphincter (EAS) injury ($n = 6$) reported more pronounced anal incontinence and had lower anal pressures than women with isolated EAS injury ($n = 10$), ($P < 0.05$). Mean maximal basal pressure (MBP) was 40 (SD 13) respectively 53 (SD 12) mmHg, and mean maximal squeeze pressure (MSP) was 25 (SD 11) respectively 39 (SD 13) mmHg, ($P=0.04$ for both MBP and MSP).
CONCLUSION: Women with a combined IAS and EAS defect had the most severe complaints and the lowest anal pressures. Special attention should be paid to women with these large combined anal sphincter defects, since anorectal function will deteriorate more and AI and sexual dysfunction are more prominent later in life.

P1548 CAN WE USE A SHORTER TEST PERIOD BEFORE DEFINITIVE SACRAL NEUROSTIMULATION FOR FECAL INCONTINENCE?

I. ETIENNEY[1], H. EL GHARBI[1], C. THOMAS[1,*], F. HASSAINE[1], P. ATIENZA[1]. [1]*proctologie medico interventionnelle, GH Diaconesses Croix Saint Simon, paris, France*

INTRODUCTION: Sacral neuromodulation may be proposed for fecal incontinence after failure of medical treatment and biofeedback. A 3-week test period is usually proposed. The length of the test period is a compromise between the variability of soiling frequency and the risk of material-related infection
AIMS&METHODS: The purpose of this study was to present a week-by-week analysis of response during the screening period in order to determine whether early response is predictive of the final implantation decision
PATIENTS AND DESIGN: From May 2010 through July 2012, 12 patients completed an exploitable bowel-movement-soiling diary before and during the test period.
RESULTS: After one week, 50% of patients (6/12) had a 50% reduction in soiling frequency. This percentage reached 66.7% (8/12) at two weeks and 83.3% (10/12) at three weeks. Among those patients whose soiling frequency fell off rapidly, the decline was considerable (89% reduction) and remained so for the next two weeks (92% and 97% reduction). The decline was also considerable (83%) when the response took longer (2 or 3 weeks). Retention time for urgency episodes increased 5.4 [0:22.5] minutes the first week, 3.1 [-9:+9.5] the second week, and 16.3 [4.1:36] minutes the third week. Urgency frequency fell off by 1.4 [-5.3:+4.3] episodes per week the first week (22.2% reduction), 1 [-6.3:+6.7] the second week (26.4% reduction) and by 3.3 [-9.3:+1] the third week (59.6% reduction). There were no problems with infection
CONCLUSION: Rapid improvement in soiling frequency during the first screening week was sustained the next two weeks so that early implantation could be proposed in half of the patients without waiting for the end of the 3-week screening period.

P1549 SCREENING THE ANAL DYSPLASIA IN HIV-POSITIVE PATIENTS: HOW EFFICIENT IS HIGH-RESOLUTION ANOSCOPY?

D. Cuen[1,*], I. Berkelmans[1], A. Lion[1], T. Wallenhorst[1], K. Marcel[1], B. Tchoundjeu[1], L. Siproudhis[1]. [1]*Pontchaillou University Hospital, Rennes, France*

INTRODUCTION: Human immunodeficiency (HIV) and Papillomavirus (HPV) virus are major co factors of developing anal dysplasia. Annually anal screening is recommended in HIV positive subjects because of a high-risk of anal dysplasia. The high-resolution anoscopy (HRA) has been shown to improve the exploration of the anal mucosa by magnifying the macroscopic changes. It is recommended to patients presenting anal dysplasia on cytology (low or high grade squamous intra-epithelial lesion: LSIL or HSIL, and atypical squamous cell of undetermined significance: ASCUS). Its interest remains under debate in the anal screening of dysplasia. The aim of this study was to evaluate the HRA performances in HIV-positive patients with abnormal cytology, using biopsies on both identified lesions and normal mucosal appearance as a gold standard.
AIMS&METHODS: Between October 2010 and April 2013, 70 HIV-positive patients (M/F: 66/4, aged 47.6 ± 10.1years) with anal dysplasia on cytology underwent 107 HRA. The tinctorial and macroscopic aspects of the anal canal were used to characterize the abnormal areas: acetowhite, iodonegative, mucosal punctuations, warty raised, mosaic pattern, vascular abnormalities and miscellaneous. Biopsies were systematically made on both abnormal and normal areas.
RESULTS: Macroscopic lesions were associated to ASCUS in 14.4%, LSIL in 56.7% and HSIL in 28.4%. Histological anal intra-epithelial neoplasm (AIN) was more frequently observed in association to mucosal punctuations (48.1%), warty raised (55%) and mosaic pattern (50%). No statistical significance was observed in association with vascular abnormalities. Macroscopic lesions were associated to AIN in 34/55 (61.8%) and to high-grade AIN (AIN 2-3) in 21/55 (38.2%). Acetowhite & iodonegative areas were statistically associated to AIN in 20/46 (43.5%) & 18/46 (39.1%) respectively: both abnormalities were reported I, 11/46 (24%) of AIN 2-3. AIN lesions were observed in 6/42 (15%) of patients with normal tinctorial aspects, in 17/38 (44.7%) of those without macroscopic lesion and in 35/107 (32.7%) of normal areas (AIN 2-3 in 18/107 (16.8%)). As compared to histology, sensitivity and specificity of HAR were 34/51 (66.7%) & 10/27 (37%) to detect AIN and 21/51 (41.2%) & 17/27 (63%) to detect AIN 2-3 respectively.
CONCLUSION: A normal HRA doesn't rule out the presence of AIN. Both abnormal and normal areas have to be biopsied. This technique may be preferred to detect and to treat macroscopic changes rather than to screen dysplasia.

P1550 PROGRESS OR REGRESS? NATURAL HISTORY OF ANAL DYSPLASIA IN HIV-INFECTED PATIENTS.

D. Cuen[1,*], I. Berkelmans[1], A. Lion[1], T. Wallenhorst[1], K. Marcel[1], B. Tchoundjeu[1], L. Siproudhis[1]. [1]*Pontchaillou University Hospital, Rennes, France*

INTRODUCTION: Anal screening is justified by the high incidence of anal dysplasia and carcinoma in Human Immunodeficiency Virus (HIV) infected patients. High-grade anal intra-epithelial neoplasm (AIN) may progress to invasive cancer within a short period of time. The aim of our study was to assess the temporal change of dysplasia and to identify factors associated to a pejorative evolution.
AIMS&METHODS: Between October 2010 and April 2013, 176 HIV-positive patients (M/F: 165/11; aged 47.4 ± 10.6 years) were screened, using anal cytology. In case of abnormal findings (low or high grade squamous intra-epithelial lesion: LSIL or HSIL, and atypical squamous cell of undetermined significance: ASCUS), biopsies were performed to identified low or high-grade AIN (AIN 1 or AIN 2-3). Follow-up program was a 12-month interval in those with a normal cytology, a 3-to-6 month interval in case of abnormal histology (AIN 1 and AIN 2-3 respectively). The mean duration of follow-up was 41.2 ± 40.9 months.
RESULTS: Anal cytology at inclusion was normal cytology in 75 (43%), ASCUS in 30 (17%), LSIL in 52 (30%) & HSIL in 17 (9.6%). At the end of

follow-up, new HSIL or AIN 2-3 was reported in 35/159 (22%) patients: invasive cancer was encountered in 1/159 (0.6%). In contrast, 40/101 (39.6%) down-staged their initial anal status. Median period to reach high-grade dysplasia was 39.1 weeks (23.5-52.6, CI 95%) and period to regress was similar (33.9 weeks - 14.1-52.8, CI 95%). A previous Human Papillomavirus (HPV) infection ($p=0.02$), previous anal HSIL ($p<0.01$), endo-anal condylomas at inclusion ($p<0.01$), high-risk HPV infection ($p<0.0003$) and HPV 16 infection ($p<0.0001$) were associated to progression to high-grade dysplasia.
CONCLUSION: Almost one-third of HIV-positive patients develop high-grade dysplasia of the anal canal but dysplasia may also regress in a similar proportion. These features of natural history have to be taken into account in intervention studies.

P1551 NOVEL MEASURES OF ANAL FUNCTION USING HIGH-RESOLUTION ANAL MANOMETRY (HRAM) OUTPERFORM CONVENTIONAL MANOMETRIC MEASURES IN FEMALE PATIENTS WITH FAECAL INCONTINENCE (FI)

E. V. Carrington[1,2,*], E. Tangenberg[3], A. Meek[3], C. Knowles[2], S. M. Scott[1]. [1]*The Wingate Institute,* [2]*National Centre for Bowel Research and Surgical Innovation (NCRBSI), Queen Mary University of London, London, United Kingdom,* [3]*Medical Measurement Systems (MMS) B. V., Enschede, Netherlands*

INTRODUCTION: Anal manometry is the most widely used investigation of function in patients with FI, however its impact on clinical management remains uncertain and evidence correlating findings with symptom severity are limited. The development of HRAM has enabled new analyses of manometric recordings with potential to provide better biomarkers of disease for treatment stratification and monitoring.
AIMS&METHODS: To develop and assess the utility of new derived measures of global anal sphincter function using HRAM, and to compare findings with conventional anorectal manometry (ARM) in female healthy volunteers (HV) and females with FI.
82 HV (median age 45 [18-68]) and 71 consecutive patients with FI (age 55 [22-81]; St Mark's FI score >5), underwent HRAM using a 12 channel solid-state catheter, and ARM at the same appointment. Data were collected using customized software (v9.1: MMS BV). New measures of resting tone, squeeze pressure and 30 sec endurance squeeze area (ESA.30 = an area under the curve calculation of pressure changes across the whole anal canal during prolonged squeeze) were determined using HRAM. Results from both techniques were correlated with St Mark's score using regression analysis. Data from HVs were used to derive normal ranges for new measures and their utility tested in patients with FI.
RESULTS: Normal ranges (5^{th}-95^{th} percentile) for anal resting pressure, maximum squeeze increment and ESA.30 using HRAM were 34-101 mmHg, 45-315 mmHg and 515-4795 mmHg.sec, respectively. New HRAM derived measures of squeeze pressure outperformed those of conventional ARM (Table 1A), with ESA.30 ($R^2=0.34$; $P<0.0001$) the best overall. Novel HRAM indices were better discriminators of abnormal sphincter function compared to conventional measures (Table 1B) with ESA.30 the best measure: LROC AUC = 0.87 (very good). Based on normal ranges, yields of positive test results in FI were much higher for HRAM than conventional ARM (conventional squeeze = 23% vs. HRAM ESA.30 = 55%).

1A - St Mark's FI score (all subjects)	R^2	*coeff (95% CI)*	*P*	
Conventional ARM max squeeze incr.	0.1	-2.2 (-3.5-0.83)	0.002	
HRAM max average anal squeeze incr.	0.31	-7.7 (-9.7- -5.7)	**0.0001**	
HRAM ESA.30	0.34	-111 (-137 - -85)	**0.0001**	
1B. FI vs. HV	R^2	*OR (95% CI)*	*P*	*LROC AUC*
Conventional ARM max squeeze incr.	0.07	0.98 (0.97-1.0)	0.023	0.68
HRAM max average anal squeeze incr.	0.29	0.98 (0.97-0.99)	**0.0001**	**0.84**
HRAM ESA.30 (mmHg)	0.32	0.998 (0.997-0.999)	**0.0001**	**0.87**

CONCLUSION: Derived measures of anal sphincter function using HRAM outperform conventional ARM measures and may provide better disease biomarkers.

P1552 12 MONTH OUTCOME AND PATIENT SATISFACTION WITH STRUCTURED GASTROENTEROLOGICAL EVALUATION FOR CHRONIC GASTROINTESTINAL SYMPTOMS FOLLOWING PELVIC RADIOTHERAPY

C. C. Henson[1], J. McLaughlin[2,*], Y. Ang[2], C. Babbs[3], J. Crampton[4], M. Kelly[4], S. Lal[3], J. K. Limdi[5], G. Whatley[6], R. Swindell[7], W. Makin[7], S. E. Davidson[7]. [1]*Radiotherapy Related Research, Christie Hospital,* [2]*University of Manchester, Manchester,* [3]*Salford Royal Foundation Trust, Salford,* [4]*Wythenshawe Hospital, Manchester,* [5]*Fairfield Hospital, Bury,* [6]*Tameside Hospital, Ashton-under-Lyne,* [7]*Christie Hospital, Manchester, United Kingdom*

INTRODUCTION: 17000 patients are treated with pelvic radiotherapy annually in the UK.50% develop chronic GI symptoms.The structured approach to management used in this service evaluation has been shown to identify treatable diagnoses and improve symptoms in the short term. We report the first 12 month outcome data for the effect of structured GI evaluation on symptom burden and patient satisfaction.
AIMS&METHODS: 56 patients with GI symptoms$\geq$6 months after radical pelvic radiotherapy underwent structured GI assessment as part of a service evaluation. They were assessed using the following questionnaires:inflammatory bowel disease questionnaire(IBDQ);Vaizey incontinence questionnaire (VIQ); and the CTCAE pelvic symptom questionnaire.12 month assessments were compared to the previously reported baseline and 6 month assessments to determine if the improvement in symptoms was sustained. Patient satisfaction with the service was assessed at 12 months by an in-house questionnaire.
RESULTS: 40 patients(71%)completed the 12 month assessment and 37(66%)completed the patient satisfaction questionnaire. The initial statistically significant improvement in GI symptoms from baseline to 6 months in parallel to GI evaluation was sustained up to 12 months in all questionnaires(IBDQ $p=0.019$,IBDQB and CTCAE rectum bowel subset $p<0.0005$)except the VIQ($p=0.098$). There was also a clinically significant improvement as defined by an increase in IBDQ score of$\geq$0.5 points per question. Total IBDQ and IBDQB score increased by 25 and 11 points respectively between baseline and 12 months.97% of patients found the appointments convenient,97% felt their problems were understood;86% were satisfied with the outcome and 89% with the service. Dissatisfaction related to communication(n=3), travel(n=2)and ongoing symptoms(n=3).
CONCLUSION: The clinically and statistically significant improvement in GI symptoms found in parallel to structured GI evaluation for chronic GI symptoms following pelvic radiotherapy was sustained over 12 months follow up. These data suggest that structured investigation on the basis of the BSG guidelines can lead to a sustained improvement in symptoms and is acceptable to patients. Further research is essential to optimise patient care.

P1553 DEVELOPMENT OF RADIATION-INDUCED PROCTOPATHY: THE ROLE OF HYPOXIA-INDUCED FACTOR

L. H. Eusebi[1,*], G. Gasparre[2], I. Kurelac[2], A. Guido[3], A. M. Porcelli[4], L. Laterza[1], V. Eusebi[5], F. Bazzoli[1], L. Fuccio[1]. [1]*Gastroenterology Unit,* [2]*Medical genetics unit, Sant'Orsola-Malpighi hospital, University of Bologna,* [3]*Division of Radiation Oncology, Sant'Orsola-Malpighi hospital,* [4]*Department of Pharmacy and Biotechnologies, University of Bologna,* [5]*Section of Surgical and Cytopathology, Bellaria hospital, University of Bologna, Bologna, Italy*

INTRODUCTION: Radiotherapy is a current standard for prostate cancer patients treatment. Side-effects such as rectal bleeding, diarrhea and urgency occur in a third of treated cases. Mucosal and submucosal areas in the rectum of such patients suffer a rapid inflammatory process, which evolves into moderate to severe inflammation with blood vessels damage, ischemia and finally to fibrosis. Hypoxia inducible factor (HIF-1-alpha) and other angiogenic factors have been related to radiation-induced late rectal injury, suggesting that radiation-induced hemorrhagic proctopathy could be treated by targeting such molecular factors.
AIMS&METHODS: Our aim was to define the mechanism through which radiotherapy induces proctopathy evaluating the role of HIF-1-alpha expression in radiation-induced proctopathy.
Patients were examined by rectosigmoidoscopy before and 4 weeks after radiotherapy, and biopsy samples of the rectal mucosa were collected in both occasionswere for histological diagnosis and CD31 immunohistochemistry analysis to evaluate angiogenesis. Endoscopic findings were classified using the Vienna Rectoscopy Score (VRS: 0=normal; 1=reddening, single angiectasia and oedema; 2=more than One angiectasias). Moreover, total protein content was extracted from the rectum samples and western blot analysis was performed to evaluate HIF1-alpha levels before and after radiotherapy.
RESULTS: Twenty-five patients were enrolled in the study. Rectosigmoidoscopy performed 4 weeks upon the termination of a 3-month radiotherapy revealed no mucosal damage in 13 patients, while proctopathy with VRS grade 1 lesions was present in 12 patients (48%). Molecular analysis showed up-regulation of HIF-1-alpha in 9 out of 25 patients, while in the rest of the samples HIF-1-alpha was either slightly down-regulated (6/25) or unchanged (10/25). Interestingly, significant association was observed between the presence of mucosal damage and HIF-1-alpha up-regulation (two-tailed Fisher: p=0.04). In particular, 77% of the cases (7/9) with higher post-radiotherapy levels of HIF-1-alpha showed VRS grade 1 lesions; when HIF-1-alpha was not up-regulated, mucosal damage was observed only in 31% of cases.
CONCLUSION: About half of the patients who underwent pelvic radiotherapy in our study developed radiation-induced proctopathy. In this setting, presence

of higher levels HIF-1-alpha was associated with a more severe mucosal acute inflammation.

P1554 HIGH PREVALENCE OF ANAL CANAL INFECTION WITH HUMAN PAPILLOMA VIRUS IN FRENCH MEN AND WOMEN WITHOUT RISK FACTORS.

L. Vuitton[1,2,*], E. Jacquin[3], F. Mauny[4], S. Koch[1], L. Plastaras[1], F. Fein[1], A.-C. Dupont-Gossart[1], P. Soussan[5], J.-L. Pretet[3], C. Mougin[3], S. Valmary-Degano[2,6]. *[1]Gastroenterology unit, university hospital, [2]EA3181 "carcinogenèse épithéliale", [3]EA3181 "carcinogenèse épithéliale", Laboratoire de Biologie cellulaire et Moléculaire, University of Franche-Comté, [4]Centre de Méthodologie Clinique, university hospital, Besançon, [5]Service de Virologie, Hôpital Tenon et Université Pierre et Marie Curie, Paris, [6]Service d'anatomo-pathologie, university hospital, Besançon, France*

INTRODUCTION: Currently the incidence of anal canal (AC) cancer increases by 2% each year and the sex ratio tends towards 1. Human papilloma virus high risk genotypes (HPV HR) are now well recognized as the causal agents for this cancer, with a large overrepresentation of HPV type 16. Concomitant infection with HIV is the main risk factor. However, only few data are available on the presence of HPV in AC and in the non-HIV population.
AIMS&METHODS: The aim of this study was to analyse prospectively the prevalence and the distribution of HPV genotypes in the AC of patients without risk factor for AC cancer. Secondary objectives were to evaluate 1) the relevance of cytology for screening HPV 2) the prevalence of precancerous lesions and 3) the study of viral parameters: viral load, DNA integration. Enrolment was proposed to all patients who underwent a colonoscopy under general anesthesia, whatever the indication, in the gastroenterology unit of a French university hospital. Two AC smears were taken for each patient in order to 1) look for HPV DNA by real time PCR and 2) perform cytological examination and immunocytochemistry with p16/Ki67 double staining.
RESULTS: Sixty two patients were enrolled (men: 60%; women: 40%) between 2011/12/01 and 2012/05/01. The prevalence of HPV infection was 19% (13% in men and 29 % in women). The prevalence of HPV HR was 16% and HPV HR 16 was predominant. Several genotypes were often found in one patient. Seventy % of patients carrying HPV in AC were women. When HPV HR 16 was found, viral load was low (60-120 copies/1'000 cells) and HPV DNA was not integrated to host cell genome. Cytological analysis revealed only few abnormalities. Preliminary data showed a positive p16/Ki67 double staining in a few HPV HR + samples.
CONCLUSION: This study, one of the rare ones describing AC infection with HPV in non-HIV patients, reports a prevalence of 1/5 subjects. The higher prevalence in women indicate that gynecologic current or past infection is likely to play a role. Our study is ongoing with the recruitment of 1'000 patients to get an accurate estimation of HPV prevalence in AC. These results may help guide prevention strategies against AC cancer through better understanding of HPV-related lesions and appropriate HPV screening and vaccination.

P1555 CHRONIC SACRAL NERVE STIMULATION: EFFECTS ON RECTAL EPITHELIAL BARRIER AND ON NEUROMUSCULAR TRANSMISSION IN A PORCINE MODEL

M. Dewitte[1,*], G. Meurette[2], S. Bruley Des Varannes[1], M. Neunlist[3]. *[1]IMAD, Hepato-gastro-enterology, [2]Digestive surgery units, [3]Inserm U913, CHU Hôtel Dieu, Nantes University, Nantes, France*

INTRODUCTION: Sacral nerve stimulation (SNS) is a validated treatment option for fecal incontinence although the mechanism-of-action remains unknown. In a pilot study we previously showed that short-term SNS induced a significant reduction in rectal mucosal paracellular permeability together with a concomitant decrease of mucosal thickness and an increased mucosal secretion (1). The objective of this work was to determine the impact of a long-term period of SNS on the intestinal epithelial barrier in a preclinical model.
AIMS&METHODS: The objective of this work was to determine the impact of a long-term period of SNS on the intestinal epithelial barrier in a preclinical model. Fourteen pigs were implanted for bilateral S3 root stimulation. Seven pigs received a seven-day permanent stimulation (Medtronic *041828-004*, Minneapolis, USA; 14 Hz, 210ms) whereas the remaining animals received no stimulation. Rectal biopsies were performed before and after seven days. Intestinal epithelial permeability (Ussing chambers), mucosal-tight-junction and cytokines mRNA expression, IL-6 production in an organotypic culture model, and *ex vivo* neuromuscular transmission in rectal muscle strips were assessed.
RESULTS: No severe advert effect occurred in animals. Intestinal epithelial permeability was not modified after seven-day stimulation compared with baseline. The stress-induced (PAR-2) significant (n=7; p=0.03) increase of epithelial permeability observed in controls at D7 did not occur in SNS group. Likewise a significant decrease of ZO-1 mRNA expression was observed at D7 in controls which did not occur in SNS group (n=7; p=0.25). Cytokine overexpression was not observed in the mucosa in either group. SNS decreased IL-6 production in the organotypic culture model. In the stimulated group, the area-under-the-curve of the electrical field stimulation-induced contractile response was significantly increased as compared with D0 (p=0.03).
CONCLUSION: Despite no occurrence of changes in physiologic conditions, chronic SNS modified the properties of the intestinal epithelial barrier, mainly by inhibiting the stress-induced increase of permeability. Neuromuscular transmission was modified by SNS, leading to neuronal hyper-excitability. These results add evidence to the reinforcement of the intestinal epithelial barrier induced by SNS.

P1556 WICH LESIONS SHOULD BE BIOPSIED DURING HRA? PROSPECTIVE DESCRIPTIVE STUDY OF SIMPLE MORPHOLOGICAL CRITERIA

M. Camus[1,*], A.-C. Lesage[2], J.-F. Flejou[3], P. Atienza[2], I. Etienney[2]. *[1]Department of Digestive Disease, LARIBOISIERE UNIVERSITY HOSPITAL APHP, [2]Proctology, Diaconesses Hospital, [3]Pathology, University Paris 6, Saint Antoine Hospital, Paris, France*

INTRODUCTION: High-resolution anoscopy (HRA) is a useful screening tool for anal intraepithelial neoplasia (AIN), although reputedly challenging for interpretation of suspected lesions.
AIMS&METHODS: The purpose of this study was to identify straightforward descriptive criteria predictive of the histological grade of suspected lesions visualized during HRA. All patients undergoing HRA from November 2010 through March 2012 with a biopsy of a suspected AIN lesion were included prospectively. All procedures were performed by senior proctologists. The characteristic features of the suspected lesion were noted. The characteristic features were compared with the histology findings.
RESULTS: Biopsy specimens were obtained from 168 suspected AIN lesions found in 103 patients (68% men) aged 49.8±9 years; 57.3% of patients were HIV-positive. Histologically, the lesions were classed: high-grade AIN (57.7%); low-grade AIN (35.6%); non-dysplastic tissue (23.8%, including 11.9% considered normal). The epithelium was irregular in 68.5% of the high-grade lesions and in 37.9% of the low-grade lesions. Similarly, the vascularization was irregular in 61.4% of the high-grade lesions and in 37.9% of the low-grade lesions. A flat surface was noted for 41.4% of the high-grade lesions versus 17.2% for the low-grade lesions. 91.4% and 94.8% of the high-grade and low-grade lesions respectively were acetowhite versus 70% of the normal specimens. Lugol's iodine staining was negative for 62.9% of the high-grade lesions versus 31% of the low-grade lesions. Combining the different criteria produced positive predictive values as follows:

Group	High-grade AIN n=70	Low-grade AIN n=58	PPV for high-grade AIN
I. Acetic acid-positive (single criterion)	64 (91.4%)	56 (94.6%)	43.2%
II. Acetic acid-positive + Lugol-negative + irregular epithelium	46 (65.7%)	20 (33.9%)	62.2%
III. Acetic acid-positive + Lugol-negative + irregular epithelium + irregular vascularization	35 (50%)	14 (23.7%)	68.6%

CONCLUSION: Several simple morphological criteria significantly associated with high-grade AIN are found less often in low-grade lesions. Combining morphological criteria provides a satisfactory PPV for guiding HRA biopsies.

P1557 ANORECTAL CONDYLOMA IS ASSOCIATED WITH ONCOGENIC HUMAN PAPILLOMAVIRUS INFECTION IN THE ANUS OF HIV-INFECTED MEN WHO HAVE SEX WITH MEN

N. Nagata[1,*], T. Nishijima[2], K. Sekine[1], S. Tanaka[1], K. Watanabe[1], T. Sakurai[1], C. Yokoi[1], M. Kobayakawa[1], H. Gatanaga[2], J. Akiyama[1], M. mizokami[3], N. Uemura[4], S. Oka[2]. *[1]Department of Gastroenterology and Hepatology, [2]Department of AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, [3]The Research Center for Hepatitis and Immunology, National Center for Global Health and Medicine, [4]Department of Gastroenterology and Hepatology, National Center for Global Health and Medicine, Kohnodai hospital, Chiba, Japan*

INTRODUCTION: High-risk oncogenic human papillomavirus (HPV) types are responsible for the majority of HPV-caused cancers.
AIMS&METHODS: To elucidate the prevalence of oncogenic HPV infection in the anus and its association with anorectal condyloma in HIV-infected men who have sex with men (MSM). MSM with HIV infection who underwent colonoscopy were prospectively enrolled in this single-center study. Anorectal condyloma was diagnosed based on endoscopic findings and confirmed by biopsy. A Dacron swab was used to obtain samples of anal canal cells for detection of HPV DNA by polymerase chain reaction (PCR). PCR and genotyping was conducted by standard methods. Associations between

oncogenic HPV infection (strains 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, and 66), anorectal condyloma, and other factors were determined by univariate and multivariate logistic regression analyses.
RESULTS: A total of 122 patients were enrolled. Median age and CD4 count were 42 (IQR 37–52) years and 362 (IQR 121–577) cells/mm^3, respectively. Of the patients, 85 (70%) were on antiretroviral therapy (ART), and 76 (62%) had a HIV viral load of <200 copies/ml. Of 100 patients infected with HPV, 90 (74%) were infected with oncogenic HPV, and 18 (15%) patients had biopsy-confirmed anorectal condyloma. Anorectal condyloma was found to be marginally associated with oncogenic HPV infection (OR 7.219, 95% CI 0.920–56.65, p=0.060), and this tendency persisted after adjustment for age, CD4 count, and ART (adjusted OR 6.162, 95% CI 0.761–49.91, p=0.088). On the other hand, older age was associated with a lower frequency of oncogenic HPV infection (OR 0.952, 95% CI 0.918–0.987, p=0.007).
CONCLUSION: The prevalence of oncogenic HPV infection is high in MSM patients with HIV infection. Regular screening for anal cancer is warranted in HIV-infected MSM, especially those with anorectal condyloma.

P1558 QUALITY OF LIFE AMONG THE CASES WITH FUNCTIONAL CONSTIPATION

N. Özkütük[1,*], Rukiye Vardar, Nalan Gülsen Ünal, Suna Yapalı, Esin Turasan, Serhat Bor. [1]*Gastroenterology, ege university medical school, izmir, Turkey*

INTRODUCTION: For the functional diseases such as functional constipation; enabling the patients to cope with the disease and helping them lead a life of quality should be the main objective of the treatments. We aimed at exploring clinical and demographic characteristics that affected quality of life among the cases with chronic functional constipation.
AIMS&METHODS: 268 cases who were admitted to our Constipation Outpatient Clinic were diagnosed with functional constipation according to Rome III criteria were included in the study. Constipation Quality of Life Questionnaire (CQLQ) was filled in by the cases after registring of the demographics, constipation features (stool frequency, consistency, amount, urge for bowel movement, need to strain, feeling of incomplete evacuation) and type of stool using Bristol Stool Scale were obtained.
RESULTS: 75% of the cases were women (201/268) and mean age was 45.1±1.1 years. 47% had infrequent defecation (<3 weekly), 33.6% had straining for 1-5 minutes, 43.3% had the sensation of incomplete evacuation, 39.6% defined to make pressure around anus, 31.3% had the feeling of incomplete evacuation. According to the Bristol Stool Scale, 104 patients (38.8%) had type 1 stool. Mean CQLQ was found to be 92.9±1.2. No correlation existed between mean CQLQ scores and age (p=0.4), sex (p=0.8), educational status (p=0.3), marital status (p=0.4), defecation frequency (p=0.07), incomplete defecation (p=0.15), defecation assisted with finger (p=0.06), straining (p=0.1), the feeling of incomplete evacuation (p=0.06), type of stool (p=0.1). Mean CQLQ scores were found to be considerably higher among those without feeling of incomplete evacuation than those with (99.8±17 vs 91.9±19.6 p=0.02) and among those with abdominal distension than those without (94±18.8 vs 83.6±23.9 p=0.01). The subscale of worries and concerns was significantly higher among those with defecation once a month (p=0.024), those with no feeling of incomplete evacuation, those who defecated assisted with finger (p=0.01) and abdominal distension (p=0.005); the subscale of physical discomfort was significantly higher among those aged 15-40 (p=0.021), those with hard defecation (p=0.009); the subscale of psychosocial discomfort was significantly higher among those without no sensation of obstructed anus (p=0.025) and the subscale of satisfaction was significantly higher among those aged ≥60 (p=0.045) and those with incomplete evacuation (p=0.005).
CONCLUSION: Quality of life worsened due to functional constipation. Worsening was higher in subscale of worries and concerns. Since improving quality of life was the main objective of the treatment in functional constipation, CQLQ could be used as an objective criterion in the evaluation of the treatment response.

P1559 THE IMPACT OF SPHINCTER EXERCISES ON ANORECTAL PHYSIOLOGY, FREQUENCY OF INCONTINENCE AND QUALITY OF LIFE IN PATIENTS WITH FUNCTIONAL FECAL INCONTINENCE

S. Yapali[1], R. Vardar[1,*], N. Ozkutuk[2], S. Bor[1]. [1]*Gastroenterology,* [2]*School of Nursing, Ege University, Izmir, Turkey*

INTRODUCTION: Fecal incontinence greatly affects social activity and quality of life and may even lead to social isolation. We aimed to examine the effects of sphincter exercise on anorectal physiological tests, frequency of incontinence and quality of life in patients presenting with fecal incontinence.
AIMS&METHODS: A total of 19 functional fecal incontinence patients [14 female, 5 male; mean age: 53±17 (median 56)], whose anorectal physiological tests were compatible with fecal incontinence were prospectively followed on a regular program of sphincter exercises during 3 months. Patients with abnormal electromyography (EMG) activity of the anal sphincter and subjects with a history of anorectal surgery were excluded. Frequency of defecation, incontinence, anal resting pressure and anal squeeze pressure, rectal sensation and quality of life were compared after the exercise program. Chi-square and t test were used in statistical analysis.
RESULTS: 5 (26%) patients had passive, 10 (52%) patients had urge, 4 (21%) patients had leakage type incontinence. Frequency of incontinence decreased from 7/week to 1 /week (p: 0,00009), from 25 /month to 7 /month (p=0,0001), endurance squeeze time improved from 17,5 sec to 24, 9 sec (p=0,016) following an exercise program of 92±5 days and median 18 times/day. In rectal sensation test, desire to defecate volume increased from 57,6 mL to 79,4 mL (p= 0,009) and urge to defecate volume increased from 107,8 mL to 137,3 mL (p=0,008) after exercise. Weekly and monthly bowel movements, anal resting and squeeze pressure, first sensation of content in the rectum and maximum tolerable volume to defecate did not change significantly. Following exercise, physical role (p=0,007), pain (p=0,003), general health (p=0,002), vitality (p=0,009) and mental health (p=0,004) improved according to the quality of life scales. Sex and differences in defecation patterns did not have a significant association with anal resting and squeeze pressures and endurance squeeze time.
CONCLUSION: Sphincter exercises decrease frequency of fecal incontinence and improve quality of life; by increasing endurance squeeze time, desire to defecate and urge to defecate volumes.

P1560 EFECTIVENESS OF TREATMENT WITH BOTULINUM TOXIN TYPE A VERSUS BIOFEEDBACK IN PATIENTS WITH DYSSINERGIC DEFECATION

Y. C. Aguilar[1,*], A. L. Haro[2], H. Gómez[3], E. Contreras[4], B. M. T. Mendoza[5], I. D. S. Pedroza[6]. [1]*ENDOSCPY /GASTROINTESTINAL MOTILITY, ISSSTE, Guadalajara,* [2]*ENDOSCPY /GASTROINTESTINAL MOTILITY, University of Guadalajara, GUADALAJARA,* [3]*University of Guadalajara, University of Guadalajara, Guadalajara,* [4]*Instituto nacional Nutrición, Instituto Nacional de Nutrición, México,* [5]*CUCS,* [6]*University of Guadalajara LAMAR, University of Guadalajara, Guadalajara, Mexico*

INTRODUCTION: Efficacy with TBA and BRT are not compared universally the biofeedback therapy is often used only with qualified personal. Botulinum toxin in the muscle diminish the activity of motor neurons alfa and reduction of aferent signal and feedback with reduction of muscular contraction, affect the perception in the region due to the brain-gut axis allows bi-directional input, links emotional and cognitive centers of the brain with peripheral functioning of the GI tract and viceversa, then the motor reactivity could be modified by botulinum toxin similar to biofeedback
AIMS&METHODS: Prospective randomized study,33 patients with dyssinergic defecation referred to motility service at Hospital Issste, Jalisco, México(dec 2010-dec 2011). Diagnosis of DD:clinical Rome III, anorectal manometry and balloon expulsion test, TTC. **Excluded:** Pregnant, altered colonic and anorectal region.**Anorectal manometry**:Air catheter four balloon spaced 0.5 cms (Sierra Inst®).**Protocol performance:**stationary pull-through technique recording anal pressure, mean squeeze pressure, RIAR, cough, bear-down manouver, Group A (BTA) 16 patients, incobotulinum toxin 80 U diluted at 0.4 cc injected at each side of puborectalis muscle once a time. Group B (BFB) (17 patients), eigth sesions twice a week. Clinical and manometric evaluation:four months. Dyssinergic defecation by anorectal manometry was made if basal pressure increase 10mmHg, three attempts. Ballon expulsion test at least 1-3 min. Primary outcomes variable was expulsion baloon test and clinical improvement.
RESULTS: Baloon expulsión: Significant difference in the median from 180 to 20 seconds. This represents an improvement in time to allow evacuation. The analysis of variables of the 17 patients evaluated with botulinum toxin type A, showed improvement in expulsion balloon test. The rest and intrarectal pressure did not differ with treatments.
CONCLUSION: BTA is safe and an option to treat dyssinergic defecation. We do not have infraestructure for Biofeedback treatment. The difference in results between the groups in this study has been demonstrated the feasibility of their use as initial therapy in patients with disturbed defecation with severe chronic constipation refractory to standard treatments.

P1561 MALLORY-WEISS SYNDROME: IS IT POSSIBLE TO PREDICT A COMPLICATED OUTCOME?

A. R. Alves[1,*], L. Elvas[1], A. Oliveira[1], P. Figueiredo[1], C. Sofia[1].
[1]*Gastroenterology, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal*

INTRODUCTION: Mallory-Weiss Syndrome (MWS) is a common cause of upper gastrointestinal bleeding, which usually has a benign outcome; however, some cases may have a complicated course.
AIMS&METHODS: The aim of this study was to identify predictive factors of a complicated clinical course in an inpatient population, defined as hemodynamic instability on admission (tachycardia/hypotension), blood transfusion, bleeding recurrence or death. We retrospectively analyzed all consecutive admissions in our Gastroenterology unit due to MWS between 2006 and 2012. Data collected included symptoms, precipitating factors, pharmacological and medical records, vital signs and analytic results at admission, endoscopic findings, treatments and outcomes. Statistical analysis was performed with SPSS ® v20.
RESULTS: We included 121 patients (mean age 65 ± 17 years, 84.3% males). Hemodynamic instability on admission was present in 40% of patients, with male having a higher risk (OR 6.1). Univariate analysis identified the following predictors of transfusion requirement (received by 42% of the patients): melena (OR 2.7), tachycardia (OR 2.62), lower systolic arterial tension (123vs135mmHg), longer time between bleeding onset and endoscopy (28vs11hours) and higher values of blood urea nitrogen (49.8vs29.8mg/dl). Independent predictors for transfusion identified by multivariate analysis were: tachycardia, melena, higher blood urea nitrogen and time to endoscopy. There was bleeding recurrence in 6.6% (n=8) of patients. Statistical analysis didn't identify any predictor of recurrence. No deaths related with MWS were recorded in this series.
CONCLUSION: This study highlights the benign course of MWS, despite relatively high frequencies of hemodynamic instability and transfusion requirements. The authors emphasize the importance of individual risk assessment of each patient, taking into account the absence of unequivocal predictive factors of bleeding recurrence.

P1562 IS ENDOSCOPIC THERAPY SAFE FOR UPPER GASTROINTESTINAL BLEEDING IN SUPRATHERAPEUTIC ANTICOAGULATED PATIENTS WITH SUPRATHERAPEUTIC INTERNATIONAL NORMALIZED RATIO?

C. N. Shim[1,*], H. S. Chung[1], J. C. Park[1], S. K. Shin[1], S. K. Lee[1], Y. C. Lee[1], M. K. Song[2], D. R. Kang[2], H. Lee[1]. [1]*Department of Internal Medicine, Institute of Gastroenterology, Yonsei University College of Medicine, Seoul, Korea,* [2]*Biostatistics Collaboration Unit, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Rebleeding is the most important predictive factor of mortality for patients with upper gastrointestinal bleeding (UGIB). The purpose of this study was to evaluate the safety of endoscopic therapy for UGIB in anticoagulated patients with supratherapeutic international normalized ratio (INR).
AIMS&METHODS: 192 anticoagulated patients who underwent endoscopic treatment for UGIB were enrolled in the study. Patients were divided into two groups based on the occurrence of rebleeding within 30 days of the initial therapeutic endoscopy; no-rebleeding group (without rebleeding, n=168) and rebleeding group (with rebleeding, n=24).
RESULTS: The overall rebleeding rate was 12.5% among enrolled patients. The supratherapeutic INR at the time of presentation (P=0.047) and bleeding from gastric cancer (P=0.025) were significantly related to rebleeding in a univariate analysis, while melena as a presenting symptom (P=0.003) and bleeding from gastric ulcer (P=0.020) were significant factors related to no-occurrence of rebleeding. In multivariate analysis, presenting symptoms except melena (hematemesis, hematochezia, or others) (P=0.008, OR=3.9, 95% CI=1.4–10.8) and bleeding from gastric cancer (P=0.024, OR=6.1, 95% CI=1.3-29.3) were significant risk factors predictive of rebleeding. The supratherapeutic INR at the time of endoscopic therapy had the increasing tendency of rebleeding in univariate analysis (P=0.052), but did not reveal the significant association with rebleeding in multivariate analysis (P=0.192, OR=4.3, 95% CI=0.5-37.8). The rebleeding group revealed the significant differences of success of initial endoscopic therapy (P=0.006), additional interventions to control bleeding (P=0.006), length of hospital stay (P=0.017), transfusion requirements (P=0.001), and bleeding-related (P=0.009) or all-cause mortality (P=0.010), comparing to the no-rebleeding group. There were no significant differences of therapeutic outcomes between patients with INR less than or equal to 3.0 and with INR more than 3.0.
CONCLUSION: The supratherapeutic INR at the time of endoscopic therapy did not affect rebleeding and therapeutic outcomes. The endoscopic therapy should be considered the anticoagulated patients with supratherapeutic INR.

P1563 COMPARISON OF THE GLASGOW BLATCHFORD AND ROCKALL SCORES IN THE PREDICTION OF CLINICAL END-POINTS AFTER UPPER GASTROINTESTINAL BLEEDING

D.-A. BENAJAH[1,*], K. SAADA[1], M. EL YOUSFI[1], I. MELLOUKI[1], N. AQODAD[1], M. EL ABKARI[1], A. IBRAHIMI[1]. [1]*hepatogastroenterology, HASSAN II university hospital, fez, Morocco*

INTRODUCTION: The Glasgow Blatchford Score (GBS) is increasingly being used to predict intervention and outcome following upper gastrointestinal bleeding (UGIB).
AIMS&METHODS: The aim of this study is to compare the GBS with both the admission and full Rockall scores in predicting clinical end-points following UGIB. Retrospective study including patients with UGIB, admitted to the department of Hepato-Gastroenterology, Hassan II University Hospital, of within two years. Admission history, clinical and laboratory data, endoscopic findings, treatment and clinical follow-up were recorded. Using ROC curves, we compared the three scores: GBS and the admission and full Rockall scores in the prediction of death, endoscopic intervention and transfusion.
RESULTS: 284 patients were included. The average age was 51 years. Thirteen (4.5%) died, 72 (25.3%) had endoscopic intervention and 116 (66%) required transfusion. The comparison of the GBS with admission Rockall score and full Rockall score, shows that this one was higher than admission Rockall score (AUROC 0.705 vs 0.530) and full Rockall (AUROC 0.705 vs 0.537) in predicting need for a transfusion, and lower than both the admission Rockall score (AUROC 0.655 vs 0.735) and full Rockall score (AUROC 0.655 vs 0.772) in predicting endoscopic intervention. For predicting death, the GBS was higher than admission Rockall score (AUROC 0.801 vs 0.776) and comparable to full Rockall score (AUROC 0.801 vs 0.812).
CONCLUSION: Comparing the three scores,GBS was superior to both Rockall scores in predicting a transfusion's need and death.

P1564 RISK SCORING SYSTEMS IN PREDICTING OUTCOME IN PATIENTS WITH UPPER GASTROINTESTINAL BLEEDING

D. Matei[1,*], B. Furnea[2], I. Groza[2], L. Puie[2], A. Chiru[2], M. Tantau[1]. [1]*University of Medicine and Pharmacy "Iuliu Haţieganu", [2]Regional Institute of Gastroenterology and Hepatology Prof Dr "Octavian Fodor", Cluj Napoca, Romania*

INTRODUCTION: Rockall and Glasgow-Blatchford score can be used in stratifying the risk in patients with upper gastrointestinal bleeding (UGIB).
AIMS&METHODS: AIM
The importance of scoring systems in predicting outcome in patients with upper gastrointestinal bleeding
MATERIAL AND METHOD
299 patients with UGIB admitted in RIGH Cluj Napoca's Emergency Department between November 2012 - March 2013 were included in the study. Upper endoscopy was performed in all patients and they were followed prospectively until discharge.
Pre-endoscopy Rockall score, post-endoscopy Rockall and Glasgow-Blatchford score were determined; rebleeding episodes, death and the need for blood transfusion were recorded.
RESULTS: The mean time from admission to endoscopy was 4h 38 min, and the average admission time was 8 days.
Rebleeding occurred in 7.69 % of the patients. The mean scores for the patients who had at least one more bleeding episode while they were admitted, compared to those who did not, were: pre-endoscopy Rockall score 2.39 vs 2.83; post-endoscopy Rockall score 4.70 vs 4.76; Glasgow-Blatchford score 11.83 vs 11.42 ($p > 0.05$).
Death occurred in 13.71% of the patients. The mean scores for the patients who died compared to those who survived were: pre-endoscopy Rockall 3.83 vs 2.64; post-endoscopy Rockall 5.76 vs 4.60; Glasgow-Blatchford 13.63 vs 11.11 ($p < 0.05$).
Regarding the need for blood transfusion, the patients were divided into 4 categories: A – no need for transfusion; B - a need between 1 to 5 units of blood; C- 6 to 10 units; D – more than 10 units of blood needed. The mean pre-endoscopy Rockall scores were 2.43; 2.91, 3.19 and 3.80 (p=0.021); mean post-endoscopy Rockall scores were 4.29; 4.89, 5.31 and 6 (p=0.023); mean Glasgow-Blatchford scores were 8.98; 12.54, 12.62 and 14.20 (p=0.000).
CONCLUSION: The pre-endoscopy Rockall, post-endoscopy Rockall and Glasgow-Blatchford scores were significantly higher in patients who died compared to those who survived.
All of these 3 scoring systems were higher in patients who needed blood transfusions, and there was a correlation between these scores and the number of blood units needed.
None of these scores correlated with the occurrence of a new bleeding episode.

P1565 THE ROLE OF EARLY ENDOSCOPY VS URGENT ENDOSCOPY IN UPPER GATROINTESTINAL BLEEDING

D. Matei[1,*], L. Puie[2], I. Groza[2], B. Furnea[2], A. Chiru[2], M. Tantau[1]. [1]*University of Medicine and Pharmacy "Iuliu Haţieganu", [2]Regional Institute of Gastroenterology and Hepatology Prof Dr "Octavian Fodor", Cluj Napoca, Romania*

INTRODUCTION: Upper gastrointestinal bleeding (UGIB) is one of the major emergencies in gastroenterolgy. The endoscopy is recommended to be performed in the first 24 hours.
AIMS&METHODS: The aim of the study is to follow the influence of endoscopy timing on hospitalization period, mortality rate and rebleeding risk in patients with UGIB.
Material and method. It is a prospective study done in a tertiary medical service with permanent access to Endoscopy Department, for 5 months interval (between November 2012 and March 2013). 294 patients with UGIB were included in the study. In all patients the endoscopy was performed in the first 24 hours after admission. The patients were followed the whole duration of hospitalization. According to the time interval after the endoscopy was done, the patients were divided in 2 groups: urgent endoscopy - first 3 hours (UE) and early endoscopy – 3-24 hours (EE).
RESULTS: In the studied group of 294 patients, 163 of them had UE (55.44%), while 131 had EE (44.56%). The mean age was 62.5 years (min 19 years, max 94 years), with a predominance of male patients (68.71%).
13.9% of the patients died during hospitalization period. The mortality rate was lower in patients with UE compared with EE group (13.5% versus 14.5%), without statistic significance (p=0.804).
Rebleeding episodes occur in 7.82 % of the patients, more frequently in patients with UE compared to EE group (8.59% versus 6.87%), without statistic significance (p=0.585).
Even the hospitalization period is slighty prolonged in patients with EE vs UE group (8.24 days vs 7.96 days), this was not significantly influenced by the endoscopy timing (p=0,74).
CONCLUSION: Urgent endoscopy compared to early endoscopy has not been significantly superior regarding the mortality rate, rebleeding episodes and hospitalization period in patients with UGIB.

P1566 EFFICACY OF LONG-ACTING RELEASE OCTREOTIDE IN RECURRENT BLEEDING FROM GASTROINTESTINAL ANGIODYSPLASIA: A RETROSPECTIVE STUDY OF 98 CONSECUTIVE CASES

D. Compare[1,*], A. Rocco[1], M. Sanduzzi Zamparelli[1], O. M. Nardone[1], M. Guarracino[1], C. Sgamato[1], G. Nardone[1]. [1]*Clinical and Experimental Medicine, University Federico II of Naples, NAPOLI, Italy*

INTRODUCTION: Management of recurrent bleeding due to gastrointestinal angiodyplasias (GIADs) is a clinical challenge, mainly because it occurs in elderly patients. The inaccessibility or numerosity of the lesions as well as the patient comorbidities, strongly limit the suitability of endoscopical or surgical procedures. The rarity of bleeding due to GIADs, the heterogeneity of the patient population and the natural course of the disease critically hamper to plan prospective studies.
AIMS&METHODS: To assess the efficacy and safety of long-acting release (LAR)-octreotide in definitively control recurrent bleeding due to GIADs.
Medical records of consecutive patients diagnosed with GIADs from January 2000 to December 2008 were retrieved for the study. All patients received octreotide 0.1 mg three times/day SC for 28 days and, starting from the 14th day LAR octreotide 20 mg IM monthly for 6 months.
RESULTS: Ninety-eight out of 147 patients were eligible for the analysis. The history of bleeding before starting therapy lasted at least two years and the mean follow-up was 78 months (range 36-120 months). In respect to the observation period before starting therapy, during the follow-up the mean hemoglobin level increased ($p < 0.0001$), and the number of bleeding episodes, patients requiring blood transfusion, unit of transfused red cells and number of hospitalizations decreased ($p < 0.0001$, $p < 0.0001$, $p < 0.0001$ and $p < 0.0001$, respectively). Overall, 72/98 (74%) patients did not have overt bleeding nor presented recurrent anemia during the whole follow-up, and in particular 40/98 after the first cycle of therapy (full responders) and 32/98 by the third cycle of therapy (relapsers), while the remaining 26/98 patients required continuous therapy (poor responders). At multivariate stepwise analysis, chronic antiplatelet therapy (OR, 5.7; 95% CI 2.0 to 16.0; $p = 0.001$), overt bleeding (OR, 7.5; 95% CI 0.7 to 78; $p = 0.09$) and multiple sites of GIADs (OR, 4.0; 95% CI 1.4 to 11.4; $p = 0.009$) were the only covariates independently associated with poor response to therapy.
CONCLUSION: LAR octreotide is a safe and effective treatment in controlling recurrent bleeding due to GIADs, even definitely stopping bleeding in a substantial percentage of the cases. Therefore, LAR octreotide is useful to global well-being, health-related quality of life and public health cost streamlining.

P1567 OUTPATIENT MANAGEMENT OF LOW-RISK PATIENTS WITH UPPER GI BLEEDING: CAN WE SAFELY EXTEND THE GBS IN CLINICAL PRACTICE?

Z. Mustafa[1,*], A. Cameron[2], E. Clark[2], B. Reed[3], A. J. Stanley[1]. [1]*Gastroenterology,* [2]*Acute Medicine, Glasgow Royal Infirmary, Glasgow,* [3]*Gastroenterology, Royal Alexanda Hospital, Paisley, United Kingdom*

INTRODUCTION: The pre-endoscopy Glasgow Blatchford Score (GBS) accurately predicts outcome in patients presenting with upper GI bleeding (UGIB).[1] A GBS of zero identifies low-risk patients in whom out-patient management is recommended.[2] There is debate whether this low-risk score can be extended above zero. The aim of this study was to prospectively assess the introduction of a protocol for out-patient management of patients with UGIB and GBS <2.
AIMS&METHODS: After adjusting our hospital UGIB protocol to avoid admission if GBS <2 (unless required for other reasons), we undertook hospital educational meetings and introduced the new protocol in December 2011. A research nurse prospectively collected demographic and outcome data on consecutive patients presenting with UGIB during the 12 month period to December 2012. All data were cross referenced with the A&E Information System. An endpoint of death, endotherapy, transfusion or HDU/ITU admission within 30 days was used to define adverse outcome. The negative predictive value of GBS <2 was calculated with 95% confidence intervals.
RESULTS: 516 patients presented to our hospital with UGIB during the study period. 180 (34.9%) had GBS <2 (109 GBS=0 and 71 GBS=1).89 (49.4%) were managed as outpatients, of whom none had an adverse outcome within 30 days. Of the 91 (50.6%) managed as inpatients, 76 (83.5%) had other acute morbidities requiring inpatient care, of whom one died within 30 days from an unrelated malignancy. Of the 15 admitted without other acute morbidities, one was discharged for out-patient endoscopy but readmitted with a Mallory-Weiss tear requiring transfusion. The overall negative predictive value of GBS <2 in predicting adverse outcomes at 30 days was 98.9% (95% CI: 96.0% to 99.9%)
CONCLUSION: GBS <2 had a high negative predictive value for adverse outcomes in clinical practice. This suggests outpatient management of patients with UGIB and GBS <2 is safe.

P1568 LEFT-SIDED PORTAL HYPERTENSION – A COMPLEX CLINICAL PROBLEM

A. I. Fernandes[1,*], N. Almeida[1], A. M. Ferreira[1], A. Casela[1], E. Camacho[1], F. Portela[1], A. Rosa[1], C. Sofia[1]. [1]*Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: Sinistral or left-sided portal hypertension (LSPH) is an uncommon entity in our clinical practice. Among its multiple aetiologies, chronic pancreatitis is the most common, and among its various manifestations, gastric variceal bleeding is the most worrying.
AIMS&METHODS: Characterization of a series of patients with an established diagnosis of LSPH with a retrospective analysis of epidemiological, clinical, endoscopic and imaging characteristics of the identified cases.
RESULTS: Included 9 patients, 8 male, with a mean age of 52±9 years (42-68), with an established diagnosis of LSPH, confirmed with CT scan and/or Endoscopic Ultrasonography. Median follow-up of 7 months (3 to 108). Eight patients had pancreatic disease (chronic pancreatitis - 4; sequelae of acute necrotizing pancreatitis – 1; pancreatic tumor – 3) and the other had an arteriovenous malformation involving the splenic artery and vein. None of the patients had evidence of liver disease and only two of them had abnormal liver biochemical parameters, secondary to biliary obstruction due to pancreatic mass and chronic pancreatitis. The diagnosis of fundal varices was established in all patients by endoscopy and/or CT scan, but only two had gastrointestinal bleeding, and emerging obliteration of gastric varices with cyanoacrylate was necessary in one of them. Splenomegaly was observed in two patients and thrombocytopenia in three. Regarding the definitive treatment, two patients underwent splenic artery embolization (those who had gastrointestinal bleeding) and one was submitted to splenectomy, although there was recurrence of LSPH in this one.
CONCLUSION: Left-sided portal hypertension is a rare clinical syndrome, usually secondary to pancreatic pathology and with subtle clinical manifestations, but occasionally can lead to life-threatening gastric variceal bleeding. The therapeutic approach is not consensual, may have significative risks and the results are not always satisfactory.

P1569 EVALUATION OF ENDOSCOPIC BAND LIGATION IN THE MANAGEMENT OF ACUTE NON-VARICEAL UPPER GI BLEEDING

A. Krishnan[1,*], V. Velayutham[1], J. Satyanesan[1], None. [1]*Department of Gastroenterology and Liver Transplant, Stanley Medical College, Chennai, India*

INTRODUCTION: Acute nonvariceal upper-GI bleeding (NVUGIB) is a challenging emergency condition. Early endoscopic therapy has recommended as the first-line treatment for upper gastrointestinal bleeding as it has been shown to reduce recurrent bleeding.
AIMS&METHODS: Aims of the study determine the various causes of non variceal gastrointestinal hemorrhage and discuss the role of band ligation.. Between November 2006 and December 2012, 184 patients were treated with EBL who had NVUGIB were included for the study. Bleeding lesions included Dieulafoy's ulcer, Mallory- Weiss tear, duodenal ulcer, post surgical anastomosis bleed and gastric ulcer after polypectomy. After basic life support was provided, all patients underwent emergent and elective endoscopy.
RESULTS: These comprised 123 (66.8%) males and 61 (33.2%) females. The mean age was 48.2±6.4years for males and 40.6±2.2years for females.

Mallory-Weiss tear and Dieulafoy's lesion constituted the majority of bleeding lesions 64 (34.9%) and 48(26.1%) respectively requiring EBL. Other causes were: pre-pyloric ulcer 23(12.5%); duodenal ulcer 17(9.2%); ulcers in antrum 14(7.6%); post polypectomy bleed 11(6%); Anastomosis bleed 3(1.6%); malignant lesions 4(2.2%). Bleeding stopped after endoscopic therapy in 96.5% of patients. The single failure was in bleeding from a pre pylori lesion. Injection sclerotherapy with 1:10000 adrenaline solution and EBL was not successful
CONCLUSION: EBL provides safe and effective modality for hemostasis in NVUGIB. EBL could be considered as a primary or alternative method of choice for treatment of endoscopic hemostasis in patients with NVGIB.
Disclosure of Interest: None Declared

P1570 FEATURES OF THE ABDOMINAL HEMODYNAMIC IN PATIENTS OF THE ASTHENIC CONSTITUTION

H. Lyalyukova[1,*], M. Livzan[2]. [1]*OMSK STATE MEDICAL ACADEMY, OMSK,* [2]Омская государственная медицинская академия, ОМСК, *Russian Federation*

INTRODUCTION: The abdominal hemodynamics is one of the factors defining structural and functional features of the alimentary system.
AIMS&METHODS: Research objective: To estimate features of the abdominal hemodynamics in patients of various constitutional types
Materials and methods. 121 patients of the asthenic constitution and 43 patients of the normosthenic constitution (group of control) were included in the research. An average age was 22,28 ±3,7 years. Patients were comparable according to their age and sex, they had no acute or chronic diseases. The computer angiography of the abdominal aorta and ultrasonic dopplerography of the portal vein, the general hepatic artery, the upper mesenteric artery, splenic artery on an empty stomach and after alimentary assay were executed. For the description of data the median (Me) with the indication of interguartile scope was used. Mann-Whitney U Test was applied to detect the differences between groups.
RESULTS: Results. In patients of the asthenic constitution smaller mass of the body was registered (p=0,0017), body mass index (p=0,0001). At the computer angiography smaller diameters of the abdominal aorta were found: 17,0 mm [15,3-18,0mm] at the level of Th 12, 21,00 mm [19,0-22,0] (p=0,0001) in control, 13,00 mm [12,4-13,8mm] at the level of L4, 16,50 mm [15,0 - 17,0 mm] (p=0,0001)in control. In patients of the asthenic constitution low volumetric rates of blood flow were defined against a background of smaller diameter of vessels: on the portal vein on an empty stomach (p=0,0314) and after alimentary assay (p=0,0443), on the arteries after an alimentary assay (p=0,00070; p=01430; p=0399). The body mass index Indicators correlated with the diameter, volumetric rate of the blood flow on the upper mesenteric artery (r=0,43; r=0,34); on the general hepatic artery (r=0,34; r=0, 36), with a linear rate of the blood flow on the portal vein r=-0, 35).
CONCLUSION: Conclusions: Patients of the asthenic constitution were established to have a reliable decrease of the diameter of an abdominal aorta becomes perceptible, smaller indicators of a volume blood flow on the visceral vessels were registered. Features of the abdominal blood flow in patients of the asthenic constitution can determine the trophological status of patients.

P1571 GASTRIC ANTRAL VASCULAR ECTASIA: CLINICAL FEATURES, ASSOCIATIONS AND PROGNOSIS

L. Y. Lee[1], V. Santharam[1,*], G. Macfaul[1]. [1]*MILTON KEYNES NHS FOUNDATION TRUST, Buckinghamshire, United Kingdom*

INTRODUCTION: Gastric antral vascular ectasia (GAVE) is a rare disorder characterised by upper GI bleeding, chronic iron-deficiency anaemia and endoscopic findings of columns of red tortuous vessels along the longitudinal folds of the antrum of the stomach. Although the pathogenesis of this condition is largely unknown, it is associated with a number of medical conditions including portal hypertension and scleroderma. There have been few studies analysing the prevalence of the associated conditions in a cohort of GAVE cases, and none in a sample size of greater than 15.
AIMS&METHODS: This is a retrospective cohort study of all patients diagnosed with GAVE an Milton Keynes district general hospital between November 2007 and November 2012. Information was gathered from electronically stored patient records.
RESULTS: 20 patients were identified, 50% of cases were male. Average age at diagnosis overall was 65 years. The most common symptom that lead to a diagnosis of GAVE was of iron deficiency anaemia. 45% of cases had a co-existing diagnosis of liver cirrhosis (n=9), 35% chronic renal failure, 25% (n=7) had diabetes (n=5), 20% had rheumatologic disease (n=4) and in half of these the condition was scleroderma, 11% of the cohort had thyroid function abnormalities (n=2). Patients were followed up for a mean period of 1.9 years and in this period one patient had an acute GI bleed. Argon Plasma Coagulation was performed in 5 cases and the remaining cases were treated medically. Following APC the haemoglobin increased by an average of 3.75g/dL.
CONCLUSION: GAVE is an important differential diagnosis in the setting of iron deficiency anaemia on a background of cirrhotic liver disease or portal hypertension, especially in patients in their sixties or older. This cohort confirms the associations in previous studies but also notes that acute bleed risk is low and that APC appears an effective treatment modality
Disclosure of Interest: None Declared

P1572 THE ROLE OF ENDOSCOPY AND HISTOPATHOLOGY OF THE UPPER GASTROINTESTINAL TRACT IN THE MANAGEMENT OF PATIENTS WITH ORGANIC AND FUNCTIONAL DYSPEPSIA

A. Piatek-Guziewicz[1], M. Zwolińska-Wcisło[2,*], M. Przybylska-Feluś[1], T. Mach[2]. [1]*Department of Gastroenterology,Hepatology and Infectious Diseases, The University Hospital,* [2]*Department of Gastroenterology,Hepatology and Infectious Diseases, Jagiellonian University Medical College, Krakow, Poland*

INTRODUCTION: Upper gastrointestinal endoscopy with histopathological evaluation provides essential tool to differentiate the organic and functional causes of dyspepsia.
AIMS&METHODS: The aim of this study was to assess the frequency and type of endoscopic and histological changes in patients with dyspepsia. A retrospective study was performed on 212 patients with dyspepsia, at the age of 18-84 years, who underwent gastroscopy. Patients were divided into two age groups: ≤ 45 years (group I,60 patients) and ≥ 40 years (group II,152 patients). Biopsy specimens were taken from the gastric and duodenum for histological examination. The presence of *H.pylori* infection has been established.
RESULTS: 1 patient (61 years) was diagnosed with gastric cancer (0.5%) and 1 person was diagnosed with Crohn's disease (0.5%)(group I). Peptic ulcer was found in 10 patients (4.7%). Reflux esophagitis was found in 18 patients (8.5%). The most common inflammatory changes of esophagus were mild inflammation - Grade A classification Los Angeles. A more advanced form and Barrett's esophagus was found only in patients > 45 years of age. In 25% of patients in group I and 5.3% in group II, gastric mucosa appeared to be normal. The most common endoscopic change was gastritis (74%). The most frequent type of gastritis were erythematous-exudative (23.6%) and atrophic (18.4%). Erosive gastritis was present in 15% of patients. The percentage of associated *H. pylori* infection, was slightly more than 30%. The main location of *H. pylori* infection was antrum. The patients with *H. pylori* infection had mainly a moderate degree of inflammation (55.2%). Atrophy, metaplasia, and dysplasia were significantly frequent in patients > 45 years of age. In no one of the group ≤ 45 years of age there was dysplasia or metaplasia of the third degree. The majority of patients (77.4%) had normal duodenal mucosa. In 3.3% of the respondents stated histological typical for celiac disease(I - 8.3%, II-1.3%). Microscopic examination of all samples taken from the duodenum, in the absence of endoscopic lesions, showed the presence of inflammatory infiltrates of varying degrees of severity, regardless of gastric *H. pylori* infection.
CONCLUSION: It seems that during endoscopy in patients with dyspepsia, regardless of macroscopic changes, routine biopsies from different parts of the stomach and the duodenum are appropriate. Celiac disease should be considered in the differential diagnosis of the causes of dyspepsia. Further histological study of microscopic duodenitis in patients with dyspepsia, may be needed and helpful.

P1573 GASTRIC GHRELIN AND SEROTONIN (5-HT) SIGNALING IN PATIENTS WITH FUNCTIONAL DYSPEPSIA (FD)

C. K. Cheung[1,*], L. L. Lan[1], Y. Chan[1], Y. Y. Lee[1], J. C. Wu[1]. [1]*Institute of Digestive Disease, The Chinese University Of Hong Kong, Hong Kong, Hong Kong*

INTRODUCTION: Background:
Circulating serotonin and ghrelin levels were suppressed in FD patients(Cheung et al. 2013). However, the role of serotonin and ghrelin signaling in patients with FD remains unclear.
AIMS&METHODS: Aim:
To compare the gastric mucosal expression of Ghrelin, 5-HT modulators between FD patients and healthy controls.
Methods:
Consecutive adult patients with FD (Rome III criteria) and age-and-sex matched asymptomatic healthy controls were recruited for upper endoscopy after an overnight fast. Subjects with GERD and IBS as predominant symptoms, diabetes mellitus, current *H. pylori* infection and recent use of NSAID or PPI were excluded. Mucosal biopsies from the gastric corpus were obtained for quantitative assay of mRNA Ghrelin, OCT-1, TpH-1 and GNB3 using Real Time-PCR. The Generalized Estimating Equation (GEE) approach was used to examine the differences in gene expression between patients and controls.
RESULTS: Results:
46 [M:F=14:32, mean age: 35.5(9.7)] FD patients were matched with 23 healthy controls [M:F= 8:15, mean age: 36.7(10.4)] respectively. FD patients had PDS as predominant symptoms (PDS: 44, EPS:2). Compared to healthy controls, FD patients had significantly higher relative mRNA expression of GNB3 (FD: 0.11± 0.02, Control: 0.06 ± 0.0, 1.9 fold, p=0.006) while no significant differences were observed in TpH-1 (FD: 6.9 ± 0.1 X 10-3, Control: 7.4 ± 2.3 X 10-3, 0.9 fold, p=0.798) and OCT-1 (FD: 6.9 ± 2.1 x 10-4, Control: 2.2± 0.6 x 10-4, 1.3 fold, p=0.481), Serotonin 4 receptor (FD:3.7± 0.5 X 10-4, Control: 4.2± 1.0 X 10-4, 0.9 fold, p=0.68)and ghrelin (FD: 13.0 ± 1.9, Control: 14.5± 3.6, 0.9 fold, p=0.77). However, Gastric TpH-1 mRNA in patients significantly correlated with epigastric burning (R = 0.33, p=0.04) and bloating(R=0.34, p=0.03). Gastric OCT-1 mRNA also significantly correlated with FD global symptom score (R=0.35, p=0.03), Bloating (R=0.32, p=0.05) and postprandial fullness (R=0.32, p=0.05) in patients with FD.
CONCLUSION: Conclusion:
REFERENCES:
1. Cheung, C.K.Y. et al., 2013. Decreased Basal and Postprandial Plasma Serotonin Levels in Patients with Functional Dyspepsia. *Clinical gastroenterology and hepatology : the official clinical practice journal of the American Gastroenterological Association*. Available at: http://www.ncbi.nlm.nih.gov/pubmed/23591288 [Accessed April 23, 2013].

Alternations in ghrelin and serotonin signaling in the gastric mucosa may contribute to the aberrant circulating plasma levels and the pathophysiology of FD. Modulation of ghrelin and serotonin system may provide a therapeutic option for FD.

P1574 ALARM SYMPTOMS ARE NOT ASSOCIATED WITH THE CLINICALLY SIGNIFICANT FINDINGS IN UPPER ENDOSCOPY IN AMBULATORY SETTING

L. Jonaitis[1,*], G. Kiudelis[1], S. Rimselyte[1], L. Kupcinskas[2]. [1]*Gastroenterology,* [2]*Institute for the digestive research, Lithuanian University of Health Sciences, Kaunas, Lithuania*

INTRODUCTION: The demand of esophagogastroduodenoscopies (EGDS) is steadily increasing and could hardly be satisfied. According to guidelines the presence of alarm symptoms is unequivocal indication for EGDS. Though, there are some doubts if the presence of alarm symptoms yields in much more clinically significant findings.
AIMS&METHODS: Aim. To evaluate the correlation of alarm symptoms and clinically significant findings found on EGDS in the routine clinical practice in ambulatory setting.
Methods. A prospective study performed in 4 hospitals in Lithuania: Hospital of Lithuanian University of Health Sciences (tertiary level), and 3 secondary level hospitals. Alarm symptoms that were evaluated as an indication to perform EGDS were: dysphagia, odynophagia, anemia, signs of upper GI bleeding (suspicion of melena), weight loss, recurrent vomiting, fever. The following endoscopic findings were considered as a clinically significant: erosive esophagitis, gastric ulcer, duodenal ulcer, gastric or duodenal polyps, malignant tumors.
RESULTS: Data from 502 patients (mean age- 55.6±16.7) were analysed: 204 (41%) males and 298 (59%) females. Mean age of males – 54.1±16.3, of females – 56.6±16.9 years, $p>0.05$. Alarm symptoms were found in 77 (15%) patients: in 28 (13%) female and in 39 (19%) males, $p<0.05$. Mean age of patients with alarm symptoms - 58.2±18.6, without alarm symptoms - 55.1±16.3, $p>0.05$. Clinically significant findings found in 176 (35%) patients. Malignant tumor found only in 2 (0.4%) patients. Mean age of patients with clinically significant findings was 55.7±17.0, without clinically significant findings - 55.4±16.4, $p>0.05$. Among patients with alarm symptoms, clinically significant findings was found in 28 (36%) patients, among patients without alarm symptoms – in 148 (35%), $p>0.05$. Duodenal or gastric ulcer was found in 4 (33.3%) out of the 12 patients with melena, and in 22 (4.5%) out of 490 patients without melena, $p<0.01$. We did not find any differences in clinically significant findings if the patients were referred to upper endoscopy by gastroeneterologist or not gastroenterologist.
CONCLUSION: There is no correlation between the age and alarm symptoms and clinically significant findings in our cohort. The presence of alarm symptoms in our cohort was not asocciated with the clinicaly significant findings. Only the presence of signs of upper gastrointestinal bleeding was asociated with more frequent detection of peptic ulcer. There are extremely low prevalence of malignancies in our studied cohort, therefore the role of alarm symptoms in the malignant disease must be clarified in much larger sample size.

P1575 UPPER GASTROINTESTINAL MUCOSAL INJURY AND SYMPTOMS IN LOW DOSE ASPIRIN USERS

Y. Shimada[1,*], A. Nagahara[1], H. Sasaki[1], D. Asaoka[1], M. Hojo[1], S. Watanabe[1]. [1]*Gastroenterology, Juntendo university School of medicine, Tokyo, Japan*

INTRODUCTION: It is well known low-dose aspirin(LDA) not only increases the risk of gastrointestinal(GI) mucosal injury but also worsens the quality of life(QOL) because of the symptoms like dyspepsia. Previous studies have mostly investigated the upper GI(u-GI) mucosal injury in individual organs, but there are few reports which were investigated plural organs at the same time.
AIMS&METHODS: To reveal the clinical features of LDA related u-GI mucosal injury, we investigate frequency, severity and symptom of reflux esophagitis(RE), gastric erosions and/or ulcers(GE), and duodenal erosions and/or ulcers(DE) individually between patients of LDA users(LDA) and non-LDA users(C). Data were extracted from the records of subjects who underwent u-GI endoscopy at our department between April 2008 and December 2012. Among 8280 patients answering Frequency of Scale for severity of GERD(FSSG) and SF8 QOL were analyzed after excluding proton pump inhibitor or histamine type 2 receptor antagonist users. Frequency of u-GI mucosal injury was compared between LDA and Control. Among patients who were diagnosed to have mucosal injuries, symptom and QOL was compared between LDA and Control. FSSG items were classified into a total score(TS), reflux score(RS), dyspepsia score(DS). SF8 has a physical component summary(PCS) and mental component summary(MCS).
RESULTS: Number of LDA and C was 501 and 7779, respectively. Frequency of RE in LDA:C was 10.2%(n=51): 9.6%(n=750)(p=0.69), GE was 36.5%(n=183): 26.7%(n=2076)($p<0.001$). DE was 5.4%(n=27): 4.6%(n=355)(p=0.39). Regarding symptom and QOL, TS, RS and DS of RE were LDA:C = 6.2±6.2: 8.0±7.1(p=0.07), 3.5±3.8: 4.4±4.3(p=0.16) and 2.7±2.9: 3.6±3.3(p=0.05). TS, RS and DS of GE were 5.5±6.1: 6.9±6.7(p=0.006), 2.9±3.4: 3.5±3.9(p=0.04) and 2.6±3.1: 3.4±3.4(p=0.002). TS, RS and DS of DE were = 6.0±5.7: 6.6±6.3(p=0.64), 3.1±3.9: 3.3±3.7(p=0.77) and 2.9±2.3: 3.3±3.2(p=0.56). PCS and MCS of RE were 47.0±10.8: 49.6±6.7(p=0.01) and 50.3±9.3: 48.3±7.4(p=0.07). PCS and MCS of GE were 47.6±7.9: 49.0±6.6(p=0.01) and 50.0±7.0: 48.3±7.4(p=0.005). PCS and MCS of DE were 48.7±11.6: 49.5±7.2(p=0.59) and 48.4±11.6: 48.3±8.1(p=0.95).
CONCLUSION: Frequency of gastric mucosal injury was significantly high in LDA user comparing to non-LDA user, however frequency of esophageal and duodenal mucosal injury was similar in LDA user to non-LDA user. Regarding symptoms, LDA user complained significantly less symptom score on DS with reflux esophagitis and TS, RS, DS with gastric mucosal injury. QOL was not impaired at all in upper GI mucosal injuries in LDA users. These results give us the important clinical information that symptom based management was not appropriate in LDA user in terms of upper GI mucosal injuries.

P1576 OSTEOPOROTIC FRACTURE RISK ASSESSMENT IN GASTROENTEROLOGY INPATIENTS: A MISSED OPPORTUNITY TO SCREEN?

A. A. Li[1,*], J. Goodhand[2], E. Wood[1]. [1]*Gastroenterology, Homerton University Hospital, London,* [2]*Homerton University Hospital, London, United Kingdom*

INTRODUCTION: In the general population, a majority of fragility fractures occur in patients with bone mineral densities (BMD) in the osteopaenic rather than osteoporotic range, suggesting that factors other than BMD need to be taken into account when determining both the need for screening and anti-osteoporosis treatment. The Fracture Risk Assessment (FRAX) score, developed by the WHO, is a free web-based clinical scale assessing the 10-year fracture risk and need for lifestyle advice/reassurance, dual X-ray absorptiometry (DEXA) scanning or preventive treatment.
AIMS&METHODS: We sought to compare the screening and management of osteoporosis in patients with gastrointestinal and liver diseases admitted to our hospital with treatment recommendations according to FRAX scores.
Consecutive inpatients [n=100: 37% female] admitted to our ward between January and March 2013 were included; 8 patients were subsequently excluded because they were already prescribed a bisphosphonate. The proportions of patients in whom a DEXA scan was planned/completed and those treated with a bisphosphonate were recorded. FRAX scores for hip and other major osteoporotic fractures, as well as subsequent treatment recommendations were prospectively derived using the UK specific web-based calculator [1]. Differences between observed and recommended treatments were sought using Chi-squared analysis.
RESULTS: The median age [range] of the sample was 52 [18-87] years; the median [range] predicted 1 year survival according to the Charlson co-morbidity index was 89% [64%>98%]. The mean [SEM] vitamin D level was 36.3 [5.0] and 65% [60/92] patients were deemed to be vitamin D deficient. The mean [SEM] 10 year risk of major osteoporotic fracture and hip fracture was 8.9% [2.9] and 3.5% [2.4] respectively. Overall, according to FRAX guidance; 64% [59/92] patients required no treatment; DEXA scans were recommended in 21% [19/92] patients; and based on clinical risk factors alone, 15% [14/92] patients should have been receiving a bisphosphonate: compared with 98%, 0% and 2% respectively observed in our current practice ($p < 0.0001$).
CONCLUSION: Patients admitted with gastrointestinal and liver diseases are frequently vitamin D deficient and at high risk of future osteoporotic fracture, however, few are adequately assessed and/or treated for osteoporosis. The web-based WHO FRAX tool is a readily available, easy to use, free and rapid way of assessing fracture risk based on clinical factors alone that could be utilised in the gastroenterology inpatients to predict those patients who need DEXA scans and/or consideration for specific treatment of osteoporosis.

P1577 INAPPROPRIATE USE OF PROTON PUMP INHIBITOR: AN ASIAN PERSPECTIVE

C. T. W. Chia[1,*], C. K. F. Vu[1]. [1]*Gastroenterology & Hepatology, Tan Tock Seng Hospital (TTSH), Singapore, Singapore*

INTRODUCTION: There are growing concerns that the use of proton pump inhibitors(PPI) may be inappropriate in many instances and do not conform to evidence based indications. The purpose of this point prevalence study was to investigate the frequency, indications and appropriateness of PPI use in hospitalized patients on a randomly chosen day.
AIMS&METHODS: The total number of in-patients on a randomly chosen day was documented. The number of in-patients on any form of PPI on the same day was determined. The indications for maintaining the patients on PPI were obtained from the electronic medical records. The list of accepted indications for PPI use was adapted from the Food and Drug Administration (FDA) approved list and these were cross-referenced with the indications documented from the medical records.
RESULTS: A total number of 1025 in-patients were studied. 477 (46.5%) were using PPI, of which 219(45.9%) fulfilled FDA approved indications. The remaining 258(54.1%) did not fulfill FDA approved indications. 208(43.2%) were not indicated based strictly on the FDA criteria and 52 (10.9%) had borderline indications based on expert consensus or other guidelines other than the FDA. The most prevalent indication for inappropriate PPI usage was uninvestigated anaemia in stable patients with no clinical evidence of GIT bleeding. The most

common borderline indication for PPI usage was endoscopic findings of gastropathy/gastritis.

NON-INDICATIONS FOR PPI (BY FDA)	TOTAL =206
Anaemia (no evidence of GI bleed/clinically stable)	71(34.5%)
Aspirin or antiplatelet or NSAIDs (<65yrs)	45(21.8%)
No apparent indication(in records)	24(11.7%)
Corticosteroids	15(7.3%)
Warfarin	14(6.8%)
Malignancy	14(6.8%)
Bone fractures	5(2.4%)
Others (Nasogastric tube feeding, nil per oral status, on low molecular weight heparin, musculoskeletal chest pain, bone fracture, foreign body removal in throat, high gastric residual volume, post tonsillectomy)	18(8.7%)

CONCLUSION: PPI usage is pravelent in hospitals. Less than half of the total PPI usage amongst hospitalized patients has evidence-based indications to support their use. Overuse of PPI has a negative impact on health care cost and may lead to certain adverse effects. Steps to curb inappropriate PPI use should address a few factors including indications to initiate PPI, reassessing need for on-going use while in hospital or upon discharging patients and upon out-patient reviews

P1578 ALARMINGLY POOR ADHERENCE TO LOW-DOSE ASPIRIN CAN BE IMPROVED BY CONCOMITANT PROTON-PUMP INHIBITOR USE: A LARGE COMMUNITY-BASED STUDY

G. Singh[1,*], G. Arora[2], A. Mannalithara[3], A. Mithal[4], G. Triadafilopoulos[3]. [1]*Gastroenterology And Hepatology, STANFORD UNIVERSITY, Palo Alto,* [2]*UT SouthWestern, Dallas,* [3]*STANFORD UNIVERSITY, Palo Alto,* [4]*ICORE, Woodside, United States*

INTRODUCTION: Low-dose acetylsalicylic acid (ASA) is the mainstay of cardiovascular (CV) risk management in high-risk populations. Adherence with ASA therapy is of critical importance as poor adherence or discontinuation leads to an increased risk of major CV events. ASA-associated upper gastrointestinal (GI) adverse events are important reasons for decreased compliance with ASA therapy. Concomitant treatment with proton-pump inhibitors (PPIs) reduces the incidence of GI symptoms but there are no studies evaluating the effects of this strategy on ASA compliance. We studied the effect of concomitant PPI use on compliance with ASA therapy in community practice.

AIMS&METHODS: We designed a population-based, retrospective cohort study using data from the Medi-Cal Research database in California. Medi-Cal data include details of all medication use, including over-the-counter medications. Patients aged $\geq$ 18 years who had at least one claim for an incident 30-day supply of low-dose aspirin (325 mg or less per day) formed the study population. Among these patients, a group of PPI users was identified, based on prescription claims during the 12 months following cohort entry. Patients who had no PPI use during the 1-year study follow-up served as controls. We calculated the actual number of days that each patient had "possession" of aspirin during the 12 months of study period. This ratio (number of days of aspirin possession/365 after first aspirin ingestion) was defined as the Medication Possession Ratio (MPR). All analyses were adjusted for comorbidities, GI symptoms, and concomitant NSAID and clopidogrel use.

RESULTS: A total of 80, 623 patients took aspirin with concomitant PPI and 237, 031 took aspirin without any PPI, during the study period. Only 50.6% of the cohort had a 50% or greater compliance with ASA (MPR>= 0.5). Multivariate logistic regression analyses adjusted for age, gender, comorbidity, concomitant NSAID and clopidogrel use and history of GI complaints showed that concomitant PPI use was significantly associated with the likelihood of >=50% adherence to low-dose aspirin, relative to the non-PPI group (OR 1.47, 95% CI 1.43-1.49, $p<0.0001$). Sensitivity analyses showed that high compliance (>=70%) was also significantly more likely in patients on concomitant PPIs (OR 1.33, 95% CI 1.31-1.36, $p<0.0001$).

CONCLUSION: Adherence to low-dose aspirin used for CV risk management in community practice is poor, but may be improved significantly by concomitant PPI use. It is likely that this increased adherence with ASA will translate to a more favorable CV outcome.

P1579 PROPOFOL SEDATION FOR DIAGNOSTIC ESOPHAGOGASTRODUODENOSCOPY COMPARED TO MIDAZOLAM: A RANDOMIZED COMPARISON IN SINGLE CENTRE

H. Yamamoto[1,*], T. Nakamura[1], T. Kikuchi[1], T. Yamamoto[1], H. Kikuchi[1], T. Gotoda[1,2]. [1]*Department of Gastroenterology, Tokyo East Hospital, Edogawa,* [2]*Gastroenterology and Hepatology, Tokyo Medical University, Shinjuku, Japan*

INTRODUCTION: Sedative medications are commonly used even in scheduled endoscopic examinations. Although midazolam is widely supervised by endoscopists, propofol is recently favored for rapid acting and metabolized character.

The aim of this study is to compare propofol with midazolam for outpatients' diagnostic esophagogastroduodenoscopy (EGD).
AIMS&METHODS: One hundred and six healthy patients aged 20 to 69 years requesting sedation at diagnostic EGD from October 2012 to May 2013 were randomly assigned to propofol (n=54) or midazolam (n=52). Medications were given by bolus injection and the dose was adjusted by bodyweight (P:0.6-1mg/kg, M:0.03-0.05mg/kg). Supplementary doses were tolerated up to 50% of the initial doses. Before the start of the study, endoscopists and nurses were trained in administering propofol sedation under the supervision of an anesthesiologist. Sedation level and patients' acceptability during procedures, recovery time and patients' satisfaction were assessed. Sedation level and acceptability were evaluated by American Society of Anesthesiologists (ASA) responsiveness levels and gagging reflux on a four-point scale, respectively.
RESULTS: There was no statistical difference between both groups. Among more than 80% patients in both groups, sedation level was moderate to deep without respiratory depression and gagging reflux was absent or mild. The majority of patients rated procedures as good or excellent. Among propofol sedated patients, 91% could walk out just after procedures finished while 85% of midazolam group required wheelchair to leave ($p<0.01$). Mean full recovery time was 4.7 minutes with propofol sedation, which was significantly shorter than midazolam sedation (24min, $p<0.01$). No major incidence was reported after procedure until 24 hours later.
CONCLUSION: Propofol sedation provided adequate sedation level, good acceptability and satisfaction as same as midazolam during diagnostic EGD. Furthermore, propofol sedation might be unnecessary for preparing recovery room and excessive visual task. (Clinical trial registration number: UMIN000009142)

P1580 WEEKEND VS. WEEKDAY ADMISSION FOR URGENT EGD DUE TO UPPER GASTROINTESTINAL BLEEDING, 10-YEARS SINGLE-CENTER EXPERIENCE

M. Tufegdzic[1], **N. Panic**[2,*], M. Bulajic[2], M. Krstic[3]. [1]*Internal Medicine Clinic,* [2]*Digestive Endoscopy Unit, University Clinic "Dr Dragisa Misovic-Dedinje",* [3]*Clinic for gastroenterlogy Clinical Center of Serbia, Faculty of Medicine University of Belgrade, Belgrade, Serbia*

INTRODUCTION: Acute upper gastrointestinal bleeding (UGIB) is one of the most common cause of hospital admissions for acute care and indication for urgent esophagogastroduodenoscopy (EGD). The aim of this study was to estimate whether outcomes for patients subjected to urgent EGD duo to UGIB differ depending on weekend versus weekday admission, and whether any such differences are mediated by discrepancies in presence of risk factors.
AIMS&METHODS: We conducted retrospective-prospective study on patients submitted to urgent EGD in University Clinic ...Dr Dragisa Misovic-Dedinje", Belgrade, Serbia in period from 2002 to 2012. Data were collected on patient symptoms, possible risk factors, verified causes of bleeding, modality of treatment, complications and outcome. Patients were divided in two groups based on whether they were submitted to urgent EGD on weekend (Group I) or weekday (Group II). Proportions among the groups were compared in univariate analysis.
RESULTS: Study included 1150 patents (62% male). Among patients in Group I were significantly more those with severe symptoms, including melena or hematemesis (p=0.001). Esophageal varices and gastric ulcers were more common verified as cause of UGIB in Group I (p=0.007). Patients in Group I were more often submitted to endoscopic treatment aside from traditional one (p=0.000) and were associated with more complications (p=0.000). Nevertheless, there was no difference in mortality rate among the groups (Group I=3.6%; Group II=2.5%; p=0.348). Hospitalization length was significantly longer in Group I (p=0.009). Regarding risk factors, patients in Group I were more often associated with alcohol consumption (p=0.000).
CONCLUSION: Weekend admission of patients with upper gastrointestinal bleeding is not associated with increased mortality rate, although it is associated with more severe clinical picture, higher complication rate and longer hospitalization.

P1581 ETHNIC DIFFERENCES IN UPPER GASTROINTESTINAL DISEASES IN SCOTLAND.

G. Brin[1], H. Ward[2], N. Bansal[1], R. Bhopal[1], N. Bhala[3,*]. [1]*University of Edinburgh,* [2]*Information Services Division, NHS Scotland, Edinburgh,* [3]*Queen Elizabeth Hospital, Birmingham, United Kingdom*

INTRODUCTION: There is a paucity of data assessing ethnic variations in upper gastrointestinal (GI) diseases: we sought to study the incidence of upper GI diseases using adequate measure of ethnicity in Scotland.
AIMS&METHODS: Using the Scottish health and ethnicity linkage study (SHELS), linking NHS hospital admissions and mortality to the Scottish census 2001, we explored ethnic differences in incidence (2001-2010) of specific upper GI diseases (peptic ulcer disease, oesophagitis, gastritis, gallstones and pancreatitis) in Scotland. Risk ratios (RR) were calculated using Poisson regression with robust variance and multiplied by 100, by gender, adjusted for age and subsequently country of birth. The White Scottish population was the standard reference population (100). 95% confidence intervals (CI) were calculated to enable comparison and exclude 100 in the results below.
RESULTS: The total numbers of first events within the 9 years period of interest (over almost 29 million of Person-Year (PY) at risk) was 44,612 for peptic ulcer, 102,706 for oesophagitis, 141,235 for gastritis, 87,556 for gallstones and 17,177 for pancreatitis.
Looking at risk ratios for all specific upper GI diseases and compared to respectively White Scottish men and women, other White British and other White had a lower risk of upper GI diseases even after adjustment for country of birth. White Irish had an increased risk of upper GI diseases but not significant after adjustment for country of birth.
There were consistent ethnic variations in non–White minority ethnic group even after adjustment for country of birth. Chinese men and other South Asian (SA) men and women had a 1.5 to 1.7 fold increased risk of peptic ulcer disease. Pakistani and Bangladeshi had a 1.3 to 2 fold increased risk of esophagitis whereas Chinese had a lower risk (RR [CI] = 63.5 [50.2; 80.2] for men, 67.4 [51.6; 88.1] for women). South Asian had a 1.2 to 1.5 fold increased risk of gastritis whereas it was lower for men of African origin (RR [CI] = 65.6 [49.3; 87.3]). Gallstones was more incident in Chinese men (140.2 [117.5; 167.2]) and Pakistani women (131.3 [115.4; 149.4]), the latter also had an increased risk of pancreatitis (151.7 [123.3; 186.6]).
CONCLUSION: This unique data allowing the comparison of specific upper GI diseases incidences between ethnic groups has shown major differences. Further exploration on risk factors and understanding of differences is needed to promote health equality.

P1582 A CLINICAL EXPERIENCE OF POEM FOR ACHALASIA AND ESOPHAGEAL DIFFUSE SPASM

H. Shiwaku[1,*], H. Inoue[2], K. Yamashita[1], R. Beppu[1], R. Nakashima[1], S. Takeno[1], T. Sasaki[1], S. Hoshino[1], S. Nimura[3], Y. Yamashita[1]. [1]*Department of Gastroenterological Surgery, Fukuoka University Faculty of Medicine, Fukuoka,* [2]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama,* [3]*Department of Pathology, Fukuoka University Faculty of Medicine, Fukuoka, Japan*

INTRODUCTION: Per-oral endoscopic myotomy (POEM) becomes widely accepted as a useful treatment for achalasia. We introduce the summary and present result of POEM in our institution.
AIMS&METHODS: Data on single-institution POEM were collected prospectively. Pre- and postoperative symptoms were quantified with Eckardt scores. Objective testing (manometry, endoscopy, barium swallow) was performed preoperatively and postoperatively.
RESULTS: Thirty achalasia patients and one diffuse esophageal spasm patient underwent POEM between September 2011 and December 2012. The mean age was 48.5 (26-79) years. Seven patients had prior balloon dilations or Botox inejection. Myotomy length was 14.2cm (7-26cm), and the median operating time was 154.7 minutes (80-345). No serious complications related to POEM were encountered.
All patients had relief of dysphagia and no patient had Eckardt scores greater than 2. The median hospital stay was 6.4 (5-10) days. During follow-up, medication was necessary in only one patients who developed reflux esophagitis (Los Angeles classification B); this was well controlled with regular intake of protein pump inhibitors (PPIs).
CONCLUSION: The outcome of POEM in out institution was excellent. All patients had dysphagia relief, There is significant though mild gastroesophageal reflux postoperatively in one patient but this was well controlled with regular intake of protein pump inhibitors (PPIs).

P1583 ESOPHAGEAL PRESSURE RESPONSES TO A DRINK CHALLENGE TEST FOR EVALUATION OF OBSTRUCTION ACROSS THE ESOPHAGOGASTRIC JUNCTION

I. Marin[1,*], C. Julia[1], J. Serra[1]. [1]*Motility and Functional Gut Disorders Unit, University Hospital Germans Trias i Pujol, Badalona, Spain*

INTRODUCTION: Impaired transit across the esophagogastric junction (EGJ) is a major determinant of the clinical outcome in patients with esophageal motility disorders.
AIMS&METHODS: The aim of the present study was to determine if pressure responses to a rapid drink challenge test measured by means of high resolution manometry (HRM) can discriminate patients with and without obstruction across the EGJ.
METHODS: In 20 patients with dysphagia and non-treated achalasia, 17 patients with treated achalasia, 37 patients with hypertensive esophagus and normal EGJ relaxation, and 20 healthy controls, a rapid drink challenge test, rapid drink of 200 ml water in sitting position, was performed at the end of the standard HRM protocol. Pressure responses of the esophagus were analysed and

pressure gradient across the EGJ was measured as intraesophageal minus intragastric pressure.
RESULTS: : The number of swallows performed and the time expended to drink 200 ml, was similar in all groups of patients (NS), and significantly larger than in healthy subjects (17±1 swallows during 38±2 sec, and 14±1 swallows during 24±2 sec. pooled data for patients and healthy subjects, respectively; $p<0.05$). The pressure gradient in healthy subjects was negative (-2±1 mmHg) whereas it was weakly positive in patients with hypertensive esophagus (6±2 mmHg; $p<0.05$). By contrast, patients with non-treated achalasia had a significantly greater pressure gradient across the EGJ (16±3 mmHg; $p<0.05$ vs all) that returned to levels similar to those of patients with non-obstructive hyperperistalsis after treatment (6±2 mmHg; $p< 0.05$ vs non-treated achalasia; NS vs hyperperistalsis). Overall, pressure gradient correlated with the degree of reported dysphagia (r=0.4; p=0.000). The pattern of esophageal pressures during water swallow was different among the studied groups: healthy subjects showed a complete inhibition of esophageal pressures (0±1presurizations) whereas patients with non-treated achalasia showed the largest number (8±2 vs. 3±1 presurizations, hypertensive peristalsis, $p<0.05$ for all) and the most prolonged pressure increments above 20 mmHg (mean duration 6±2 sec vs 1±0 sec, hypertensive peristalsis; $p<0.05$ for all). Patients with treated achalasia showed a trend to reduction of pressure activity (4±2 presurizations, 2±1 sec long; NS vs non-treated achalasia and hypertensive peristalsis)
CONCLUSION: Measurement of esophageal pressures during a rapid drink challenge test can be used to objectively assess functional obstruction across the EGJ in patients with esophageal motility disorders

P1584 ESOPHAGOGASTRIC JUNCTION OUTFLOW OBSTRUCTION: A NEW MANOMETRIC CONDITION UNDER INVESTIGATION.

I. Sanabria Marchante[1,*], T. Pérez Fernández[2], C. Santander Vaquero[2].
[1]*Gastroenterology, Virgen Macarena University Hospital, Sevilla,*
[2]*Gastroenterology, La Princesa University Hospital, Madrid, Spain*

INTRODUCTION: Esophagogastric junction outflow obstruction (EGJOO) is a new disorder recently included under the Chicago Classification[1]. High Resolution Manometry (HRM) can overcome some of the limitations in the evaluation of the esophagogastric junction (EGJ) experienced with earlier technologies such as conventional manometry. The EGJOO is characterized by impaired EGJ relaxation (HRM revealing high Integrated Relaxation Pressure: IRP > 15 mmHg) and preserved esophageal peristalsis.
AIMS&METHODS: Description of manometric findings of patients with EGJOO diagnosed by HRM since the implementation of the Chicago Classification.
RESULTS: A total of 24 consecutive patients were included –average age 47.6 years old, 18 females (75%)-. One patient had undergone antirreflux surgery (Nissen fundoplication). Three patients suffered from hiatus hernia. The most common symptoms were epigastric pain and heartburn.
Manometric findings: The resting expiratory pressure of the lower esophageal sphincter (LES) was normal in 50% of the patients and elevated in the remaining 50% (mean 35.4 mmHg). As defined, all patients presented elevated IRP values (mean 17.4 mmHg). Mean distal contractile integral (1031 mmHg.s.cm) and contractile front velocity (4 cm/s) were normal. Mean distal latency was normal (7.8 s). Mean Upper esophageal sphincter resting pressure was 74 mmHg. Regarding esophageal peristalsis: 16 patients (66%) presented 'intact peristalsis', 1 (4%) 'weak peristalsis with small peristaltic defects', 3 (12%) 'weak peristalsis with large peristaltic defects' and 4 (16%) 'frequent failed peristalsis'.
Seven patients (29%) showed rapid increased in intrabolus pressure.
An incomplete esophageal transit was observed in 8 patients (33%) by Multichannel Intraluminal Impedance (MII) connected to manometry.
Using a 24-h esophageal pH monitoring, we detected pathological acid gastroesophageal reflux in 5 patients (20.8%).
EGJ structural stenosis or eosinophilic esophagitis were ruled out using complementary examinations (gastroscopy, biopsies, imaging test, etc).
CONCLUSION: EGJOO is a new manometric entity with a yet undefined meaning. In this series most patients presented intact peristalsis, although some unspecific esophageal motility alterations were found.

EGJOO includes a heterogeneous group of patients with some individuals having an incomplete phenotype of achalasia (functional EGJOO) and others probably having an undetected mechanical cause of outflow obstruction such as hiatus hernia, structural esophageal stenosis (including post-surgical) or eosinophilic esophagitis.

P1585 PREVALENCE OF RELAXATION DISORDERS OF THE LOWER ESOPHAGEAL SPHINCTER IN PATIENTS UNDERGOING HIGH-RESOLUTION MANOMETRY

J. Keller[1,*], D. Menge[1], V. Andresen[1], S. Scherzberg[1], K. Schmidt[1], P. Layer[1].
[1]*Internal Medicine, Israelitisches Krankenhaus, Hamburg, Germany*

INTRODUCTION: Esophageal manometry is indicated in patients with non-obstructive dysphagia and in patients scheduled for fundoplication. In both patient subsets, one of the main reasons for performance of this investigation is identification of patients with achalasia-like disturbances. However, the prevalence of LES-relaxation disorders in patients undergoing high-resolution esophageal manometry (HRM) is unknown.
AIMS&METHODS: In a prospective study, we determined the integrated relaxation pressure (IRP) according to the Chicago Classification in 787 subjects undergoing HRM at our institution between 09/2011 and 03/2013. Demographics and symptoms including PPI-responsiveness were evaluated in all subjects with relaxation disorders (IRP > 15 mmHg) and in 227 subjects without. Moreover, data on lower esophageal sphincter (LES) resting pressure and pH-metry data were analysed.
RESULTS: 28% of our pts came from the surgical department, 63% were female. Pts were 56.5±15.6 yrs old (mean±SD), mean BMI was 26.0±5.6 kg/m2. 65% of the pts reported heartburn, 60% regurgitation, 58% dysphagia, 56% retrosternal pain, 51% epigastric pain and 37% nausea. Of those who took PPI 20% responded completely, 53% partially and 17% did not respond. 24h-pH-metry (off PPI) was performed in 44% of the pts. In these, reflux time (pH < 4) was 8.0±10.3% of time. The resting pressure of the LES was 23.3±16.7 mmHg. Mean IRP was 11.3±9.8 mmHg. IRP exceeded 15 mmHg in 93 pts corresponding to 11.8% of the total cohort. IRP was significantly higher in pts with dysphagia than without (13.5±10.5 vs. 8.1±7.8 mmHg, $p<0.0001$). Moreover, we observed negative correlations between LES resting pressure and reflux time (p=0.005) and between IRP and reflux time (p=0.0009).
CONCLUSION: LES-relaxation occur in more than 10% of our pts undergoing HRM. Increased IRP is associated with dysphagia and reduced reflux time. However, symptoms are not specific for either GERD or LES-relaxation disorders.

P1586 PREVALENCE OF AUTOIMMUNE COMORBIDITIES IN IDIOPATHIC ACHALASIA IS SIMILAR TO A MATCHED POPULATION OF PATIENTS SUFFERING FROM NON-ACHALASIA OESOPHAGEAL DISORDER

M. Pesce[1,1], A. D'Alessandro[1], R. D'Aniello[1], I. Arnone[1], M. Pesce[1], M. Della Coletta[1], F. P. Zito[1], P. Andreozzi[1], M. Della Coletta[1], I. Palumbo[1], E. Efficie[1], A. Santonicola[1], R. Cuomo[1,*], G. Sarnelli[1]. [1]*University of Naples "Federico II", Naples, Italy*

INTRODUCTION: The pathogenesis of achalasia is multifactorial and genetic, infectious and autoimmune mechanisms have been all proposed. Recently an increased prevalence of autoimmune diseases has been reported in a Canadian un-matched cohort of achalasia patients. We aimed to compare the prevalence of autoimmune disease in patients with esophageal achalasia to a matched population of control patients.
AIMS&METHODS: The study population consisted of 180 patients (71 males, mean age 55 ± 16 years) with proven clinical and instrumental diagnosis of idiopathic achalasia. Gender and age matched consecutive subjects selected from the outpatient clinic and referring of esophageal disorders other than achalasia, served as controls. All patients were investigated for the presence of the following comorbidities: hematologic diseases and cardiopathies and neoplasms. Screened autoimmune diseases were I diabetes mellitus, hypothyroidism, Sjögren's syndrome, uveitis, systemic lupus erythematosus, rheumatoid arthritis.
RESULTS: The overall prevalence of comorbidities was similar in achalasia and control patients (62 vs 57%, respectively). Cardiopathies and hyperlipidemia were the most frequently observed comorbidities in achalasia and controls (30 vs 37% and 17 vs 31%, respectively p=NS). Similarly hematological disorders and type II diabetes were similarly prevalent in the two groups. As far as the overall prevalence of autoimmune disorders, there was a tendency, but not significant, to a higher prevalence in achalasia than in controls (8 vs 5%, p= NS), without any difference for each of the considered automimmune disease (data not shown). Most interestingly, presence of comorbidities, regardless of their autoimmune origin, did not significantly affect disease's phenotype as the age of disease onset was similar in achalasia patients with and without comorbidities (46±21 vs. 49±16 years, respectively, p=NS).
CONCLUSION: We showed that type and the frequency of comorbidities, either or not autoimmune, in a large series of achalasia patients and we showed that their prevalence is similar to that of a matched control population. Although larger epidemiological studies are needed to confirm our data, our results indicate that the putative mechanisms underlying the onset of achalasia are specific for this disease.

P1587 LONG TERM OUTCOME OF PATIENTS WITH REFLUX SYMPTOMS AND SYMPTOMATIC ESOPHAGEAL DYSFUNCTION DURING AND AFTER A STANDARDIZED TEST MEAL : A HIGH-RESOLUTION MANOMETRY STUDY

R. Sweis[1], G. Brady[1], A. Anggiansah[1], A. Lee[1], A. Vales[1], T. Wong[2], M. Fox[3,*].
[1]*Oesophageal lab,* [2]*Department of Gastroenterology, Guys and St Thomas' Hospital, London,* [3]*NIHR Biomedical Research Unit and Digestive Diseases Centre, Nottingham University Hospitals, Nottingham, United Kingdom*

INTRODUCTION: Recently we presented novel methodology for the assessment of oesophageal function and symptoms not only with liquids but with solids and also during and after a standard test meal (Sweis DDW 2011, NGM 2012).
AIMS&METHODS: In the absence of a ''gold standard'' diagnosis, outcome data provides insight into the clinical impact of tests. 18 patients referred with reflux symptoms and 10 healthy controls underwent High Resolution Manometry(HRM) with 5ml water and a test meal followed by 10min postprandial observation of symptoms and events. 24hr pH studies were then performed. The number of Symptoms Associated with Dysfunction(SAD) was calculated. HRM findings and initial diagnosis were compared with the final diagnosis and outcome at 2 years
RESULTS: No symptoms occurred with 5ml water. 12/18(67%) patients had SAD (mean SAD 2 (0-7)) during/after the meal. Compared to 5ml water, manometric diagnosis was altered in 12/18(67%) after the test meal (most reclassified from hypotensive to normal motility). No healthy volunteers had SAD.
11/18 patients had GORD on pH studies. By 2 years, 5/11 that had dysmotility (e.g. hypotensive/failed peristalsis) during the meal with frequent symptomatic postprandial reflux events had anti-reflux surgery with excellent outcome. 6/11 with GORD did not have surgery, 2 with symptomatic reflux on HRM declined and remain symptomatic, 4 with symptomatic reflux were not offered surgery. 2 with severe hypotensive dysmotility and symptomatic reflux responded to optimal acid / reflux suppression. 1 with outlet obstruction (peptic stricture) and 1 with co-existing spasm did not respond to medication.
Of 7 with functional heartburn (negative pH results), 2 with normal HRM responded to diet. 2 with symptomatic reflux during HRM had good response to acid-suppression (suggests false neg pH study). The final 3 all had outflow obstruction identified only during the meal; 1 had good outcome after dilatation, 1 was too frail for therapy and remains symptomatic and the last was lost to follow-up
CONCLUSION: HRM studies which include a test meal and postprandial observation provide an objective explanation for symptoms in the majority of patients investgated for 'reflux' symptoms. Long-term follow-up suggests this information can guide management.

P1588 PREDICTIVE VALUE OF ESOPHAGEAL MOTILITY TEST IN THE PROFICIENCY OF ESOPHAGEAL SPEECH

M. Sahin[1], T. Kirazli[1], R. Vardar[2,*], A. Bozan[1], F. Ogüt[1], S. Bor[2].
[1]*Otolaryngology,* [2]*Gastroenterology, Ege University, Izmir, Turkey*

INTRODUCTION: One of the speech rehabilitation methods following the total laryngectomy surgery is esophageal speech therapy. In this method where the success rates are rather low after the therapy, predetermining the patients to benefit from the therapy will be important to choose the appropriate method for speech rehabilitation and will also help in preventing the loss of cost, time and labour. In this study conducted in accordance with this purpose, the usability of manometric data, which was measured before the therapy with esophageal motility test, has been studied in order to predetermine the candidates suitable for esophageal speech.
AIMS&METHODS: This is a prospective clinical study performed multidisciplinarily in one center.51 male patients with total laryngectomy, mean age of 58.8±8.0, who haven't been exposed to any speech rehabilitation before are included in this study. Data is collected from 44 cases completing speech therapy which lasted for 6 months in total and consisted of 11 sessions. Manometric measures have been obtained through esophageal motility test and using water-perfusion system with Dent-Sleeve catheter on the patients before the therapy. In order to assess the level of esophageal speech Wepman used a scale for esophageal speech. Following the therapy, the patients were divided into two groups by considering the ones each of whose scores is 1, 2 or 3 are at the sufficient level and the ones each of whose scores is 4, 5, 6 or 7 are at the insufficient level according to this scale. Manometric correlation was studied between the 17 cases (Group I) which were able to reach esophageal speech at good level and 27 cases (Group II) which weren't.
RESULTS: The avarege manometric values of group 1 ve 2 are respectively; LES pressure 16.4 and 14.6 mmHg, peak amplitude 66.5 and 68 mmHg, contraction duration time 3.55 and 3.74 sn, onset velocity 3.40 and 3.43 cm/sn, UES pressure 17.2 ve 16.0 mmHg. There isn't any statistically significant difference between the groups could be observed in terms of age, period between the surgey and the beginning of speech therapy, type of neck dissection, having radiochemotherapy or not and manometric values of esophagus.
CONCLUSION: No predictive value of esophageal motility test was seen, which was carried out before the speech therapy given to the patients with total laryngectomy, on determining the esophagus speech level that the patient could reach.

P1589 UPPER GASTROINTESTINAL SYMPTOMS ARE RISK FACTORS FOR LOW BMI AND POOR QUALITY OF LIFE REGARDLESS OF THEIR MEAL RELATION

A. D'Alessandro[1,*], R. D'Aniello[1], I. Arnone[1], M. Pesce[1], F. P. Zito[1], M. Della Coletta[1], E. Efficie[1], R. Cuomo[1], G. Sarnelli[1]. [1]*University of Naples "Federico II", Naples, Italy*

INTRODUCTION: The impact of functional gastrointestinal symptoms on body weight is questionable. Obesity is associated with GERD, but we know that upper GI symptoms may negatively affect body weight by limiting food intake and reducing BMI. This is the case of early satiation as a predominant symptoms of meal-related functional dyspepsia. Whether upper gastrointestinal symptoms, less strictly related to meal assumption, are able to impact body weight is not known. AIM: To examine the contribution of specific upper gastrointestinal symptoms on BMI and quality of life.
AIMS&METHODS: The subjects were 126 consecutive patients referring to the outpatients clinic for upper gastrointestinal symptoms (44 male, age 46±13 years). All subjects had a clinical and instrumental (upper GI endoscopy and 24h pH-impedance) diagnosis of GERD or FD. Subjects with underlying organic diseases or on a low calories dietary regimen were excluded (n=74). BMI was recorded and patients divided in under-, normal-, overweight or obese according to internationally accepted criteria. Also, UGI-tract symptoms were scored according to the PAGI standardized questionnaire, assessing the type, the severity (10 symptoms, scored 0-5) and the impact on quality of life (30 items, scored 0-5) of specific symptoms.
RESULTS: According to clinical and instrumental criteria 62 patients were diagnosed to have functional dyspepsia, 64 GERD, while 40 had overlapping symptoms. Averaged BMI values were 24±4 Kg/m^2, with 10, 56, and 8 % of patients being underweighted, overweighted and obese, respectively. In FD patients BMI values were similar than in GERD patients (25±4 vs. 26±4 Kg/m^2, respectively). Notwithstanding the underlying diagnosis, in underweighted patients, the pooled symptoms severity was significantly higher than in normal, overweighted or obese patients (92±40 vs. 45±34, p=0.002), and this was also associated with a worsen quality of life (85±31 vs.39±30, p=0.001). Most interestingly, this association was still significant when we excluded from the analysis items assessing meal-induced symptoms (early satiation and appettite loss) (80±38 vs.41±31 and 85±35 vs.39±31, for severity and quality of life repectively, p=0.004 and p=0.0001).
CONCLUSION: Here we show that more severe upper GI symptoms are risk factors for low BMI even in the absence of meal-related symptoms. The mechanisms underlying this association are still unclear and likely reflect the impact of the poor quality of life on patients daily life and food consumption. Larger studies are warrant to investigate how meal-unrelated GI symptoms affects BMI.

P1590 BENEFICIAL EFFECT OF BUSPIRONE, AN ORALLY AVAILABLE 5-HT1A RECEPTOR AGONIST, ON LOWER ESOPHAGEAL SPHINCTER FUNCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS.

G. Karamanolis[1,*], A. Karlaftis[1], S. Panopoulos[2], D. Kamberoglou[1], K. Denaxas[1], P. Sfikakis[2], S. Ladas[1]. [1]*Hepatogastroenterology Unit, First Department of Propaedeutic and Internal Medicine,* [2]*Rheumatology Unit, First Department of Propaedeutic and Internal Medicine, UNIVERSITY OF ATHENS, Athens, Greece*

INTRODUCTION: Domperidone is widely used for the management of symptoms in patients with Systemic Sclerosis (SSc) and esophageal involvement, but its efficacy is under question. Recently, buspirone, an orally available 5-HT_{1A} receptor agonist, was shown to enhance esophageal peristalsis and lower esophageal sphincter (LES) function in healthy volunteers.
AIMS&METHODS: Aim: To evaluate the efficacy of acute buspirone and domperidone administration in SSc patients with symptomatic esophageal involvement
Methods: Thirty consecutive SSc patients (aged 52.3±10.4 years, 26 women) underwent high resolution esophageal manometry (HRM) before and 30 minutes after administration of 10 mg buspirone (n=20) or 10 mg domperidone (n=10). We compared buspirone and domperidone effects, before and after drug administration, on: a) resting pressure of the LES; b) residual pressure of LES relaxation; c) amplitude, duration, and onset velocity of distal esophageal body contractions. Prior to HRM each patient completed a self-reported 0-10 visual analogue scale questionnaire for esophageal symptoms (ESQ). A paired t-test was performed for the comparisons.
RESULTS: There was no difference in terms of SSc characteristics, as well as of clinical severity (assessed by ESQ scores) and extent (assessed by HRM findings) of esophageal involvement between patients who received buspirone or domperidone. Buspirone significantly increased mean resting pressure of LES (11.53±3.4 vs. 9.42±2.6, $p < 0.001$), whereas domperidone has no effect on it (8.64±2.6 vs. 9.09±3, p=0.469). Comparison of the mean individual changes after administration of either drug revealed that buspirone was superior to domperidone in enhancing the resting pressure of LES (2.11±2.0 versus -0.45±2.3, p=0.006). None of the drugs has any effect on the other examined parameters.
CONCLUSION: Acute administration of buspirone, but not of domperidone, enhanced function of LES in patients with SSc, suggesting a putative role of 5-HT_{1A} receptor-mediated interactions in these patients. Prospective studies to examine whether buspirone exerts a long term beneficial effect in SSc-associated esophageal disease are warranted.

P1591 POTENTIAL VALUE OF ESOPHAGEAL BASELINE IMPEDANCE IN DIFFERENTIATING FUNCTIONAL HEARTBURN FROM NON-EROSIVE REFLUX DISEASE

K. Wang[1,*], L.-P. Duan[1], C.-J. Zhong[1], Y.-J. Han[1]. [1]*Department of Gastroenterology, Peking University Third Hospital, Beijing, China*

INTRODUCTION: : In clinical practice still lacking a simple and effective method to identify functional heartburn (FH) and non-erosive reflux disease (NERD). Esophageal baseline impedance appears to represent esophageal mucosal integrity, and dilated intercellular spaces were found existing in NERD but not in FH.
AIMS&METHODS: The aims of the study were to analyze the difference of esophageal intraluminal baseline impedance in FH and NERD patients.
Patients with heartburn and health volunteers (control) were included. All subjects underwent gastroscopy to exclude organic diseases and reflux esophagitis. Following the 24h impedance-pH monitoring and PPI test, patients were divided into two groups: NERD, with overload acid reflux; FH, with normal range of reflux parameters and negative PPI test. The controls presented normal results on gastroscopy and 24h impedance-pH monitoring. Baseline impedance values (BIV) were selected. Esophageal epithelial intercellular space (ICS) was quantitatively measured on H&E sections under light microscopy.
RESULTS: 36 NERD (f/m=20/16, 55.3±2.7 y), 40 FH (f/m=33/7, 53.1±2.1 y) and 33 controls (f/m=27/6, 42.7±2.7 y) were enrolled. The BIV of NERD (2407.7±206.6 Ω) was significantly lower than that of FH (3014.7±162.6Ω, p=0.025) and controls (3360±215.9Ω, p=0.001). NERD [1.25(1.15-1.60)μm, n=11] presented wider ICS than that of FH [0.98(0.90-1.05)μm, n=10, p=0.009] and control [1.01(0.94-1.06)μm, n=11, p=0.005]. There were no different both in BIV and ICS between FH and controls. Negative correlation was observed between BIV and ICS (r = -0.545, p=0.002).
CONCLUSION: FH patients presented significantly higher BIV and lower ICS than NERD, and the BIV which negatively correlated to ICS can represent esophageal mucosal integrity. The BIV might be a potential parameter to differentiate the FH from NERD when the heartburn patients underwent 24 hour impedance-pH monitoring.

P1592 OVERLAP OF FUNCTIONAL GASTROINTESTINAL DISORDERS WITH AUTOIMMUNE CONDITIONS

M. Jones[1,*], A. Ford[2], N. Talley[3]. [1]*Psychology Department, Macquarie University, North Ryde, Australia,* [2]*Leeds Teaching Hospitals Trust, Leeds, United Kingdom,* [3]*Faculty of Medicine, University of Newcastle, Callaghan, Australia*

INTRODUCTION: The functional gastrointestinal disorders (FGIDs) affect up to one-third of community members and arise from unknown etiology. Previous studies have suggested that intestinal permeability is increased in individuals with FGIDs, which may allow stimulation of the immune system by luminal gut bacteria, perhaps triggering autoimmune conditions.
AIMS&METHODS: We aimed to identify whether specific FGIDs are associated with autoimmune conditions.
Electronic medical records were obtained from the United Kingdom THIN database (n=23,471). FGIDs and autoimmune conditions (endocrine, psoriasis, rheumatologic, multi-system, liver and lung) were identified using Read codes. Four groups were defined, healthy control (n=14,490), IBS (n=4,080), functional dyspepsia (n=4,131), chronic constipation (n=1,874). There was some overlap between the three FGID groups. The sample was 66% female and the majority was born prior to 1950, enabling a prolonged medical record review.
RESULTS: While the prevalence of all autoimmune conditions was low, FGID groups were generally associated with higher prevalence than healthy controls (Table 1). IBS was associated with higher rates of psoriasis (OR=1.88) which was independent of control variables (Table 1). FD was associated with higher rates of psoriasis (OR=2.00) and rheumatologic conditions (OR=1.60) which was independent of control variables (Table 1). This was also true for constipation (psoriasis OR=1.55, rheumatologic OR=1.41) (Table 1). FGIDs were associated elevated prevalence of other conditions but these failed to maintain statistical significance after holding control variables constant.

Table 1. Odds ratios for selected autoimmune conditions

	Disease	OR[1]	Lower	Upper	p-value	OR[2]	Lower	Upper	p-value
IBS	Endocrine	0.73	0.60	0.89	0.0020	0.82	0.64	1.04	0.0990
	Psoriasis	1.88	1.59	2.22	<0.0001	1.28	1.04	1.58	0.0210
	Rheumatological	0.95	0.75	1.20	0.6770	1.00	0.75	1.32	0.9750
FD	Endocrine	1.21	1.03	1.43	0.0220	1.00	0.84	1.20	0.9680
	Psoriasis	2.00	1.70	2.35	<0.0001	1.52	1.27	1.81	<0.0001
	Rheumatological	1.60	1.31	1.94	<0.0001	1.52	1.23	1.88	<0.0001
Constipation	Endocrine	1.18	0.94	1.49	0.1590	0.93	0.73	1.17	0.5210
	Psoriasis	1.55	1.22	1.96	<0.0001	1.40	1.10	1.78	0.0070
	Rheumatological	1.41	1.07	1.86	0.0160	1.37	1.03	1.82	0.0320

[1]Unadjusted
[2]Adjusted for age, gender, anxiety and depression

CONCLUSION: Primary care medical records indicate FGIDs have a clear association with a number of autoimmune conditions. This supports the possibility of immune activation in these disorders leading to autoimmune disease at remote sites

INTRODUCTION: Tricyclics and SSRIs are frequently used to treat functional dyspepsia (FD). However, their effect on meal tolerance is not clear.
AIMS&METHODS: To determine whether antidepressant use affects gastric volume in FD individuals. This study is a prospective, randomized, double-blind placebo-controlled trial at 8 sites. Inclusion criteria were: EGD within 5 years; no prior ulcers, esophagitis, abdominal surgery; no antidepressants; HADS <11. 292 subjects were randomized to 1 of 3 arms: 50mg amitriptyline(AMI), 10mg escitalopram(ESC), placebo(PLA). Balancing factors were gender, HADS, FD subtype, gastric emptying, satiety, BMI, race, and study site. A Nutrient Drink Test (NDT) for accommodation was performed by administering Ensure at 30mL/min. until participants were full. The Maximum Tolerated Volume (MTV) was reported as the primary outcome. An ITT analysis of covariance (baseline value and balancing factors) of the post NDT MTV was used to assess treatment effects.
RESULTS: The mean age of the 292 participants was 44 years, 219 (75%) were female, 250 (86%) were Caucasian, and 11 (4%) had an abnormal HADS score. Between the 3 arms, there were no differences in age or distribution of gender, race, FD subtype, or baseline gastric emptying or satiety results. After the 12 weeks of treatment, there was no differential treatment effect for the post-treatment NDT (mean MTV: PLA 839 v AMI 764 v ESC 823 ml, p=N. S.). There was a borderline significant interaction for treatment effect by FD subtype (p=0.09). Tests for interactions did not demonstrate differential treatment effect based on gender, age, BMI, baseline HADS, or baseline gastric emptying or NDT results.
CONCLUSION: The positive effects of amitriptyline and escitalopram on FD do not appear to affect gastric nutrient drink volume tolerated. Antidepressants may not help those patients with FD who have difficulty eating as their primary complaint.

P1594 WHAT EXPLAINS LONG-TERM USE OF PPI? A POPULATION-BASED, CROSS-SECTIONAL ANALYSIS IN DENMARK

A. Lødrup[1,*], C. Reimer[2], P. Bytzer[1]. [1]*Medical Department, Koege Hospital, Koege,* [2]*Department of Gastroenterology, Hvidovre Hospital, Copenhagen, Denmark*

INTRODUCTION: Long-term use of PPI has for the last decades continued to increase and is considered an important challenge in health care, influencing both the individual patient and the health care system in general. It is not fully understood what motivates long-term use in the general population.
AIMS&METHODS: The aim of the study was to describe variables associated with long-term use of PPI. An internet-based survey was conducted in September 2012 among members of a web-panel (n=18,427), representative of the Danish adult population. The survey included a total of 22 items on demographics, medication use, reasons for starting PPI therapy (*e.g.*heartburn/regurgitation, dyspepsia, ulcer prophylaxis), previous endoscopy, and ongoing acid-related symptoms. We defined long-term use as use of PPI in >1/3 of the last year. All variables were compared between long-term users and 'sporadic users' (use of PPI in <1/3 of last yr) by univariate analysis. Variables differing significantly between long-term users and sporadic users were included in a multivariate stepwise logistic regression model.
RESULTS: Total number of responders was 9,390 (mean age 48 yr, 49% males). Long-term use of PPI was reported by 584 (6%) and sporadic use by 693 (7%). Logistic regression identified six variables which significantly influenced the risk for long-term PPI use (table). Odds ratio for all six variables were adjusted for ongoing acid-related symptoms, which occurred at least monthly in 73% (95% CI: 71 – 75%) of long term-users and in 59% (56 – 62%) of sporadic users. Weekly or daily symptoms were reported by 58% (55 – 61%) of long-term users and by 28% (26 – 30%) of sporadic users.

Variable	Long-term users (N=584) N (%)	Sporadic users (N=693) N (%)	Odds ratio[α] (95% CI)

(continued)

Mean age [SD]	58 [14]	52 [17]	1.01 (1.00 – 1.02)$^{\beta}$
Male gender	314 (54)	319 (46)	1.5 (1.1 – 1.9)
Multiple (≥3) reasons for starting PPI therapy	136 (23)	95 (14)	1.7 (1.2 – 2.4)
PPI prescription renewal by telephone	443 (76)	260 (38)	4.5 (3.3 – 5.7)
Polypharmacy (≥4 types of medicine)	265 (45)	153 (22)	2.3 (1.7 – 3.1)
Previous endoscopy	388 (66)	291 (42)	1.6 (1.2 – 2.0)

α: All odds ratios were adjusted for ongoing symptoms. β: Odds ratio for age is per year.

CONCLUSION: Patients reporting multiple reasons for starting PPI therapy had an increased risk for long-term use, but no single specific reason, *e.g.* heartburn or ulcer prophylaxis, increased the risk significantly. Prescription renewal without seeing the doctor (by telephone), polypharmacy and male gender were important additional variables related to long-term use of PPIs.

P1595 GASTRO-ESOPHAGEAL REFLUX AND FOOD CONSUMPTION FREQUENCY

I. Chirila[1,2], F. D. Petrariu[1], V. L. Drug[3,4,*]. [1]*Department of Hygiene-Environmental Health, University of Medicine and Pharmacy „Grigore T Popa'', Iasi, Romania,* [2]*Department of Environmental Health, National Institute of Public Health,* [3]*Department of Gastroenterology and Hepatology, University of Medicine and Pharmacy „Grigore T Popa'', Iasi, Romania,* [4]*Department of Gastroenterology, Sf Spiridon University Hospital, Iasi, Romania*

INTRODUCTION: Gastroesophageal reflux simptoms and disease(GERD) are common conditions, with multifactorial pathogenesis. Obesity and GERD are clearly related, both from a prevalence and causality association. But diet may be associated with symptomatic gastro-oesophageal reflux independent of nutritional status.

AIMS&METHODS: The aim of the study was to determine the presence of gastro-esophageal reflux symptoms and the prevalence of gastro-esophageal reflux disease (GERD) in general urban population and to evaluate the type of diet associated with this pathology.

A randomized sample of subjects (n=300), representative for general urban population, selected from the family doctors patient lists was invited for interview in the doctor's office. Selected subjects were evaluated for recent symptoms using Gastrointestinal Symptom Rating Scale (GSRS), for the diagnosis of GERD using Montreal criteria and for their diet using a food frequency questionnaire.

RESULTS: In the last 7 days preceding the survey, were present relevant symptoms for gastro-esophageal reflux in 26.4% of investigated subjects and GERD was diagnosed in 31.1% of subjects. People aged over 50 years experienced an increased prevalence of recent symptoms (36.4 %, $p<0.001$) and GERD (37.4%, $p>0.05$). Recent symptoms were more frequently present in obese and overweighed than normal weighted subjects (42.5% and 29.5% versus 10.5%, p=0.001), and GERD was present especially in overweighed people (41.1%, p=0.015). Using median as cut-off point, the GERD subjects are eating significantly more frequent the following foods: processed meat, canned food, milk, animal fat, pulses, cereals or grain bread /pasta, vegetables with 5% of carbohydrates cafeteria products, fruit compotes (canned or not) ($p<0.001$), poultry, fish, cheese, potatoes, corn powder, coffee, herb teas and alcoholic beverages ($p<0.05$). Between GERD and non-GERD subjects was not significantly different consumption for the following type of foods: red meat, eggs, vegetable oils, 10 % carbohydrates vegetables, fruits, white bread, sugar and sweets. Using a multivariate analysis to reduce the confounding factors, predictors for GERD were age, overweight and certain food (grain cereals, canned and fatty food).

CONCLUSION: Gastro-esophageal reflux is highly prevalent in adult urban population and is associated with age, nutritional status and diet.

P1596 FACTORS ASSOCIATED WITH SYMPTOM MANIFESTATIONS IN EROSIVE ESOPHAGITIS

K. J. Lee[1,*], D. M. Lee[2]. [1]*Gastroenterology, Aou University Hospital,* [2]*Gastroenterology, Ajou University Hospital, Suwon, Korea, Republic Of*

INTRODUCTION: Some patients with erosive esophagitis (EE) suffer from symptoms associated with GERD, whereas others with an apparently similar esophagitis do not. Asymptomatic EE is found incidentally by screening endoscopy. The factors associated with symptom manifestations in EE are not clear.

AIMS&METHODS: We aimed to investigate the prevalence of symptomatic and asymptomatic EE in health check-up subjects and factors associated with symptom manifestations in EE.

Among consecutive 13342 adults who underwent EGD in health check-up programs from May 2010 to April 2011, 8840 subjects (5683 men, median age 45 years) were included in the analysis. They were asked to fill in the questionnaire including smoking and alcohol history, medication history, and the Hospital anxiety and depression scale. The presence and frequency of esophageal and dyspeptic symptoms were evaluated. The mucosal damage of the esophagus was assessed using the Los Angeles grading system.

RESULTS: Seven hundred and sixty-eight subjects were diagnosed as having GERD based on heartburn and/or acid regurgitation at least once per week. EE was observed in 675 out of 8840 subjects (7.6%). The prevalence of symptomatic and asymptomatic EE in the study subjects was 4.3% and 3.3%, respectively. Forty-three percent of individuals with EE had no esophageal symptoms. Male gender (OR, 1.71; 95% CI, 1.27-2.30, $P < 0.001$) and PDS (OR, 1.80; 95% CI, 1.15-2.82, $P = 0.010$) were independently associated with asymptomatic EE. Male gender (OR, 2.01; 95% CI, 1.52-2.66, $P < 0.001$), current smoking (OR, 1.32; 95% CI, 1.03-1.68, $P = 0.028$), anxiety (OR, 3.01; 95% CI, 1.72-5.28, $P < 0.001$), EPS (OR, 3.80; 95% CI, 2.88-5.01, $P < 0.001$), and PDS (OR, 1.93; 95% CI, 1.36-2.72, $P < 0.001$) were independently associated with symptomatic EE.

CONCLUSION: Asymptomatic EE is not uncommon in health check-up subjects. Current smoking, anxiety, and epigastric pain syndrome-like dyspepsia seem to be independent factors associated with symptom manifestations in EE.

P1597 IMPEDANCE–PHMETRY: RAPID AND ACCURATE ANALYSIS OF REFLUX SYMPTOM ASSOCIATION

A. Tenca[1,*], R. Penagini[1], I. Bravi[2], P. Campagnola[3], L. Benini[3], D. Sifrim[2]. [1]*Fondazione IRCCS "Cà Granda" Ospedale Maggiore Policlinico and Università degli Studi di Milano, Milano, Italy,* [2]*Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom,* [3]*Ospedale GB Rossi and Università degli Studi di Verona, Verona, Italy*

INTRODUCTION: Reflux-symptom association analysis (S.I. and S.A.P.) is an important tool to evaluate patients with reflux symptoms refractory to PPI treatment. An accurate calculation of S.I. and S.A.P. requires manual editing after automatic analysis of impedance-pHmetry tracings (MII-pH). Review of the whole tracing is time consuming and a shorter analysis confined to the time around symptomatic episodes is advocated in clinical practice, although its reliability has never been tested.

AIMS&METHODS: To assess if a ''short'' analysis provides similar results (i.e. identifies the same patients with positive reflux-symptom association) than a complete analysis and manual editing of the 24hs recording.

Forty consecutive patients underwent MII-pHrecordings (23 women, median age 55 years) to evaluate typical oesophageal symptoms (n=24) or cough (n=16) in two Italian Centers. After automatic analysis (MMS, Enschede, The Netherlands), tracings were anonymized and randomized. Three experienced observers trained in different centers independently performed a) review and editing of 24hs tracing and b)''short'' analysis confined to the 2 minutes-window period preceding each episode of the principal symptom. Both types of analysis were performed in different days and blinded to the results of each other. Values of Symptom Index (S.I.) and Symptom Association Probability (S.A.P.) for acid and non acid reflux were transformed into binary response (i.e. positive or negative). Percentage of concordance with confidence interval between 24hs analysis and ''short'' analysis was measured.

RESULTS: Concordance in classifying patients as S.I./S.A.P. positive or negative occurred in 37 (92.5%) to 40 (100%) out of the 40 patients (see table).

Percentage of concordance with confidence interval (in brackets) between 24hs analysis and "short" analysis.

	S.I.		S.A.P.	
	Acid	Non Acid	Acid	Non Acid
Observer 1	100 (91-100)	100 (91-100)	100 (91-100)	97.5 (85-100)
Observer 2	97.5 (85-100)	95 (82-99)	97.5 (85-100)	92.5 (78-98)
Observer 3	97.5 (85-100)	100 (91-100)	100 (91-100)	100 (91-100)

CONCLUSION: Positive/negative reflux symptom association determined after "short" analysis of MII-pH recordings was highly predictive of results after the complete 24hs analysis. A "short" analysis confined to the time around symptomatic episodes is quick and reliable and can be adopted in routine clinical practice.

P1598 THE REAL PREVALENCE OF FUNCTIONAL HEARTBURN: THE LESSON OF PROLONGED WIRELESS PH MONITORING.

R. Penagini[1,*], R. Sweis[2], A. Mauro[1], G. Domingues[3], D. Sifrim[4].
[1]Gastroenterology Unit 2, Università degli Studi di Milano, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [2]Oesophageal lab, Guys and St Thomas' NHS Foundation Trust, London, United Kingdom, [3]State University of Rio de Janeiro, Rio de Janeiro, Brazil, [4]Bart's and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom

INTRODUCTION: Functional heartburn (FH) is diagnosed in patients with heartburn refractory to PPIs when endoscopy, oesophageal acid exposure time (AET) and symptom index (SI) are negative (Rome III criteria). The diagnosis of FH is important for management, however it stands on fragile pH monitoring variables, i.e. symptoms are often absent or, when present, few, making symptom/reflux association indexes less reliable and AET is known to vary from day to day.

AIMS&METHODS: To assess consistency of diagnosis of FH during 48 to 96 hrs wireless oesophageal pH monitoring (BRAVO). 50 PPI refractory patients (11M, 48 yrs; 38-57) with heartburn as dominant complaint and a diagnosis of FH according to Rome III in the first 24-hr of monitoring were retrospectively analysed as part of an international collaboration study (Brazil, Italy and UK). pH variables were analysed in the following 24-hrs periods to determine if tracings were indicative of diagnosis of NERD (either AET > 5% or normal AET and SI > 50%, provided patients had at least 3 heartburn episodes/day). Only days with at least 22 hrs recordings were included. Patients were reclassified as FH or NERD at the end of the test. Non parametric statistics and chi-squared test were used when appropriate.

RESULTS: (median, IQR) 15 out of 50 patients had a pathological AET after the first day of monitoring (10 in the second day and 5 in subsequent days), which changed their diagnosis from FH to NERD. In one patient SI became positive after the first day, but this had no influence on patients classification as it occurred together with pathological AET. There was a trend toward a younger age in the 35 FH vs. the 15 newly diagnosed NERD (45 yrs; 38-55 vs 55 yrs; 46-59, p=0.086) whereas gender composition did not differ (F 77% vs 80%, p=ns). First day AET (0.9%; 0.5-2.7 vs 2%; 1.3-2.6, p=ns), number of HB episodes in the first day (1; 0-4 vs 1; 0-4, p=ns) or during the whole monitoring (3; 0-6 vs 4; 1-12, p=ns) were not different between FH and NERD.

CONCLUSION: One third of patients classified as FH at 24-hr pH-monitoring can be re-classified as NERD after a more prolonged pH recording period and needs to be adequately treated with PPIs before excluding a role of gastro oesophageal reflux in clinical presentation. Furthermore anti-reflux surgery becomes a therapeutic option in these patients. Our data suggest usefulness of 48-hr catheter or 48 to 96-hr wireless studies for diagnosis of FH.

P1599 ESOPHAGEAL WORK-UP PRIOR TO BARIATRIC SURGERY: WHO AND HOW TO INVESTIGATE

B. Heimgartner[1,*], M. Herzig[1], Y. Borbély[1], P. Nett[1], R. Tutuian[1]. *[1]Viszerale Chirurgie und Medizin, Inselspital Bern, Bern, Switzerland*

INTRODUCTION: Gastroesophageal reflux disease (GERD) is more common in obese patients. Investigators advocate endoscopy and reflux monitoring prior to bariatric surgery as these operations influence GERD in different ways.

AIMS&METHODS: Our aim was to assess the prevalence of reflux symptoms and objective findings in a group of obese patients scheduled for bariatric surgery. The pre-operative work-up included quantification of esophageal symptoms (VAS-scores for intensity and frequency), upper GI endoscopy and 24-h impedance-pH (imp-pH) monitoring off PPI therapy. Esophagitis and/or Barrett's esophagus if present, were recorded according to Los Angeles respective Prague classification systems. Ambulatory imp-pH monitoring was classified as abnormal if either %time pH < 4 was abnormal (total > 4.2%, upright > 6.3%, recumbent > 1.2%), number of total (acid and non-acid) reflux episodes was > 73/24 hours or symptom index (SI) was > 50%.

RESULTS: The analysis included data from 100 consecutive patients (69f, age 40 ± 11y, BMI 44.9 ± 6.9 kg/m^2) investigated between Jan 2011 and Dec 2012. Overall 54% of patients reported typical reflux symptoms, 71% of patients had evidence of reflux disease (38% erosive esophagitis/Barrett's esophagus and 33% non-erosive reflux disease). A total of 11/38 (29%) patients with endoscopic visible lesion had normal imp-pH recordings whereas 27/60 (45%) patients with abnormal imp-pH recordings had erosive lesions. The sensitivity of endoscopy alone was inferior to imp-pH alone to identify GERD (54% vs. 85%, p < 0.01). Test accuracy for endoscopy and 24h imp-pH were 67% and 89% respectively.

Endoscopic visible lesions were present in 37% of symptomatic and 39% of asymptomatic patients (p=ns). Abnormal imp-pH findings were present in 68% of symptomatic and 50% of asymptomatic patients (p=ns). Typical GERD symptoms were not predictive of the presence of erosive or non-erosive reflux disease: 41/54 (76%) patients reporting heartburn/regurgitation had evidence of reflux disease as did 30/46 (65%) asymptomatic patients (p=ns).

CONCLUSION: Half of obese patients evaluated prior to bariatric surgery report typical GERD symptoms and more than two-thirds have objective evidence of GERD. Reflux monitoring is superior to endoscopy in detecting GERD, yet a substantial number of patients with erosive esophagitis have "normal" esophageal acid exposure. Since typical reflux symptoms do not predict the presence of esophagitis and abnormal acid exposure, endoscopy and reflux monitoring should be part of the pre-operative work-up prior to bariatric surgery.

P1600 QUANTIFICATION OF GASTROOESOPHAGEAL REFLUX BY MULTICHANNEL INTRALUMINAL IMPEDANCE AND PH-MONITORING IN PATIENTS WITH DENTAL EROSIONS

C. Wilder-Smith[1,*], A. Materna[1], A. Lussi[2]. *[1]Gastroenterology Group Practice, Brain-Gut Research Group, [2]Department of Preventive, Restorative and Pediatric Dentistry, University of Bern, Bern, Switzerland*

INTRODUCTION: Silent, i.e. asymptomatic acidic distal gastrooesophageal reflux (GERD) has been shown to be common in patients with advanced dental erosions[1]. However, the prevalence of weakly acidic and of proximal oesophageal GERD in these patients is unknown, but is of crucial importance in the pathophysiology of reflux-associated dental erosions. The aim of this study was to for the first time quantify these reflux variables by multichannel intraluminal impedance and pH-monitoring (MII-pH).

AIMS&METHODS: All successive patients presenting to the University of Bern Dental Clinic 2010-2012 with at least medium dental erosions (Lussi erosion index > 1 or BEWE > 8), without symptoms of reflux (less than once per week) and without GERD treatment were referred for oesophageal 24-hour MII-pH after exclusion of extrinsic and non-reflux causes of dental erosions. The numbers of acidic (pH < 4) and weakly acidic (pH 4-7) reflux episodes, the % time with pH < 4 and < 5.5 and the percentage of proximal oesophageal reflux episodes below a pH-threshold of 4 are reported.

RESULTS: 95 successive patients (56 males, mean age (range) 34yr (9-67) with advanced dental erosions (mean (95%CI) BEWE 13 (12.4-13.7)) were studied. The mean DeMeester score was 48.6 (9.2-99.2) and in the distal oesophagus the mean % time with pH < 4 was 8.8 (5.5-12.1) and with pH < 5.5 was 40.0 (36.0-44.0). The mean numbers of acidic and weakly acidic reflux episodes were 78 (68-88)(normal upper limit < 50 episodes) and 31 (25-37)(normal upper limit < 33 episodes), respectively. 33% (29-37) of all acidic reflux episodes reached the proximal oesophagus.

CONCLUSION: In patients presenting to a tertiary care dental clinic with advanced dental erosions acidic reflux is markedly increased compared to normal values, is much more common than weakly acidic reflux and frequently reaches the proximal esophagus. The reason for the development of dental erosions in association with the paucity of symptoms despite the acidity of the reflux needs to be explored further.

P1601 DIFFERENT ACCURACY OF VARIOUS IMPEDANCE-PH NORMAL VALUES IN DIAGNOSING GERD IN PATIENTS WITH PROVEN OR HIGHLY SUSPECTED REFLUX DISEASE

E. Savarino[1,*], N. de Bortoli[2], M. Furnari[3], D. Pohl[4], G. C. Sturniolo[1], S. Marchi[2], R. Tutuian[5], V. Savarino[3]. *[1]Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, [2]Department of Internal Medicine, Univesrsity of Pisa, Pisa, [3]Department of Internal Medicine, University of Genoa, Genoa, Italy, [4]Division of Gastroenterology and Hepatology, University Hospital Zurich, Zurich, [5]Division of Gastroenterology and Hepatology, University Hospital Bern, Bern, Switzerland*

INTRODUCTION: Since the introduction of impedance-pH monitoring in clinical practice different normal values have been proposed in order to diagnose gastroesophageal reflux disease (GERD). The most common used [i.e. the United States (US), Belgian-French (BF) and Italian (ITA) normal values] have different

upper limit of normal for esophageal acid exposure time (AET) and total number of reflux episodes (NREs), the two main parameters used to distinguish normal from abnormal GER.
AIMS&METHODS: To evaluate whether using different normal values influences the final impedance-pH diagnosis of GERD. In this multicenter study, 40 consecutive patients reporting heartburn and regurgitation with proven reflux disease (n=20 with erosive esophagitis) or strong evidence of GERD (n=20 with positive PPI test) underwent 24-h impedance-pH testing off-therapy. Twenty patients ate a standardized Mediterranean diet, while 20 patients were asked to follow a free diet. We evaluated distal AET (% time pH < 4), NREs, symptom association analysis using both symptom association probability (SAP+ if ≥95%) and symptom index (SI+ if ≥50%). GERD was diagnosed in case of abnormal AET or increased NREs according to different normal values.
RESULTS: No differences were found regarding the frequency of patients with abnormal values of AET, NREs and positive symptom association analysis based on the type of diet (Table). Diagnosis of GERD was done in 15 (38%) patients using US values, in 17 (43%) using BF values and in 30 (75%) using ITA values (US vs. ITA p=0.001; US vs. BF p=0.820 and ITA vs. BF p=0.006).

Patients with Abnormal Values

	Whole Population (n=40)	Patients with Standardized Diet (n=20)	Patients with Free Diet (n=20)	p Value
ITA Normal Values (Am J Gastroenterol 2008;103:1–9)				
AET,% (n=4.2)	26 (65%)	13 (65%)	13 (65%)	1,0000
NREs, n (n=54)	21 (53%)	11 (55%)	10 (50%)	1,0000
BF Nomal Values (Aliment Pharmacol Ther 2005;22:1011–1021)				
AET,% (n=5.0)	10 (25%)	5 (25%)	5 (25%)	1,0000
NREs, n (n=75)	10 (25%)	6 (30%)	4 (20%)	0,7370
US Normal Values (Am J Gastroenterol 2004; 99:1037–43)				
AET,% (n=6.3)	7 (18%)	4 (10%)	3 (8%)	1,0000
NREs, n (n=73)	11 (28%)	7 (35%)	4 (20%)	0,5179
Symptom-Reflux Association				
SAP/SI+ for acid reflux	29 (73%)	15 (75%)	14 (70%)	1,0000
SAP/SI+ for non-acid reflux				
SAP/SI+ for acid/ non-acid reflux	7 (18%)	4 (10%)	3 (15%)	1,0000
	31 (78%)	17 (85%)	14 (70%)	0,6466

CONCLUSION: Our findings demonstrate that the use of US and BF normal values in Swiss/Italian patients with symptoms suggestive of reflux disease underestimate the presence of GERD, independently of the diet followed during the monitoring.

P1602 IMPEDANCE-PH EXPLORES WITH MORE ACCURACY THAN PH-METRY ALONE THE RELATIONSHIP BETWEEN ASPIRATION OF GASTRIC CONTENTS AND GASTROESOPHAGEAL REFLUX IN PATIENTS WITH IDIOPATHIC PULMONARY FIBROSIS

E. Savarino[1,*], P. Zentilin[2], M. Furnari[2], N. de Bortoli[3], S. Marchi[3], V. Savarino[2]. *[1]Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, [2]Department of Internal Medicine, Division of Gastroenterology, University of Genoa, Genoa, [3]Department of Internal Medicine, Division of Gastroenterology, University of Pisa, Pisa, Italy*

INTRODUCTION: Previous studies demonstrated that patients with idiopathic pulmonary fibrosis (IPF) have risk of gastric aspiration [i.e. increased bile acids (BAs) and pepsin in saliva] or definite gastric aspiration [i.e. BAs or pepsin in broncho-alveolar lavage (BAL)]. However, these studies evaluated the association between gastroesophageal reflux (GER) and IPF by means of pH-metry, that has been recently overtaken by the novel impedance-pH monitoring (i.e. ability to detect acid re-reflux and non-acid reflux).
AIMS&METHODS: To assess in biopsy-proven IPF patients the relationship between the presence and concentration of BAs and pepsin in saliva/BAL and the severity of reflux disease expressed by esophageal acid exposure time (AET) and number of reflux episodes (NREs).
Saliva and BAL samples were collected in 38 and 21 IPF patients. All subjects underwent esophageal manometry and impedance-pH testing off therapy. BAs and pepsin were measured using two commercial assays. During manual analysis of impedance-pH testing, we measured AET (normal if <4.2%) and total number of acid and non-acid reflux episodes (normal if <54).
RESULTS: BAs and pepsin were found in saliva of 61% and 68% and in BAL of 62% and 67% IPF patients. Two out of 23 and 2/26 of IPF patients with BAs and pepsin in saliva had a normal AET, while only 1/23 and 1/26 had a total normal NREs, respectively. None out of 13 and 14 IPF patients with BAs and pepsin in BAL had a normal AET or a total normal NREs. Overall, all IPF with BAs or pepsin in saliva or BAL had an abnormal impedance-pH test (i.e. abnormal AET or NREs). Data on the relationship between presence/concentration of BAs and pepsin and severity of GER are found in the Table below. The higher value of correlation has been found between total NREs and presence of pepsin and BAs in saliva and BAL.

	AET	Total NREs
Presence of Pepsin in Saliva	r^2=0.2193 (p=0.003)	r^2=0.4007 (p<0.001)
Presence of BAs in Saliva	r^2=0.1493 (p=0.017)	r^2=0.5264 (p=0.001)
Concentration of BAs in Saliva	r^2=0.0129 (p=0.606)	r^2=0.0712 (p=0.218)
Presence of Pepsin in BAL	r^2=0.2344 (p=0.026)	r^2=0.2845 (p=0.013)
Presence of BAs in BAL	r^2=0.3660 (p=0.004)	r^2=0.4566 (p=0.001)
Concentration of BAs in BAL	r^2=0.0427 (p=0.498)	r^2=0.3558 (p=0.031)

CONCLUSION: Presence and concentration of BAs and pepsin in saliva and BAL correlate better with impedance-detected reflux episodes than with esophageal AET. Thus, impedance-pH is a more accurate tool to define the relationship between gastric aspiration and GER in this particular cohort of patients.

P1603 PLASMA ADIPONECTIN LEVEL AND IT'S CLINICAL VALUE IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE AND ARTERIAL HYPERTENSION

E. Kitaeva[1], O. Khlynova[1,*], A. Tuev[1], L. Vasiletz[1]. *[1]Perm State Medical Academy, Perm, Russian Federation*

INTRODUCTION: Adiponectin, an adipocyte-derived plasma protein, is considered to be an important modulator for metabolic and vascular diseases. The role of adiponectin in the context of cardiovascular risk assessment and stratification is currently receiving growing attention. The relations between adiponectin level and gastroesophageal reflux disease (GERD) remain unclear.
AIMS&METHODS: to investigate the plasma adiponectin level in hypertensive patients with different levels of blood pressure (BP) and different risk of cardiovascular events, to study adiponectin level in patients with different variants of GERD, and to examine whether the level of adiponectin could have an additive effect on subclinical target organ damage in these groups of patients. 40 patients with AH and 40 patients with GERD were enrolled into a study. Among patients with arteria hypertension (AH) 10 patients suffered from the 1st grade of hypertension and had low cardiovascular risk (CVR); 25 patients had moderate grade of hypertension, moderate (16 patients) and high (3 patients) CVR, and 5 patients had severe AH. The group of patients with GERD was performed by 29 patients without endoscopic signs of esophagitis, 8 patients with reflux-esophagitis, 2 patients with Barrett's esophagus, and 1 patient with esophageal adenocarcinoma. The group of comparison was performed by 20 healthy individuals. All patients were comparable with patients of the main group. Plasma adiponectin concentrations were measured with an enzyme-linked immunosorbent assay (ELISA) method. Differences between the groups at baseline and maximum changes from baseline were determined with a Mann-Whitney *U* test. Differences were considered significant with a $P < 0.05$.
RESULTS: Both men and women with AH when compared with patients with GERD exhibited significantly lower plasma adiponectin levels (9,45 vs. 15,46 mg/ml in women, 8,24 vs. 12 mg/ml in men, $P < 0.05$. Hypoadiponectinemia was significantly and independently correlated with cardiovascular risk in patients with AH. In patients with GERD increased circulating adiponectin levels were associated with erosive esophagitis ($p < 0,05$). Plasma adiponectin concentrations were negatively correlated with grade of AH and extent of erosive esophagitis. When counted in patients with both AH and GERD, the adiponectin plasma level was the same as in group of healthy individuals.
CONCLUSION: Our study demonstrates that adiponectin appears to serve as a biomarker for progressive course of AH in patients with high CVR. At the same time, plasma adiponectin level is closely connected with the extent of mucose damage in patients with GERD

P1604 IMPAIRED OESOPHAGEAL MOTILITY IS MORE RELATED TO EROSIVE OESOPHAGITIS THAN REFLUX SYMPTOM GENERATION

F. Izbéki[1,*], A. Rudas[1], I. Hritz[1], A. Légner[2], Á. Altorjay[2], T. Wittman[3], A. Rosztóczy[3]. *[1]1st Department of Medicine, [2]Department of Surgery, SAINT GEORGE UNIVERSITY HOSPITAL, SZÉKESFEHÉRVÁR, [3]1st Department of Medicine, University of Szeged, Szeged, Hungary*

INTRODUCTION: Decreased oesophageal motility has been described in patients with GORD; however it is not clear if this impairment is consequence or cause of increased acid exposure. Since non-acid reflux is known to cause symptoms and may contain pancreatic enzymes and bile as well, it may be harmful to the oesophageal motility.
AIMS&METHODS: The aim of the study was to investigate the oesophageal motility in patients with symptomatic acidic and non-acidic reflux with or without erosive oesophagitis (EO).
Fifty-four patients (age: 44(18-73) years; male 21; female: 33) with suspected GORD or symptoms refractory to double dose PPI treatment were underwent upper gastrointestinal endoscopy, oesophageal manometry and Multichannel

intraluminal impedance and pH (MII-pH) monitoring. The presence of oesophagitis was graded according to the Los Angeles (LA) system. On manometry lower oesophageal sphincter (LOS) pressure, duration of relaxation, complete bolus transit, distal oesophageal amplitude and velocity were evaluated. During pH-MII acid refluxers were defined by abnormal DeMeester score, or either having positive acid reflux indices and/or positive symptom correlation with positive Symptom Association Probability (SAP) and/or positive Symptom Index (SI). Non-acid refluxers were defined by having positive symptom correlation to non-acid reflux events (SAP and/or SI) without positive acid reflux indices of abnormal % time pH <4, and normal DeMeester score.

RESULTS: Fifty-nine per cent (32/54) of the patients were predominantly acid refluxers and 41% (22/54) had primarily non-acidic reflux. EO was seen in 12 of the 32 acid refluxers (37.5%) but none in the group with non-acid reflux. The severity of EO ranged between LA-A and C with 4 patients in each category. No significant difference was observed between the groups with respect to LOS pressures, duration of LOS relaxation, complete bolus transit, distal oesophageal amplitude and velocity. In contrast, patients with EO and acid reflux had significantly lower LOS pressure, distal oesophageal amplitude and velocity compared either to non-acid relfuxers or to acid refluxers without EO. Furthermore, the number of acid reflux episodes in supine position was twice higher than in patients without EO.

CONCLUSION: While patients with acidic reflux and EO had commonly impaired oesophageal motility, subjects without erosions had mostly normal motility irrespectively to the acidic or non-acidic type of their reflux. These data suggest that oesophageal dysmotility is less important in the development of reflux symptoms than mucosal damage.

P1605 CAN 3-HOUR POST-PRANDIAL ANALYSIS PREDICT THE DIAGNOSIS OF GERD MADE ON 24-HOUR IMPEDANCE-PH TESTING?

M. Furnari[1,*], E. Marabotto[1], A. Moscatelli[1], N. de Bortoli[2], L. Bruzzone[1], L. Gemignani[1], P. Zentilin[1], V. Savarino[1], E. Savarino[3]. [1]*Di.M.I., Gastroenterology Unit, UNIVERSITY OF GENOA, GENOA, ITALY, genoa,* [2]*Gastroenterology Unit, university of Pisa, Pisa,* [3]*Gastroenterology Unit, University of Padua, Padua, Italy*

INTRODUCTION: Esophageal 24-hour Multichannel Intraluminal Impedance-pH (MII-pH) testing is the gold standard investigation to diagnose gastroesophageal reflux disease (GERD). Recently we applied this technique to evaluate post-prandial (PP) reflux patterns in GERD patients and controls observing that the majority of reflux events occur during the 1st PP hour. It is well known that manual analysis of MII-pH tracings is mandatory because of the well-known drawbacks of the current automated diagnostic software.

AIMS&METHODS: To assess whether the manual analysis of PP period alone may be used to diagnose GERD, using the 24-hour test as reference standard. We studied 30 patients with functional heartburn [FH; 21F; mean age 50y], 40 with pH-positive non-erosive reflux disease [pH-POS NERD; 28F; 49.5y] and 30 with erosive esophagitis [EE; 15F; 43.5y]. We also enrolled 25 healthy volunteers [HVs; 8F; 25y] for normal values. All patients underwent upper endoscopy, manometry and MII-pH studies off-therapy. During the 24-h study, patients and HVs ate three standard meals. Acid exposure time (AET) and total number of reflux events were assessed during the 24-h period and during the 1st hour after each meal. A test was considered abnormal/positive for GERD when AET was >4.2 and/or total number of refluxes were >54 in case of the 24h-analysis and when AET was >4.6 and/or total number of refluxes were >21 in case of the 3-h PP-analysis.

RESULTS: None of the HVs had abnormal PP- or 24h-analysis. Out of 30 patients with FH, 26 (87%) were negative for both evaluations, whereas 4/30 (13%) had a positive PP- and a negative 24h-analysis. Among pH-POS NERD patients, 32/40 (80%) had both positive PP- and 24h-analysis, whereas 8/40 (20%) had negative PP- but positive 24h-analysis. Patients with EE were positive for both analyses in 20/30 (67%) cases and both negative in 1/30 (3%) cases. Moreover, 4/30 (13%) had positive PP- but negative 24h-analysis, whereas 5/30 (17%) had negative PP- but positive 24h-analysis. Overall, compared to the 24-h manual analysis, the 3-h PP manual analysis showed an accuracy of 0.83 (IC95% 0.76-0.90), a sensitivity of 0.80 (0.70-0.90), a specificity of 0.87 (0.77-0.96), a positive predictive value of 0.87 (0.78-0.95) and a negative predictive value of 0.80 (0.70-0.90) in diagnosing GERD.

CONCLUSION: Our data show that MII-pH manual analysis of the 3-h PP period alone may be used to diagnose GERD. This finding is particularly relevant in case of failure of 24h MII-pH monitoring due to technical drawbacks or in case of limited time to manually analyze each tracing in clinical practice.

P1606 GASTRO-ESOPHAGEAL REFLUX DISEASE SYMPTOMS IN AGED PATIENTS

M. Hojo[1,*], A. Nagahara[1], D. Asaoka[1], H. Ueyama[1], H. Sasaki[1], Y. Shimada[1], K. Matsumoto[1], S. Watanabe[1]. [1]*Gastroenterology, Juntendo University School of Medicine, Tokyo, Japan*

INTRODUCTION: Aged patients may tend to have milder symptoms than younger patients, possibly resulting in delayed diagnosis. Because severe reflux esophagitis (RE) sometimes causes complications with bleeding or stenosis, quick diagnosis of severe RE is important. The difference of gastro-esophageal reflux disease (GERD) symptoms between aged and younger RE patients has not been fully studied so far.

AIMS&METHODS: The aim of this study is to examine if there is any difference in the degree of the GERD symptoms between aged and younger RE patients. The inclusion criteria of subjects were as follows: subjects who took an upper endoscopic examination in Juntendo university from April in 2008 to March in 2013, and were diagnosed as Los Angeles classification (LA) grade A, B, C, or D; subjects who did not take any proton pump inhibitors, H_2 receptor antagonists, non-steroidal anti-inflammatory drugs, and aspirin; subjects who did not suffer from organic diseases except RE; and subjects who answered the questionnaire of frequency scale for the symptoms of GERD (FSSG). Aged and younger subjects were defined as patients aged 65 or over and less than 65, respectively. Statistical analysis was performed using Student's t test. The level of statistical significance was set at 0.05.

RESULTS: 596 subjects were examined. 184 subjects (mean age 71.1 years; 114 males) were classified into the aged patient group, and 412 subjects (mean age 51.2 years; 307 males) were classified into the younger group. The average of the FSSG score in the aged patient group was 6.7, whereas the average of the FSSG score in the younger group was 8.4. Significant difference between the two groups was observed ($p=0.0024$). Similar results were also obtained in reflux symptoms of the FSSG questionnaire and dysmotility symptoms. Further analyses on the basis of gender indicated that all the scores examined in the aged patients were less than those in the younger patients. When esophagitis severity was examined, although the score of the aged group was less than that of the younger group in mild esophagitis of LA grade A and B (the scores of the aged and younger groups were 6.6 and 8.4, respectively; $p=0.002$), the score of the aged group was almost equal to that of the younger group in severe esophagitis of LA grade C and D (the scores of the aged and younger groups were 8.5 and 8.7, respectively; $p=0.47$).

CONCLUSION: The aged RE patients likely tend to have minor symptoms compared with the younger RE patients; however, no significant difference regarding severe esohagitis was observed between them. The findings suggest that there may be no significant, age-related differences in complaining of GERD symptoms in severe RE patients.

P1607 HISTOLOGICAL DIAGNOSIS OF GASTROESOPHAGEAL REFLUX DISEASE: INTER-ASSESSOR AGREEMENT

M. Vieth[1,*], N. Vakil[2], J. Dent[3], I. Baldycheva[4], B. Wernersson[5], M. Ruth[5], L. Mastracci[6], R. Fiocca[6]. [1]*Klinikum Bayreuth, Bayreuth, Germany,* [2]*University of Wisconsin School of Medicine and Public Health, Madison, United States,* [3]*Royal Adelaide Hospital and University of Adelaide, Adelaide, Australia,* [4]*AstraZeneca R&D, Wilmington, United States,* [5]*AstraZeneca R&D, Mölndal, Sweden,* [6]*University of Genoa, Genoa, Italy*

INTRODUCTION: Definitions of standardized criteria for histological assessment of gastroesophageal reflux disease (GERD) have been developed and evaluated by an international working group.[1,2] Using these criteria, we showed previously that total epithelial thickness and papillary length measured at 0.5 cm and 2.0 cm above the Z-line are significant predictors of GERD.[3] Here, we report on inter-assessor agreement in these measurements.

AIMS&METHODS: Inter-assessor agreement in measurement of histological markers for GERD was assessed using biopsies from the Diamond study (NCT00291746).[4] The study included primary care patients who had not taken a proton pump inhibitor in the previous 2 months, and who had upper gastrointestinal symptoms of any severity on $\geq$2 days/week for $\geq$4 weeks and of at least mild severity on $\geq$3 days in the week before the study. GERD was diagnosed when at least one of the following was present: reflux esophagitis (Los Angeles grades A–D); pathological esophageal pH (<4 for $>5.5\%$ of the time); positive symptom association probability ($\geq$95%). Biopsies were collected at 0.5 cm and 2.0 cm above the Z-line (3 o'clock position) and were analysed independently in a single-blind manner by assessors at two pathology centres (MV; RF/LM). Variables assessed included total epithelial thickness, basal cell layer thickness and papillary length (all in μm), and dilated intercellular spaces (severity score: 0–2).

RESULTS: Our histology analyses included biopsies from 117 patients with and 78 without investigation-diagnosed GERD. The two independent readings were in agreement ($p>0.05$) for total epithelial thickness (error count rate from MV: 0.39, from RF/LM: 0.39; estimated difference in two independent readings: 16.78; standard error [SE]: 10.57; $p=0.11$) and for basal cell layer thickness (error count rate from MV: 0.52, from RF/LM: 0.35; estimated difference in two independent readings: –1.82; SE: 4.19; $p=0.66$) at 2.0 cm above the Z-line. Results were comparable at 0.5 cm above the Z-line. There was significant disagreement between readings for papillary length and dilated intercellular spaces, at both 0.5 cm and 2.0 cm above the Z-line.

CONCLUSION: These analyses further support the conclusion that total epithelial thickness is a robust histological marker for GERD.

P1608 CAN APPEARANCE OF GASTROESOPHAGEAL FLAP VALVE BE A USEFUL PREDICTOR OF GASTROESOPHAGEAL AND ASSOCIATED LARYNGOPHARYNGEAL REFLUX STATUS?

M. Kaplan[1,*], Y. Yazgan[1], A. Tanoglu[1], M. Kara[1], K. Oncu[1], E. Erkul[2], I. Kucuk[1], H. O. Ozari[1]. *[1]Gastroenterology Department, [2]Otorhinolaryngology Department, GATA Haydarpasa Training Hospital Istanbul/Turkey, Istanbul, Turkey*

INTRODUCTION: Gastroesophageal flap valve (GEFV) is related as one of the common etiologic factors of reflux symptoms. We want to evaluate the effects of GEFV on laryngopharyngeal symptoms and signs in patients with gastroesophageal reflux (GER) and suspected laryngopharyngeal reflux (LPR).
AIMS&METHODS: Two hundred and fifty seven consecutive patients (151 men and 106 women; mean age 50,22 years) who underwent routine endoscopy were enrolled to our study. Symptoms of laryngopharygeal and upper gastrointestinal systems and endoscopic severity of esophageal and gastric mucosal injury were correlated to GEFV grades according to the Hill classification. GEFV was graded I through IV using Hill's classification. The GEFV was largely classified into two groups: Normal GEFV group (grades I) and the abnormal GEFV group (grades II-III and IV). The reflux symptom index (RSI) was used as the diagnostic method for LPR. The statistical analyses were made according to the changes in the severity and frequency of each symptom and sign.
RESULTS: The incidence of symptoms of laryngopharygeal and gastroesophageal reflux diseases were associated with abnormal GEFV grades. The frequency of abnormal valves (Hill grades II-III and IV) was 30,7%. Of these, 47,4% had erosive esophagitis (EE). The majority of patients with EE were classified as Los Angeles Classification Grades A and B (33,1 and 3,9%, respectively). Correlations and differentiation between the reflux symptom index with gastroesophageal flap valve grade and gastroesophageal reflux were investigated by the Spearman correlation test ($p<0,01$ and $p>0,05$ respectively).
CONCLUSION: Endoscopic grading of GEFV is simple and provides useful diagnosis on the status of laryngopharygeal and gastroesophageal reflux. But we did not find any correlation between reflux symptom index with gastroesophageal reflux as Los Angeles classification.

P1609 ESOPHAGEAL IMPEDANCE BASAL VALUES IN PATIENTS WITH PATHOPHYSIOLOGICAL CHARACTERISTICS OF FUNCTIONAL HEARTBURN.

N. de Bortoli[1,*], I. Martinucci[1], E. Savarino[2,3], R. Franchi[1], L. Bertani[1], M. Furnari[3], M. Bellini[1], V. Savarino[3], S. Marchi[1]. *[1]Gastroenterology Unit, UNIVERSITY OF PISA, Pisa, [2]Division of Gastroenterology, University of Padua, Padua, [3]Gastroenterology Unit - DIMI, University of Genoa, Genoa, Italy*

INTRODUCTION: Proton pump inhibitors (PPIs) are considered the first line approach to gastroesophageal reflux disease (GERD) symptoms. On the other hand, patients with functional heartburn (FH) do not show any symptom improvement under PPI therapy. Sometimes, in clinical practice, patients with pathophysiological characteristics related to FH have a satisfactory response to PPIs. Recently, it has been suggested that low basal impedance may reflect impaired mucosal integrity and increased acid sensitivity.
AIMS&METHODS: The aim was to compare basal impedance values in patients with heartburn and pathophysiological characteristics related to FH divided into two groups on the basis of symptom relief after PPI therapy.
A group of patients with non-erosive reflux disease were treated with esomeprazole or pantoprazole 40 mg daily for 8 weeks. All patients performed two questionnaires (GIS and VAS) to evaluate the symptom relief during PPI therapy. All patients underwent manometry and impedance monitoring (MII-pH) previous wash-out from PPIs. We selected 50 patients with normal acid exposure time (AET), normal reflux number, and lack of association between symptoms and refluxes. For each patient, we evaluated the basal impedance value at channel 3, during the overnight rest, at three different times: 1, 2, 3 am. Patients who had a symptom relief higher than 50% during PPI therapy composed Group A, and patients who did not record any symptom relief composed Group B. The recorded values were compared in the two groups with a student paired t-test.
RESULTS: We evaluated 60 patients with GERD symptoms but without any pathophysiological characteristic of GERD. Group A was composed of 30 patients (7M, 23F) with mean age 49.7 (±12.3). Mean symptom relief during PPI therapy was 74.5 (±8.6). Mean AET 1.4 (±0.8), mean reflux number 30.4 (±8.7). Each patient had a mean of 3.7 symptoms during MII-pH. Group B was composed of 30 patients (10M, 20F) with mean age 50.3 (±11.5). Mean symptom relief during PPI therapy was 23.6 (±10.6). Mean AET 0.5 (±0.6), mean reflux number 24 (±6.9). Each patient had a mean of 3.4 symptoms during MII-pH. Basal impedance values were significantly lower in Group A (2338.3 ±725.9) than in Group B (4289 ±897.9) ($p<0.05$).
CONCLUSION: Patients with pathophysiological characteristics related to FH and a satisfactory response to PPIs showed lower basal impedance values. Consistently with the concept that low basal impedance may reflect impaired mucosal integrity, our result could partially explain the different response to PPI therapy in the two groups.

P1610 THE DIAGNOSTIC ACCURACY OF REFLUX SYMPTOMS IS IMPROVED BY ASSESSING EPIGASTRIC PAIN AND HISTOLOGY

N. Vakil[1,*], J. Dent[2], J. Wissmar[3], B. Wernersson[3]. *[1]University of Wisconsin School of Medicine and Public Health, Madison, United States, [2]Royal Adelaide Hospital and University of Adelaide, Adelaide, Australia, [3]AstraZeneca R&D, Mölndal, Sweden*

INTRODUCTION: International consensus guidelines characterize symptom-defined gastroesophageal reflux disease (sGERD) as: 1) ≥mild reflux symptoms on ≥2 days/week or ≥moderate reflux symptoms on ≥1 day/week (for research), or 2) troublesome reflux symptoms (for clinical practice).[1] Here, we report on further validation of sGERD diagnostic criteria (overall and without epigastric pain) against GERD defined by investigation (iGERD; with total epithelial thickness [TET] ≥430 μm as an additional, validated histological criterion[2]).
AIMS&METHODS: We assessed the specificity/sensitivity of sGERD, overall and without epigastric pain, against iGERD. Primary care patients were included if they had not taken a proton pump inhibitor in the past 2 months, and had upper gastrointestinal (GI) symptoms of any severity on ≥2 days/week for ≥4 weeks and of ≥mild severity on ≥3 days in the 7 days before the study (NCT00291746).[3] Patients completed the Reflux Disease Questionnaire (RDQ), were interviewed about a pre-specified list of 19 upper GI symptoms, and underwent upper GI endoscopy with esophageal biopsy (2.0 cm above the Z-line) and wireless pH-metry. iGERD was defined as ≥1 of: reflux esophagitis (Los Angeles grades A–D), pathological esophageal pH (<4 for >5.5% of the time), positive symptom association probability (SAP ≥95%). TET ≥430 μm was an additional criterion. sGERD was diagnosed if heartburn/regurgitation frequency/severity data from the RDQ met research definition criteria or if heartburn/regurgitation was reported as the most/second most bothersome symptom(s) at interview (clinical practice definition).
RESULTS: Of 231 biopsied patients, 55% had iGERD (30% RE, 37% pathological esophageal pH, 16% positive SAP and 39% TET ≥430 μm). Table 1 shows the specificity/sensitivity of sGERD research and clinical practice definitions, overall and without epigastric pain, for iGERD.
Table 1. Specificity/sensitivity (%) of sGERD definitions for iGERD

sGERD definition	iGERD with TET ≥430 μm	iGERD with TET <430 μm
For research		
Overall	32.9/87.7	12.3/67.1
No epigastric pain	78.9/41.3	58.7/21.1
For clinical practice		
Overall	71.1/52.3	47.7/28.9
No epigastric pain	86.8/31.0	69.0/13.2

CONCLUSION: Adding TET ≥430 μm as an iGERD criterion improves the specificity/sensitivity of sGERD definitions for iGERD. Absence of epigastric pain further increases the specificity, but with a decline in sensitivity. The sGERD research definition has higher sensitivity but lower specificity for iGERD than the sGERD clinical practice definition.

P1611 THE RESTECH LARYNGOPHARYNGEAL PROBE MEASURES VAPORIZED ACID BUT DOES NOT UNIFORMLY CORRESPOND WITH THE BRAVO PH PROBE IN SIMULTANEOUS STUDIES

N. Vakil[1,*], C. Ziegler[2], J. Schipper[3], L. Fisk[3], L. Roucher[3]. *[1]Gastroenterology, University of Wisconsin, Madison, [2]Gastroenterology, Aurora Summit Hospital, Summit, [3]Respiratory Technologies, San Diego, United States*

INTRODUCTION: The Restech pH probe has been developed to measure vaporized acid in the laryngopharyngeal area
AIMS&METHODS: The aim of this study was (1) to determine if the Restech probe measures vaporized acid in vitro, (2) to determine the concordance of the

Restech probe placed in the pharynx with a Bravo pH probe placed in the distal esophagus. Methods: In vitro experiments: In a laboratory environment a water bath was set up set at 38 degrees Celsius. Multiple liquids that span the pH spectrum encountered in the upper GI tract and airways were studied. pH was recorded on the remote receiver by an investigator blinded to the substance being tested. Liquid pH was measured by dipping the catheter in the liquid medium. In random sequence the liquids were vaporized using an aerosol generator and the Restech probe was suspended in the vapour. The effect of drying the catheter was studied in vitro. In vivo studies: Simultaneous Restech and Bravo pH studies performed in 10 patients were analyzed.

RESULTS:

Substance	Published pH	Measured Liquid pH	Measured pH vapor	Difference Vaporized & liquid pH
0.1N HCl	1	1.1	1.1	0
Vinegar	2.4	2.4	2.4	0
Coca Cola	2.4	2.7	2.7	0
Diet Coke	3.1	3.2	3.4	0.2
Orange Juice	3.8	4.1	4.3	0.2
pH 4 buffer	4.0	4.2	4.1	-0.1
pH 7 buffer	7	7	7	0
pH 8 buffer	8	8.1	8	-0.1

CONCLUSION: Dehydration of the catheter resulted in activation of detection circuitry within 30 seconds and a pH of 15 was displayed. The Bravo probe showed reflux in 9/10 patients in the upright position and the Restech showed upright reflux in 6/10 patients. However, in the supine position, 7/10 Restech studies demonstrated reflux in the laryngo-pharynx with only 2 Bravo studies were positive in the supine period.Conclusions: 1. The Restech probe accurately measures the pH of liquids and the nebulized vapor of liquid. 2. The Restech probe records acidic events that are not recorded by the Bravo pH probe particularly in the supine position. 3. The supine events are not due to drying of the catheter as dessication of the probe is rapidly detected by inbuilt circuitry 4. Nocturnal acidification of the laryngo-pharynx may be important in extra-esophageal GERD.

P1612 CARDIAC MUCOSA AT THE GASTROESOPHAGEAL JUNCTION: INDICATOR OF GASTROESOPHAGEAL REFLUX DISEASE?

N. Schneider[1,*], W. Plieschnegger[2], B. Schmack[3], H. Bordel[4], B. Höfler[5], A. Eherer[6], E.-M. Wolf[1], P. Rehak[7], M. Vieth[8], C. Langner[1]. [1]*Institute of Pathology, Medical University of Graz, Graz,* [2]*Internal Medicine, Krankenhaus der Barmherzigen Brüder, Academic Teaching Hospital, St. Veit / Glan, Austria,* [3]*Gastroenterology, Private Practice, Bayreuth,* [4]*Gastroenterology, Private Practice, Osnabrück, Germany,* [5]*Department of Surgery, Division of General Surgery,* [6]*Department of Internal Medicine, Division of Gastroenterology and Hepatology,* [7]*Department of Surgery, Research Unit for Biomedical Engineering & Computing, Medical University of Graz, Graz, Austria,* [8]*Institute of Pathology, Klinikum Bayreuth, Bayreuth, Germany*

INTRODUCTION: The native stratified squamous epithelium of the esophagus is unable to tolerate the acidic and/or proteolytic nature of persistent reflux, and it adapts to the damaging stimuli by converting into metaplastic columnar epithelium. Cardiac mucosa at the gastroesophageal junction is characterized by the presence of glands composed of mucous cells without parietal cells. The origin and significance of cardiac mucosa remains to be controversial.

AIMS&METHODS: Our study aimed to assess the prevalence of cardiac mucosa and to relate its presence to features related to gastroesophageal reflux disease (GERD). From the prospective Central European multicenter *histo*GERD trial we recruited 1,071 individuals (576 female, 495 males; median age 53 years) undergoing gastroscopy for various non-selected reasons. Biopsy material was systematically sampled from above and below the gastroesophageal junction and from the stomach.

RESULTS: Overall, cardiac mucosa was observed in 713 (66.6%) individuals. Its presence was associated with patients' symptoms and/or complaints, assessed by a questionnaire and clinical evaluation ($p=0.0025$), body mass index ($p<0.001$), histologic changes of the squamous epithelium indicating GERD (basal cell layer hyperplasia, papillary elongation, dilation of intercellular spaces, and presence of intraepithelial mononuclear cells; $p<0.001$, respectively), intestinal metaplasia ($p<0.001$), as well as the endoscopic diagnosis of esophagitis assessed according to the modified Los Angeles classification ($p<0.001$). No association with the endoscopic diagnosis of Barrett's esophagus and no association with gastric pathology, particularly *Helicobacter* infection was observed.

CONCLUSION: Cardiac mucosa is a common finding in biopsies sampled from the gastroesophageal junction. Its association with reflux symptoms, histologic changes of the squamous epithelium indicating GERD, as well as the endoscopic diagnosis of esophagitis suggests that injury and repair related to GERD contribute to its development and/or expansion.

P1613 THE ASSOCIATION BETWEEN GASTROESOPHAGEAL FLAP VALVE FUNCTION AND GASTROESOPHAGEAL REFLUX SYMPTOMS, ENDOSCOPIC FEATURES, HELICOBACTER PYLORI STATUS AND BODY MASS INDEX

O. Keskin[1,*], A. Tüzün[1], A. Yaman[1], H. Çetinkaya[1], I. Soykan[1]. [1]*Gastroenterology, ANKARA UNIVERSITY, Ankara, Turkey*

INTRODUCTION: Endoscopic investigation is usually preferred in patients with symptoms of gastroesophageal reflux disease (GERD) in clinical practice. It has been reported that grading of gastroesophageal flap valve (GEFV) function during endoscopy adds useful information in the evaluation of these patients. However, endoscopists frequently encounter patients with impaired GEFV function, but without symptoms of GERD. Therefore, primary aim of this study was to investigate relationship between GEFV appearance and reflux symptoms, secondary aims were to explore whether any association exists between GEFV and clinical diagnosis, *Helicobacter pylori* status, body mass index and other factors that might affect GEFV function.

AIMS&METHODS: 1070 consecutive patients (643 women) who had been referred for upper gastrointestinal endoscopy were enrolled into the study. Along with demographic characteristics, reflux symptoms including heartburn and regurgitation were gathered from each patient. The body mass index, smoking, alcohol, concomitant diseases, and proton pump inhibitors were also recorded. During endoscopic procedure, patients were assessed for the presence of esophagitis and hiatal hernia. Esophagogastric junction was inspected while endoscope in a retroflexed position and graded I to IV according to the Hill's classification. Grades I and II were classified as normal valves and grades III and IV as abnormal valves. Biopsy specimens were obtained from each patient in order to identify presence of *Helicobacter pylori* infection.

RESULTS: At endoscopic investigation, 348 patients had GEFV dysfunction considered as having Hill grade III&IV, 146 patients had esophagitis and 84 patients had hiatal hernia. 583 patients reported regurgitation while 507 patients had heartburn. Presence of hiatal hernia ($p=0.000$), esophagitis ($p=0.000$), regurgitation ($p=0.021$), and body mass index (>30 kg/m^2) ($p=0.015$) are independent risk factors that affect GEFV function. However, presence of heartburn ($p=0.438$), *Helicobacter pylori* infection ($p=0.855$), smoking ($p=0.446$) and alcohol ($p=0.833$) are not risk factors for GEFV function.

CONCLUSION: Although endoscopic grading of the GEFV appearance is useful as a prognostic factor, presence of hiatal hernia, esophagitis, regurgitaiton and body mass index >30 kg/m^2 are independent risk factors for GEVF appearence. Patients with abnormal valves (Hill grades III &IV) but without hiatal hernia, esophagitis and regurgitation should be evaluated individually by means of having or not having gastroesophageal reflux disease.

P1614 THE ASSOCIATION OF BERNSTEIN TEST WITH PH-IMPEDANCE MONITORING AND DILATED INTERCELLULAR SPACE IN SUBTYPES OF GERD

S. Yapali[1], R. Vardar[1], E. Yildirim[1], B. Doganavsargil[2], S. Bor[1,*]. [1]*Gastroenterology,* [2]*Pathology, Ege University School of Medicine, Izmir, Turkey*

INTRODUCTION: Diagnostic tools in gastroesophageal reflux disease (GERD) has undergone significant evolution from Bernstein test to multichannel intraluminal impedance and pH (MII-pH) monitoring including the symptom association. Dilated intercellular space (DIS) may have a role in decreasing perception thresholds, particularly in NERD.

AIMS&METHODS: We aimed to investigate the relevance of Bernstein test in patients with different subtypes of GERD and to investigate the association of DIS with acid-induced heartburn. 81 GERD patients [mean age: 46±12, 41 F, 40 M] were prospectively divided into 3 subgroups by Roma III criteria. Bernstein test was performed and of the 33 who had distal esophagus biopsies; the severity, extent and level of DIS were evaluated. The definitions were as following: severity of DIS; mild if detected on X40 magnification, moderate if detected on X20 magnification and severe if detected on X10 magnification, extent of DIS; focal if detected on ≤ 4 high-powered fields, and diffuse if detected on >5 high-powered fields, level of DIS; 1/3 lower (basal and parabasal layer), 1/3 middle (spinocellular layer), 1/3 upper (granular cells). The severity, extent and level of DIS were compared between Bernstein(+) and Bernstein(-) patients.

RESULTS: Bernstein test was positive in 51.7%, 42.9% and 29.2% of ERD, NERD and functional heartburn, respectively. Bernstein positivity did not differ among GERD subtypes. Although total number of reflux episodes were higher in

Bernstein (+) group(p=0.03); acid refluxes, weak acid refluxes, pH < 4% and De Meester scores were similar. Age, sex, reflux symptom score, extraesophageal symptoms, PPI response, BMI, time for pH < 4%, number of acid refluxes, symptom index (SI) and symptom association probability (SAP) were not associated with Bernstein test significantly. Bernstein test was positive in 51% of patients examined for DIS. Severity of DIS was mild in 59%, moderate in 6%, severe in 35%; extent of DIS was focal in 53%, diffuse in 46%; level of DIS was 1/3 lower in 65%, 1/3 middle in 29% and 1/3 upper in 6% of Bernstein (+) patients. Severity, extent and level of DIS were not associated with Bernstein test.
CONCLUSION: Despite the higher level of total acid refluxes; the irrelevance of acid induced heartburn with mucosal inflammation, SI, SAP and PPI response denotes the role of sensitivity remote from the site of injury. Furthermore, the severity, extent and level of DIS were not associated with Bernstein test and GERD subtypes. Apart from the intraluminal acid stimuli, esophageal receptors, visceral afferent neurons and central perception may have a role in subtypes of GERD.

P1615 EDEMA OF THE INTERARYTENOID MUCOSA SEEN ON ENDOSCOPY IS RELATED TO BARRETT'S ESOPHAGUS AND IS AN INDEPENDENT PREDICTOR FOR NON-EROSIVE REFLUX DISEASE (NERD) IN JAPANESE POPULATION

Y. Yamaguchi[1,*], N. Ogasawara[1], Y. Kondo[1], Y. Hijikata[1], S. Izawa[1], H. Noda[1], M. Sasaki[1], K. Kasugai[1]. [1]*Gastroenterology, Aichi Medical University School of Medicine, Nagakute, Japan*

INTRODUCTION: Laryngopharyngeal reflux (LPR) is defined as the retrograde flow of gastric contents up through the esophagus to the larynx and hypopharynx; this is an extra-esophageal manifestation of gastroesophageal reflux disease (GERD). Non-erosive reflux disease (NERD) refers to a syndrome that is characterized by complaints of reflux symptoms such as heartburn without endoscopic evidence of mucosal injury. It accounts for more than half of gastroesophageal reflux disease (GERD) cases in Japan, as it does in Europe. NERD and erosive GERD cannot be distinguished by the severity of symptoms or their frequency, and they are equally characterized by compromised quality of life (QOL). Although both LPR and GERD are caused by reflux of stomach contents and the relationship between LPR and GERD are well understood, the relationship between LPR and NERD are still unknown.
AIMS&METHODS: In this study, we assessed esophago-gastroendoscopic findings related to GERD, specifically Barrett's esophagus, hiatal hernia, laryngopharyngeal findings, and GERD symptoms on the 12-question Frequency Scale for the Symptoms of Gastroesophageal Reflux Disease (FSSG). Then, independent predictors of Barrett's esophagus were analyzed, and the relationships among Barrett's esophagus, and hiatal hernia, laryngopharyngeal findings, and patients' symptoms and characteristics were investigated.
RESULTS: Among 652 NERD patients (307 females and 345 males) of the 704 patients who enrolled in this study were evaluated on univariate and multivariate analysis. Barrett's esophagus and hiatal hernia were present in 303 (46.4%) and 299 patients (45.9%), respectively. Barrett's esophagus was significantly related with male, aging, edema of the interarytenoid mucosa, redness of inferior portion of larynx and hiatal hernia on univariate analysis. However, patients' LPR and GERD symptoms had no significant relationship with Barrett's esophagus. Male (OR: 2.24; 95% CI: 1.58-3.19; p value < 0.001), aging (OR: 1.03; 95% CI: 1.02-1.04), edema of the interarytenoid mucosa (OR: 1.58; 95% CI: 1.06-2.37; p value =0.026) and hiatal hernia (OR: 4.04; 95% CI: 2.87-5.73; p value < 0.001) were independent predictors of Barrett's esophagus on multivariate analysis.
CONCLUSION: Although LPR and GERD symptoms had no significant relationship with the findings of Barrett's esophagus, edema of the interarytenoid mucosa and hiatal hernia were significantly related with Barrett's esophagus and they were considered to be clues for reflux of stomach contents involving gastric acid in Japanese NERD patients.

P1616 THE RESULTS OF THE OBSERVATIONAL STUDY ON THE USE OF GERDQ INTERNATIONAL QUESTIONNAIRE FOR DIAGNOSIS OF GASTROESOPHAGEAL REFLUX DISEASE IN THE RUSSIAN POPULATION

V. Ivashkin[1], A. Trukhmanov[1], I. Maev[2], Y. Kucheryaviy[2,*], V. Kaibysheva[1], O. Storonova[1]. [1]*1st Moscow State Sechenov Medical University,* [2]*Moscow State University of Medicine and Dentistry, Moscow, Russian Federation*

INTRODUCTION: Modern guidelines recommend symptom-based approach to gastroesophageal reflux disease (GERD) management. Brief, reliable and valid self-administered questionnaire could facilitate the diagnosis of GERD in primary care.
AIMS&METHODS: A prospective, multicenter, observational study was conducted to estimate the sensitivity and specificity of GerdQ international questionnaire for the diagnosis of GERD in routine practice in Russia. The study included 150 patients (aged ≥18) with upper gastrointestinal symptoms planned for endoscopy and pH-metry for diagnosis clarification. Patients completed GerdQ (6-question patient-centered self-assessment questionnaire). Gastroenterologists established GERD diagnosis based on clinical data followed by endoscopy and 24-hour pH-metry. The results of GerdQ questionnaire survey and gastroenterologist examination were compared with the results of instrumental methods (reflux esophagitis or pathological acid exposure to esophagus were used as diagnostic references for GERD).
RESULTS: 5 patients had short-term pH-metry, thus only 145 patients were included in PP analysis. According to PP-analysis GerdQ sensitivity for cut-off score ≥8 was 65,4%, specificity – 91,7%. ROC-analysis demonstrated high sensitivity and specificity of GerdQ, area under the curve (AUC) was 84,8% (95% CI 71,1-98,5; p < 0,001). Sensitivity of GERD diagnostics by gastroenterologist was 91%, specificity – 91,7%. The frequency of reflux-esophagitis revealed by endoscopy correlated with GerdQ total score: esophagitis presented in 72,2% patients with GerdQ score 3-7, 92,9% patients with GerdQ score 8-10 and 96,9% patients with GerdQ score 11-18. The frequency of pathological acid exposure to esophagus detected by 24-h pH-metry (esophageal pH < 4 during more than 5% of monitoring time) was 61,1%, 88,9% and 75,0%, respectively.
CONCLUSION: GerdQ is sufficiently sensitive and specific complementary tool for GERD diagnosis which allows reducing the need for upper endoscopy.

P1617 FREQUENCY AND TIME TO ONSET OF RESPIRATORY TRACT INFECTIONS IN ESOMEPRAZOLE AND PLACEBO TREATED PATIENTS IN 24 RANDOMIZED CONTROLLED TRIALS

L. Estborn[1,*], S. Joelson[1]. [1]*AstraZeneca, Mölndal, Sweden*

INTRODUCTION: A causal association has been suggested between the use of potent gastric acid suppressive medication and occurrence of community-acquired respiratory tract infections (RTIs), particularly pneumonia, based on data from observational studies.
AIMS&METHODS: We aimed to compare the frequency and time to onset of community-acquired RTIs, including pneumonia, in patients receiving either the proton pump inhibitor esomeprazole or placebo in randomized, double-blind, controlled trials. The AstraZeneca ARIADNE safety database, which contains data on approximately 350 000 patients obtained from over 2 500 clinical trials, was searched for comparative, randomized, controlled, blinded clinical studies in which patients received either esomeprazole or placebo and that recorded all non-serious and serious adverse events (AE). The following categories of AE were analyzed: all RTIs (including signs and symptoms potentially indicating RTI); lower RTIs; and pneumonia. Events were analyzed in accordance with MedDRA v. 15.1 terminology. Patient data were pooled by treatment group, and AE frequencies and relative risks (RRs; with 95% confidence intervals [CIs], adjusted for time on treatment) were calculated. In addition, AE occurrence was analyzed according to patients' age, sex, treatment indication and time to onset of AE.
RESULTS: Twenty-four relevant placebo controlled-studies were identified, in which 9877 patients received esomeprazole and 5551 patients received placebo. The frequencies of occurrence of all three categories of AE were similar in patients receiving esomeprazole and patients receiving placebo (all RTIs: 10.8% versus 10.5%; lower RTIs: 1.9% versus 2.1%; and pneumonia: 0.2% versus 0.3%, respectively), and events were evenly distributed over patients' duration of treatment. The adjusted RR estimates for AEs in patients receiving esomeprazole relative to patients receiving placebo were as follows: all RTIs, 0.93 (95% CI: 0.84–1.02); lower RTIs, 0.81 (95% CI: 0.65–1.01); and pneumonia, 0.65 (95% CI: 0.35–1.20). The distribution of all three categories of AE showed similar age, sex, treatment indication and time to onset patterns in esomeprazole and placebo-treated patients.
CONCLUSION: This pooled analysis of data from randomized, double-blind, placebo-controlled clinical trials found no causal association between the use of potent acid suppressive therapy (esomeprazole) and occurrence of community-acquired RTIs, including pneumonia. The onset of events was evenly distributed over patients' duration of therapy, and presented similar age, sex, treatment indication and time to onset patterns in esomeprazole and placebo treated groups.

P1618 TEMPORAL CHANGES IN THE GASTROINTESTINAL RISK PROFILE OF PATIENTS RECEIVING LOW-DOSE ACETYLSALICYLIC ACID FOR SECONDARY PREVENTION OF CARDIOVASCULAR EVENTS

L. García Rodríguez[1], A. Ruigómez[1,*], S. Johansson[2], P. Nagy[2], L. Cea-Soriano[1]. [1]*Spanish Centre for Pharmacoepidemiologic Research (CEIFE), Madrid, Spain,* [2]*AstraZeneca R&D, Mölndal, Sweden*

INTRODUCTION: The use of low-dose acetylsalicylic acid (ASA) is associated with an increased risk of gastrointestinal (GI) complications, which may lead to discontinuation of ASA treatment. For patients at high GI risk, concomitant

gastroprotective strategies are recommended (Bhatt *et al.* 2008). However, it is unclear how GI risk changes with time in new users of low-dose ASA.
AIMS&METHODS: This retrospective cohort study assessed the GI risk profile among new users of low-dose ASA. The Health Improvement Network (THIN) UK primary care database was used to identify patients who initiated low-dose ASA between 2000 and 2007 for secondary prevention of cardiovascular events. GI risk was assessed at baseline (the date of their first ASA prescription), and again after 1 year. Patients were considered to be at high GI risk if they met at least one criterion from a list of established GI risk factors (Bhatt *et al.* 2008). Patients were classified according to their initial indication for low-dose ASA treatment: secondary prevention of ischaemic heart disease (IHD), cerebrovascular disease (CD), unstable angina (UA), or myocardial infarction (MI).
RESULTS: Overall, 39% of ASA users at baseline were at high GI risk, and this proportion increased by calendar year (30% for patients initiating ASA in 2000, versus 52% in 2007). The proportion of patients at high GI risk at baseline was higher in individuals prescribed low-dose ASA for secondary prevention of MI (52%) than among those prescribed ASA for other indications (IHD, 35%; CD, 34%; UA, 43%). After 1 year, the proportion of patients at high GI risk was 36% overall, and was similar for all indications. Of patients who were at low GI risk at baseline, 16% were at high GI risk after 1 year. The proportions of patients whose risk increased were similar for all indications. Of patients who were at high GI risk at baseline, 67% continued to be at high GI risk after 1 year. The proportion of patients whose GI risk decreased the most was in patients prescribed ASA for secondary prevention of MI (62%) relative to other indications (IHD, 67%; CD, 73%; UA, 71%).
CONCLUSION: Results from this study show that the GI risk profile of users of low-dose ASA may change over time and vary by indication. Thus, physicians need to review regularly the GI risk of patients prescribed low-dose ASA, and tailor adequate gastroprotective strategies accordingly.

P1619 ARE PATIENTS ON ANTICOAGULANTS ADEQUATELY PROTECTED AGAINST UPPER GASTROINTESTINAL BLEEDING?

M. Vujasinovic[1,*], M. Tretjak[1], A. Marolt[1], B. Tepes[2], M. Miljkovic[1], K. Klancnik[1]. [1]*Department of Internal Medicine, General Hospital Slovenj Gradec, Slovenj Gradec,* [2]*Abakus Medico Diagnostic Centre, Rogaska Slatina, Slovenia*

INTRODUCTION: Due to the high prevalence of cardiovascular diseases anticoagulant medications (AC) are commonly prescribed. Treatment with AC is related to an increased incidence of acute upper gastrointestinal bleeding (AUGIB) especially in older patients and concomitant treatment with acetylsalicylic acid (ASA), clopidogrel, corticosteroids, nonsteroidal anti-inflammatory drugs (NSAID) and serotonin reuptake inhibitors (SRI). Proton pump inhibitors (PPI) are drugs with good protective effect against AUGIB.
AIMS&METHODS: A retrospective analysis of medical documentation of 440 consecutive patients with anticoagulant treatment was performed. We analyzed demographic features, indications for treatment with AC, history of AUGIB and the prescription of PPI.
RESULTS: There were 440 patiens (242 male and 196 female), mean age 75,8 ± 6,22 years (range 65-94). Indications for treatment with AC were: atrial fibrillation (AF) and stroke in 282 patients, valve replacement in 59 patients, pulmonary embolism in 52 patients and deep venous thrombosis in 47 patients. Warfarin was prescribed in 389 (88,4%) patients, acenocoumarol in 49 (11,1%) patients and dabigatran in 2 (0,5%) patients. ASA, NSAID, corticosteroids and SRI were concomitantly prescribed in 11 (2,5%), 7 (1,6%), 3 (0,7%) and 35 (8,0%) cases, respectively. Eight (1,8%) patients had history of AUGIB. PPI were prescribed in 97 (22,0%) patients with AC in monotherapy, in 26 (41,3%) patients with AC and concomitant therapy (17 with SRI, 7 with NSAR and 2 with corticosteroids) and in 2 patients (25%) with AC and history of AUGIB. There were 343 (78%) patients (all older than 65 years) without PPI despite the indication for use. In 57 (58,8%) patients PPI was prescribed in proper dose (standard), in 26 (26,8%) the prescribed dose of PPI was too high and in 14 (14,4%) the dose was unknown.
CONCLUSION: Gastric protection in patients on AC therapy is not satisfactory. All patients were older than 65 years which classifies them as a group of patients with higher risk of AUGIB. All patients with ACM therapy and concomitant NSAID or/and ASA therapy should be treated with PPI in standard dose, especially those older than 65 years and history of AUGIB. Gastric protection in patients with AC therapy without concomitant therapy (ASA, NSAR) and history of AUGIB should be exactly specified in national guidelines.

P1620 CLINICAL COURSE AND GASTROINTESTINAL BLEEDING IN JAPANESE PATIENTS TAKING LOW-DOSE ASPIRIN - RETROSPECTIVE COHORT STUDY-

T. Yamamoto[1,*], Y. Kawashima[1], H. Aoyagi[1], S. Kimura[1], T. Shirai[1], A. Isono[1], T. Ebato[1], K. Abe[1], T. Ishii[1], H. Kita[1], Y. Kuyama[1]. [1]*Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan*

INTRODUCTION: As a number of patients taking low-dose aspirin (LDA) increases for prophylaxis of atherothrombotic diseases, the adverse effect of gastrointestinal (GI) toxicity is also increasing. However, information regarding clinical course and the incidence of GI bleeding in Japanese patients taking LDA has not been fully elucidated.
AIMS&METHODS: We conducted this retrospective cohort study to clarify the incidence of GI bleeding in patients taking LDA. Among 5555 patients who underwent EGD in Teikyo University Hospital (Tokyo, Japan) from 2005 till 2006, 466 having received LDA continuously before and after EGD (>1 month) were included as the subjects. Those who had advanced malignant disesases were excluded. Age-, sex-, and examination month-matched controls were also selected to compare the difference. Based on the medical records, the patients' status (GI bleeding requiring hospitalization, death, discontinuation of aspirin, change of hospital) were investigated every month till the end of April, 2013.
RESULTS: The observation period ranged from 2 to 103 months (average 59 months, 2295 patient-year). The underlying diseases were ischemic heart diseases (71%), cerebrovascular diseases (31%), peripheral arterial disease (9%), and other thrombotic disease (5%). Of these, 57 patients died (12.2%, 24.8/1000 patient-year), which was comparable to the controls (50 patients, 10.7%). The major causes of death were infections, heart disease, neoplasms, and intracranial hemorrhage, and there was no death because of hemorrhage from the GI organs. GI bleeding occurred in 27 patients (5.8%, 11.8/1000 patient-year); 9 from the upper GI and 18 from the middle or lower GI. The majority of the patients were elderlies over 75 years old. The most common disease was colonic diverticular hemorrhage (11 patients, 41%). On the other hand, only 3 patients of the control developed the upper GI bleeding (0.6%), and there was no lower GI bleeding
CONCLUSION: In patients taking LDA, the rate of GI bleeding was almost half of the mortality rate. Gastrointestinal bleeding was much more common in aspirin users than in control, especially elderly patients. Over the half of the lesions responsible for bleeding in aspirin users was found in the middle or the lower portion of GI rather than the upper GI, and colonic diverticular hemorrhage were the most common disease.

P1621 H2S-RELEASING NSAID ATB-346 POSSESSES THE REDUCED GASTROTOXICITY IN MUCOSA OF RATS WITH EXPERIMENTAL STRESS-INDUCED ULCERS

I. Fomenko[1,*], T. Bondarchuk[1], A. Sklyarov[1]. [1]*biochemistry, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine*

INTRODUCTION: H_2S possesses strong anti-oxidative, anti-apoptic and anti-inflammatory activities in different tissues, including the gastric mucosa. However, NSAIDs reduce endogenous H_2S synthesis, while administration of H_2S donors can reduce the severity of NSAID-induced gastric damage. It is barely known what would happen to mechanisms of gastric defence and healing, including H_2S production, when the use of NSAIDs is accompanied by acute stress.
AIMS&METHODS: The purpose of our study was to explore effects of different NSAIDs (conventional – naproxen, selective cox-2 inhibitor – celecoxib, and H_2S-releasing – ATB-346) in experimental stress-related gastric lesions in rats, and to determine the role of lipoperoxidation and the nitric oxide (NO) system in ulcerogenesis and gastroprotection in rats. Two stress models of gastric ulceration were used: water-immersion restraint stress (WRS) and epinephrine-induced gastric damage. Naproxen, ATB-346 and celecoxib were examined in both models of gastric damage. In the gastric mucosa were determined: area and degree of destructive changes, alterations in malonic dialdehyde (MDA) concentration, activity of NO-synthases (inducible – iNOS and constitutive – cNOS) and arginase, the content of nitrite anion.
RESULTS: Oral administration of naproxen at the dose of 10 $mg \times kg^{-1}$ produced gastric mucosal lesions, whereas when ATB-346 and celecoxib were given at the same dose, gastric damage did not develop. In contrast, lipoperoxidation processes were enhanced in all groups as was the activity of NO-synthases. Both naproxen and ATB-346 increased the activity of NOS (total and iNOS) by the same rate. Pretreatment with naproxen in the WRS model in rats caused on the one hand an increase of area and severity of damage. On the other hand there was a decrease of NOS activity (both isoforms). ATB-346 displayed a cytoprotective effect, manifested by the decrease of total area of gastric damage, however parameters of lipoperoxidation and NO-syntase system did not differ substantially from those in the group treated with napoxen prior to WRS. In contrast, in the WRS model, none of the tested NSAIDs exacerbated gastric mucosal injury; indeed, they all reduced the extent of damage.
CONCLUSION: In our study we showed, that H_2S released from ATB-346 probably did not play the pivotal role in activation of iNOS, but it was certainly involved in other mechanisms (NOS-independent) of gastroprotection.

We hypothesize that the reduction of gastric damage with an H_2S-releasing NSAID in the both stress models of gastric ulceration is a result of its maintenance of gastric blood flow and inhibition of leukocytes adherence.

P1622 EFFECTS OF BENEXATE HYDROCHLORIDE BETADEX FOR GASTRIC ULCER: AN EXPERIMENTAL STUDY

H. J. Chun[1,*], J. M. Lee[1], H. S. Choi[1], E. S. Kim[1], B. Keum[1], Y. T. Jeen[1], H. S. Lee[1], S. H. Um[1], C. D. Kim[1], H. S. Ryu[1]. [1]*Gastroenterology, Korea University Anam Medical Center, Seoul, Korea, Republic Of*

INTRODUCTION: Benexate hydrochloride betadex (BHB) is used as anti-ulcer agent, which is thought to increase blood flow in the gastric mucosa. However, the mechanism of pharmacological action that increases blood flow in a gastric mucosa by BHB is not certain. Also, BHB action of inflammation, which is closely related to tissue injury and ulcer healing, were not fully investigated. This study was performed to investigate BHB action of ulcer healing in rat by an enhancement of microcirculation mediated by nitric oxide (NO) and anti-inflammatory activity.
AIMS&METHODS: Benexate hydrochloride betadex (BHB) is used as anti-ulcer agent, which is thought to increase blood flow in the gastric mucosa. However, the mechanism of pharmacological action that increases blood flow in a gastric mucosa by BHB is not certain. Also, BHB action of inflammation, which is closely related to tissue injury and ulcer healing, were not fully investigated. This study was performed to investigate BHB action of ulcer healing in rat by an enhancement of microcirculation mediated by nitric oxide (NO) and anti-inflammatory activity.
Material and Methods: Gastric mucosal injury rat model was made by injecting 60% acetic acid solution into the stomach. After ulcer induction, rats were randomly allocated to one of the following 4 groups, water; BHB 1000 mg/kg; L-N-nitroarginine methyl ester (L-NAME); BHB and L-NAME. The rats were orogastrically gavaged with BHB or L-NAME for 5 days, and then sacrificed. We measured the area of gastric ulcers by planimetry and the expression of COX, cytokines, NO synthase (NOS) of stomach tissues by western blot analysis.
RESULTS: The size of ulcer lesions decreased in the group treated with BHB as compared with control group. The administration with L-NAME aggravated ethanol-induced mucosal injury. The iNOS and nNOS signals increased in gastric ulcerous mucosa treated with BHB. l-NAME administration significantly decreased the expressions of NOS compared to the control group. The degree of inhibited eNOS and nNOS levels increased after 70 mg/kg l-NAME + 1000 mg/kg BHB administration. The level of COX-2, IL-1β and TNF-α was significantly decreased in BHB-treated group.
CONCLUSION: These results suggest that BHB as anti-ulcer agent enhances microcirculation and reduces proinflammatory cytokines. BHB could be responsible for protection against acetic acid-induced gastric mucosal injury.

P1623 N-3 POLYUNSATURATED FATTY ACID TO RESCUE FROM NSAID-ASSOCIATED GI DAMAGES THROUGH LIPID RAFT PRESERVATION

K. B. Hahm[1,*], E. H. Kim[1], S. P. Hong[1]. [1]*Gastroenterology, CHA UNIVERSITY OF MEDICINE AND SCIENCE, Seongnam, Korea, Republic Of*

INTRODUCTION: n-3-PUFAs had been applied in diverse clinical conditions including inflammatory diseases, anti-aging as well as cancer prevention supported with its anti-inflammatory and anti-oxidative actions. There is no clear result whether the n3-PUFAs rich in docosahexanoic acid and eicosapentanoic acid can be solving strategy against NSAID-damages.
AIMS&METHODS: Using *fat-1* transgenic mice, which can synthesize n-3-PUFA owing to over-expression of 3-*desaturase*, we investigated whether n-3-PUFA can attenuate NSAID-induced GI injury. Wild-type C57BL/6 and *fat-1* transgenic mice were deprived of food 24 h before indomethacin and treated with 20mg/kg indomethacin or vehicle by gavage and killed after 16 h for gastric injury and 2 days for duodenal injury.
RESULTS: Indomethacin induced erosive and ulcerative lesions in GI tract of wild-type C57BL/6 mice, whereas gross and pathologic scores were significantly decreased in *fat-1* transgenic mice. The expressions of inflammatory genes, adhesion molecules, apoptotic executors were significantly lower in the *fat*-1 mice compared to wild-type littermates. There was significant correlation between mucosal injury and n-3 PUFAs levels ($p<0.001$). Lipid raft was significantly disrupted after indomethacin, leading to increased apoptosis as well as autophagy, whereas n-3 PUFA preserved normal signaling of lipid raft to stabilize cell as well as attenuated apoptosis through receptor GPCR120.
CONCLUSION: All of our results can open healthy future to secure NSAID-induced GI damages as well as the development of safer NSAIDs such as n-3 PUFA formulated NSAIDs.

P1624 TWO-WEEK TREATMENT WITH PROTON PUMP INHIBITOR IS ENOUGH FOR HEALING POST ESD ULCER COMPARED TO FOUR-WEEK: A PROSPECTIVE, RANDOMIZED STUDY

M. Arai[1,*], T. Matsumura[1], K. Okimoto[1], A. Oyamada[1], K. Saito[1], S. Minemura[1], D. Maruoka[2], T. Tanaka[3], T. Nakagawa[1], T. Katsuno[1], O. Yokosuka[1]. [1]*Gastroenterology and Nephrology, Graduate School of Medicine, Chiba Univeristy,* [2]*Gastroenterology, Chiba Univeristy Hospital,* [3]*Environmental Biochemistry, Graduate School of Medicine, Chiba Univeristy, Chiba, Japan*

INTRODUCTION: There has been no consensus regarding the optimal period of treatment in patients with post endoscopic submucosal dissection (ESD) ulcers. A previous study reported that the healing speed of post ESD ulcers was different from that of usual ulcers. Therefore we evaluated the optimal period of treatment for post ESD ulcers.
AIMS&METHODS: Patients who underwent ESD for gastric cancer without using antithrombotic drug were randomized to two groups. They were treated by esomeprazole 20 mg per day for 4 weeks (4W group) or 2 weeks (2W group). At 4 weeks after ESD, we measured the size of artificial ulcers by endoscopy and determined the ulcer healing rate and speed compared with the size of ESD specimens. All patients received rebapimide 300mg per day for 4 weeks. We got written informed consent from all study subjects. This randomized controlled trial study was approved by ethics committee and registered in the UMIN Clinical Trial Registry (UMIN000006951).
RESULTS: A total of 36 consecutive patients (age; 71.8±8.8 years) were included in this study Because the patient (2W group) showed re-bleeding within two weeks and received the additional endoscopic treatment, he was excluded for further analysis, but other patients could finish the treatment for 4 weeks without re-bleeding or any complications. The numbers of patients in healing / scar stage of ulcer in 2W and 4W group at 4 weeks after ESD were 12 / 3 and 16 / 4, respectively, which showed no significant difference (chi-square test). In patients with healing stage of ulcer at 4 weeks, we evaluated the ulcer healing rate and speed in 2W and 4W groups were 95.2±3.1 % vs. 95.8±4.5 % and 835.8±451.7 vs. 1262.3±835.1 cm^2 per 4 weeks, respectively, which showed no statistical difference (unpaired t-test).
CONCLUSION: Two-week treatment with proton pump inhibitor is as effective as four-week one for healing post ESD ulcer.

P1625 TWO WEEKS TREATMENT WITH ESOMEPRAZOLE IS USEFUL FOR THE ARTIFICIAL ULCERS INDUCED BY ESD

T. Shibata[1], M. Okubo[1,*], T. Tahara[1], T. Kawamura[1], Y. Ichikawa[1], K. Sumi[1], M. Miyata[1], T. Ishizuka[1], I. Hirata[1]. [1]*Gastroenterology, FUJITA HEALTH UNIVERSITY, Toyoake, Japan*

INTRODUCTION: Endoscopic submucosal dissection (ESD) for gastric cancer is widely performed in worldwide, and the ulcers developed after ESD are usually treated with proton pump inhibitor (PPI).
Several studies have been reported regarding use period of PPI for these ulcers, however two weeks PPI administration has not been well studied yet.
Esomeprazole (EPZ) is enantiomer of omeprazole. The treatment effect of EPZ for artificial ulcer is unclear.
AIMS&METHODS: We aimed to clarify the effect of EPZ for the ulcer healing after ESD, and we compared healing effect between 2 weeks (w) and 4w EPZ treatment for the artificial ulcer.
Thirty three gastric cancer patients who were treated by ESD were prospectively enrolled and randomely assigned to treatment with EPZ 20mg/day for 2w + rebamipide 100mg tid /day for 8w or EPZ 20mg/day for 4w + rebamipide 100mg tid /day for 8w, and these groups were compared about the rate of ulcer healing after 8w.
Moreover, in order to check the validity to the ulcer healing of EPZ treatment group, comparison with other PPI (Lansoprazole: LPZ or Rabeprazole: RPZ) for 4w+ rebamipide 100mg tid /day for 8w groups used in the past was also examined.
RESULTS: Analyzed cases were total 156 cases, including 16 cases of EPZ 2w treatment group, 17 cases of EPZ 4w group, 79 cases of LPZ 4w group and 44 cases of RPZ 4w group. In these 4 groups, gender, age, lesion site, tumor size, macroscopic findings, depth of tumors, histopathology and procedure times were not different statisticaly. There was no difference in the frequency of perforation and bleeding rate. Postoperative ulcer reduction ratio after 1w was 23%/ 32%/

31%/ 20% in each of the four group (p = 0.039), LPZ 4w+ rebamipide group was significantly better than RPZ 4w+ rebamipide group, and EPZ 4w + rebamipide group showed better tendency compared to the RPZ 4w+ rebamipide group (p = 0.0689).
On the other hand, there was no difference in the reduction ratio of more than 99% in all groups 8w after ESD (p> 0.21).
About stage of ulcer healing, 75% cases in each group was at H2 stage or higher healing stage at the time of the 4w after ESD, and there was no difference of healing stage ratio among the four groups 4w, 8w after ESD (p = 0.48, p = 0.65).
CONCLUSION: Two weeks treatment with EPZ was useful for the artificial ulcers induced by ESD. This new combination therapy by EPZ 2 weeks + rebamipide 8 weeks is safe and cost-effective for ESD-induced artificial ulcer treatment.

P1626 GASTRIC ULCER BLEEDING: IS THE NEOPLASTIC RISK FORGOTTEN?

T. Correia[1,*], A. Oliveira[1], C. Rodrigues[1], S. Carlos[1]. [1]*Gastrenterology department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: Gastric ulcer has well-known malignant potential. For this reason even in benign looking ulcers, not only biopsies at the edges of the ulcer should be performed but also the proof of his complete healing. Gastric ulcer bleeding is potentially fatal, but should not minimize the risk of underlying malignancy. We intend to evaluate the handling of patients admitted with a diagnosis of gastric ulcer bleeding.
AIMS&METHODS: Retrospective study of patients admitted to a general hospital with a diagnosis of gastric ulcer bleeding (without initial diagnosis of neoplasia), during a period of two years. We collected demographic, analytical and endoscopic data. Follow-up after discharge and in consultation was assessed.
RESULTS: We identified 101 admissions for gastric ulcer, corresponding to 95 patients, mostly elderly (73.3% older than 65 years) and male (66.3%). The main reasons for admission to the emergency department were suspected gastrointestinal bleeding (melena, hematemesis), abdominal pain and syncope. Most lesions were located in the antrum (46.5%), followed by the body and incisura angularis. Eleven ulcers had endoscopic signs of malignancy. During hospitalization, biopsies were taken at the edge of the ulcer in 48.5% of patients diagnosed with two gastric adenocarcinomas. Only 8.9% of biopsies identified the presence of Helicobacter pylori. Endoscopic reassessment was held in the hospital after discharge in 34.7% of patients (biopsies in 73.5%), with the identification of two more gastric neoplasms. Twenty-one patients were lost in follow-up.
CONCLUSION: The prevalence of neoplasia in gastric ulcer bleeding is low, but not negligible, so there should be a correct clinical and endoscopic follow-up of these patients. This study highlighted a small number of endoscopic biopsies and reassessments.

P1627 INCIDENCE OF GASTRIC ADENOCARCINOMA AMONG PATIENTS WITH INTESTINAL METAPLASIA

C.-Y. Wu[1,2,*], T.-Y. Lee[1], Y.-C. Lee[3], J.-T. Lin[4], M.-S. Wu[3], Taiwan Helicobacter Consortium. [1]*Division of Gastroenterology, TAICHUNG VETERANS GENERAL HOSPITAL, Taichung,* [2]*Falculty of Medicine, National Yang-Ming University,* [3]*Division of Gastroenterology, National Taiwan University Hospital,* [4]*School of Medicine, Fu Jen Catholic University, Taipei, Taiwan, Province of China*

INTRODUCTION: Gastric intestinal metaplasia (IM) has been known as a premalignant lesion, but how harmful is the presence of IM for the development of gastric cancer (GCA) is not fully determined.
AIMS&METHODS: We conducted a hospital-based cohort study based on 7,059 patients who were diagnosed for the first time between 1992 and 2010 with IM by endoscopic biopsy. The cumulative incidence and standardized incidence rate (SIR) were determined.
RESULTS: The total follow-up person-year was 42,325 and the median follow-up duration was 5.1 years. Eighty-one patients developed GCA during the follow-up period. The 5-year and 10-year cumulative incidences of GCA were 0.9% (95% confidence interval [CI], 0.6-1.1%) and 2.0% (95% CI, 1.5-2.6%), respectively. Compared with the general population, IM patients had significantly higher risk of GCA (SIR, 2.46; 95% CI, 1.96-3.06). The SIRs of GCA decreased steadily with increasing age (3.61, 3.82, 2.39, 2.01, for age <54, 55-64, 65-74, and >75 years, respectively). Compared with patients without dysplasia (SIR, 2.01; 95% CI, 1.54-2.57), patients with dysplasia had significantly higher risk of GCA (mild-to-moderate dysplasia, SIR, 7.82; 95% CI, 3.75-14.39; severe dysplasia, SIR, 35.23; 95% CI, 15.17-69.41).
CONCLUSION: IM is a risk factor for GCA with moderate increased risk, but the existence of dysplasia significantly increase the risk of GCA.

P1628 LOW GRADE GASTRIC DYSPLASIA: THE LONG-TERM EVOLUTION

D. G. Ferreira[1,*], R. Marcos-Pinto[1], M. Salgado[1], R. Dias[2], I. Pedroto[1]. [1]*gastroenterology,* [2]*Pathology, centro hospitalar do porto, Oporto, Portugal*

INTRODUCTION: Although we recognize the importance of dysplasia as the penultimate stage of gastric carcinogenesis, its natural history is not clarified.
AIMS&METHODS: The aim of the present study is to evaluate the long - term evolution of the low grade gastric dysplasia, not submitted to endoscopic/surgical treatment.
RESULTS: Of the 51 patients, 46% belong to the male sex. 5/51 (9.8%) of the patients were less than 55 years of age and simultaneously had a family history of gastric cancer. 48/51 (94%) had extensive intestinal atrophy/metaplasia and 37 (72.5%) dysplasia only in the antrum. In regard to the endoscopic aspect, 27/51 (53%) showed dysplasia in flat mucosa, 20/51 (39.2%) in nodular mucosa and 4/51 (7.8%) in depressed mucosa. The histological degree regressed in 30/51 (58.8%) of the cases (average time: 9.1 months), maintained in 13/51 (25.5%) and developed in 8/51 (15.7%, average time 32 months). Of the lesions that regressed, 20/30 (66.7%) were initially detected in flat mucosa (p<0,008). The eight who had a histological evolution of the lesions initially showed low degree multifocal dysplasia, while none of the rest showed any signs of multifocality (p<0,001).
CONCLUSION: Almost all the patients showed regression of the lesions in the follow up. 15.4% of the cases had an evolution of histological degree. In this study the initial detection of the changes in the flat mucosa correlated significantly with its regression. The multifocality of the lesions was related with its progression in a significant statistical way.

P1629 ENDOSCOPY RESEARCH OPPORTUNITIES IN DIFFERENTIAL DIAGNOSIS OF MALIGNANT GASTRIC ULCER.

D. Tashkhodjaev[1,*]. [1]*National Research Center of Oncology, Tashkent, Uzbekistan*

INTRODUCTION: To study the endoscopy research opportunities in differential diagnosis of malignant gastric ulcer from chronic ulcer.
AIMS&METHODS: We have examined 79 patients with initial diagnosis of chronic gastric ulcer, who appealed in the consultative clinic of NCRC during the period from 2009 to 2012 years. All patients were checked with endoscopy with target biopsy (4-5 margins) Next examination was done in average in 12 months. During the time between examinations, patients received conservative treatments, herewith 25 of them (31,6%) got antiulcer eradication heatment Helicobacter pylori.
RESULTS: In our researches, gastric ulcers of 29 patients (36,7%) were becoming malignant in average in 12 months after first visit. Malignancy of gastric ulcer happened, generally, at the margings where gastric mucosa had prolonged non-healing defects. In some cases malignancy happened unicentric from one margin or multicentric up to malignancy of all the periphery of the ulcer, and later on distributed to the bottom. Endoscopically margings of gastric ulcer are high, rough, folds were converging to the edge of the ulcer. With malignancy of the ulcer from the margins of ulcerative defect, neither gastric mucosa itself, nor the scar in the area of the bottom of the ulcer don't become malignant completely. Efficiency of the targeted biopsy with multiply takes of pieces of tissue along the whole periphery of the ulcer reached 94-100%. In most of the cases we noticed malignancy of distal stomach - 19 patients (65,5%), less of proximal stomach (in subcardinal site on the greater curvature - 7 patients (24,1%), and of the body (at the border of the antral) - 3 patients (10,3%) (table#1). With examination of the biopsies of 4 patients (13,8%), with malignant ulcers also were discovered complexes of well formed cancer. In 3 cases (10,3%) depth of the invasion of cancer cells was limited by mucous layer, in 4 cases (13,8%) - by mucous and submucosal, in 7 cases (24,1%) - by mucous, submucosal and muscular layers, in 15 cases (51,7%) tumor elements were spreading at the entire thickness of the gastric wall. 7 patients from 29 with malignant ulcers, revealed metastasis in regional lymph nodes ligaments and along the main blood vessels.
CONCLUSION: Very high percentage of the malignancy of gastric ulcers leads to the need of constant oncological alertness for general practitioners at inspection and treatment of peptic ulcer patients. So, the prerequisite of the successful treatment of patients with malignant gastric ulcers is the prompt diagnostics of the nature of the pathological process, on which depends the choice of tactics of the surgery.

P1630 THE FACTORS ASSOCIATED WITH DEVELOPMENT OF INTESTINAL METAPLASIA: A NESTED CASE-CONTROL STUDY

J.-T. Lin[1,*], C.-Y. Wu[2,3], J.-M. Wu[3], M.-S. Wu[4], Taiwan Helicobacter Consortium. [1]*School of Medicine, Fu Jen Catholic University, New Taipei City,* [2]*Faculty of Medicine, National Yang-Ming University,* [3]*Division of Gastroenterology, Taichung Veterans General Hospital, Taichung,* [4]*Division of Gastroenterology, National Taiwan University Hospital, Taipei, Taiwan, Province of China*

INTRODUCTION: Gastric cancer remains one of the leading causes of cancer mortality worldwide. Intestinal metaplasia, the key precancerous lesion of stomach, increases 6-times risk of gastric cancer and usually has no specific symptoms to detect.

AIMS&METHODS: We aim to investigate the factors associated the development of intestinal metaplasia in the general population and relatives of gastric cancer. We conducted a hospital-based nested case-control study based on gastric cancer family cohort and healthy control cohort. This is a hospital-based case control study with age- and gender-matching between 2007 and 2012 at Taichung Veterans General Hospital. Multivariate analyses were conducted to examine the independent factors associated with intestinal metaplasia.
RESULTS: Between 2007 and 2012, we identified 199 subjects with IM and 597 age- and gender-matched controls. Multivariate analyses found family history of gastric cancer (OR: 2.16, 95%CI: 1.38-3.37), *H. pylori* infection (OR: 1.60, 95%CI: 1.14-2.24), and gastric ulcer (OR: 1.78, 95%CI: 1.18-2.68) were independent risk factors for intestinal metaplasia development. Daily consumption of fruit was found to be inversely related with intestinal metaplasia (OR: 0.51, 95%CI: 0.36-0.74).
CONCLUSION: In conclusion, family history, *H. pylori* infection, and gastric ulcer were independent risk factors associated with intentional metaplasia. Daily fruit intake was a protective factor.

P1631 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION IN GASTRIC NEUROENDOCRINE TUMOR IN KOREA :A NATIONWIDE MULTICENTER STUDY

J. Choi[1,*], D. H. Jung[1], J. H. Kim[1], Gastrointestinal neuroendocrine tumor study group. [1]*Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

INTRODUCTION: Gastric neuroendocrine tumor (NET) less than 10 mm and limited to the sub mucosa has a low possibility of lymph node and distant metastasis. Therefore, the endoscopic resection (ER) has been used for these tumors. However, there were several reports about the clinical outcomes of ER in gastric NET.
AIMS&METHODS: We aimed to investigate the safety and efficacy of ER in gastric NET. From January 2002 to December 2011, 181 patients were diagnosed with gastric NET from 25 institutions, Korea. Among them, 80 patients (44%) were treated by ER. The clinicopathologic factor, therapeutic efficacy and follow up results were retrospectively evaluated.
RESULTS: The mean age of the patients was 52.8 ± 11.2 years. The 2 patients have carcinoid symptoms. The proportions of antrum, body, and fundus were 8.8%, 81.2%, and 10.0%. The mean size of the tumors 8 ± 5mm and the elevated lesions in endoscopic gross appearance was most prevalent (65/80). The endoscopic mucosal resection (EMR) was performed on 70 lesions and endoscopic submucosal resection was performed on 10 lesions. The complete resection rate was 89% and the lymphovascular invasion was 6.3%. The proportions of tumor negative lateral and vertical resection margin was 90%. During a mean follow up period of 28 months (range 1 – 106 months), the local recurrence occurred 5 patients and systemic recurrence occurred 1 patients. Among 5 patients with local recurrence, 4 patients underwent successful repeat EMR.
CONCLUSION: The ER may be considered for treatment of gastric NETs because the ER shows a high complete resection rate and provides accurate histopathologic evaluation. However, the appropriate selection criteria for ER in gastric NETs should be applied and the long term follow up data will be needed.

P1632 RISK FACTORS OF RESIDUAL OR RECURRENT TUMOR IN PATIENTS WITH A LATERAL RESECTION MARGIN POSITIVE AFTER ENDOSCOPIC RESECTION OF EARLY GASTRIC CANCER.

K. J. Park[1,*], Y. S. Park[1], C. M. Shin[1], H. J. Kim[1], N. Kim[1], D. H. Lee[1]. [1]*Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Korea, Republic Of*

INTRODUCTION: Tumor-positive resection margins after endoscopic resection in early gastric cancer (EGC) patients pose a conflict in the outcome. Therefore, many treatment methods have been proposed such as close follow up with endoscopic exam, surgical resection, argon plasma coagulation (APC) and endoscopic resection (ER).
AIMS&METHODS: The aim of this study was to identify the associated risk factors in positive endoscopic lateral resection margin of EGC and therefore estimating the outcomes. A retrospective analysis of 602 patients (625 lesions) who underwent endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) of EGC at a single institute was performed. The patients with positive lateral resection margin after ER were divided into two groups, with and without residual/recurrent tumor. Clinicopathological characteristics and risk factors in lateral resection margin positive patients were analyzed.
RESULTS: A total of 91 patients with a positive lateral resection margin after EMR (n = 49) or ESD (n = 42) were enrolled. The residual/recurrent tumor rate was 35.4% (33 of 93 lesions). 19 had additional surgical gastrectomy, 25 had ER, 13 had argon plasma coagulation and 34 had close observation. Univariate analysis found that residual/recurrent tumor was associated with endoscopic resection type (EMR, ESD), gross type (elevated 37 lesions, flat or depressed 56 lesions), differentiation (differentiated 84 lesions, undifferentiated 9 lesions), and depth of invasion (mucosa 73 lesions, submucosa 20 lesions). Multivariate analysis found the independent risk factor of residual or recurrent tumors to be associated with the type of endoscopic resection (OR 2.885; 95 % CI 1.472–5.653, p = 0.002) and differentiation (OR 4.554; 95 % CI 1.045–19.846, p = 0.044).
CONCLUSION: Patients with EMR, undifferentiated in positive lateral resection margin after endoscopic resection of EGC are recommended to undergo additional endoscopic or surgical resection due to a high risk in residual/recurrent tumor.

P1633 VOLATILE COMPOUNDS IN BREATH TO DIFFERENTIATE BETWEEN GASTRIC CANCER AND BENIGN CONDITIONS

M. Leja[1,2,*], H. Amal[3], K. Funka[1,2], I. Liepniece-Karele[1,2], R. Skapars[1,2], H. Haick[3]. [1]*Faculty of Medicine, University of Latvia,* [2]*Riga East University hospital, Riga, Latvia,* [3]*Department of Chemical Engineering and Russell Berrie Nanotechnology Institute, Technion – Israel Institute of Technology, Haifa, Israel*

INTRODUCTION: Most of the gastric cancers are diagnosed at advanced stages when the survival results are unsatisfactory. Therefore, there is a need for non-invasive markers to diagnose the disease at early stage. Here we report the initial results of volatile marker diagnostic development approach program.
AIMS&METHODS: The study aimed to identify potential volatile organic compounds (VOCs) present in exhaled breath characteristic to gastric adenocarcinoma.
Altogether 364 patients (148 men, 216 women; median age 62; range 22-87) were included to the study. Out of them 82 patients had morphologically confirmed gastric adenocarcinoma prior to surgery or chemotherapy; 45 patients had peptic ulcer disease (either active or a scar), 21 patients were diagnosed low-grade dysplasia in the gastric mucosa, while 216 patients were serving as group of control (all with documented stomach mucosa status according to Updated Sydney system; this group included also patients with atrophy and/or intestinal metaplasia).
Exhaled breath samples were collected in adsorbent tubes and stored until analyzed. The analysis was performed by using gas chromatography coupled with mass spectrometry (GC-MS) in order to identify the chemical composition of the samples.
Student t-test was used to judge the difference in VOCs between the groups; the significance level was set at 0.05.
RESULTS: Altogether 133 volatile components were identified; 17 of them revealed differences between some of the comparisons. Eleven VOCs were found in significantly higher concentrations in the cancer group when compared to the controls (see Table). Six compounds (2- methyl-1-propene; 2,4 dimethyl-Heptane; 4- methyl-Octane; 1,2,3 trimethyl-Benzene; 4- methyl-Decane; Naphtalene) were higher in cancer than in dysplasia cases. Four compounds (o-Xylene; alpha-Methylstyrene; 1,2,3 trimethyl-benzene; 1,2,3,4 tetramethyl-benzene) were higher in peptic ulcer than in controls. However, no difference was revealed between the dysplasia and control as well as between the cancer and peptic ulcer groups.
CONCLUSION: Specific volatile components in exhaled breath can discriminate between gastric cancer and benign conditions. This finding provides background for further new developments of volatile component applications in diagnostics, including for nanosensor based applications.
Disclosure of Interest: None Declared
Keywords: breath test, Gastric adenocarcinoma, volatile markers

P1634 CLINICAL UTILITY OF MOLECULAR CHARACTERIZATION OF GASTRIC CANCERS BASED ON SOMATIC MUTATIONS AND GENE AMPLIFICATIONS

P. Minarikova[1,*], L. Benesova[2], B. Belsanova[2], L. Dusek[3], I. Tuckova[4], F. Belina[5], M. Zavoral[1], M. Minarik[2]. [1]*Internal clinic, 1st Faculty of Medicine, Charles University and Central Military Hospital, Military Faculty Hospital,* [2]*Center for applied genomics of solid tumors, Genomac Research Institute, Prague,* [3]*Institute of Biostatistics and Analyses, Masaryk University, Brno,* [4]*Department of pathology, Central Military Hospital, Military Faculty Hospital,* [5]*Surgery clinic, 2nd Faculty of Medicine, Charles University and Central Military Hospital, Military Faculty Hospital, Prague, Czech Republic*

INTRODUCTION: According to the Czech national cancer register the prognosis of gastric cancer patients has remained unchanged over the course of the past 20 years. With a 5-year survival of just 30% (for all stages) it is the third most fatal malignancy of the gastrointestinal tract and sixth overall among solid cancers. The recent trends in discovery and use of biomarkers in other cancers have been mainly derived from detailed tumor profiling. Somatic mutations and gene amplifications are among the molecular aberations frequently studied.
AIMS&METHODS: It is the main purpose of this work to investigate frequency of somatic mutations and gene amplifications from FFPE sections as well as fresh biopsies in a group of 85 gastric cancer patients and to evaluate their potential utility in early diagnosis as well as therapy prediction and prognosis. We screened 7 genes frequently mutated in gastrointestinal cancers including APC, CTNNB1, KRAS, BRAF, EGFR, PIK3CA and TP53. In addition, we evaluated gene amplifications in a panel consisting of 70 genes often implicated in tumorogenesis.
RESULTS: The overall success rate of DNA extraction from the gastric FFPE samples was at a level of 85%. We have recorded fequencies of somatic mutations similar to the reports by Catalogue of Somatic Mutations in Cancer (COSMIC). The portion of mutated patients in the group was 24% (16/69) with TP53 as the most frequently mutated gene (12x), followed by PIK3CA (3x). When applying Lauren classificaion, most mutations were detected in samples of intestinal compared to the diffuse type, however, no effect of presence of somatic mutation on tumor localization, stage or survival was observed. The complex gene amplifications patterns were processed by hierarchical classification resulting in distinct clusters.

CONCLUSION: Somatic mutations are not associated with localization or stage and are likely not factors in prognosis of the disease. Molecular classification of gastric cancer based on gene amplification patterns results in distinct tumor similarities that may have clinical relevance for clinical management of gastric cancer.

P1635 RECURRENCE OF GASTRIC POLYPS AFTER ENDOSCOPIC REMOVAL WITH OR WITHOUT H. PYLORI ERADICATION

S. Y. Kim[1,*], J. J. Hyun[1], S. W. Jung[1], J. S. Koo[1], R. S. Choung[1], S. W. Lee[1], J. H. Choi[1]. [1]*Korea University Ansan Hospital, Ansan, Korea, Republic Of*

INTRODUCTION: Gastric polyps are not rare finding during endoscopic examination. Evidence indicates that eradication of Helicobacter pylori (H. pylori) leads to disappearance of hyperplastic polyps in the stomach. However, little is known about the effect of the eradication of *H. pylori* on recurrence of hyperplastic or other gastric polyps following endoscopic removal.

AIMS&METHODS: The aim of the study was to evaluate the recurrence rate of gastric polyps after endoscopic removal and the association between the polyp recurrence and *H. pylori* eradication. The medical records of patients diagnosed with gastric polyps between January 2008 and December 2009 were reviewed. Gastric polyps were removed by biopsy or polypectomy according to the size or polyps. *H. pylori* infection and the success of eradication were assessed by endoscopic biopsy or urea breath test. At follow-up endoscopy, recurrence of gastric polyps was investigated.

RESULTS: Of the 248 patients with gastric polyps, 134 patients who underwent the follow-up endoscopy at least 2 months later after removal of polyps were analyzed. Thirty-three patients had hyperplastic polyps, 30 patients had fundic gland polyps and 71 patients had inflammatory polyps. Among 58 patients with *H. pylori* infection, 41 received the eradication therapy. During mean follow-up for 29.5 months, 2 patients showed the recurrence of gastric polyp after *H. pylori* eradication and no recurrence was observed in patients who did not receive the eradication therapy. There was no significant difference in recurrence rate of gastric polyps between patients with and without *H. pylori* eradication.

CONCLUSION: The eradication of *H. pylori* dose not reduce the recurrence of gastric polyp following endoscopic removal of gastric polyps.

P1636 THE ASSOCIATION OF MUCIN PHENOTYPIC EXPRESSION OF GASTRIC CANCER AND SURVIVAL RATE

T. Shibata[1,*], T. Tahara[1], J. Yonemura[1], T. Kawamura[1], K. Sumi[1], Y. Ichikawa[1], M. Okubo[1], M. Miyata[1], T. Ishizuka[1], M. Nakamura[2], T. Arisawa[2], I. Hirata[1]. [1]*Gastroenterology, FUJITA HEALTH UNIVERSITY, Toyoake,* [2]*Gastroenterology, Kanazawa Medical University, Uchinada, Japan*

INTRODUCTION: So far, gastric cancers were classified into intestinal type and diffuse type based on Laurens criteria. Recently new immunohistochemical technique developed new classification criteria to gastric cancer. This classification is divided to gastric type and intestinal type. Moreover it has been gradually clarified that gastric type is often associated with poor prognosis and bad behavior.

AIMS&METHODS: In this study, we examined about mucin phenotype and analyzed about survival rate of gastric cancer patients.

Gastric cancer phenotype was classified by immunohistochemical method. We used anti-MUC2, MUC5AC, MUC6 and CD10 antibodies. Over 10% positive area in a specimen was considered positive phenotype. Along with the expression pattern of these mucin antibodies, we divided into gastric type, intestinal type, mixed type, and non-expression type. Gastric cancer patients were all received chemotherapy, and median survival time (MST) was calculated. The survival curve for each phenotype was showed by the Kaplan-Meyer method, and statistical analyses were applied by log-rank test.

RESULTS: Gastric type was defined as MUC5AC and MUC6 positive type and 12 patients were this phenotype. Intestinal type was defined as MUC2 or CD10 positive type and 6 patients were this phenotype. Mixed type was defined as these mucin positive type and 15 patients were this phenotype. Undifferentiated type was all mucin negative type and 8 patients were this phenotype. Survival curve after chemotherapy along with Kaplan-Meyer methods showed better prognosis in gastric phenotype patients, whereas intestinal phenotype patients showed poor prognosis (MST of gastric type vs. intestinal type, 1033 vs.191 days).

These survival rates were significantly different between these two groups by log-rank test (p=0.0062). Mixed type survival curve showed intermediate survival time (MST: 425 days).

CONCLUSION: Gastric phenotype by mucin expression patterns may be a predictive factor for the gastric cancer prognosis before chemotherapy. Further study is needed to clarify the mechanism of the association of these mucin phenotype and gastric cancer survival rate.

P1637 UTILITY OF EUS TO IDENTIFY THE EFFECTIVE RESPONDERS FROM PATIENTS WITH GASTRIC CARCINOMA WHO RECEIVE NEO-ADJUVANT CHEMOTHERAPY

X. Zhang[1,*], X. Wang[1], N. Liu[1], K. Wu[1], Institute of digestive diseases, Xijing hospital, Xian,China. [1]*Institute of Digestive Diseases, Xijing Hospital, Xian, China*

INTRODUCTION: EUS is an effective method to evaluate the preoperative stage of gastric cancer. But its clinical usage as an effective evaluator of chemotherapy response is not clear.

AIMS&METHODS: This study aimed to investigate if EUS can be chosen as an effective method to evaluate the treatment response and decide best time for operation of gastric cancer patients who receive neo-adjuvant chemotherapy.39 consecutive patients (Male: 23, median age : 50.5 +/-12.2) with histologically confirmed gastric carcinoma underwent EUS (Olympus-Eum2000-25R) and their EUS TN staging showed T3N0 or above stage and no distant metastasis. These patients were given a standard ECF neo-adjuvant chemotherapy. All these patients who receive neo-adjuvant chemotherapy were examined the TN stage by EUS again after 2 cycles, 3 cycles, 4 cycles till the results showed down-stage or 4 cycles were finished. After that, surgery were performed. All EUS examinations were performed at the day before next cycle. In addition to TN stage, the tumor size was recorded with 3 parameters—the maximum thickness, longitude of tumor and width by EUS. The surgical TN stage and pathological complete response (No residual carcinoma in the primary), pathological partial response (<10% residual carcinoma in the primary) were compared with EUS stage and tumor size change.

RESULTS: After neo-adjuvant chemotherapy, EUS correctly identified 53.8% (21/39) T stage and 46.1% (18/39) N stage of patients, respectively, in line with their histological staging. Whereas, 78.6% patients who EUS showed down-stage (11/14) were confirmed by pathology as partial response. In the same time, the tumor size changes were found correlated with pathological response.

CONCLUSION: Although EUS had relatively low accuracy of TN stage after neo-adjuvant chemotherapy comparing with preoperative EUS staging, the study showed a good correlation between down-stage or dramatic decreased tumor size checked by EUS and pathological response of tumor. So, EUS could be an effective method to evaluate the treatment response and decide best time for operation of gastric cancer patients who receive neo-adjuvant chemotherapy.

***H. PYLORI* III – Poster Area**

P1638 PROSPECTIVE VALIDATION OF ENDOFASTER FOR A REAL-TIME DIAGNOSIS OF H. PYLORI INFECTION DURING UPPER ENDOSCOPY

A. Repici[1,*], A. Bizzotto[2], G. Strangio[1], C. Hassan[2], C. Spada[2], M. E. Riccioni[2], C. Marmo[2], T. A. Di Rienzo[1], G. Cammarota[3], A. Gasbarrini[3], G. Costamagna[2]. [1]*Endoscopy, IRCCS Istituto Clinico Humanitas, Milan,* [2]*Digestive Endoscopy Unit,* [3]*Internal Medicine and Gastroenterology, Catholic University, Rome, Italy*

INTRODUCTION: EndoFaster is a new technology based on a real-time analysis of the gastric juice that can provide informations regarding Hp infection and pH value of the gastric contents. In a previous pilot study, the potential accuracy of EndoFaster in diagnosing *H. pylori* infection during upper GI-endoscopy has been shown.

AIMS&METHODS: Aim of this prospective multicenter study was to validate the efficacy of EndoFaster in a wide cohort of patients undergoing upper GI-endoscopy. Consecutive patients aged 40-75 years undergoing upper GI-endoscopy without either PPI or antibiotic therapies in the previous 4 weeks were prospectively enrolled. EndoFaster is an innovative device that is interposed between the endoscope and the suction system. After aspiration of 4-6 ml of gastric juice, EndoFaster performs an automatic analysis of the ammonium concentration of gastric juice within 2 minutes. Based on the previous pilot study, the test was considered positive for *H. pylori* infection when the ammonium concentration was >65 ppm/ml and negative when ≤55 ppm/ml, being indeterminate in the 56-65 ppm/ml interval. Histology with the addition of urea breath testing in discordant cases was considered as the reference standard for assessing *H. pylori* infection.

RESULTS: Overall, 209 patients were included in the study. However, 26 (12.4%) were excluded, because the aspirated gastric juice was insufficient for determining ammonium concentration. In the remaining 183 patients *H. pylori* infection was present in 71 (39%) patients at reference standard. The test with EndoFaster resulted to be positive in 77 (42%), negative in 86 (47%), and indeterminate in 20 (11%) cases, respectively. When excluding the patients with an indeterminate result, sensitivity, specificity, PPV and NPV of EndoFaster for *H. pylori* infection resulted to be 98.5%, 87.6%, 84.4% and 98.8 % respectively.

CONCLUSION: In this validation study, EndoFaster showed an overall feasibility of 78% and accuracy of 92% for a real-time determination of *H. pylori* status. The test appeared to confirm the high accuracy for *H. pylori* shown in the previous pilot study.

P1639 DUODENAL HYPERPLASTIC ENTEROPATHY WITH INCREASED DENSITY OF ΓΔ INTRAEPITHELIAL LYMPHOCYTES IN HELICOBACTER PYLORI INFECTION

A. Popp[1,*], J. Taavela[2], M. Jinga[1], V. Balaban[3], K. Laurila[2], I. Anca[1], M. Maki[2]. [1]*UMF Carol Davila, Bucharest, Romania,* [2]*Tampere Center for Child Health Research, University of Tampere and Tampere University Hospital, Tampere, Finland,* [3]*University Emergency Military Hospital, Bucharest, Romania*

INTRODUCTION: Not all duodenal biopsy specimens showing villous atrophy with crypt hyperplasia and increased intraepithelial lymphocytes (IELs) are explained by gluten sensitivity. In the present study we measured by morphometry the architectural and inflammatory changes in the duodenum seen in Helicobacter pylori (Hp.)
AIMS&METHODS: Altogether 25 untreated adults (N=25) and children (N=3) with dyspepsia positive for Hp. infection were included in the study. Multiple duodenal biopsies were obtained for the purpose of this study. All patients declared gluten-containing diet and were negative for serum endomysial antibodies. Further, they did not have duodenal IgA deposits targeting transglutaminase 2, a typical finding in coeliac disease. No chronic inflammatory bowel diseases were detected in these patients. Duodenal biopsy villous height : crypt depth ratio (VH:CrD) were measured from well oriented biopsy specimens. The densities of all T cells (CD3, cut off in frozen biopsy samples 37 cells/mm epithelium) as well as $\gamma\delta$ T cell receptor bearing IELs (cut off 4.3 cells/mm) were also measured. If patchy lesions were observed, the densities of IELs were counted in the biopsy specimen with most severe morphological lesions. The study was approved by the Ethical Committee of University of Medicine and Pharmacy "Carol Davila" Bucharest.
RESULTS: Shortened duodenal villi, less than 300 μm in length, were seen in 7/25 Hp.patients (28%). VH:CrD < 2, typical for untreated coeliac disease was observed in 16/25 individuals (64%) (range 0.5-4.0) together with crypt hyperplasia in 12/25 patients. All three of the Hp. infected children also had enteropathy with crypt hyperplasia. Duodenitis, expressed as increased density of CD3 positive IELs, was seen in 76% of the patients. Remarkably, 21/25 (84%) had an increased density of $\gamma\delta$ IELs ranging from 4.7 to 18.7 cells/mm epithelium, comparable to densities seen in coeliac disease.
CONCLUSION: We show for the first time small intestinal architectural changes, villus atrophy with crypt hyperplasia, to occur in acute Hp. infection. The duodenitis part is well known but also Hp. infected individuals react with an inflammation resulting in an increased density of $\gamma\delta$ T cells in the epithelial compartment. Acute Hp. infection, prevalent in many parts of the world, may result in a duodenal enteropathy mimicking coeliac disease, partial and subtotal villous atrophy together with mucosal inflammation. The finding of this kind of "coeliac-type" small intestinal mucosal behavior in Hp. infection should be repeated in larger patient cohorts.

P1640 EFFICACY OF SEQUENTIAL THERAPY AND CVADRUPLE THERAPY AS FIRST-LINE REGIMENS IN HELICOBACTER PYLORI ERADICATION

A.-M. Singeap[1,2,*], A. Trifan[1,2], C. Cojocariu[1,2], I. Girleanu[1,2], C. Sfarti[1,2], C. Stanciu[1,3]. [1]*Center of Gastroenterology and Hepatology,* [2]*University of Medicine and Pharmacy "Gr. T. Popa",* [3]*Romanian Academy, Iasi, Romania*

INTRODUCTION: *H. pylori* is an important pathological factor for gastritis, ulcer, gastric carcinoma and gastric MALT lymphoma. Eradication of infection depends of patient compliance and resistance of bacteria to antibiotics. In the regions with high resistance to clarithromicin, first treatment choices are sequential or cvadruple therapy.
AIMS&METHODS: AIM: To evaluate the efficacy of sequential and cvadruple therapy as first-line regimens for H. Pylori eradication in patients with actual documented infection, untreated previously. PATIENTS AND METHODS: We studied the efficacy and tolerance of two eradication regimens, administered to two groups of patients with actual infection (proven by respiratory test, fecal antigen or biopsy): A-sequential therapy with PPI double dose+Amoxicillin 1gx2/day 5 days followed by PPI double dose+Clarithromicin 0.5gx2/day+ Metronidazol 0.5gx2/day 5 days, B-cvadruple therapy with PPI double dose+Tetracyclin 0.5gx4/day+ De-Nol 120mgx4/day + Metronidazol 0.25gx4/day, 10 days. We analysed also the secondary effects by questionning the patients.
RESULTS: 48 patients were treated. In group A (26 patients), eradication was tested in 22 patients and was obtained in 18 patients (ITT 69%, PP 84%). In group B (22 patients), eradication was tested in 19 patients and was obtained in 18 patients (ITT 72%, PP 86%). Adverse events appeared in A - 15% cases, B-18% cases, with no influence on finalizing the treatment.
CONCLUSION: The efficacy of both eradication treatments proposed as first-line regimens is high. The eradication rate was superior to triple therapy (70-80% in studies) but lower that similar regimens metaanalysis.

P1641 IS THE ERADICATION OF HELICOBACTER PYLORI POSSIBLE WITH HIGH-DOSE PPI IN EXTENSIVE METABOLISERS WITH RESPECT TO CYP2C19 GENOTYPE POLYMORPHISM?

A. Örmeci[1,*], Z. Emrence[2], B. Baran[1], O. soyer[1], S. Gokturk[1], F. Akyuz[1], C. Karaca[1], F. Besisik[1], S. Kaymakoglu[1], D. Ustek[2], K. Demir[1]. [1]*Gastroenterology,* [2]*DETAM, Istanbul University, Istanbul, Turkey*

INTRODUCTION: CYP2C19 genotype polymorphism is a significant factor on the treatment success of *H. pylori* eradication. In terms of genotype polymorphism in CYP2C19, the eradication of *H. Pylori* has been found unsuccessful in consequence of the insufficient rise of intragastric pH and the low level of antibiotic bioavailability in extensive metabolisers.
AIMS&METHODS: It is our aim to determine whether the eradication rate increases with the treatment of high-dose PPI in extensive metaboliers in which the eradication ended unsuccessfully with the previous treatment of standard dose PPI. H. Pylori eradication could not be achieved with standard eradication treatment in extensive metabolisers were included in the study. In our previous study in addition to a standard dose of antibiotics, an eradication treatment with rabeprazole and pantoprazole were performed for the patients (n156) with extensive metabolisers during 14 days. Among this group, 25 patients who did not respond to the eradication treatment were administered a high dose of PPI for the 2nd eradication treatment. As in the first eradication treatment, clarithromycin 2x500 mg and amoxicilline 2x1 gr were given. The dose of rabeprazole for PPI was increased to 3x20 mg and for the group given 3x40 mg pantoprazole in the second treatment.
RESULTS: The eradication rate with normal dose of PPI is 64.7% (n:101) for the 156 extensive metabolisers. The usage of rabeprazole or pantoprazole on the eradication rate was not found. The eradication was not achieved in 55 of 156 patients with extensive metabolisers. Among this group the 25 patients whose eradication treatments were unsuccessful were administered the second eradication treatment with high-dose PPI. 68% (n:17) of them were female. 48% (n:12) of the patients were given rabeprazole. The eradication rate in high dose of PPI (n:25) group was 80% (n:20). The eradication rate was higher for the patients eradicated with high dose of PPI treatment (standart dose 64.7% vs. high dose 80%). In the extensive metaboliser, the impact of different PPI usages on the success of eradication was not been determined (p=0.54).
CONCLUSION: In *H. pylori* eradication, in terms of antibiotic bioavailability the intragastric pH should be 5 or over for 24 hours. In extensive metabolisers, in case of a failure of the eradication treatment before applying to different treatment protocols, the treatment may become successful with the increase of PPI on condition that the antibiotic and the duration are reserved.

P1642 HELICOBACTER PYLORI ERRADICATION WITH STANDARD TRIPLE THERAPY - FORGET OR USE?

D. G. Ferreira[1,*], F. Castro-Poças[1], R. Marcos-Pinto[1], S. Barrías[1], G. Pereira[1], I. Pedroto[1]. [1]*gastroenterology, centro hospitalar do porto, Oporto, Portugal*

INTRODUCTION: The most popular first line Helicobacter pylori eradication scheme is the called triple standard (STT): PPI bid and clarithromycin (500mg bid) associated with amoxicillin (1g bid) 7 to 14 days. The Maastricht IV consensus recommended based mainly in Italian studies, a novel first-line quadruple therapy (sequential or concomitant) in countries with high clarythromycin resistance. This scheme adds complexity and costs to the eradication schemes. Also, some recent studies have not demonstrated differences between the effectiveness of STT and the sequential therapy.
AIMS&METHODS: AIM: Evaluate the efficacy of HP eradication with STT (14 days) in a cohort of patients treated in the period of between January 2005 and December 2012 in a tertiary center in Northern Portugal. METHODS: Retrospective cohort study. Inclusion criteria: 1) proven HP infection; 2) eradication treatment with STT 14 days ; 3) HP eradication confirmed by urease breath (UBT) test 6-8 weeks after treatment. Exclusion criteria: 1) previous treatment with HP; 2) age inferior to 18 years; 3) previous gastric surgery; 4) PPI, antacid or misoprostol 4 weeks before UBT.
RESULTS: RESULTS: 1073 patients were included in this study. 44.7% (n=480) of male sex. Average age: 50.6 years old. HP was successful eradicated in 67.1% of the patients treated with IAC 14 days. We found a relation statistically significant between: 1) age and the therapy result (p=0,029) with younger patients showing lower eradication rates and 2) the year of eradication and therapy result (p=0.039) with athe lowest eradication success with STT in 2012 (53%)
CONCLUSION: CONCLUSION: This study is consistent with the most recent literature which reports the eradication levels with STT inferior to 70% much less than desirable. This study supports that this eradication scheme shoul be abandoned in our area.

epidemiological research laboratory, Faculty of medicine and pharmacy. Mohammed V – Souissi University, RABAT, Morocco

INTRODUCTION: Eradication rates following standard triple therapy for *Helicobacter pylori* infection are declining. Recent studies, conducted in some countries, have shown that sequential therapy for *H. pylori* infection yields high cure rates.
AIMS&METHODS: Aim: To compare the efficacy and tolerability of a sequential regimen as a first-line treatment of *H. pylori* infection with a standard triple regime in Morocco.
Methods: A total of 281 naive *H. pylori* infected patients, confirmed by histological examination, were assigned randomly to either standard triple therapy (omeprazole (20 mg) bid plus amoxicillin (1g) bid and clarithromycin (500 mg) bid for 7 days) or sequential therapy groups (omeprazole (20 mg) twice daily (bid) plus amoxicillin (1g) bid for 5 days, followed by omeprazole (20 mg) bid plus tinidazole (500 mg) bid and clarithromycin (500 mg) bid for a further 5 days. *H pylori* eradication was checked four to six weeks after treatment by using a 13C-urea breath test. Compliance and adverse events were assessed.
RESULTS: The two groups did not differ significantly in gender, age, previous disease history, endoscopic and histological features and smoking. The intention-to-treat and per-protocol eradication rates were 65.9% and 71% in the standard triple group, and 82.8% and 89.9% in the sequential group, respectively. The eradication rate was significantly higher in the sequential group compared with the standard triple group ($p < 0.001$), There was no statistically significant difference in compliance (97.5% vs. 96.3%) and incidence of side-effects (27.5% vs 27.9%) between the two groups.
CONCLUSION: for eradication of *H. pylori*infection, the ten-day sequential therapy is more effective than the standard triple therapy and it is equally tolerated compared with.

P1644 ENHANCING BACTERICIDAL EFFECT (IN VITRO) AGAINST HELICOBACTER PYLORI AND AMELIORATING TOXIC EFFECT BY PRE-TREATMENT OF CHITOSAN IN PHOTODYNAMIC THERAPY USING ENDOSCOPIC LIGHT SOURCE AND METHYLENE BLUE.

H. Chae[1,*], K. Kim[1], S. Y. Ko[1], S. Jung[1], H. Kim[1], Y. Cho[1], S. Choi[2]. [1]*Internal Medicine, St. Mary's Hospital, Catholic University of Medical College, Uijongbu,* [2]*College of Pharmacy, Sahmyook University, Seoul, Korea, Republic Of*

INTRODUCTION: Photodynamic therapy (PDT) is a method for inactivating cells (viral, bacterial and cancer cells) using photosensitizers (PS) and light of various wavelengths. Recently, we have reported the killing effects against *Helicobacter pylori* (Hp) by PDT using endoscopic light (*J Photochem Photobiol B 2010;101:206, J Photochem Photobiol B 2012;117:55*). Methylene blue (MB) has been used commonly as standard PS but it has also genotoxic effects to DNA of human cells. To decrease these cytotoxic effects, the authors investigated the study to minimize the dose of MB in PDT by pretreatment of chitosan.
AIMS&METHODS: The standard strain of *H. pylori*, 26695, was purchased from the Korean Culture Type Collection (KCTC, Taejeon, Korea) for use as a test strain. Hp was cultured at 37 °C in a standard microaerobic (5% O_2, 10% CO_2 and 85% N_2 gas) atmosphere. After pre-incubation for 15min with or without low molecular chitosan (50 KDa, Sigma Chemical Co, St. Louis, MO, USA) along with various kinds of concentration of MB (Sigma Chemical Co, St. Louis, MO, USA). Endoscopic white light source from endoscopy (Olympus Co. Japan) were irradiated for 5, 10 and 15 min. For detection of DNA injury by irradiation, alkaline gel electrophoresis was done with DNA from harvested Hp after treatment with Endonuclease III (NEB, Ipswich, MA, USA).
RESULTS: The bactericidal effects were measured by counting viable cells after PDT. In the control group, the number of viable cells was maintained constantly during the experiment. In the groups treated with either 0.02 mg/ml MB alone for 15 min, bacteria decreased approximately a tenfold. The group that treated with 0.02mg/ml MB with 0.005% chitosan showed 100 fold reductions. In the group treated with 0.04 mg/ml of MB alone for 15 min, bacteria decreased about 100,000 fold. The group treated with 0.04 mg/ml MB with 0.005% chitosan, showed 1,000,000 fold reductions. The bacterial killing effects of PDT using MB substantially increased by the treatment of 0.005% chitosan.
CONCLUSION: Bacterial killing by using methylene blue with pre-treatment of chitosan under endoscopic light might be more effective than by only methylene blue. Furthermore, it might ameliorate the genotoxic injury by decreasing the dose of methylene blue.

P1645 EVALUATION OF CHANGES IN SERUM PEPSINOGEN AND GASTRIN LEVELS IN RESPONSE TO THE ERADICATION OF HELICOBACTER PYLORI INFECTION

Z. Torabizadeh[1], I. Maleki[2,3,*], F. Montazer[1], F. Naghshvar[1], M. Mokhtare[2]. [1]*Pathology,* [2]*Internal Medicine,* [3]*Inflammatory Diseases of Upper Gastrointestinal Tract Research Center, Mazandaran University of Medical Sciences, Sari, Iran, Islamic Republic Of*

INTRODUCTION: Gastric *H. pylori* infection is the leading cause of gastritis, peptic ulcer disease, gastric adenocarcinoma and lymphoma (MALT). Evaluation of the infection eradication after treatment is important. Chronic *H. pylori* infection is associated with gastric gland atrophy and dysfunction, causing increased serum levels of gastrin and pepsinogen. In recent years measurement of serum gastrin and pepsinogen subtypes has been considered to evaluate the eradication of *H. pylori* eradication and as a marker of gastric mucosal health.
AIMS&METHODS: Eighty patients with positive *H. pylori* infection were enrolled. All of the patients were endoscopied and had been scheduled for eradication therapy. We evaluated the changes of serum gastrin and pepsinogen type 1 and 2 in these patients before and after eradication therapy in two weeks intervals until eight weeks after the initiation of treatment. The results were classified according to the success rate of eradication.
RESULTS: Pepsinogen type 1 and 2 and gastrin serum levels significantly decreased after successful eradication in comparison with failed eradication. All three markers decreased after 8 weeks of therapy significantly. Pepsinogen 1 decreased by 41.1% after 8 weeks of eradication (p value < 0.001). These rates were 64.1% for pepsinogen 2 and 31% for gastrin levels (p values < 0.001 for both). Even after two weeks of initiation of the successful eradication therapy significant decreases in these markers have been recorded ($p < 0.001$ for all biomarkers).
CONCLUSION: According to the findings of this study, changes in the type1 and 2 pepsinogen and gastrin serum levels can be a reliable indicator of successful eradication of *H.pylori* infection. These results can even be used as early as two weeks after prescription of the eradication regimens.

P1646 COMPARISON OF QUADRUPLE AND TRIPLE DRUG REGIMENS CONTAINING FURAZOLIDONE ON ERADICATION OF HELICOBACTER PYLORI

V. Hosseini[1,2], M. Mokhtare[1], H. Fakheri[1,2], T. Taghvaei[1,2], I. Maleki[1,2,*], M. Valizadeh[1], M. S. Massarrat Mashhadi[3], A. Khalilian[4]. [1]*Internal Medicine,* [2]*Inflammatory Diseases of Upper Gastrointestinal Tract Research Center, Mazandaran University of Medical Sciences, Sari,* [3]*Gastroenterology, Digestive Disease Research Center, Tehran,* [4]*Biostatistics, Mazandaran University of Medical Sciences, Sari, Iran, Islamic Republic Of*

INTRODUCTION: The effectiveness of most commonly recommended eradication regimens of *Helicobacter pylori* has decreased to unacceptably low levels, largely related to development of resistance to metronidazole and clarithromycin and successful eradication of H pylori infections remains a challenge. Alternative treatments with superior efficacy and safety should be designed and appropriately tested in all areas depending on their native resistance patterns. Furazolidone has been used successfully in eradication regimens previously.
AIMS&METHODS: *Helicobacter pylori* infected patients with proven peptic ulcer, duodenal and /or gastric erosions were randomly allocated into three groups: group A (OABF) with furazolidone (F) (200 mg b.i.d.), group B (OABM-F) metronidazole (M) (500 mg b.i.d.) for the first five days, followed by furazolidone (F) (200 mg b.i.d.) for the second five days and group C (OAF) with furazolidone (F) (200 mg t.i.d.). Omeprazole (O) (20 mg b.i.d.) and amoxicillin (A) (1000 mg b.i.d.) were given in all groups; bismuth (B) (240 mg b.i.d.) was prescribed in groups A & B. Duration of all eradication regimens were ten days. Two months after treatment, a C14-urea breath test was performed.
RESULTS: Three hundred and seventy two patients were enrolled (124 patients in each group). One hundred and twenty patients in group A (OABF), 120 patients in group B (OABM-F) and 116 patients in group C (OAF) completed the study.
The intention-to-treat eradication rates were 83.7% (95% CI = 77.3–90.4), 79.8% (95% CI =72.6–87), and 84.6% (95% CI = 78.2–91.1) and per-protocol eradication rates were 86.6% (95% CI = 80.5–92.8), 82.5% (95% CI = 75.6–89.4), and 90.5% (95% CI = 85.1–95.9) for groups OABF, OABM-F, and OAF, respectively. No statistical significant differences were found in severe drug adverse effects between the above mentioned three groups. The most common deleterious effect, nausea and fever, occurred in all groups, but more frequently in group C (OAF) with $p < 0.05$.
CONCLUSION: In developing countries, furazolidone-based regimens can substitute clarithromycin-based regimens for *Helicobacter pylori* eradication because of a very low level of resistance and low cost. Considering per-protocol eradication rate of ten days OAF regimen, and the acceptable limit of ninety percent, we recommend this regimen in developing countries like Iran. In order to minimize rare serious adverse effects, one week high dose OAF regimen should be taken into consideration in later studies.

P1647 MAASTRICHT IV: IS IT THE END FOR THE EMPIRICAL TRIPLE THERAPY OF HELICOBACTER PYLORI IN A SOUTH-EUROPEAN COUNTRY?

J. M. Romãozinho[1,2], N. P. Almeida[1], M. M. Donato[2], C. Luxo[3], O. Cardoso[3], M. A. Cipriano[4], C. Marinho[4], A. Fernandes[1,*], C. Sofia[1]. [1]*Gastroenterology, Centro Hospitalar e Universitário de Coimbra,* [2]*Gastroenterology Center, Faculty of Medicine,* [3]*Microbiology Laboratory, Faculty of Pharmacy,* [4]*Pathology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

INTRODUCTION: The most widely used empirical eradication treatment for *Helicobacter pylori* (Hp) involves the association of a proton pump inhibitor

(PPI) with clarithromycin and amoxicillin or metronidazole. The Maastricht IV consensus report recommends that this treatment protocol should not be prescribed if the clarithromycin resistance rate in a specific population exceed 15 to 20%.

AIMS&METHODS: This prospective unicentric study, involving adult patients with positive ^{13}C Urea Breath Test (UBT), was performed to evaluate the success rate of the standard triple therapy for Hp eradication in a south-european country, the corresponding clarithromycin resistance rate and possible factors associated with treatment failure (age, sex, urban/rural residence, personal and family history of gastric pathology, consumption of olive oil/alcohol/tobacco, Body Mass Index, frequent infections requiring antibiotherapy, genetic profiles of Hp, therapy compliance and adverse events). All patients were submitted to upper digestive endoscopy with gastric biopsies for histological and microbiological characterization (genotyping with determination of cagA, babA, vacA and IceA status, and minimum inhibitory concentration determination against metronidazole, clarithromycin, levofloxacin, amoxicillin and tetracycline). They were then treated with standard, triple-therapy protocol (Pantoprazol+ Amoxicillin+Clarithromycin, 14 days). Hp eradication rate was assessed with UBT after 8 to 12 weeks. Statistical analysis with SPSS v20.0.

RESULTS: Eighty patients were enrolled in the protocol (males sex – 23; mean age – 41±13 years) and 75% completed the 14 day therapy. There were adverse effects in 46.3%. Hp eradication was sucessful in 68.8%. Clarithromycin resistance rate was 20% and mutation A2143G was the most commonly identified (18.8%). The factors associated with treatment failure (Hp+ vs Hp-) were: frequent infections (32% vs 10.9%), active smoking (20% vs 3.6%); vacAs2 gene (72% vs 47.3 %); vacAm2 gene (96% versus 74.5%).

CONCLUSION: In this south-european country Hp eradication rate with empirical triple-therapy is very low. Clarithromycin resistance rates are high and, following the Maastricht IV recommendations, the traditional triple treatment should not be used as first choice in this country, especially in patients with a history of smoking or frequent infections.

P1648 THE EFFECT OF AMALGAM FILLING ON HELICOBACTER PYLORI ERADICATION

B. Aktas[1], S. Coban[1,*], O. Yuksel[1], A. Kuşçu[2], A. Albayrak[3], F. Ekiz[1], A. Altinbas[1], B. Yilmaz[1], Ö. Başar[1], K. Karaman[1]. [1]*Gastroenterology, Diskapi Yildirim Beyazit Education and Research Hospital,* [2] *Oral and Dental Health, Mamak Oral and Dental Health Clinic,* [3]*Pathology, Diskapi Yildirim Beyazit Education and Research Hospital, Ankara, Turkey*

INTRODUCTION: Mercury is a toxic and non-essential metal in the human body.

AIMS&METHODS: We aimed to evaluate whether amalgam filling including mercury is an efficient factor on the treatment of H. Pylori (Hp) eradication. A total of 189 dyspeptic cases including 96 patients who have at least one amalgam filling and 93 patients with normal dental examination were enrolled into the study. All the patients were examined by single dentist. The dentist performed the patients' mouth examination in terms of rotting teeth, dental amalgam filling, damaged dental filling, the number of dental filling, and recorded the duration of having dental amalgam filling. The Hp diagnosis was made based on the histology. The patients received the standart triple therapy consisting of lansoprazole, 30 mg b.d., clarithromycin, 500 mg b.d., amoxicillin, 1gr b.d., for 14 days for Hp eradication. Carbon-13 urea breath test was used to determine Hp after drug treatment.

RESULTS: Hp infection in the filling group (74%) was significantly higher than non-filling group (59%) (p:0.031). But there was no significant correlation between Hp colonization severity and both the numbers of amalgam filling and the duration of filling. There was no significant difference regarding endoscopic lesions in both groups. In histopathological examination, atrophy and intestinal metaplasia were similar in both groups. But inflammation and activiation (91.7%, 68.8 %, respectively) were signifancantly higher in the filling group than non-filling group (78,5%, 54.8% ; p:0.011, p:0.049, respectively). Hp infection was detected in 126 (66,67%) subjects in all group. We suggested eradication treatment for Hp infection to the patients. But, 50 patients came after treatment follow-up. The eradication rate following the treatment was 68 % (34/50). Higher eradication rate was seen in the non-filling group (92%, 23/25) compared to filling group (44%, 11/25) (p:0.001). In filling group, there are 11 patients who have filling deformation. The eradication rate in patients with damaged filling were lower (36%, 4/11) than in the patients with undamaged filling (58,3%, 7/12) (p:0.292). Logistic regression analysis of risk factors including age, gender, fillings, endoscopic lesions, and gastric histological findings showed existence of amalgam filling is an independent predictor for *H. pylori* eradication (p:0.001).

CONCLUSION: Hp colonization rate is higher in patients with amalgam filling than unfilling ones and the presence of dental amalgam filling is an independent predictor for insufficent Hp eradication.

P1649 SYSTEMATIC CHARACTERIZATION OF MIR-21 EXPRESSION IN GASTRIC MUCOSA

A. Link[1,*], C. Langner[1], J. Bornschein[1], M. Varbanova[1], T. Wex[1], P. Malfertheiner[1]. [1]*Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke University Hospital Magdeburg, Magdeburg, Germany*

INTRODUCTION: Gastric cancer (GCA) is a complex, *H.pylori*-triggered malignant disease. Global and specific deregulation of microRNA (miRNA) expression patterns are frequently detected in patients with gastric cancer. The aim of our study was to characterize miR-21 expression, the most highly-upregulated miRNA in GCA, in regard to various conditions such as *H. pylori* infection and its preneoplastic precursors in gastric mucosa.

AIMS&METHODS: The aim of our study was to characterize miR-21 expression, the most highly-upregulated miRNA in GCA, in regard to various conditions such as *H. pylori* infection and its preneoplastic precursors in gastric mucosa. In a prospective study, patients were systematically characterized for the presence of *H. pylori* infection, inflammatory, atrophic or malignant changes in gastric mucosa. MiR-21 expression was analyzed using total RNA from biopsies (corpus, antrum and/or primary tumor) of 80 patients (20 normal mucosa (N), 24 chronic gastritis (CG), 20 atrophic gastritis / intestinal metaplasia (AG) and 16 with gastric cancer (GCA) by qRT-PCR. RNU6b has been used for normalization.

RESULTS: As expected, biopsies from the GCA showed higher expression levels of miR-21 ($p = 0.0004$ and 0.0002 for Corpus und Antrum, respectively) in comparison to normal tissue. In the assessment of regional differences in miR-21 expression, we found significantly higher expression in antrum compared to the corpus ($p = 0.016$). Especially in the antrum, presence of *H. pylori* was associated with significantly higher miR-21 expression (mean ± SD for N 0.22 ± 0.08 vs. 0.32 ± 0.12, $p < 0.002$). In confirmation of the histopathological changes, a gradual increase in miR-21 expression was detected in the gastric mucosa from normal mucosa to chronic and atrophic gastritis (N 0.22 ± 0.08, CG 0.33 ± 0.18, AG 0.39 ± 0.11, p=0.0009). Interestingly, not only tumor tissue, but also adjusted normal tissue from GCA patients showed significantly higher miR-21 expression levels (1.2 ± 1.69, $p < 0.02$) as compared to N and CG/AG/IM.

CONCLUSION: Increased expression of miR-21 is characteristic not only for tumors, but also for surrounding mucosa and for antrum and corpus of patients with gastric cancer. *H. pylori* and preneoplastic conditions, such as chronic gastritis and intestinal metaplasia, are also associated with miR-21 upregulation. These findings provide valuable information for the clinical implementation of miRNAs.

P1650 ASSESSMENT OF DISEASE DISSEMINATION IN GASTRIC MUCOSA-ASSOCIATED LYMPHOID TISSUE LYMPHOMA USING EXTENSIVE STAGING: A SINGLE-CENTER EXPERIENCE.

A. Amiot[1,*], M. Levy[1], N. Bousfiha[1], L. Baranes[2], J. Dupuis[3], E. Itti[4], C. Haioun[3], C. Copie-Bergman[5], J.-C. Delchier[1]. [1]*gastroenterology,* [2]*radiology,* [3]*hematology,* [4]*nuclear Medicine,* [5]*pathology, Henri Mondor Hospital, Creteil, France*

INTRODUCTION: Endoscopic ultrasonography (eUS) is considered as the best tool for locoregional staging of patients with gastric mucosa-associated lymphoid tissue (MALT) lymphoma. Diagnostic yield of computed tomography (CT) and (18)F-fluorodeoxyglucose positron emission tomography/computed tomography ((18)FDG-PET) needs to be evaluated in a large cohort.

AIMS&METHODS: Between 1995 and 2013, a total of 218 consecutive patients with gastric MALT lymphoma underwent 328 staging procedures (age 60 (22-86) yrs, 162 males). The standardized staging protocol included gastroscopy with multiple biopsies, eUS, colonoscopy, CT of thorax and abdomen, otorhinolaryngologic assessment and bone marrow biopsy. (18)FDG-PET was also performed in 43 pts. The diagnosis of MALT lymphoma was ascertained on histologic analysis of gastric biopsies in all patients. Performance of CT-scan and (18)FDG-PET were evaluated. The AUROC curves for gastric wall thickness and nodal involvement were calculated.

RESULTS: According to eUS, 145 (51%) out of 287 patients had increased (>5 mm) gastric wall thickness. Ninety-three (32%) out of 287 pts had perigastric lymph node involvement. Both CT and (18)FDG-PET were less efficient than eUS to assess gastric wall thickness and perigastric lymph node involvement.

Increased gastric wall thickness	Se	Sp	AUROC	*p*
Computed tomography	54%	87%	0.70 ± 0.03 (0.64-0.77)	<0.001
(18)FDG-PET	94%	42%	0.70 ± 0.08 (0.54-0.86)	0.03
Lymph node involvement assessment	Se	Sp	AUROC	*p*
Computed tomography	34%	95%	0.65 ± 0.04 (0.58-0.72)	<0.001
(18)FDG-PET	58%	96%	0. 77 ± 0.08 (0.61-0.92)	0.003

However, CT also showed lung and/or liver involvement and superior diaphragmatic lymph nodes in 19 and 2 cases, respectively. (18)FDG-PET showed lung and/or liver involvement in 3 more pts and concomittant neoplasia in 3 cases. Colonoscopy showed colonic involvement in only 2 (0.6%) cases but also permitted to detect adenomas in 29 (9%) pts. Twenty-five (8%) pts had bone marrow involvement. Otorhinolaryngologic assessment showed 3 (1%) pts with dissemination of MALT lymphoma.

CONCLUSION: eUS has an higher diagnostic yield for locoregional staging of pts with MALT lymphoma, compared to CT and (18)FDG-PET. However, dissemination to another MALT organ is frequent (12.5%) and needs to be assess with bone marrow biopsy, otorhinolaryngologic assessment and (18)FDG-PET.

P1651 POTENTIAL ROLE OF THE IQGAP1 PROTEIN DURING HELICOBACTER PYLORI INFECTION AND GASTRIC ADENOCARCINOMA

E. Bessède[1], M. Tsuchiya[1], L. Chambonnier[1], P. Dubus[2], A. Buissonnière[1], A. Giese[2], F. Mégraud[1], C. Varon[1,*]. [1]*Bactériologie, INSERM U853, Université de Bordeaux,* [2]*Laboratoire d'Histologie, Université de Bordeaux, Bordeaux, France*

INTRODUCTION: IQGAP1 is a member of the IQGAP family of scaffold proteins, it is a component of pathways via which Cdc42 or Rac1 modulates cadherin-based cell adhesion. This protein plays a crucial role in the cell adhesion. The gastric adenocarcinomas are classified in 2 different types, the intestinal type which is the more frequent one and the diffuse type. Almost 30% of the diffuse gastric cancer is associated to a mutation of the *cdh*1 coding for the E-cadherin, but the origin of the other 70% is not elucidated. Mutations of IQGAP1 have been detected only in diffuse gastric cancer and not in the intestinal type.
AIMS&METHODS: Our aim was to identify the role of IQGAP1 in *Helicobacter pylori* infection and gastric adenocarcinoma.
Eighty mice, wild type or mutant IQGAP1+/-, were infected with different *Helicobacter* sp. strains (*Helicobacter felis*, *Helicobacter pylori* SS1 and HPARE). Stomachs were recovered 6 months and 1 year after infection. A histologic analysis was performed to evaluate inflammation, hyperplasia, atrophy, metaplasia, and dysplasia.
RESULTS: Six months post-infection, IQGAP1+/- mice had developed more mucous metaplasia than the wild type mice, but no difference was shown between wild type and IQGAP1+/- mice for the other items. Globally, all of the mice infected by Helicobacter strains had developed more inflammation, hyperplasia, atrophy and dysplasia than the non-infected mice. One year post-infection, differences between wild type mice and IQGAP1+/- mice were more important. Finally, IQGAP1+/- mice infected with *H. pylori* HPARE showed significantly more hyperplasia, atrophy, mucous metaplasia, pseudo-intestinal metaplasia and dysplasia.
CONCLUSION: These results suggest than IQGAP1 is a crucial protein in gastric adenocarcinoma linked to *H. pylori* infection.

P1652 PSCA, MUC1, PLCE1 GENE POLYMORPHISMS IN GASTRIC CANCER AND HIGH RISK ATROPHIC GASTRITIS

J. Kupcinskas[1,*], T. Wex[2], A. Link[2], M. Leja[3], L. Jonaitis[1], G. Kiudelis[1], J. Skieceviciene[1], L. Kupcinskas[1], P. Malfertheiner[2]. [1]*Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Lithuania,* [2]*Department of Gastroenterology, Hepatology and Infectious Diseases, Otto von Guericke University, Magdeburg, Germany,* [3]*Digestive Diseases Center, University of Latvia, Riga, Latvia*

INTRODUCTION: Gastric cancer (GC) is one of the major malignant diseases worldwide with very high mortality rates. Intestinal type GC is linked with *H. pylori* infection, while the pathogenesis of diffuse type GC is less understood. Recent genome-wide association studies (GWAS) revieled a link between GC and single nucleotide polymorphisms (SNPs) of the genes encoding prostate stem cell antigen (PSCA), phospholipase C epsilon 1 (PLCE1) and mucin 1 (MUC1) genes. Most of the replication studies of these GWAS results so far have been conducted in Asian populations, while data in Caucasian subjects with GC and premalignant gastric conditions are higly lacking.
AIMS&METHODS: The aim of the study was to evaluate the relationship between SNPs of the genes encoding PSCA (rs2976392, rs2294008), MUC1 (rs4072037) and PLCE1 (rs2274223) with the risk of developing GC or high risk atrophic gastritis (HRAG) in individuals of Caucasian ethnicity.
Gene polymorphisms were analyzed in 634 subjects (GC: n=252; HRAG: n=136, controls: n=246) of Caucasian origin. DNA was extracted from peripheral blood leukocytes using salting out method. PSCA A>G (rs2976392), PSCA C>T (rs2294008), MUC1 G>A (rs4072037) and PLCE1 A>G (rs2274223) SNPs were genotyped by real-time PCR (RT-PCR), using predesigned Taqman primers.
RESULTS: Frequencies of genotypes in our study are similar to the data reported on subjects of Caucasian ethnicity. Analysis of data revealed that the frequencies of all SNP genotypes are in line with Hardy-Weinberg equilibrium. MUC1 A allele (rs4072037) was associated with higher incidence of GC (53.2%, OR – 1.57; p=0.00064) and HRAG (51.5%, OR-1.47, p=0.0136) when compared to controls (42.0%). PSCA T/T genotype of rs2294008 was linked with higher risk of GC (26.3%, OR – 2.41, p=0.00021) and HRAG (17.2%, OR – 1.72, p = 0.04303) when comparing to the control group (12.9%). There was a higher frequency of PSCA rs2976392 A/A genotype in GC group (41.2%, OR-2.35, p=0.00032) and HRAG group (34.8%, OR – 1.82, p=0.0285) than in control group (23.3%). No significant differences were determined between the frequencies of genotypes for PLCE1 rs2274223 with similar distribution of A/A, A/G, G/G genotypes between controls (37.8%, 48.1%, 14.1%), GC (38.5%, 49.8%, 11.7%) and HRAG (41.5%, 42.2%, 16.3%) groups.
CONCLUSION: SNPs of PSCA (rs2976392, rs2294008) and MUC1 (rs4072037) genes are linked with the presence of GC and HRAG and appear as potential biomarkers to identify the risk of these conditions. No significant association was determined between PLCE1 rs2274223 and the risk of GC or HRAG.

P1653 A PILOT STUDY OF CONFOCAL LASER ENDOMICROSOPY FOR STAGING AND FOLLOW-UP OF GASTROINTESTINAL MALT-LYMPHOMA

W. Dolak[1,*], B. Kiesewetter[2], L. Müllauer[3], A. Chott[4], M. Trauner[1], M. Raderer[2], A. Püspök[1]. [1]*Gastroenterology and Hepatology,* [2]*Oncology,* [3]*Pathology, Medical University of Vienna,* [4]*Pathology, Otto Wagner Spital, Vienna, Austria*

INTRODUCTION: The extranodal marginal zone B-cell lymphoma of the mucosa associated lymphoid tissue (MALT-lymphoma) requires lifelong follow-up due to the risk of relapse or transformation into high-grade lymphoma.
AIMS&METHODS: To improve the diagnostic yield for gastrointestinal (GI) MALT-lymphoma during staging and follow-up, we investigated the diagnostic role of confocal laser endomicroscopy (CLE) in the context of a prospective clinical pilot trial (NCT01583699). Patients with suspect of upper-GI MALT-lymphoma underwent endosonography (EUS) followed by upper-GI endoscopy using a CLE-colonoscope (Pentax EC-3870CIFK, working length 150cm, Pentax, Tokyo, Japan and Optiscan Pty Ltd, Notting Hill, Victoria, Australia). After i.v.-administration of 5 ml of 10% flourescein 4-quadrant CLE-pictures and conventional biopsies were taken randomly every 10 centimeters during withdrawal from the deep small bowel to the pylorus, then from the antrum, body and, if technically feasible, the fundus of the stomach, and from the esophagus. Additional CLE-pictures and biopsies were taken from distinct looking areas. At the end of each examination, a preliminary diagnosis based on the CLE-pictures was set. This was later compared to the histological result.
RESULTS: Between January 2012 and April 2013 a total of 22 patients (12 male, 10 female, median age 69 years, range 35 to 80 years) had been studied. Initial MALT-onset included the stomach in 18 cases, the small bowel in 6 cases, the lungs in 2 cases and the colon in 1 case. Histological assessment of conventional biopsies taken during the study revealed MALT-lymphoma of the stomach and duodenum in 13 and 4 patients, respectively. In 7 patients no MALT-lymphoma was found. Compared to histology, the sensitivity of EUS, white light endoscopy and CLE for MALT-lymphoma was 60%, 93% and 87%, the specificity was 71%, 43% and 100%, respectively. In those cases where MALT-lymphoma presence was missed by CLE, infiltration of lymphoma cells was limited to deeper wall layers that could not be assessed by CLE.
CONCLUSION: The results of this first prospective study on the diagnostic role of confocal laser endomicroscopy in GI MALT-lymphoma showed a promising clinical value of this new endoscopic method. Current drawbacks like the limited tissue penetration might be overcome by future technical improvements to make endomicroscopy a reliable tool for a safe and biopsy-sparing surveillance of gastrointestinal MALT-lymphoma.

SMALL INTESTINAL III – Poster Area

P1654 AUTOLOGOUS STEM CELL TRANSPLANTATION FOR REFRACTORY COELIAC DISEASE TYPE II: A PROMISING THERAPEUTIC OPTION - THE IRISH EXPERIENCE

C. Kiat[1,*], I. Feeley[2], Y. Y. Hong[1], P. Maheshwari[2], A. Hayat[3], C. Goulding[2], V. Byrnes[1]. [1]*Gastroenterology, University Hospital Galway, Galway,* [2]*Gastroenterology, Midwestern General Hospital, Limerick,* [3]*Haematology, University Hospital Galway, Galway, Ireland*

INTRODUCTION: Refractory Coeliac disease (RCD II) is serious complication of celiac disease. The risk of progression from RCD II to enteropathy-associated T-cell lymphoma (EATL) is estimated at 60-80% and has poor survival. Therapeutic options for RCD II are limited. To date, the use of a novel therapeutic approach of high-dose chemotherapy followed by autologous stem cell transplant (ASCT) in a small cohort of patients with RCD II has stimulated great interest world wide with promising results.
AIMS&METHODS: We describe two patients with RCD II who received ASCT.
RESULTS: CASE 1: 36-year-old female with an 8 year history of CD who presented with a weight loss, bdominal pain, bloating, and diarrhoea. She was compliant with GFD and negative anti-tTG. Panendoscopy revealed severe ulcerative jejunitus. Duodenal biopsies revealed loss of CD8-positive cells and T cell clonality consistent with RCD type II. Abdominal CT showed abnormal thickening of her jejunum with mesenteric lymphadenopathy. Investigation for overt lymphoma were negative. She required total parenteral nutrition as she was not able to maintain nutrition. Cladribine was commenced as she failed to respond to steroid. Despite that, she was still severely malnourished and she proceeded to ASCT in July 2012. Post-transplant, she is well clinically with resolution of her symptoms. CASE 2: 67-year-old female with a one year history of celiac disease presented with weight loss despite strict GFD. At presentation she weighed 37kg and has progressive ataxia. Panendoscopy showed severe villous atrophy with ulcerative jejunitis. Duodenal biopsies revealed abnormal phenotypic expression of T-lymphocytes with loss of CD8-positive cells with T-cell clonality consistent with RCD type II. Investigations for lymphoma were

negative. She failed to respond to steroid and azathioprine and proceeded to ASCT in December 2011. Post transplant she has maintained her weight and her ataxia has remained stable.
CONCLUSION: RCD II remains very difficult to treat. In the absence of published randomized clinical trials, evidence is growing for the safety and feasibility of ASCT in this disease. 24 patients worldwide (including the 2 described here) have received ASCT for this condition and only one patient to date has developed lymphoma (4 years post ASCT). Our 2 patients are the first and only patients in Ireland and the UK to receive an ASCT for RCD II. Multicentre randomized trials or trials with historical control groups will be needed to consolidate ASCT for patients with RCD II.

P1655 MOLECULAR BASIS FOR THE MYOCARDIUM INVOLVEMENT IN COELIAC DISEASE

I. R. Korponay-Szabo[1,*], B. Tóth[2], B. Ujházi[2], L. Fésüs[2], E. Zilahi[1], M. Maki[3], E. Felszeghy[1], G. Mogyorósy[1]. [1]*Paediatrics,* [2]*Biochemistry and Molecular Biology, University of Debrecen, Debrecen, Hungary,* [3]*Tampere Center for Child Health Research, Univ. of Tampere, Tampere, Finland*

INTRODUCTION: Coeliac disease (CD) is characterized by autoantibodies against endomysium (EMA), a connective tissue sheet around muscle cells. These antibodies target tissue transglutaminase (TG2). It has earlier been reported that CD prevalence is higher among patients with end-stage heart failure or cardiomyopathy.
AIMS&METHODS: Aim of this study was to characterise the myocardial lesions and assess if anti-TG2 antibodies play a role in the cardiac manifestations of CD. Myocardium and mediastinal lymph node biopsy samples were analysed by immunohistochemistry in two adolescent patients (18 and 20 years old) with known CD who presented with severe myocarditis after stopping the gluten-free diet. Consecutive childhood myocarditis cases treated at the intensive care unit were prospectively followed up and investigated for coeliac disease antibodies (anti-TG2 and EMA) and HLA-DQ. Human umbilical cord cells prepared from high-risk newborn first degree relatives of CD patients or cells prepared from the intestinal biopsy specimens of CD patients were differentiated into striated muscle cells and investigated in vitro in the presence of tissueeluted or cloned coeliac antibodies.
RESULTS: Both coeliac adolescents were critically ill and required balloon pump-assisted cardiac support, one of them died. Ultrasound and MRI studies revealed low ejection fraction and signs consistent with myocardial oedema and inflammation, but no viral agent could be identified. Frozen samples of the affected myocardium specimens contained high amounts of in vivo EMA deposition bound to TG2, but no cellular infiltrate of inflammatory cells. Severe myocarditis was diagnosed in 8 children of whom 3 died, 2 were diagnosed with CD by anti-TG2 and EMA serum antibody positivity and jejunal biopsy, both DQ2 positive. The other 3 survivors had neither anti-TG2/EMA antibodies nor DQ2 or DQ8 at the screening for CD, one was later diagnosed with cystic fibrosis and one other with Alström syndrome. During prospective follow up of the risk cohort two children developed CD. In vitro experiments with normal, risk and coeliac muscle cells revealed high susceptibility of affected persons to TG2-specific antibody action.
CONCLUSION: Severe myocarditis could be a sentinel sign of other chronic childhood diseases and HLA-DQ2 or DQ8 carriers should be screened for CD. Anti-TG2 antibodies deposited around myocardial fibres can play a role in the severe clinical presentation upon an otherwise benign (perhaps viral) precipitating illness.

P1656 SIGNIFICANCE OF ANTI A-ENOLASE ANTIBODIES IN CELIAC DISEASE PATIENTS

M. Zwolinska-Wcislo[1,*], M. Przybylska-Felus[1], A. Piatek-Guziewicz[1], P. Rozpondek[1], W. Dynowski[1], T. Mach[1]. [1]*Gastroenterology, Jagiellonian University Collegium Medicum, Krakow, Poland*

INTRODUCTION: Celiac disease (CD) is an autoimmune gluten sensitive enteropathy occuring in genetically predisposed individuals. It is accompanied by presence of multiple antibodies, typically anti endomysium (EMA) or anti transglutaminase (tTG) antibodies (Ab). Some recent studies showed that α-enolase, a multifunctional glycolytic enzyme described as glycolytic pathway component, heat shock protein and plasminogen binding protein might be a possible novel autoantigen in CD. Anti α-enolase Ab were reported in several autoimmunological disorders but data about its presence and role in CD has not been explained so far.
AIMS&METHODS: The aim of this study was to determine the frequency of anti α-enolase Ab, its correlation with the presence of IgA tTG Ab and the intensity of duodenal mucosa lesions in CD patients, depending on the adherence to gluten free diet (GFD).
Methods: We examined 43 CD patients (aged from 18-72 years, mean age 40), including patients newly diagnosed CD (n=9), CD patients non adhering to gluten free diet (n=10), adhering gluten free diet (n=14) and 10 healthy volunteers, the control group. *Clinical investigation* included disease history, gastroscopy with biopsies from the distal part of duodenum. Biopsies for *histology* were stained with H-E and evaluated according to Marsh scale. *Serologic investigation* of blood serum collected from patients included anti α-enolase Ab titer, evaluated with αENOL ELISA Kit (ElAb company, China) and IgA tTG Ab evaluated with ELISA (Demeditec diagnostic GmbH, Germany).
RESULTS: Mean anti α-enolase Ab titer was higher in all CD patients in comparison with control group (1,1 ng/mL and 0,795 ng/mL respectively, p=0,8). In newly diagnosed CD mean titer of anti α-enolase Ab was lower compared to CD patients non adhering to gluten free diet (0,556 ng/mL and 1,4 ng/mL respectively). The highest mean titer of α-enolase Ab in that last group corresponded with grade III intensity of duodenal mucosa lesions, according to Marsh scale. No statistical differences were found between titer of IgA tTG Ab and anti α-enolase Ab in examined groups.
CONCLUSION: 1/Increased anti α-enolase Ab titer is observed in CD patients in comparison with healthy people. 2/ Anti α-enolase Ab may be considered as an indicator of inflammation of small intestinal mucosa in CD patients exposed to gluten. 3/Further investigation on the usefulness of anti α-enolase Ab in clinical control of CD is needed.

P1657 SMALL INTESTINAL BACTERIAL OVERGROWTH AND GASTROINTESTINAL SYMPTOMS IN CELIAC DISEASE PATIENTS AND IN PATIENTS RECEIVING PROTON POMP INHIBITORS.

M. Zwolinska-Wcislo[1,*], M. Przybylska-Felus[1], A. Piatek-Guziewicz[1], W. Dynowski[1], P. Rozpondek[1], K. Koziol[1], T. Mach[1]. [1]*Gastroenterology, Jagiellonian University Collegium Medicum, Krakow, Poland*

INTRODUCTION: Small intestinal bacterial overgrowth (SIBO) is a heterogeneous syndrome characterized by quantitative and/or qualitative changes of the small intestinal bacterial microflora. In the clinical setting, the most useful diagnostic method of SIBO is the Hydrogen Breath Test. SIBO is observed in some anatomical or motility disorders. Recently other diseases, such as irritable bowel syndrome, Crohn's disease, or prolonged proton pomp inhibitor (PPI) treatment are supposed to be SIBO risk factors. But still the prevalence of bacterial overgrowth and its influence on the course of gastrointestinal disorders such as celiac disease (CD) is not fully explored.
AIMS&METHODS: Aims We determined the SIBO prevalence in CD and in patients on prolonged PPI treatment. Furthermore we evaluated the symptoms experienced by each group of patients presenting SIBO.**Methods** We examined 50 patients (aged from 23-72 years, mean age 42), including 20 patients with CD disease, 20 treated with PPI for at least 2 months and 10 healthy volunteers (control group). *Clinical investigation*. A medical history was obtained, including information pertaining to current symptoms, medicine taken and duration of its use. *Diagnosis of SIBO*. The patients underwent a Hydrogen Breath Test. Lactulose was used as a substrate (10g in 100ml of water). Four samples of exhaled breath were analyzed. SIBO was diagnosed when there was a rise in exhaled hydrogen by 12 ppm above the baseline.
RESULTS: Bacterial overgrowth was found in 87% of CD patients and in 90% of patients on the prolonged PPI therapy in comparison with 50% cases in the control group. Such symptoms as flatulence, dyspepsia and abdominal pain were significantly more frequent in celiac patients with SIBO (96%, 28% and 21% respectively) compared with CD without bacterial overgrowth. In patients treated with PPI, such symptoms as flatulence (60%), dyspepsia (45%) and diarrhea (35%) were coexisting with positive result of Hydrogen Breath Test.
CONCLUSION: Celiac disease and the use of PPI may predispose to SIBO. SIBO may contribute to development of such symptoms as abdominal pain, heartburn, flatulence, and diarrhea in the course of CD or PPI treatment. Non-invasive SIBO screening should be recommended in patients presenting the above symptoms or risk factors of bacterial intestinal overgrowth. Concomitant probiotics administration or antibiotics, such as rifaximin could decrease the level of symptoms in this group of patient.

P1658 THE SEROPREVALENCE OF POSITIVE CELIAC DISEASE TESTS SUBSTANTIALLY DIFFERS DEPENDING UPON THE CRITERIA SET FOR A POSITIVE TEST RESULT

M. Leja[1,*], M. Gavars[1], L. Nikitina-Zake[2], G. L. Norman[3], Z. Shums[4], J. Pahomova[5], V. Dzerve[5], V. Pirags[6], A. Erglis[5], J. Klovins[2]. [1]*University of Latvia,* [2]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [3]*INOVA Diagnostics, Inc., San Diego, United States,* [4]*INOVA Diagnostics, Inc., San Diego,* [5]*Research Institute of Cardiology,* [6]*Faculty of Medicine, University of Latvia, Riga, Latvia*

INTRODUCTION: Serology is frequently used to access the prevalence of celiac disease in a population; several tests are being used for the purpose. In individuals who are HLA DQ2.5 and DQ8 negative the disease practically can be excluded.
AIMS&METHODS: We aimed to detect the prevalence of celiac disease based on serological tests and HLA typing in Latvia. : In 1444 subjects being selected for a population cross-sectional study in Latvia were enrolled. Samples were screened by FDA-cleared ELISAs (QUANTA Lite®, INOVA) for antibodies to human tissue transglutaminase IgA(h-tTG-IgA), deamidated gliadin IgA and IgG (DGP IgA,DGP IgG), and combined h-tTG/DGP IgG/IgA. All cases that were positive with any of the serological tests were HLA sequenced. HLA DQ2.5 or DQ8 positive cases were considered at genetic risk for celiac disease.

RESULTS:

Tests considered	Cut-off	Serology positive	Serology and HLA positive
Any test positive	>20 Units	7.34%	2.84%
Any individual test positive*	>20 Units	2.98%	1.25%
Any individual test positive*	>30 Units	1.39%	0.69%
Two individual tests positive*	>20 Units	0.55%	**0.49%**
Two individual tests positive*	>30 Unit	0.42%	**0.42%**
h-tTG-IgA positive	>20 Units	1.66%	**0.69%**
h-tTG-IgA positive	>30 Units	0.76%	**0.49%**

*tTG/DGP IgG/IgA screen excluded

Altogether 104 samples gave a positive result to at least one of the tests. The positivity rates are given in the Table.

CONCLUSION: The seroprevalence is depends substantially upon the test used and the selected cut-off value. Addition of HLA typing to analyze patients with a positive serology is changing the prevalence figures substantially. The prevalence of celiac disease in Latvia could be lower than previously thought and lower than in Europe in average based on presence HLA DQ2.5 or DQ8 and serological markers. The real prevalence of celiac disease should not exceed the proportion of HLA positive cases that are double-test positive or at least h-tTG-IgA positive (i.e. is below 0.69% or even below 0.42%>0.49%).

P1659 COELIAC DISEASE: DOES DIETICIAN FOLLOW UP IMPROVE OVERALL OUTCOME

M. Toqeer[1,*], T. Errington[2], N. Rahman[2], A. Zubir[2]. [1]*Gastroenterology,* [2]*Gastro, Conquest Hospital, St Leonards On Sea, United Kingdom*

INTRODUCTION: Coeliac disease is a chronic, permanent potentially life-threatening condition. Regular follow-up is an opportunity to provide patient-centered care that is sensitive to the individual's circumstances. The annual assessment should involve assessment of, and motivation towards, strict adherence to a gluten-free diet. Assessment of these patients should also involve measurement of their TTG, B12, folate, ferritin, Hb, calcium and vitamin D levels to prevent any complications and provide supplementation if required and role of dieticians is very important in this regards.

AIMS&METHODS: Aim of this audit was to compare compliance and nutritional assessment in diagnosed CD patients in dietician followed up patients against the patients who were not followed up by dieticians. We looked at results of 173, biopsy proven CD patients over the last 10 years. We reviewed their TTG, B12, folate, calcium, vitamin D, Hb. and ferritin.

RESULTS: 87 patients were followed up in dietician clinic and 86 were not followed up. 53 male patients (31 followed up, 22 non-follow up). 120 females (56 follow up and 64 non follow up patients) TTG performed in follow up vs. non-follow group up was 89.7% and 57% respectively, $\chi 2$ 23.661 and $p < 0.001$. B12, folate and calcium 94.3% and 76.7% in follow up vs non-follow up respectively. $\chi 2$ 0.724 And p.001. Vitamin D was checked in 90.8% in followed up and 38.4% in non- followed up patients with a $\chi 2$ 52.086. All the patients followed up had their ferritin and Hb checked. 18/87 in the non-follow up group did not have ferritin checked. 8/87, not followed up did not have their Hb monitored.

CONCLUSION: The results clearly demonstrate that assessment of compliance and supplement monitoring is much better in the follow up group of patients. Measurement of vitamin D level was particularly poor in the non-follow up group. The benefits may not be immediately obvious but definitely helps in the long term in preventing any coeliac disease related complications eg osteoporosis, refractory anaemia, malnutrition and lymphoma.

Previous studies have shown that adherence to gluten-free diet can be poor; ranging from 45-87%. Coeliac disease is not simply a malabsorptive gastrointestinal disorder. It is a multisystem, autoimmune disease that carries a significant health burden and risk of complications. Treatment of coeliac disease is primarily nutritional and the dietician's role is therefore of paramount importance. These micronutrient deficiencies require monitoring which is best provided by a dietician.

P1660 ROUTINE DUODENAL BIOPSIES IN THOSE WITH POTENTIAL COELIAC DISEASE- IS IT WORTHWHILE ?

S. Beg[1], **R. Badiani**[1,*], M. Raza[1], R. Swamy[2], D. L. Morris[1]. [1]*Gastroenetrology,* [2]*Histopathology, North East Hertfordshire NHS trust, Hertfordshire, United Kingdom*

INTRODUCTION: Coeliac disease (CD) is a common condition affecting as many as 1% of the UK adult population. It has increasingly been understood that patients may present with subtle or atypical symptoms, consequently the time to diagnosis may be protracted. With this in mind the threshold for investigation has lowered, with an anti-tissue transglutaminase (tTG) level usually used as the first line of investigation.

The British Society of Gastroenterology guidelines suggest that if there is a possibility of CD, taking a duodenal biopsy at the time of endoscopy is a worthwhile practice. The aim of this study is to determine the diagnostic yield of a histological diagnosis of CD in those with low clinical suspicion.

AIMS&METHODS: We retrospectively reviewed all duodenal biopsies performed in order to investigate a potential diagnosis of CD over a 16 month period, excluding biopsies taken to investigate other conditions or as part of the monitoring of known CD. 730 cases were identified using our histopathology computer-database, which were then analysed with respect to indication, histological features and correlation with anti-tTG levels.

RESULTS: The population which underwent gastroscopy with duodenal biopsies was predominantly female (66%), with an average age of 60 years old. Of the biopsies performed 41 were taken to prove a serological diagnosis of CD, of which 59% confirmed this diagnosis.

Of the remaining 689 patients the most common indication for taking a duodenal biopsy was anaemia accounting for 52%, followed by weight loss (9%), diarrhoea (9%), abdominal pain (3%), endoscopic features of CD (2%) with the remainder made up of patients with non-specific symptoms. Only 54% of patients had an anti-tTG level taken prior to obtaining histology. The diagnostic yield for a tissue diagnosis of CD when clinical suspicion was low was 11%, with anaemia being the most likely indication to engender this diagnosis. 38 patients who had histological evidence of CD did not have an anti-tTG prior to endoscopy.

There were 20 patients who had histological evidence of CD in the presence of negative serology and normal IgGA levels, accounting for 5.8% of this study group.

CONCLUSION: Our data shows that when the clinical suspicion of CD is low and anti tTG negative, histology is usually normal, with a number needed to test of 17.

REFERENCES:

1. BSG Guidance on coeliac disease 2010

When analysing the 20 patients who had histology positive, serology negative CD there were no features in their history to suggest that they would be particularly high risk for having CD. A low threshold for performing duodenal biopsy would therefore be the only way to identify this cohort of patients.

P1661 DUODENAL BULB BIOPSY MORPHOMETRY AND IGA DEPOSITS IN THE DIAGNOSIS OF COELIAC DISEASE

A. Popp[1,2,*], J. Taavela[3], K. Kurppa[3], D. Raducanu[2], A. Pirvan[4], M. Jinga[1], I. Anca[1,2], M. Maki[3]. [1]*UMF Carol Davila,* [2]*Institute for Mother and Child Care, Bucharest, Romania,* [3]*Tampere Center for Child Health Research, University of Tampere and Tampere University Hospital, Tampere, Finland,* [4]*UMF Iuliu Hatieganu, Cluj-Napoca, Romania*

INTRODUCTION: It has been recently shown that celiac disease (CD) can be diagnosed solely on duodenal bulb biopsies. We wanted to re-evaluate this by morphometric measurements as in the duodenal bulb, villi may be stumpy and distorted next to Brunner's glands. Also other diseases may result in villous atrophy and further, the quality of bulb biopsies is a concern. We also hypothesized that bulb IgA deposits targeting transglutaminase 2 (TG2) could be a specific indicator of CD.

AIMS&METHODS: 70 consecutive patients, 30 adults and 40 children went to endoscopy because of gastrointestinal symptoms or suspicion of CD. Bulb and duodenal villous height to crypt depth ratio (VH:CrD) was evaluated by two independent observers and TG2-specific IgA deposits were examined by double color immunofluorescence in frozen biopsy samples.

RESULTS: 25 patients (3 adults and 22 children) received CD diagnosis, duodenal VH:CrD was in all <2 and they all had typical IgA deposits targeting TG2, especially around the Brunner glands. The remaining 45 patients received other diagnoses and were excluded for CD. The final diagnoses were Helicobacter pylori (n=18), Giardia (n=5), IBD (n=7), chronic diarheea (n=2), dyspepsia (n=6), recurrent abdominal pain (n=5), Entamoeba hystolitica (n=1), malnutrition (n=1). Also duodenal IgA deposits were negative in these patients. However, we found in the non-CD bulb specimens histological lesions mimicking CD (VH:CrD<2) in 12/27 adults and 7/8 children. Altogether 37 bulb biopsies were not qualified for accurate morphometric evaluations even after recuttings. None of the non-CD patients had bulb mucosal TG2-specific IgA deposits.

CONCLUSION: In our series the bulb specimens were often of poor quality and difficult to interpret in morphometric analyses. Further, other conditions may cause bulb injury, when morphometrically analyzed, similar to CD. These results indicate that bulb biopsies alone should be evaluated with caution in the diagnosis of CD. Measurement of TG2-specific IgA deposits might prove to be a strong tool to prove or exclude CD in bulb specimens.

P1662 PUSH ENTEROSCOPY: A NOVEL METHOD TO ASCERT DIFFICULT TO DIAGNOSE COELIAC DISEASE IN PAEDIATRICS

A. Barclay[1,*], R. Saddler[1], N. Laird[2], H. Duncan[2], T. Cardigan[2], E. Buchanan[2], P. McGrogan[1]. [1]*Paediatric Gastroenterology,* [2]*Dietetics, RHSC, Glasgow, United Kingdom*

INTRODUCTION: New ESPGHAN guidelines on the diagnosis of coeliac disease (CD) suggest a move away from upper GI endoscopy (UGE) for symptomatic patients with tissue transglutaminase (tTG) >10 times normal and positive HLA typing (1). CD is a patchy disease and tTG may be more sensitive than

UGE in such cases. However guidelines do not cover patients with moderatley raised tTG or asymptomatic 'at risk patients' who have inconclusive histopathology on UGE. Push enteroscopy (PE) can achieve biopsies more distally in the small bowel and may characterise patchy disease in such 'difficult to diagnose CD'. To our knowledge PE has not been described in the diagnosis of paediatric CD.

AIMS&METHODS: We aim to describe the novel use of PE in a tertiary paediatric CD service. All patients screened with tTG are prospectively logged on the department dietetic CD database. We identified patients from July 2009- July 2012 who had a positive tTG but negative/inconclusive UGE histopathology and were referred for PE. Details on demographics, symptomatology, screening investigations, were extracted. Initial UGE biopsies were assesed as to whether biopsy site and number complied with ESPGHAN guidelines (1) and graded according modified Marsh criteria. Details on repeat screening, timing of PE, location of repeat biospies were also taken.

RESULTS: From 163 patients screened with tTGs, 8 patients (5F) were referred for PE due to initial positive screening but negative/inconclusive UGE biopsies (Table). All patients were EMA positive. 6/8 patients had a diagnosis of CD confirmed on PE, although only 4/8 were from the distal sites alone. 1/8 patients could have potentially been given a dx of CD on serology and HLA typing alone if ESPGHAN guidelines had been followed (1).

Age (yrs)	Symptoms	TTG	UGE ESPGHAN compliant?	UGEPath	HLA DQ2/DQ8	PE Path	Dx Sites
6.1	Pain	3.2	Yes	Normal	Pos	3b	Proximal + distal
6.9	Pain	4.6	Yes	Normal	NK	1a	Distal
13.7	Pain	128	Yes	Normal	Pos	3b	Distal
12.4	Diabetic	73	Yes	Normal	Pos	3a	Proximal+Distal
9.4	Diabetic	>128	No	1	Pos	3b	Distal
13.4	Hypocalcaemic	39	Yes	Normal	Pos	3a	Distal
3	Diabetic	>128	No	Normal	Pos	3a	Proximal +Distal
4.5	Diarrhoea	25	Yes	1	NK	1	Proximal

CONCLUSION: PE may have a role in the diagnosis of CD in children where serology is inadequately high to obviate need for UGE and initial pathology is inconclusive. The relative increased diagnostic yield of PE in comparison to performing a repeat UGE is not yet well characterised and the authors note that compliance to ESPGHAN guidelines in terms of initial UGE biospy site and numbers is important. However further study into the use of PE in difficult diagnose CD in children is warranted.

P1663 EVOLUTION AND HLA-ASSOCIATION OF THE EARLY INFANTILE GLIADIN ANTIBODY RESPONSE IN A HIGH-RISK COHORT FOR COELIAC DISEASE

I. Korponay-Szabo[1,2,*], S. Koletzko[3], J. Gyimesi[2], G. Castillejo[4], E. Mummert[5], E. Bravi[6], C. Ribes-Koninckx[7], I. Polanco[8], R. Shamir[9], S. Kolacek[10], R. Troncone[11], L. Mearin[12]. *[1]Paediatrics, Univ. of Debrecen, Debrecen, [2]Heim Pal Children's Hospital, Budapest, Hungary, [3]von Hauner Children Hospital, Ludwig Maximilian Univ., Munich, Germany, [4]Hospital Universitari Sant Joan, Reus, Spain, [5]Phadia GmbH, Freiburg, Germany, [6]Eurospital, Trieste, Italy, [7]La Fe University Hospital, Valencia, [8]La Paz University Hospital, Madrid, Spain, [9]Schneider Children's Medical Center, Tel-Aviv Univ, Tel Aviv, Israel, [10]Univ. Children's Hospital, Zagreb, Croatia, [11]Univ. Federico II, Naples, Italy, [12]Univ. Medical Center, Leiden, Netherlands*

INTRODUCTION: Antibodies against gliadin (AGA) and deamidated gliadin peptides (DGP) are regarded as early signs of developing coeliac disease in young children, but their predictive value is still uncertain.

AIMS&METHODS: To characterize the outcome of serum AGA and DGP antibody positivity observed in infancy. During 2007-2010, 1324 infants with a 1st degree relative with coeliac disease (CD) were recruited in 8 countries shortly after birth (EU-PreventCD project www.preventcd.com) and 931 HLA DQ2 and/or DQ8 positives were randomised double-blind to 100 mg of gluten suspension/day or placebo from 4 months of age. From 6 months all children consumed gluten-containing foods and serum samples were collected at 4,6,9,12,18,24 and 36 months Small bowel biopsies were performed based on symptoms suggestive of CD and/or anti-tissuetransglutaminase (TG2A) or AGA antibodies.

RESULTS: As of 5/2013, 814 children have been followed till 3 years and CD diagnosis was obtained in 56. At least 5-fold transient increase over baseline in AGA-IgA without TG2A occurred in 134 infants at 6 months, median 16.7 U/ml (range 6-100); the antibodies equally recognised native and deamidated peptides. This early response was associated with the duration of exclusive breast feeding. A smaller AGA peak was observed in 35 children ($p<0.0001$) at 9 months who were stationary at 6 months, median 8.2 U/ml (range 6-100, $p<0.001$). Both these groups had in 41% HLA DQ2.2 (with or without DQ2.5) compared to 14.4% in children without an AGA or DGP peak. Evaluating the children with complete sets of follow-up samples, the outcome was:

	At 2 years of age (n=723)			At 3 years of age (n=588)		
	N	CD (%)	TG2A (%)	N	CD (%)	TG2A (%)
AGA >5x baseline at 6 months	115	3.4*	5.2	97	6.2*	7.2
AGA >5x baseline at 9 months	21	9.5**	9.5	17	23.5***	23.5
AGA not >5x baseline during first year of life	524	5.5	7.1	416	9.6	13.7
Other pattern	63	4.7	7.9	58	10.3	12.07

Odds ratios: *0.62, **1.80, ***2.79

CONCLUSION: Both AGA and DGP had low predictive value for CD in these children. An early IgA AGA response at 6 months of age or earlier seems to be beneficial while at 9 months or later is associated with higher CD risk.

P1664 COELIAC DISEASE MANIFESTATION IN EARLY AGE IN A PROSPECTIVELY FOLLOWED CONTEMPORARY NATURAL HISTORY COHORT OF FIRST DEGREE RELATIVES

J. Gyimesi[1], É. Nemes[2], E. Vajda-Nagy[1], O. Kadenczki[2], I. R. Korponay-Szabo[1,2,*], The PreventCD Study Group. *[1]Heim Pal Children's Hospital, Budapest, [2]Univ. of Debrecen, Debrecen, Hungary*

INTRODUCTION: The manifestation of coeliac disease (CD) in genetically predisposed subjects may be dependent on the way of gluten introduction in infancy, but also on other environmental factors (e.g. seasonal infections, vaccinations, baby food items and local food preferences) that vary from one time period to the other. A multinational study, EU-PreventCD project (www.preventcd.com) is underway, where children born between September 2006 – July 2010 and having a first-degree relative with CD were recruited shortly after birth and received in double-blind placebo-controlled way 100 mg/day gluten from 4 months of age followed by gradual introduction scheme of 250-1000 mg gluten after 6 months of age in all. By the time the outcome of the PreventCD study will be known, it will be of interest to establish the baseline prevalence of CD in a similar cohort living in the same environment without the intentional modification of the diet.

AIMS&METHODS: The aim of this study was to collect a natural history cohort similar to the Hungarian PreventCD participants (n=186) and follow them prospectively with active screening for anti-transglutaminase (anti-TG2) and endomysial antibodies. Consecutively presented children born in the same time period as PreventCD participants were enrolled with the similar inclusion criteria and typed for HLA-DQ alleles. Gluten introduction and consumption were allowed according to the parents' wish. Gluten intake was recorded by a food frequency questionnaire. A small bowel biopsy was offered to children who developed seropositivity.

RESULTS: Altogether 303 children met the inclusion criteria and were enrolled. The median follow up time was 3.6 years (range 0.4.-6.4). The index coeliac patient was a sib in 115 cases (38%), the mother in 153 cases (50%) and the father in 35 cases (12%) and 84% of the children had DQ2 or DQ8. The median time of gluten introduction was 9 months, but there was no significant difference in gluten consumption at the age of 1.5, 2 or 3 years as compared to the Hungarian PreventCD participants. Anti-TG2 antibodies appeared in 43 subjects (14.2%) in the natural history cohort and frequency of CD confirmed by histology was 12.2%. The majority of these children (92%) was asymptomatic at the time when seropositivity was detected.

CONCLUSION: Prospective follow up and screening was able to detect a high prevalence of coeliac disease already in young age in this genetically predisposed cohort. Similar cohort composition and food preferences make this cohort suitable for a future comparison with the PreventCD study.

P1665 COMPARATIVE STUDY OF ANTIGLIADIN ANTIBODIES IN BREAST MILK OF CELIAC AND NON CELIAC MOTHERS

M. Roca[1,*], M. Bolonio[1], D. Hervas[2], E. Donat[1], B. Polo[1], E. Masip[1], G. Castillejo[3], E. Martínez-Ojinaga[4], M. C. Mena[5], I. Polanco[4], C. Ribes-Koninckx[1]. *[1]Pediatric Gastrohepatology Unit, Hospital La Fe, [2]BiostatisticsUnit IIS La Fe, Instituto de Investigación Sanitaria La Fe, Valencia, [3]Hosp. Universitari San Joan, Reus, [4]Hosp. Universitario La Paz, [5]Centro Nacional de Biotecnología, Consejo Superior de Investigaciones Científicas, Madrid, Spain*

INTRODUCTION: Results on the influence of diet on food antibodies production, including antigliadin antibodies (AGA), in breast milk (BM) and colostrum are contradictory[1,2]. Moreover, there is scarce information on AGA in BM of general population and coeliac mothers.

AIMS&METHODS: Objectives: To study the presence of antibodies against gliadin in BM and their relationship with maternal diet.

Methods: samples of mature milk were obtained at different months of lactation (1-32) from 23 mothers: 12 on a normal diet (ND) and 11 on a gluten free diet

(GFD) (coeliac mothers) and were analyzed for Secretory AGA-IgA (S-AGA) and AGA-IgA by indirect homemade ELISA. Total IgA (g/L) was measured in human milk whey using an ELISA kit from Bethyl Laboratories.
RESULTS: AGA levels vary from one mother to another, but are stable in each mother from the first month of lactation onwards. S-AGA and AGA-IgA were detected in BM, both in mothers on a GFD and mothers on a normal gluten containing diet.
The comparison of the estimated kernel density curves for S-AGA showed a difference between both groups, with slightly lower values for mothers on GFD. Similar results were obtained for AGA-IgA. However differences between the 2 groups of mothers did not reach statistical significance (repeated measures ANOVA, S-AGA p-value = 0.12, AGA-IgA p-value=0.16); analysis of these results suggests however this was related to the low sample size: 106 observations but only 23 different individuals.
Total IgA values varied between 0.1 and 1 g/L in most individuals, the median IgA value being 0.66 g/L and the interquartile range [0.44; 0.94]. We observed a great variability among mothers, some cases showing unusually high values.
To assess the relationship between IgA and the other variables, a linear mixed model approach was used. The model including S-AGA instead of AGA-IgA had a considerably higher AICC (Corrected Akaike Information Criterion) (229.2 vs. 235.7), indicating that a positive association exists between levels of AGA and total IgA. This association is higher between levels of AGA-IgA and total IgA than for S-AGA and total IgA
CONCLUSION: AGA was present in all BM samples, independently of mother's diet. Thus breastfeeding is a way of transferring antibodies to the baby, so this practice could be relevant for CD prevention in breastfed infants.

P1666 TOWARDS NON-INVASIVE DIAGNOSIS AND MONITORING OF CELIAC DISEASE: A PROSPECTIVE STUDY TO THE USEFULNESS OF I-FABP

M. P. Adriaanse[1,*], A. Mubarak[2], D. Leffler[3], C. Kelly[3], D. Schuppan[3], A. van den Neucker[1], W. Buurman[4], R. Houwen[2], A. Vreugdenhil[1]. [1]*Paediatrics, Maastricht University Medical Centre, Maastricht,* [2]*Paediatrics, Wilhelmina Children's Hospital, Utrecht, Netherlands,* [3]*The Celiac Disease Center, Department of Gastroenterology, Beth Israel Deaconess Medical Centre, Boston, United States,* [4]*Surgery, Maastricht University Medical Centre, Maastricht, Netherlands*

INTRODUCTION: Our retrospective studies showed the differentiating potential of intestinal fatty acid binding protein (I-FABP), a sensitive marker for enterocyte damage, for celiac disease (CD) in patients with positive CD autoantibodies (IgA-tTG). This study evaluates the usefulness of plasma I-FABP in diagnosing CD in children with positive IgA-tTG titers, and for monitoring disease activity in patients on a gluten-free diet (GFD) and during gluten challenge (GC).
AIMS&METHODS: In a prospective, multicentre study 80 children presenting with positive CD autoantibodies were included. Patients fulfilling the ESPGHAN criteria for CD (villous atrophy and/or IgA-tTG >10x cut-off level) started a GFD. Plasma I-FABP and IgA-tTG were determined at presentation and after 3, 6, 12 and 26 weeks of GFD. The control group consisted of 90 children with a clinical suspicion of CD but normal CD autoantibody titers. Moreover, 20 adult CD patients in clinical remission underwent a two-week GC. Study visits occurred at -14, 0, 3, 14 and 28 days after starting GC.
RESULTS: Plasma I-FABP levels were significantly elevated at presentation in children with CD (775 pg/ml [438-1354]) compared with the controls (207 pg/ml [123-288], $p<0.001$) and correlated with Marsh grade (R=0.37, $p<0.05$, n=61). The positive and negatie predictive values of I-FABP for CD were 95.2% and 77.0%, respectively. I-FABP levels decreased significantly to 444 (n=18), 378 (n=57), 258 (n=50) en 221 (n=52) pg/ml after 3, 6, 12 and 26 weeks GFD, respectively. Median IgA-tTG titers did not normalize within 6 months of GFD. Adult CD patients on a GC showed a significant increase in I-FABP levels from baseline to day 14, and a decrease after gluten withdrawal, while autoantibody titers increased slightly from baseline to day 14 but markedly by day 28, when gluten was already eliminated. I-FABP levels correlated significantly with intraepithelial lymphocyte count, while no correlation with autoantibodies, villous atrophy or symptoms was found.
CONCLUSION: An elevated I-FABP level confirms the diagnosis of CD in 91.7% of children with positive autoantibody titers. I-FABP analysis could reduce the need for a duodenal biopsy with almost 75%. I-FABP levels increase and decrease faster after gluten introduction and gluten withdrawal in CD patients, respectively, as compared with the currently used CD autoantibodies. Plasma I-FABP is a reliable additional marker for CD diagnosis and might provide insight in intestinal damage in CD children on a GFD and adults on a GC.

P1667 PREVALENCE AND CLINICAL PICTURES OF THE DISEASE IN ITALY: RESULTS OF THE SALIVARY SCREENING.

R. Nenna[1,*], L. PETRARCA[1], C. TIBERTI[2], A. TURCHETTI[1], M. Mennini[1], M. Florio[1], N. Pietropaoli[1], G. Mastrogiorgio[1], M. Guido[1], F. Lucantoni[1], M. Bavastrelli[1], M. Bonamico[1]. [1]*Department of Paediatrics,* [2]*Department of Experimental Medicine, "SAPIENZA" UNIVERSITY OF ROME, Rome, Italy*

INTRODUCTION: Coeliac disease (CD) is a common, autoimmune pathology, caused by a permanent intolerance to gluten contained in wheat and to similar prolamines present in barley and rye. There are several patterns of MC: symptomatic CD, and silent CD, both characterized by typical histological lesions in the duodenum mucosa. The typical manifestation is distinguished by gastrointestinal symptoms such as diarrhoea, vomiting, abdominal distension and failure to thrive. On the other hand atypical forms are characterized by extraintestinal symptoms (anaemia, low height, delayed puberty, headaches).
AIMS&METHODS: The aim of our study was to perform a CD screening in school-age children in order to obtain a timely diagnosis of the disease that might permit a propter growth and to compare clinical appearance of the disease in three different cohorts: a big metropolis (Rome), a small mountain city (L'Aquila) and a small seaside city (Civitavecchia).
Salivary samples were collected and tested for anti-transglutaminase antibodies (tTGAb) using a fluid-phase radioimmunoprecipitation method. Subjects salivary tTGAb-positive were subsequently tested for serum CD-specific antibodies (RIA tTGAb and ELISA tTGAb). Confirmed positive children underwent endoscopy with multiple duodenal biopsies, and at CD diagnosis, started a gluten-free diet. The study was performed on: Group 1: 5733 out of 7377 school-children who were invited to participate in the city of Rome; Group 2: 751 out of 954 school-children who were invited to participate in the city of L'Aquila; Group 3: 816 out of 1004 school-children who were invited to participate in the city of Civitavecchia.
RESULTS: The coeliac children were: Group 1: 68 (45 newly diagnosed and 23 already coeliacs), Group 2: 13 (7 newly diagnosed and 6 already coeliacs), Group 3: 11 (8 newly diagnosed and 3 already coeliacs). The CD prevalence in the three groups investigated were: Group 1: 1.2%, Group 2: 1.7% Group 3: 1.3%. The clinical pictures of the three groups showed that under the water level the iceberg depht were different: Group 1: 66% of CD children; Group 2: 54% of CD children; Group 3: 73% of CD children.
CONCLUSION: CD prevalence is higher than expected, particularly in group 2 children, with a modified clinical spectrum. Our study demonstrates the high compliance of the parents and of the children to the salivary test. CD iceberg is still deep, hence, the salivary tTGAb, that is a non-invasive, simple, reproducible and sensitive screening method has proved to be a powerful tool in identifying celiac children.

P1668 THE 'SUSPECTED BLOOD INDICATOR' (SBI) IN SMALL BOWEL BLEEDING FOR DETECTION OF BLEEDING LESIONS BY CAPSULE ENDOSCOPY: NO ACTIVE BLEEDING IN CASE OF NEGATIVE SBI

A. Tal[1,*], K. Makhlin[1], M. Friedrich-Rust[1], S. Zeuzem[1], J. G. Albert[1]. [1]*Department of Internal Medicine I, JOHANN WOLFGANG GOETHE UNIVERSITY HOSPITAL, Frankfurt/Main, Germany*

INTRODUCTION: Capsule endoscopy is the gold standard to diagnose small bowel bleeding. The latest generation of the suspected blood indicator (SBI) algorithm offers a technical feature that might easily and quickly detect the bleeding site in the small bowel but validity of this feature has not been evaluated yet.
AIMS&METHODS: All patients who presented at our clinic for suspected bleeding of the small bowel between 2010 and 2012 were retrospectively analyzed. Intestinal bleeding remained obscure after gastroscopy and colonoscopy, and small bowel capsule endoscopy (CE) was performed. The second-generation PillCam SB 2 capsule endoscope (Given Imaging, Yonkheam, Israel) and Rapid Access 6 software were used to detect (1) luminal blood content and (2) small bowel lesions responsible for bleeding. The findings of an independent and experienced investigator were correlated to the results of the SBI.
RESULTS: A total of 188 patients (126 m, 62f, mean age 59.6 years) were investigated. Red blood cell transfusion was necessary in 56 cases (29%). The SBI showed positive findings in 169 patients whereas the investigator detected active bleeding in 42 cases. None of the active bleedings as diagnosed by the investigator was SBI negative (sensitivity 100%, specificity of 13%). Small bowel lesions were described by the investigator in 46 cases, of which SBI was positive in 45 (97.8%). One angiectasia was missed by the SBI.
CONCLUSION: The new SBI software is a reliable tool to exclude active bleeding and relevant lesions and the patient might be dismissed from the hospital in case of negative SBI. Nevertheless analysis of capsule videos by an investigator remains important for the detection and differentiation of polyps, tumors and other type of lesions.

P1669 DIABETES, ATRIAL FIBRILATION AND LARGE BOWEL DIVERTICULOSIS: RISK FACTORS FOR SMALL BOWEL ANGIODYSPLASIAS

P. Tsibouris[1], P. Apostolopoulos[1], C. Kalantzis[1], E. Vlachou[1,*], A. Koumi[1], I. Koumoutsos[1], P. Dogantzis[1], C. Beltsidou[1], G. Alexandrakis[1].
[1]*GASTROENTEROLOGY, NIMTS GENERAL HOSPITAL, Athens, Greece*

INTRODUCTION: Small bowel angiodysplasias is one of the main causes of small bowel bleeding.
AIMS&METHODS: Aim: To identify risk factors for small bowel angiodysplasias.
Methods: 984 patients (mean age 60±18 years, 543 men, 256 smokers) undergone small bowel capsule endoscopy, gastroscopy and colonoscopy were evaluated. 490 were evaluated for iron deficiency anemia, 311 for diarrhea, 60 for unexplained abdominal pain and for 123 other causes. Stat: X2, logistic regression analysis.
RESULTS: 451 (42%) patients presented small bowel angiodysplasias, 308 (78%) anemic and 107 (22%) non-anemics ($p<0.0001$). Mean age of patients with small bowel angiodysplasias was 68±14 years versus 55±19 years in those without angiodysplasias ($p<0.0001$) and mean BMI 26.5±4 versus 25.7±5.3 respectively ($p=0.01$). Small bowel angiodysplasias were found in: 255 (61%) men and 90 (22%) smokers; while they were not present in 289 (51%) men ($p=0.0009$) and 165 (29%) smokers ($p=0.01$). Small bowel angiodysplasias were found in: 119 (64%) diabetics versus 296 (37%) non-diabetics ($p<0.0001$), 81 (67%) patients with chronic renal failure versus 361 (40%) without ($p<0.0001$), 90 (64%) patients with large bowel diverticula versus 278 (36%) without ($p<0.0001$), 23 (48%) with heart valve disease versus 392 (42%) without ($p=0.41$), 147 (35%) patients with ischemic heart disease versus 110 (19%) without ($p<0.0001$), 52 (13%) with atrial fibrillation versus 24 (4%) without ($p<0.0001$), 38 (9%) with COPD versus 29 (5%) without ($p=0.01$), 26 (6%) with stroke versus 12 (2%) without ($p=0.0008$), 9 (1%) with parkinsons disease versus 26 (5%) without ($p=0.04$). In logistic regression analysis for all the above mentioned risk factors: age ($p<0.0001$), male gender ($p=0.02$), presence of diabetes ($p=0.002$), atrial fibrillation ($p=0.02$) and large bowel diverticulosis ($p=0.02$), as well as absence of parkinsons disease ($p=0.05$) were significant risk factors for the presence of small bowel angiodysplasias.
CONCLUSION: Small bowel angiodysplasias were more frequent among patients with small bowel related anemia. Old age, male gender, presence of diabetes, atrial fibrillation and large bowel diverticulosis, as well as absence of parkinsons disease were significant risk factors for the presence of small bowel angiodysplasias.

P1670 FACTORS ASSOCIATED WITH POSITIVE CAPSULE ENDOSCOPY FINDINGS IN PATIENTS WITH OBSCURE GASTROINTESTINAL BLEEDING

I. Ribeiro[1,*], J. Marques[2], R. Pinho[1], A. Rodrigues[1], T. Pinto Pais[1], C. Fernandes[1], S. Leite[1], J. Carvalho[1], M. Figueiredo[2], J. Fraga[1].
[1]*Gastroenterology,* [2]*Centro Hospitalar Vila Nova Gaia, Vila Nova Gaia, Portugal*

INTRODUCTION: Capsule endoscopy (CE) is the first line examination to evaluate obscure gastrointestinal bleeding (OGIB). The identification of factors associated with the detection of lesions by CE could improve resource utilization and thereby improve patient selection for CE examination.
AIMS&METHODS: To identify factors associated with positive CE findings in patients with OGIB.
Retrospective study of 214 CE procedures (208 patients) performed between 2005-2013, in the setting of OGIB. Demographic variables, type of OGIB (occult versus overt), number of transfusions, type of positive finding, number of endoscopies (EGD) and colonoscopies performed prior to CE, hemoglobin value, comorbidities and medication; and Charlson comorbidity index was evaluated. Overt bleeding was subdivided into ongoing and previous. Only lesions with high hemorrhagic potential (P2-ulcers, vascular lesions, tumors / masses, multiple erosions and blood) were classified as positive findings.
Statistical tests: t-student; $\chi 2$.
RESULTS: 59% - female, mean age-62years. Occult bleeding-64.5% (88.4%-microcytic anemia, 11.6% positive fecal occult blood test). Overt bleeding-35.5% (previous-63.2% ongoing-36.8%). Positive finding-43% (angiodysplasia-31.9%; ulcers-28.6%; blood-25.3%, tumor/mass-6.6%).
The identification of positive findings was significantly higher in those with ongoing-overt bleeding ($p<0.001$). Increasing number of pre-capsule EGD ($p<0.001$) and colonoscopies ($p<0.001$), increasing transfusion requirements ($p<0.001$), moderate/severe renal disease ($p=0.009$) and NSAID intake ($p=0.005$) were all significantly associated with the identification of positive findings in CE.
CONCLUSION: Our study suggests that CE should be used early in OGIB. Ongoing-overt bleeding, increasing number of endoscopies and transfusion requirements, a more severe renal disease and NSAIDs intake, were associated with more positive findings on CE.

P1671 THE BLOOD UREA NITROGEN/CREATININE RATIO IS USEFUL FOR DISTINGUISHING THE COLONIC BLEEDING FROM THE SMALL BOWEL BLEEDING IN OBSCURE GASTROINTESTINAL BLEEDING.

K. Mitsui[1,*], M. Suzuki[1], S. Fujimori[1], A. Ehara[1], T. Kobayashi[1], S. Tanaka[1], A. Tatsuguchi[1], C. Sakamoto[1]. [1]*Gastroenterology, NIPPON MEDICAL SCHOOL, Tokyo, Japan*

INTRODUCTION: The diagnosis of a bleeding source is still challenging in obscure gastrointestinal bleedings (OGIBs). Capsule endoscopy and device assisted enteroscopy are useful for the small bowel exploration. However, in about 10% of OGIB cases, the bleeding source is extra-small bowel area and hemorrhagic diverticulum of the colon is one of the common extra-small bowel sources. To increase the probability of the small bowel bleeding before endoscopy is important for an accurate diagnosis.
AIMS&METHODS: We conducted a retrospective case series study to evaluate the blood urea nitrogen (BUN)/creatinine (Cre) ratio for distinguishing the colonic bleeding from other sites in OGIB.
198 consecutive OGIB patients who had undergone the double balloon endoscopy (DBE) from June 2003 to Dec. 2012 at Nippon Medical School Hospital were enrolled. The clinical characteristics (such as gender and age), bleeding types (such as occult and overt), blood transfusions, initial blood tests (such as hemoglobin(Hb), mean corpuscular volume (MCV), total protein(TP), BUN, Cre and BUN/Cre ratio) were assessed.
We divided OGIB patients who could be identified the source of bleeding by DBE into two groups. One group is a colonic bleeding, and the other group is the source above the ileocecal valve (ICV). We analyze the differences of each clinical parameter among two groups. Fisher's exact test was used for categorical variables, and Mann-Whitney test was used for continuous variables. A p value of <0.05 was considered significant.
RESULTS: 138 (69.7%) of 198 OGIB patients were diagnosed. There were 53 females (38.4%) and 85 (62.6%) males. The mean age was 62.9 (SD 14.8 range 19-87) years old. The bleeding types were occult and overt in 22 (15.9%) and 116 (84.1%) patients, respectively. The colonic bleedings were in 17 patients (12.3%). 111 patients (80.4%) were small bowel bleedings and 10 patient (7.2%) were upper GI bleedings.
The colonic bleeding group was a lower BUN/Cre ratio than other group with a statistically significance ($p = 0.04$, 17.4±4.2 in colonic bleeding group, and 24.2±15.1 in above ICV group). Gender, age, bleeding types, blood transfusions, Hb, MCV, TP, BUN, and Cre were not statistically significant.
CONCLUSION: The BUN/Cre ratio is helpful to distinguish the colonic bleeding from small bowel bleeding in OGIB. When the higher probability of the small bowel bleeding is confirmed, diagnostic rate will be improved. The higher BUN/Cre ratio may suggest a small bowel bleeding and lower BUN/Cre ratio patients may need a repeat colonoscopy for the detection of a source.

P1672 LUBIPROSTONE, A STIMULATOR OF CLC-2, PREVENTS NSAID-INDUCED SMALL INTESTINAL DAMAGE IN RATS THROUGH EP4 RECEPTOR-DEPENDENT MECHANISM

K. Takeuchi[1,*], K. Amagase[1], S. Hayashi[1]. [1]*Division of Pathological Sciences, Department of Pharmacology and Experimental Therapeutics, Kyoto Pharmaceutical University, Kyoto, Japan*

INTRODUCTION: Lubiprostone, a bicyclic fatty acid of the prostone group, is used for the treatment of chronic constipation, and this action is due to stimulation of intestinal fluid secretion through the activation of ClC-2-type Cl^- channels. Other studies showed that lubiprostone modulated gastrointestinal motility, via different prostaglandin (PG) EP receptor subtypes, and increased duodenal HCO_3^- secretion through the activation of EP4 receptors. Recently, NSAID-induced enteropathy has become an important topic to gastroenterologists. However, it remains unknown whether lubiprostone has any effect on these lesions.
AIMS&METHODS: We examined the effect of lubiprostone on the intestinal ulcerogenic response to indomethacin in rats and investigated the underlying mechanisms of the protective action.
Male SD rats were used without fasting. The animals were given indomethacin (10 mg/kg) SC and killed 24 h later to examine the hemorrhagic lesions developed in the small intestine. Lubiprostone (0.01-1 mg/kg) was given once PO 30 min before the administration of indomethacin. Various EP antagonists were given PO 30 min before lubiprostone. Enterobacterial count was determined by a culture method, mucus secretion was examined by PAS staining, and the protein expression of iNOS was examined by Western blotting. Furthermore, intestinal fluid (Cl^-) secretion was measured electrically by short circuit current (Isc) using a Ussing chamber.
RESULTS: Indomethacin caused hemorrhagic lesions in the small intestine, accompanied by increases in bacterial invasion and iNOS expression as well as myeloperoxidase (MPO) activity in the mucosa. Lubiprostone dose-dependently reduced the severity of these lesions, with the concomitant suppression of bacterial invasion, iNOS expression and MPO activity. The amelioration effects of lubiprostone on the indomethacin-induced intestinal lesions and accompanying inflammatory changes were significantly abrogated by pretreatment of the animals with the EP4 antagonist AE3-208 but not the EP1 (ONO-8711) or the EP3

(AE5-599) antagonists. In addition, lubiprostone dose-depdently increased mucus secretion as well as the Isc of the small intestine, and these responses were also attenuated by prior administration of the EP4 antagonist.
CONCLUSION: Lubiprostone prevents the indomethacin-induced small intestinal lesions via the EP4 receptor-dependent mechanism, and this effect may be functionally associated with the increase of mucus and fluid (Cl^-) secretions that are known to be important for suppression of bacterial invasion and iNOS expression, the major pathogenic factors in NSAID-induced small intestinal lesions.

P1673 ANGIODYSPLASIAS OF THE JEJUNUM ARE THE MOST FREQUENT CAUSE OF OBSCURE GASTROINTESTINAL BLEEDING: OUR EXPERIENCE FROM 3050 PATIENTS SUBJECTED TO SMALL BOWEL CAPSULE ENDOSCOPY

N. Viazis[1,*], M. Giakoumis[1], T. Koukouratos[1], K. Katopodi[1], E. Anastasopoulos[1], M. Chanias[1], G. Zacharakis[1], K. Markoglou[1], D. G. Karamanolis[1]. [1]*2nd Department of Gastroenterology, EVANGELISMOS HOSPITAL, Athens, Greece*

INTRODUCTION: Angiodysplasias of the small intestine are a common cause of obscure gastrointestinal bleeding. We aimed to determine the yield and distribution of angiodysplasias in different age groups in patients subjected to small bowel capsule endoscopy.
AIMS&METHODS: From March 2003 till March 2013, 3050 patients (males/females: 1492/1558, mean age ± SD: 60.8±18.4) have been subjected to small bowel capsule endoscopy (Given imaging, Yoqneam, Israel) in our Department. Among them, there were 2017 patients (66.13%) who had a history of gastrointestinal bleeding (melena or blood per rectum) or a positive fecal occult blood test result and/or iron-deficiency anemia, with a negative gastroscopy and colonoscopy and were categorized as having obscure gastrointestinal bleeding.
RESULTS: In patients with obscure gastrointestinal bleeding subjects to small bowel capsule endoscopy, positive findings were noted in 1146 (56.81%); precisely, angiodysplasias (n=661, 57.67%), apthoid ulcerations (n=186, 16.23%), ulcers (n=127, 11.08%), polyps (n=119, 10.38%) and tumors (n=53, 4.62%). In patients with angiodysplasias, those were more frequently seen in the first half of the capsule recording (jejunum) as opposed to the second half (ileum) (72% versus 54%, $p<0.01$). Angiodysplasias were more commonly seen in patients $\geq$ 65 years old, as opposed to those $<$ 65 years old (61% versus 39%, $p<0.01$).
CONCLUSION: Most patients are subjected to small bowel capsule endoscopy because of obscure gastrointestinal bleeding and among them angiodysplasias are the commonest findings. When present, angiodysplasias are more frequently seen in the jejunum and in patients $\geq$ 65 years old.

P1674 REPEAT ENDOTHERAPY FOR SMALL INTESTINE VASCULAR LESIONS BY DOUBLE-BALLOON ENDOSCOPY IS ASSOCIATED WITH FAVOURABLE OUTCOMES

S. Shinozaki[1,*], H. Yamamoto[1], T. Yano[1], K. Sunada[1], Y. Hayashi[1], H. Shinhata[1], H. Sato[1], E. J. Despott[2], K. Sugano[1]. [1]*Department of Medicine, Division of Gastroenterology, Jichi Medical University, Shimotsuke, Japan,* [2]*Royal Free Unit for Endoscopy and Centre for Gastroenterology, The Royal Free Hospital and University College London Institute for Liver and Digestive Health, London, United Kingdom*

INTRODUCTION: Gastrointestinal bleeding secondary to small intestine vascular lesions (SIVL) is associated with rebleeding despite initial haemostasis by double-balloon endoscopy (DBE).
AIMS&METHODS: Our study evaluated the long-term outcomes of DBE endotherapy of SIVL (as described by the Yano-Yamamoto classification); impact of repeat DBE endotherapy for recurrent bleeding was also assessed. Retrospective cohort study of 43 patients (male 24, female 19, age (±SD) 63.9 ± 14.9), who underwent 69 sessions of DBE endotherapy of SIVL. Each patient underwent 1.6 sessions of DBE haemostasis on average (range, 1-6). The mean (±SD) follow-up period was 4.9 ± 1.7 years (range: 2.4 to 9.1 years).
RESULTS: Overt rebleeding occurred in 16/43 patients (37%). Patients with multiple SIVL showed a significantly higher rate of overt rebleeding than those with solitary SIVL (12/23 (52%) vs. 4/20 (20%) P = 0.017). The trend for frequency of rebleeding after first DBE haemostasis, appeared to be higher for patients with type 1a SIVL than those with type 1b or type 2 lesions; type 1a 8/16 (50%) vs. type 1b 5/19 (26%) (P = 0.12) and type 1a 8/16 (50%) vs. type 2 2/7 (29%) (P = 0.31), respectively. While 12 of the 16 patients (group A) underwent repeat DBE haemostasis at every episode of overt bleeding, the remaining 4 patients (group B), did not undergo repeat DBE haemostasis during every episode of overt rebleeding. We assessed the frequency of overt rebleeding/year/patient during 2 phases after initial DBE endotherapy. Phase 1 included the 1st year of follow up, while phase 2 included follow up during the 2nd year and later. In group A, the frequency of overt rebleeding during phase 1 was significantly higher than during phase 2; 1.58 ± 0.90 vs. 0.12 ± 0.19 times/year/patient, respectively (P < 0.001). In group B, the frequency of overt bleeding was almost the same between 2 phases; phase 1: 0.50 ± 0.57 times/year/patient vs. phase 2: 0.50 ± 0.29 (P = 0.495). With focus on phase 2, patients in group B showed a significantly higher rate of overt rebleeding than those in group A; group A 0.12 ± 0.19 vs. group B 0.50 ± 0.29 times/year/patient (P = 0.007).
CONCLUSION: While the presence of multiple SIVL was associated with rebleeding, repeat DBE endotherapy resulted in an improved long-term outcome in patients with refractory SIVL bleeding.

P1675 A PRELIMINARY REPORT OF SEARCHING GENOTYPE ASSOCIATED WITH NSAID-INDUCED SMALL INTESTINAL INJURY

S. Fujimori[1,*], T. Mushiroda[2], K. Mitsui[1], Y. Takahashi[1], M. Yonezawa[1], S. Tanaka[1], A. Tatsuguchi[1], C. Sakamoto[1]. [1]*Depertment of Gastroenterology, NIPPON MEDICAL SCHOOL, Graduate School of Medicine, Tokyo,* [2]*Reserach Group for Pharmacogenomics, RIKEN Center for Integrative, Yokohama, Japan*

INTRODUCTION: We previously reported finding individual variability in NSAID-induced small intestinal injury in two RCTs administering diclofenac sodium to healthy volunteers (1,2). Recent upper gastrointestinal studies show the possibility that genetic polymorphisms of NSAID-metabolizing enzymes (CYP2C9, CYP3A4) and cyclooxygenase (COX-1) are associated with NSAID-induced gastroduodenal injuries (3,4).
AIMS&METHODS: The aim of the study was to investigate the association of genetic polymorphisms for traditional NSAID-induced small intestinal injury among 17 genes which are reported to possibly be associated with NSAID-induced gastroduodenal injuries. Subjects were 55 healthy volunteers and 8 patients who were clear on NSAIDs-induced small intestinal injury by the aforementioned studies and clinical course. Subjects were divided into three groups based on the number of small intestinal mucosal breaks after NSAID treatment as evaluated by capsule endoscopy. The severe group was defined as the detection of five or more mucosal breaks; the mild group was defined as detecting one to four mucosal brakes, and the control group was defined as no mucosal breaks being detected. 45 SNPs on 17 genes (CDKN2BAS, COX-1, COX-2, CRP, CYP2C9, CYP2C19, three types of CYP3A4, CYSLTR1, ITGB3, IL-1β, IL-1RN, IL-6, PLA2G4A, PON1, TNF-α) were genotyped by multiplex PCR-based invader assay. The frequency of genotype in 45 SNPs was compared among the three groups in various combinations.
RESULTS: As a result of capsule endoscopy evaluation, there were 16 subjects categorized in the severe group, 15 in the mild group, and 32 in the control group, respectively. When comparing the severe and mild groups with the control group, there was a significant tendency of SNP (rs1330344) on the COX-1 gene (P=0.060) and SNP (rs1205) on the CRP gene (P=0.077). In comparing the severe group to the mild and control groups, there was also a significant tendency of SNP (rs12721627) on the CYP3A4*16 gene (P=0.061) for which genotype C/G was detected only in subjects with severe small intestinal mucosal breaks.
CONCLUSION: COX-1, CRP, and CYP3A4*16 are candidate genotypes for identification of patients with a high risk of NSAID-induced small intestinal injury.

WEDNESDAY, OCTOBER 16, 2013 9:00–14:00
NUTRITION III – Poster Area

P1676 HOW USEFUL IS PATIENTS OWN ASSESSMENT OF THEIR NUTRITIONAL STATUS?

D. Longbotham[1,*], L. Malins[1], E. Yones[1], J. Sarveswaran[1], G. Kaur[1]. [1]*Surgery, SCUNTHORPE GENERAL HOSPITAL, Scunthorpe, United Kingdom*

INTRODUCTION: Many patients admitted to acute surgical specialties are at risk of malnutrition, and there are many screening tools in use, including the MUST screening. This has recently been added to NICE guidelines. Certain assessments use patients' own perceptions of their nutrition, such as SGA.
AIMS&METHODS: The aim of this study is to see if patient's subjective assessment is predictive of and possible to use in place of their MUST score.
An adapted form of the Subjective Global Assessment (SGA) was used, basing the questionnaire for patients own assessment, looking at the domains of weight's perception of their weight loss in the past month, food intake over a month, medical barriers to stopping them eating (such as nausea, vomiting, unable to tolerate foods) and activity levels.
Data was collected over a 2 month period, with patients completing the nutrition questionnaire and the project time collecting data for MUST.

RESULTS: 108 patients admitted between November and December 2012 was included. 21 were elective and 87 were acute admissions. 59 were managed conservatively, 32 had open abdominal surgery, 14 laparoscopic and 3 soft tissue or breast surgery. The patients MUST score was calculated, and the duration of patients stay was calculated. 4 patients died within 28 days of admission

MUST score vs patients subjective assessment of weight loss

	High risk (39 patients) %	Moderate risk (12 patients) %	Low risk (57 patients) %
No recent weight loss	38.5	33.4	77.2
Recent weight loss in past month	61.5	66.6	22.8

CONCLUSION: Patient's interpretation of their recent nutrition does not reflect on their BMI on admission

There seems to an association with increasing MUST score with subjective weight loss, decreased appetite, increased symptoms preventing adequate nutrition, and decreased patient activity.

There is significant statistical difference for patients' subjective weight loss and subjective decrease in food intake with increased hospital stay. There is no difference between their interpretations of symptoms preventing eat nor their activity status with increased hospital stay.

This shows that patient's subjective assessment of their nutrition is predictive of their MUST score and weight loss and type and amount of food is associated with increased length of stay.

Subjective views could well be used in future as part of nutrition risk scoring.

P1677 LONG-TERM TAUROLIDINE LOCK THERAPY IS MORE EFFECTIVE IN PREVENTING CATHETER RELATED BLOODSTREAM INFECTIONS IN ADULT HOME PARENTERAL NUTRITION PATIENTS THAN HEPARIN: A FOLLOW-UP OF 212 PATIENTS

E. D. Olthof[1,*], G. J. Huisman- de Waal[1], M. W. Versleijen[1], W. Kievit[2], G. J. Wanten[1]. [1]*Department of Gastroenterology and Hepatology,* [2]*Department of Health Evidence, RADBOUD UNIVERSITY NIJMEGEN MEDICAL CENTRE, Nijmegen, Netherlands*

INTRODUCTION: Home parenteral nutrition (HPN) patients are at risk for developing catheter-related bloodstream infections (CRBSI). In a previous prospective open-label randomized controlled trial in 30 HPN patients presenting with CRBSI we showed that catheter locking with 2% taurolidine (TauroSept®) dramatically (90%) reduced re-infections compared with low-dose (150 U/ml) heparin. Our complete HPN population therefore switched to taurolidine in 2008.

AIMS&METHODS: Aim of the present retrospective study was to compare taurolidine with heparin catheter lock therapy for their efficacy regarding the prevention of CRBSI in HPN patients. Data of positive peripheral blood cultures, which were related to the patients venous access, were retrospectively collected from 212 patients that received HPN between January 2000 and November 2011, comprising 175 and 761 central venous catheter (CVC) access years during catheter lock therapy with taurolidine and heparin, respectively.

RESULTS: Thirty-two peripheral positive blood cultures were found in 194 taurolidine locked CVCs of 86 patients in total, while 276 peripheral positive blood cultures were detected in 699 heparin locked CVCs of 187 patients in total. Therefore, bloodstream infection incidence rates of CVC were 0.5/year and 0.99/year for taurolidine and heparin, respectively. Since 66 taurolidine locked CVCs are still *in situ*, the number of bloodstream infections per catheter will probably decrease even more.

CONCLUSION: Long-term use of the lock solution taurolidine is more effective in preventing CRBSI in HPN patients than heparin.

P1678 LEUKOCYTE ACTIVATION BY MEDIUM-CHAIN TRIGLYCERIDES IS NOT MODULATED BY FISH OIL OR OLIVE OIL-BASED LIPIDS

E. D. Olthof[1,*], H. M. Schaap - Roelofs[1], G. J. Wanten[1]. [1]*Department of Gastroenterology and Hepatology, RADBOUD UNIVERSITY NIJMEGEN MEDICAL CENTRE, Nijmegen, Netherlands*

INTRODUCTION: Medium-chain triglycerides (MCTs) as part of parenteral nutrition formulations activate leukocytes *in vitro*. Novel parenteral lipid emulsions have been developed that contain mixed lipids: MCTs, long-chain triglycerides (LCTs), fish oil (FO) and/or olive oil (OO).

AIMS&METHODS: Aim of this study was to investigated whether leukocyte activation by MCTs involves shared signaling pathways with fish oil and olive oil, which have anti-inflammatory and immune neutral characteristics. *In vitro* effects of various mixed lipids, and effects of addition of n-3 fatty acids (eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)) to LCT/MCT, on the expression of surface activation markers and reactive oxygen species (ROS) production of leukocytes was studied.

RESULTS: We found that MCT-containing lipids (LCT/MCT, LCT/MCT/FO, LCT/MCT/FO/OO) activated immune cells, with decreased L-selectin expression (30, 36, 24%, respectively), increased degranulation (71, 83, 62%, respectively) and adhesion (46, 48, 37%, respectively) in granulocytes compared to lipid-free medium. Immune cells exposed to MCT-free lipids (LCT, FO, SO/OO) had a similar immune status compared to immune cells not exposed to lipids. Stimulus-induced ROS production decreased in MCT-containing lipids by 6 to 25%, and remained unchanged in MCT-free lipid emulsions, except for a 13% decrease in ROS production after incubation with FO. Incubation with LCT/MCT and micelles of EPA slightly activated granulocytes (12% decrease in L-selectin, 15% increase of degranulation) and monocytes (9% increase in adhesion), whereas addition of micelles of DHA did not alter the immune status, compared to LCT/MCT alone. Addition of EPA or DHA micelles to LCT/MCT did not alter ROS production.

CONCLUSION: Leukocyte activation by MCTs is not modulated by fish oil or olive oil-based lipids, suggesting that MCTs exert their effects via different signaling pathways.

P1679 MICROBIOCIDAL EFFECTS OF VARIOUS TAUROLIDINE CONTAINING CATHETER LOCK-SOLUTIONS

E. D. Olthof[1,*], A. F. Guelich[1], A. J. Rijs[2], R. Nijland[3], G. J. Wanten[1]. [1]*Department of Gastroenterology and Hepatology,* [2]*Department of Medical Microbiology, RADBOUD UNIVERSITY NIJMEGEN MEDICAL CENTRE, Nijmegen,* [3]*Department of Medical Microbiology, UNIVERSITY MEDICAL CENTRE UTRECHT, Utrecht, Netherlands*

INTRODUCTION: We have recently shown that use of a catheter lock solution containing taurolidine dramatically decreased catheter related bloodstream infections in patients on home parenteral nutrition (HPN) when compared to heparin. Several taurolidine containing solutions are commercially available, some in combination with citrate or heparin.

AIMS&METHODS: Aim of this study was to investigate the effect of these different lock solutions on growth and biofilm formation of Gram negative, Gram positive and fungal pathogens (*Escherichias coli* (*E. coli*), *Staphylococcus aureus* (*S. aureus*) and *Candida glabrata* (*C. glabrata*), respectively). To this end, clinical isolates obtained during CRBSI episodes of HPN patients were grown in the presence of 10x, 20x, 33x and 100x diluted lock solutions (2%taurolidine, 1.3%taurolidine-citrate, 1.3%taurolidine-heparin and heparin) or PBS (control) in LB-medium and RMPI medium for bacteria and yeasts, respectively. Crystal violet was used for biofilm staining. Biofilm formation and growth of clinical isolates was determined by optical density measurement at 595 and 660 nm, respectively.

RESULTS: Preliminary results show that 10x diluted solutions of all taurolidine lock solutions completely prevented growth of *E. coli*, *S. aureus* and *C. glabrata* over a three day experiment. Growth of *S. aureus* and *E. coli* was detected about 10 hours earlier in 33x diluted 1.3%taurolidine-citrate and 1.3%taurolidine-heparin compared with 2%taurolidine lock solution, while heparin did not inhibit growth of clinical isolates compared to PBS. Effects of lock solutions on biofilm formation were in line with the effects on microbial growth.

CONCLUSION: Taurolidine containing lock solutions have a potent microbiocidal effect on fungal, Gram positive and Gram negative pathogens. While 2%taurolidine appears to be the most potent in this respect, the relevance of this finding for clinical practice remains to be established.

P1681 PERCUTANEOUS ENDOSCOPIC GASTROSTOMY: CLINICAL INDICATION AND PATIENT TOLERABILITY.

L. Y. Lee[1], P. J. Melo[1,*], S. Lanzon-Miller[1]. [1]*MILTON KEYNES NHS FOUNDATION TRUST, BUCKINGHAMSHIRE, United Kingdom*

INTRODUCTION: Percutaneous endoscopic gastrostomy (PEG) is an effective long-term alternative to parenteral feeding for patients with functioning gastrointestinal tract. It has been established that mortality following PEG depends on the underlying condition, and patients with oropharngeal cancer and cerebrovascular accidents generally have a poor prognosis. However, there have been no studies analysing the patient tolerability of PEG based on underlying condition.

AIMS&METHODS: A retrospective analysis of all patients who had undergone a PEG insertion at Milton Keynes hospital between 2008 to 2012 was performed. Patients were identified form the endoscopy unit database.

RESULTS: 118 patients were included in this study with a median age of 75 years and 49.8% were male. 21% had PEG for cancer, 38% for cerebrovascular accidents, 34.7% for progressive neurological disorders and 6% for dementia. Rates of moderate/severe patient discomfort during the procedure were 24% for patients with cancer, 8.9% for patients with cerebrovascular accidents, 19.5% for patients with progressive neurological disorders and 57.1% for patients with dementia.

	Cancer (n=25)	Cerebrovascular accidents (n=45)	Neurological conditions (n=41)	Dementia (n=7)
Moderate/severe discomfort	24%	8.9%	19.5%	57.1%
Duration of procedure	18 minutes	17 minutes	18 minutes	21 minutes
Mean amount of midazolam	2.0mg	1.5mg	1.8mg	2.0mg

CONCLUSION: Patient tolerability of PEG is known to depend on endoscopist skill and amount of sedation used. However, it is clear that different patient cohorts have different experiences of the procedure. Patients with dementia experience significant discomfort, require more sedation and the procedure is longer. Patients with cerebrovascular accidents tolerate the procedure far better, experiencing less discomfort ($p<0.001$) and require less sedation compared to the other cohorts. We theorise that the underlying reasons may be a result of oropharngeal paresthesia and strongly supports its continuing use for this indication. Patients who have PEGs performed for other indications may warrant higher doses of sedation to improve patient tolerability.

P1682 PREDICTIVE FACTORS FOR ENTERAL NUTRITION IN PATIENTS RECEIVING NEOADJUVANT CHEMORADIOTHERAPY FOR LOCALLY ADVANCED OESOPHAGEAL CARCINOMA.

M. W. Van Den Berg[1,*], S. A. Haijtink[1], E. M. ies[1], E. B. Haverkort[1], J. E. van Hooft[1]. [1]*Academic Medical Center, Amsterdam, Netherlands*

INTRODUCTION: Dysphagia and weight loss are the two major symptoms of oesophageal cancer. Neoadjuvant treatment with chemoradiotherapy (CRT) for locally advanced oesophageal cancer could further aggravate these symptoms and potentially jeopardize nutritional status. As poor nutritional status is associated with an increased risk for peroperative morbidity and mortality, early nutritional support is warranted. The aim of this study is to identify predictive factors for starting enteral nutrition in these patients.

AIMS&METHODS: Data were retrospectively collected from medical records of all consecutive patients who were treated with the same course of neoadjuvant CRT for locally advanced oesophageal cancer in our hospital between April 2009 and October 2012. Univariate and multivariate logistic regression analysis were performed to determine significant associations between patient parameters and the overall use of enteral nutrition as well as the use of enteral nutrition after the start of CRT ('reactive enteral nutrition'). Tested parameters were age, gender, ASA-score, dysphagia, smoking, alcohol use, tumour histology, tumour location, cTNM stage, tumour stricture diameter of <10mm. Only parameters with a p-value of <0.1 in the univariate analysis were used in the multivariate model.

RESULTS: A total of 255 patients (mean age 63 ± 8.9, 193 males [76%], 197 adenocarcinoma [77%], 57 squamous cell carcinoma [22%]) were included, of which 76 (29.8%) received enteral nutrition. For the overall use of enteral nutrition, univariate analysis showed significant associations ($p<0.1$) for dysphagia, squamous cell carcinoma, tumour length and a tumour stricture diameter of <10mm. After multivariate analysis, a tumour stricture diameter of <10mm appeared to be the only significant predictor (OR 4.96 [95% CI 2.49-9.87]) for the overall use of enteral nutrition. Cigarette smoking was the only parameter significantly associated with the start of 'reactive enteral nutrition' in univariate analysis (OR 1.93 [95% CI 1.02-3.648]). Therefore no multivariate analysis was performed for 'reactive enteral nutrition'.

CONCLUSION: This study demonstrates that a tumour stricture diameter of <10mm is the only objective predictor for the need of enteral nutrition in patients with locally advanced oesophageal cancer during neoadjuvant CRT. This predictor may be helpful in avoiding a delay in the start of enteral nutrition in high risk patients.

P1683 ENDOSCOPIC OR RADIOLOGICALLY PLACED GASTROJEJUNOSTOMIES IN HIGH-RISK PATIENTS: A RANDOMISED STUDY

A. Latchford[1], T. Grunnung[2], S. Jackson[3], S. Cochrane[1,*], S. Lewis[4]. [1]*Gastroenterology,* [2]*Nuclear Medicine,* [3]*Radiology,* [4]*Derriford Hospital, Plymouth, United Kingdom*

INTRODUCTION: In patients at risk of aspiration pneumonia due to gastro-oesophageal reflux who require gastrojejunostomy feeding tubes, the tubes are placed either radiologically (RIGJ) or endoscopicaly (PEGJ). There is little published evidence to inform which is superior.

AIMS&METHODS: Consecutive patients referred for long-term jejunal feeding because of high risk of aspiration pneumonia (proven GORD or pneumonia whilst being NG fed) were randomly allocated to have a RIGJ or PEGJ inserted. A Tc^{99m} colloid study was done to determine the presence of gastro-oesophageal reflux and jejunal gastric reflux after feeding tube placement. We recorded pneumonia, death, feeding tube displacement, blockage and replacement to 90 days post placement.

RESULTS: 65 patients were randomised, 31 RIGJ and 34 PEGJ. Baseline characteristics including Barthell index were similar between groups. GORD was demonstrated by Tc99m tracer injected intragastrically in 52% but in no patient when injected jejunally.

Jejunal feeding tube and clinical complications (number)

	RIGJ n=31			PEGJ n=34		
*p<0.05	**30days**	**30-90days**	**Total**	**30days**	**30-90days**	**Total**
Jejunal tube fallen out of position	0	0	**0**	7	2	**9***
Jejunal tube irreversibly blocked	3	0	**3**	3	2	**5**
Jejunal tube replaced	2	0	**2**	5	3	**8**
Blockage cleared by patient/carer	8	4	**12**	22	12	**34***
Blockage cleared by community H/C	2	2	**4**	8	3	**11**
Blockage cleared in hospital	3	0	**3**	10	5	**15***
Further Pneumonia	2	1	**3**	2	3	**5**
Death	2	2	**4**	2	1	**3**

CONCLUSION: There was little difference in clinical outcomes between RIGJ *vs* PEGJ tubes for feeding patients at high risk of pneumonia. However, RIGJ tubes were considerably less prone to blockage and displacement than PEGJ tubes. Tube blockage was a major cause of frustration for patients and resource use for health care services. Replacing enteral tubes in frail patients was distressing and a significant use of health care resource. Consideration should be given to placing RIGJ in preference to PEGJ tubes.

P1684 FOOD PREFERENCE AND TASTE CHANGES AFTER GASTROINTESTINAL SURGERY

P. Hiotis[1], S. Welchman[1], S. Cochrane[2,*], S. Lewis[3]. [1]*Surgery,* [2]*Gastroenterology,* [3]*Derriford Hospital, Plymouth, United Kingdom*

INTRODUCTION: Early postoperative nutrition is of clinical benefit. However, patients are often initially reluctant to eat after surgery. Dysguesia and alterations in food preference are often reported. We conducted a study to describe perioperative changes in taste and food preference with a view to being able to optimise food choices and thus improve intake.

AIMS&METHODS: Consecutive patients undergoing colorectal surgery were recruited. Three sets of tests were conducted, pre-operatively and on post-operative days (POD) 1, 2 and 3. In Test 1, patients were asked to rate the palatability (Horrible-Nice, using Likert scales (0-100%)) of a neutral flavoured nutritional supplement flavoured with 'standard' concentrations of the 6 core tastes (sweet, sour, salt, bitter, spicy and savoury). In Test 2, patients were shown photos of foods representative of the core tastes and asked to rate them in terms of appeal as in Test 1. Test 3 comprised provision of a snack box containing representative foods of the core tastes which patients were asked to rate as before. Differences from baseline were assessed using t-tests.

RESULTS: 31 patients completed the study, M:F=21:10, median age of 72 (33-82). Test 1, enhanced taste from baseline was seen on POD1 ($p<0.01$) for salty, sweat & spicy taste.

....Day.of.test....	Taste Test				Photographs			
	Salty	Sweat	Spicy	Savoury	Salty	Sweat	Spicy	Savoury
Baseline reading	27	48	48	47	29	34	40	54
% change POD 1	+58%*	+18%*	+20%*	+8%	+33%*	+3%	-30%	-30%
% change POD 2	+53%*	+14%*	+4%	+7%	+4%	-1%	-32%	-28%
% change POD 3	+48%*	+11%	-3%	0	-1%	-1%	-21%	-12%

POD=Post Operative Day, Increased score from baseline $p<0.01$

Test 2, only salty food (popcorn) scored higher ($p<0.01$) than baseline (figure 2) all other foods scored lower. Foods representing bitter and sour exhibited the greatest decline (40.4% for gherkins, 38.7% for grapefruit). Test 3, patients rated sweat (fudge) 63%, salty (crackers) 50% best at POD 1 ($p<0.01$) and sour (gherkins) 22%, spicy (Bombay mix) 16% worst. With all 3 Tests, scores reverted to baseline by POD 3.

CONCLUSION: After surgery patients rated sweat and salty snack foods greatest. This was confirmed by tests of palatability and appeal. Though while spicy and savoury palability tests scored highly patients did not find the snakes particularly desirable. Further work is required to explore patients food preferences post surgery.

P1685 SAFETY OF GASTROSTOMY FEEDING TUBE PLACEMENT IN PATIENTS WITH VENTRICULO-PERITONEAL SHUNTS INSITU

S. Haywood[1,*], C. Murray[1], J. Bennell[1], S. Black[1], Royal Free Nutrition and Gastroenterology Team. [1]*Gastro, Royal Free Hospital, London, United Kingdom*

INTRODUCTION: Gastrotomy feeding tubes placed in patients with ventriculo-peritoneal (VP) shunts are thought to be more susceptible to infection of the ventriculo-peritoneal shunt, At the Royal free hospital we have placed 7 gastrostomy feeding tubes over a 3 year period in patients with VP shunts.
AIMS&METHODS: We carried out a retrospective chart review of all patients in the Royal Free hospital with VP shunts having Percutaneous Endoscopic Gastrostomy (PEG) tubes placemented between 2010 and 2012. We assessed timing of PEG insertion in relation to VP shunt placement, the use of prophylactic antibiotics, general complications, specific complication of shunt infection/meningitis and 30 day mortality.
RESULTS: Between 2010 and 2012 we identified 7 patients in our institution with VP shunts who attended for PEG insertion. No PEG tubes were inserted within 1 month of VP shunt placement.
In one case the endoscopist was unable to site the tube endoscopically and the procedure was converted to a surgical gastrostomy. There were no complications associated with any of the procedures and specifically there were no episodes of shunt infection or meningitis. 30 day mortality was 0%. All patients received prophylactic antibiotics.
CONCLUSION: In our series of PEG insertions in patients with VP shunts in situ there was no increased risk in complications and no episodes of shunt infection/meningitis. In this small series this is compatible with the published rate of VP shunt infection of around 5% and suggests that in patients requiring long term enteral nutritional support the presence of a VP shunt should not be considered a contraindication to PEG insertion.

P1686 PREDICTIVE LABORATORY FACTORS OF EARLY DEATH AFTER PERCUTANEOUS ENDSCOPIC GASTROSTOMY

Y. Hiyama[1,*], T. Kuwai[1], A. Tsuboi[1], K. Boda[1], K. Yamashita[1], T. Mizumoto[1], T. Yamaguchi[1], A. Yamaguchi[1], H. Kouno[1], H. Kohno[1]. [1]*Gastroenterology, KURE MEDICAL CENTER AND CHUGOKU CANCER CENTER, Kure, Japan*

INTRODUCTION: Percutaneous endoscopic gastrostomy (PEG) is an accepted method to enable enteral feeding in patients with swallowing difficulties. However, complications and early death are considerably prevalent after PEG. To decrease early mortality after PEG, it is very important to definite risk factors of this procedure.
AIMS&METHODS: The aim of our study was to clarify laboratory factors that could predict early death within 30 days following the PEG procedure. A retrospective analysis of all patients who underwent PEG at Kure Medical Center and Chugoku Cancer Center from April 2008 to January 2012 were performed. We examined clinical date and preoperative laboratory date and extracted predictive factors of early death after PEG using univariate and multivariate analyses.
RESULTS: A total of 544 patients [253 female (46.5%) and 291 male (53.5%); mean age 78 y.o.] were assessed. Cerebral vascular disorder was the most common primary disease (176 of 544, 32%). The 30-day mortality rate following the PEG procedure was 5.3% (29 of 544), and pneumonia was the most common cause of death (10 of 29, 34%). Multivariate analysis on predictive laboratory factors of early death revealed a significant correlation between values of C-reactive protein and blood urea nitrogen and early death.
CONCLUSION: The values of C-reactive protein and blood urea nitrogen may be useful predictive laboratory factors for early death after PEG. To avoid early death after PEG, it is necessary to assess these factors and provide some treatment against inflammation and dehydration before PEG.
